
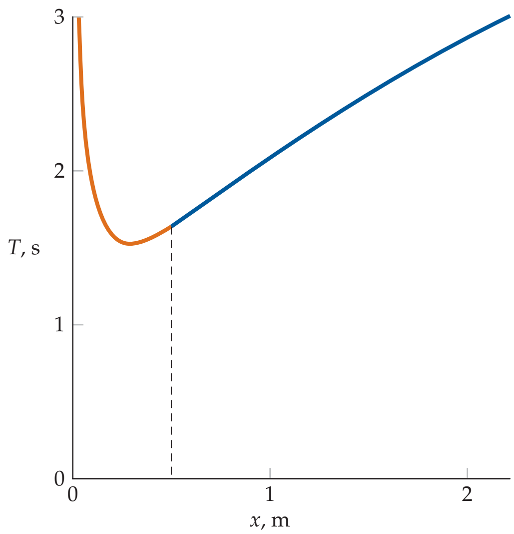

FIGURE 14-20 Plot of the period versus the distance from the pivot to the center of mass. For $x > 0.5$ m the pivot point is beyond the end of the rod.

PRACTICE PROBLEM 14-7 Show that the step-3 expression for the period gives the same period for $x = L/6$ as for $x = L/2$.

Example 14-12 The Swinging Rod Revisited

Try It Yourself

Find the value of x in Example 14-11 for which the period is a minimum.

PICTURE At the value of x for which T is a minimum, $dT/dx = 0$.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps / **Answers**

1. The period, given by the Example 14-11 result, is $T = 2\pi\sqrt{Z/g}$, where $Z = (\frac{1}{12}L^2 + x^2)/x$. Find the period both as x approaches zero and as x approaches infinity.

   $$T = 2\pi\sqrt{\frac{(\frac{1}{12}L^2 + x^2)}{gx}} = 2\pi\sqrt{\frac{Z}{g}}$$
   where $Z = (\frac{1}{12}L^2 + x^2)/x$
   As $x \rightarrow 0$, $Z \rightarrow \infty$, and $T \rightarrow \infty$.
   As $x \rightarrow \infty$, $Z \rightarrow \infty$, and $T \rightarrow \infty$.

2. The period goes to infinity as x approaches zero and as x approaches infinity. Somewhere in the range $0 < x < \infty$ the period is a minimum. To find the minimum, evaluate dT/dx, set it equal to zero, and solve for x.

$$\frac{dT}{dx} = \frac{dT}{dZ}\frac{dZ}{dx} = \frac{\pi}{\sqrt{g}} Z^{-1/2}\frac{dZ}{dx}$$

$Z > 0$ throughout the range $0 < x < \infty$, so

$$\frac{dT}{dx} = 0 \Rightarrow \frac{dZ}{dx} = 0.$$

$$\frac{dZ}{dx} = 0 \Rightarrow x = \boxed{\frac{L}{\sqrt{12}} = 0.289L}$$

CHECK We expect an answer between 0 and 0.5L. The step-2 result of $x = 0.289L$ meets that expectation.

14-4 DAMPED OSCILLATIONS

Left to itself, a spring or a pendulum eventually stops oscillating because the mechanical energy is dissipated by frictional forces. Such motion is said to be **damped.** If the damping is large enough, as, for example, a pendulum submerged in molasses, the oscillator fails to complete even one cycle of oscillation. Instead, it just moves toward the equilibrium position with a speed that approaches zero as the object approaches the equilibrium position. This type of motion is referred to as **overdamped.** If the damping is small enough that the system oscillates with an amplitude that decreases slowly with time—like a child on a playground swing when a parent stops providing a push each cycle—the motion is said to be **underdamped.** Motion with the minimum damping for nonoscillatory motion is said to be **critically damped.** (With any less damping, the motion would be underdamped.)

Underdamped motion The damping force exerted on an oscillator such as the one shown in Figure 14-21*a* can be represented by the empirical expression

$$\vec{F}_d = -b\vec{v}$$

where b is a constant. Such a system is said to be *linearly damped.* The discussion here is for linearly damped motion. Because the damping force is opposite to the direction of motion, it does negative work and causes the mechanical energy of

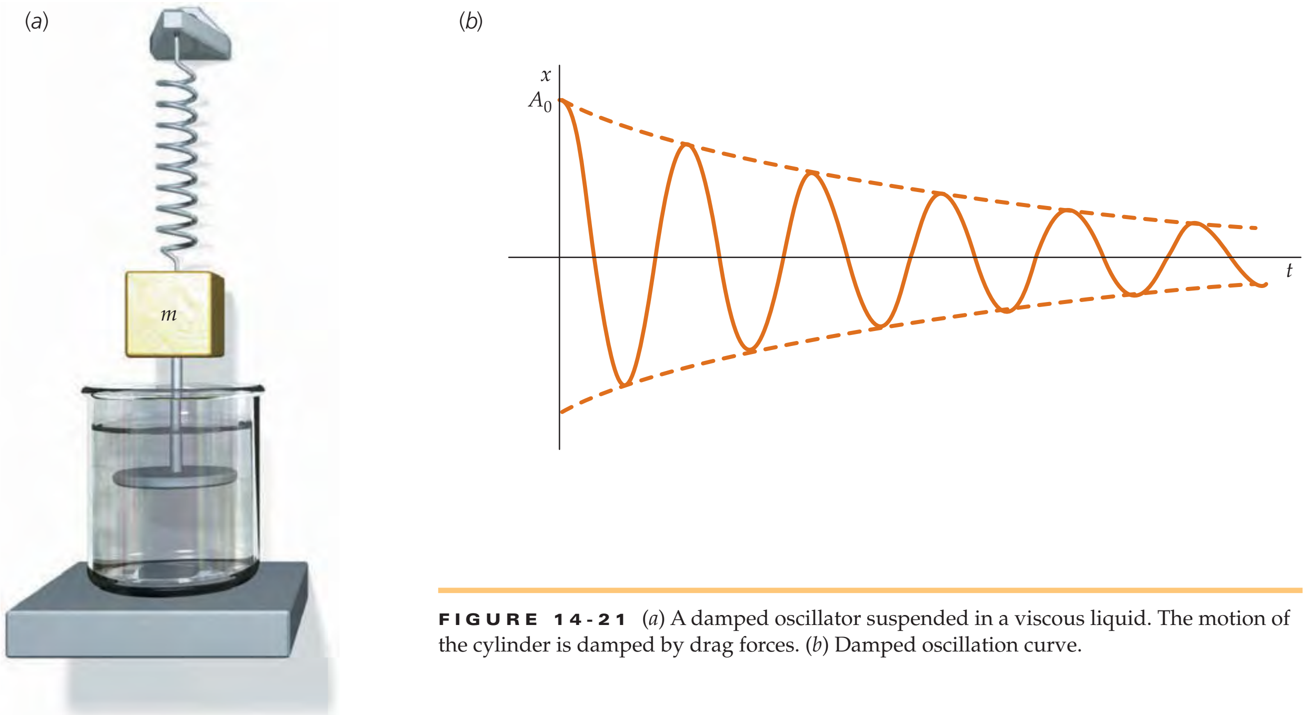

FIGURE 14-21 (*a*) A damped oscillator suspended in a viscous liquid. The motion of the cylinder is damped by drag forces. (*b*) Damped oscillation curve.

the system to decrease. This energy is proportional to the square of the amplitude (Equation 14-17), and the square of the amplitude decreases exponentially with increasing time. That is,

$$A^2 = A_0^2 e^{-t/\tau} \tag{14-37}$$

DEFINITION—TIME CONSTANT

where A is the amplitude, A_0 is the amplitude at $t = 0$, and τ is the decay time or time constant. The **time constant** is the time for the energy to change by a factor of e^{-1}.

The motion of a damped system can be obtained from Newton's second law. For an object of mass m on a spring that has a force constant k, the net force is $-kx - b(dx/dt)$. Setting the net force equal to the mass times the acceleration d^2x/dt^2, we obtain

$$-kx - b\frac{dx}{dt} = m\frac{d^2x}{dt^2}$$

which we rearrange to appear as

$$m\frac{d^2x}{dt^2} + b\frac{dx}{dt} + kx = 0 \tag{14-38}$$

DIFFERENTIAL EQUATION FOR A DAMPED OSCILLATOR

The exact solution of this equation can be found using standard methods for solving differential equations. The solution for the underdamped case is

$$x = A_0 e^{-(b/2m)t}\cos(\omega' t + \delta) \tag{14-39}$$

where A_0 is the initial amplitude. The frequency ω' is related to the natural frequency ω_0 (the frequency with no damping) by

$$\omega' = \omega_0\sqrt{1 - \left(\frac{b}{2m\omega_0}\right)^2} \tag{14-40}$$

For a mass on a spring $\omega_0 = \sqrt{k/m}$. For *weak damping*, $b/(2m\omega_0) \ll 1$ and ω' is nearly equal to ω_0. The dashed curves in Figure 14-21*b* correspond to $x = A$ and $x = -A$, where A is given by

$$A = A_0 e^{-(b/2m)t} \tag{14-41}$$

By squaring both sides of this equation and comparing the results with Equation 14-37, we have

$$\tau = \frac{m}{b} \tag{14-42}$$

If the *damping constant b* is gradually increased, the angular frequency ω' decreases until it becomes zero at the critical value

$$b_c = 2m\omega_0 \tag{14-43}$$

When b is greater than or equal to b_c, the system does not oscillate. If $b > b_c$, the system is overdamped. The smaller b is, the more rapidly the object returns to equilibrium. If $b = b_c$, the system is said to be critically damped and the object returns to equilibrium (without oscillation) very rapidly. Figure 14-22 shows plots of the displacement versus time for a critically damped and an overdamped oscillator. We often use critical damping when we want a system to avoid oscillations and yet return to equilibrium quickly.

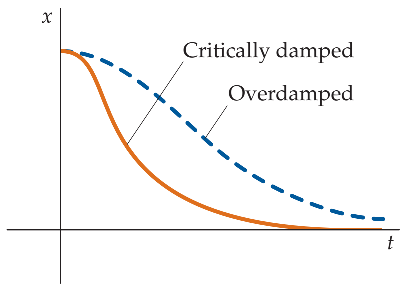

FIGURE 14-22 Plots of displacement versus time for a critically damped and an overdamped oscillator, each released from rest.

Example 14-13 Sprung Mass of a Passenger Car

The sprung mass of an automobile is the mass that is supported by the springs. (It does not include the mass of the wheels, axles, brakes, and so on.) A passenger car has a sprung mass of 1100 kg and an unsprung mass of 250 kg. If the four shock absorbers are removed, the car bounces up and down on its springs with a frequency of 1.0 Hz. What is the damping constant provided by the four shocks if the car, with shocks, is to return to equilibrium as quickly as possible without passing it after hitting a speed bump?

PICTURE Because the car returns to equilibrium as quickly as possible without passing it, we know the car is a critically damped oscillator. Use $b_c = 2m\omega_0$ (Equation 14-43) to solve for the damping constant for critical damping.

SOLVE

1. The damping constant for critical damping is related to the natural frequency by $b_c = 2m\omega_0$ (Equation 14-43): $b_c = 2m\omega_0$
2. With the tires in contact with the pavement, only the inertia of the sprung mass enters the picture: $m = 1100\text{ kg}$
3. The natural frequency ω_0 is given in the problem statement: $\omega_0 = 1.0\text{ Hz}$
4. Calculate the damping constant: $b = b_c = 2(1100\text{ kg})/(1.0\text{ Hz}) = \boxed{2.2 \times 10^3\text{ kg/s}}$

CHECK The damping force is given by $\vec{F} = -b\vec{v}$, so bv has SI units of newtons. Our step-4 value for b has units of kg/s, so bv has units of $(\text{kg/s})(\text{m/s}) = \text{kg}\cdot\text{m/s}^2$, which are the SI units for mass times acceleration. Thus, kg/s are appropriate units for b.

TAKING IT FURTHER The optimal shock absorber for any vehicle is a shock absorber that has a damping constant such that the oscillations are critically damped. Thus, the optimal choice for the critical damping constant b_c is determined by the sprung mass of the vehicle and the force constant k of the suspension springs.)

Weights are placed in automobile wheels when the wheels are "balanced." The purpose of balancing the wheels is to prevent vibrations that will drive oscillations of the wheel assembly. *(David Wrobel/ Visuals Unlimited.)*

Because the energy of an oscillator is proportional to the square of its amplitude, the energy of an underdamped oscillator (averaged over a cycle) also decreases exponentially with time:

$$E = \tfrac{1}{2}m\omega^2A^2 = \tfrac{1}{2}m\omega^2(A_0e^{-(b/2m)t})^2 = \tfrac{1}{2}m\omega^2A_0^2e^{-(b/m)t} = E_0e^{-t/\tau} \qquad 14\text{-}44$$

where $E_0 = \tfrac{1}{2}m\omega^2A_0^2$ and $\tau = m/b$.

A damped oscillator is often described by its Q factor (for quality factor),

$$Q = \omega_0\tau \qquad 14\text{-}45$$

DEFINITION—Q FACTOR

The Q factor is dimensionless. (Because ω_0 has dimensions of reciprocal time, $\omega_0\tau$ is without dimension.) We can relate Q to the fractional energy loss per cycle. Differentiating Equation 14-44 gives

$$\frac{dE}{dt} = -(1/\tau)E_0e^{-t/\tau} = -(1/\tau)E \quad \text{or} \quad \frac{dE}{E} = -\frac{dt}{\tau}$$

If the damping is weak so that the energy loss per cycle is a small fraction of the energy E, we can replace dE by ΔE and dt by the period T. Then $|\Delta E|/E$ in one cycle (one period) is given by

$$\left(\frac{|\Delta E|}{E}\right)_{\text{cycle}} = \frac{T}{\tau} = \frac{2\pi}{\omega_0\tau} = \frac{2\pi}{Q} \tag{14-46}$$

so

$$Q = \frac{2\pi}{(|\Delta E|/E)_{\text{cycle}}} \qquad \frac{|\Delta E|}{E} \ll 1 \tag{14-47}$$

PHYSICAL INTERPRETATION OF Q FOR WEAK DAMPING

Q is thus inversely proportional to the fractional energy loss per cycle.

Example 14-14 Making Music

When middle C on a piano (frequency 262 Hz) is struck, it loses half its energy after 4.00 s. (*a*) What is the decay time τ? (*b*) What is the Q factor for this piano wire? (*c*) What is the fractional energy loss per cycle?

PICTURE (*a*) We use $E = E_0e^{-t/\tau}$ and set E equal to $\frac{1}{2}E_0$. (*b*) The Q value can then be found from the decay time and the frequency.

SOLVE

(*a*) 1. Set the energy at time $t = 4.00$ s equal to half the original energy:

$$E = E_0e^{-t/\tau} \quad \text{so} \quad \tfrac{1}{2}E_0 = E_0e^{-(4.00\text{ s}/\tau)}$$
$$\tfrac{1}{2} = e^{-(4.00\text{ s}/\tau)}$$

2. Solve for the time τ by taking the natural log of both sides:

$$\ln\frac{1}{2} = -\frac{4.00\text{ s}}{\tau}$$
$$\text{so} \quad \tau = \frac{4.00\text{ s}}{\ln 2} = 5.771 = \boxed{5.77\text{ s}}$$

(*b*) Calculate Q from τ and ω_0:

$$Q = \omega_0\tau = 2\pi f\tau$$
$$= 2\pi(262\text{ Hz})(5.771\text{ s}) = 9.500\times10^3 = \boxed{9.50\times10^3}$$

(*c*) The fractional energy loss in a cycle is given by Equation 14-46 and the frequency $f = 1/T$:

$$\left(\frac{|\Delta E|}{E}\right)_{\text{cycle}} = \frac{T}{\tau} = \frac{2\pi}{\omega_0\tau} = \frac{1}{f\tau} = \frac{1}{(262\text{ Hz})(5.771\text{ s})}$$
$$= 6.614\times10^{-4} = \boxed{6.61\times10^{-4}}$$

CHECK Q can also be calculated from $Q = 2\pi/(\Delta E/E)_{\text{cycle}} = 2\pi/(6.61\times10^{-4}) = 9.50\times10^3$. Note that the fractional energy loss after 4.00 s is not just the number of cycles (4.00×262) times the fractional energy loss per cycle, because the energy decreases exponentially, not linearly.

TAKING IT FURTHER Figure 14-23 shows the relative amplitude A/A_0 versus time and the relative energy E/E_0 versus time for the oscillation of a piano string after middle C is struck. After 4.00 s, the amplitude has decreased to about 0.7 times its initial value, and the energy, which is proportional to the amplitude squared, drops to about half its initial value.

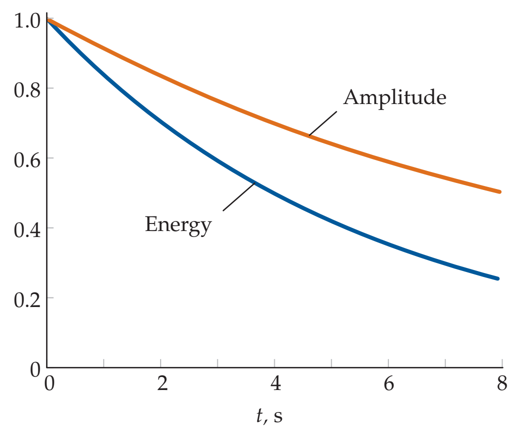

FIGURE 14-23 Plots of A/A_0 and E/E_0 for a struck piano string.

Note that the value of Q in Example 14-4 is relatively large. You can estimate τ and Q for various oscillating systems. Tap a crystal wine glass and see how long it rings. The longer it rings, the greater the value of τ and Q and the lower the damping. Glass beakers from the laboratory may also have a high Q. Try tapping a plastic cup. How does the damping compare to that of the glass beaker?

In terms of Q, the exact frequency of an underdamped oscillator is

$$\omega' = \omega_0\sqrt{1 - \left(\frac{b}{2m\omega_0}\right)^2} = \omega_0\sqrt{1 - \frac{1}{4Q^2}} \qquad \text{14-48}$$

Because b is quite small (and Q is quite large) for a weakly damped oscillator (Example 14-14), we see that ω' is nearly equal to ω_0.

We can understand much of the behavior of a weakly damped oscillator by considering its energy. The power dissipated by the damping force equals the instantaneous rate of change of the total mechanical energy

$$P = \frac{dE}{dt} = \vec{F}_d \cdot \vec{v} = -b\vec{v} \cdot \vec{v} = -bv^2 \qquad \text{14-49}$$

For a weakly damped oscillator with linear damping, the total mechanical energy decreases slowly with time. The average kinetic energy per cycle equals half the total energy

$$\left(\frac{1}{2}mv^2\right)_{\text{av}} = \frac{1}{2}E \quad \text{or} \quad (v^2)_{\text{av}} = \frac{E}{m}$$

If we substitute $(v^2)_{\text{av}} = E/m$ for v^2 in Equation 14-49, we have

$$\frac{dE}{dt} = -bv^2 \approx -b(v^2)_{\text{av}} = -\frac{b}{m}E \qquad \text{14-50}$$

Rearranging Equation 14-50 gives

$$\frac{dE}{E} = -\frac{b}{m}\,dt$$

which upon integration gives

$$E = E_0 e^{-(b/m)t} = E_0 e^{-t/\tau}$$

which is Equation 14-44.

14-5 DRIVEN OSCILLATIONS AND RESONANCE

To keep a damped system going indefinitely, mechanical energy must be put into the system. When this is done, the oscillator is said to be *driven* or *forced*. When Mom (or Dad) kept your swing going by pushing on it once each cycle, she was driving an oscillator. Likewise, when you keep a swing going by "pumping," you are driving an oscillator. If the driving mechanism puts energy into the system at a greater rate than it is dissipated, the system's mechanical energy increases with time, and the amplitude increases. If the driving mechanism puts energy in at the same rate it is being dissipated, the amplitude remains constant over time. The motion of the oscillator is then said to be steady-state motion.

Figure 14-24 shows a system consisting of an object on a spring that is being driven by moving the point of support up and down with simple harmonic motion of frequency ω. At first the motion is complicated, but eventually steady-state motion is reached in which the system oscillates with the same

By pumping the swing, the young woman is transferring her internal energy into the mechanical energy of the oscillator. *(Eye Wire/ Getty.)*

FIGURE 14-24 An object on a vertical spring can be driven by moving the support up and down.

frequency as that of the driver and with a constant amplitude and, therefore, at constant energy. In the steady state, the energy put into the system per cycle by the driving force equals the energy dissipated per cycle due to the damping.

The amplitude, and therefore the energy, of a system in the steady state depends not only on the amplitude of the driving force, but also on its frequency. The **natural frequency** of an oscillator, ω_0, is its frequency when no driving or damping forces are present. (In the case of a spring, for example, $\omega_0 = \sqrt{k/m}$.) If the driving frequency is sufficiently close to the natural frequency of the system, the system will oscillate with a relatively large amplitude. For example, if the support in Figure 14-24 oscillates at a frequency close to the natural frequency of the mass-spring system, the mass will oscillate with a much greater amplitude than it would if the support oscillates at significantly higher or lower frequencies. This phenomenon is called **resonance.** When the driving frequency equals the natural frequency of the oscillator, the energy per cycle transferred to the oscillator is maximum. The natural frequency of the system is thus called the **resonance frequency.** (Mathematically, the angular frequency ω is more convenient to use than the frequency $f(f = \omega/2\pi)$. Because ω and f are proportional, most statements concerning angular frequency also hold for frequency. In verbal descriptions, we usually omit the word angular when the omission will not cause confusion.) Figure 14-25 shows plots of the average power delivered to an oscillator as a function of the driving frequency for two different values of damping. These curves are called **resonance curves.** When the damping is weak (large Q), the width of the peak of the resonance curve is correspondingly narrow, and we speak of the resonance as being sharp. For strong damping, the resonance curve is broad. The width of each resonance curve $\Delta\omega$, indicated in the figure, is the width at half the maximum height. For weak damping, the ratio of the width of the resonance to the resonant frequency can be shown to equal the reciprocal of the Q factor (see Problem 106):

$$\frac{\Delta\omega}{\omega_0} = \frac{1}{Q} \qquad 14\text{-}51$$

RESONANCE WIDTH FOR WEAK DAMPING

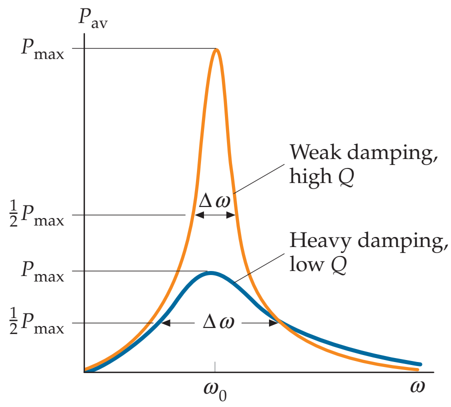

FIGURE 14-25 Resonance for an oscillator. The width $\Delta\omega$ of the resonance peak for a high-Q oscillator (the orange curve) is small compared to the natural frequency of ω_0. The resonance peak of the low-Q oscillator (the blue curve) with the same natural frequency has a width that is considerably larger that that for the high-Q oscillator.

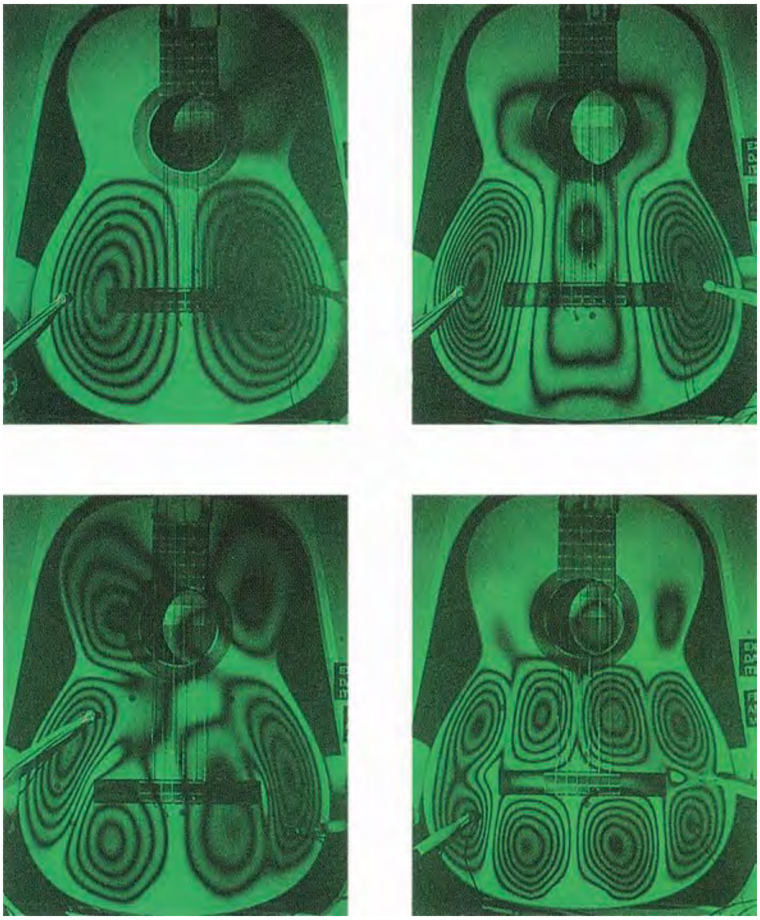
Thus, the Q factor is a direct measure of the sharpness of resonance.

You can do a simple experiment to demonstrate resonance. Hold a meterstick at one end between two fingers so that it acts like a pendulum. (If a meterstick is not available, use whatever is convenient. A golf club works fine.) Release the stick from some initial angular displacement and observe the natural frequency of its motion. Then, move your hand back and forth horizontally, driving it at its natural frequency. Even if the amplitude of the motion of your hand is small, the stick will oscillate with a substantial amplitude. Now move your hand back and forth at a frequency two or three times the natural frequency and note the decrease in amplitude of the oscillating stick.

There are many familiar examples of resonance. When you sit on a swing, you learn intuitively to pump with the same frequency as the natural frequency of the swing. Many machines vibrate because they have rotating parts that are not in perfect balance. (Observe a washing machine in the spin cycle, for example.) If such a machine is attached to a structure that can vibrate, the structure becomes a driven oscillatory system that is set in motion by the machine. Engineers pay great attention to balancing the rotary parts of such machines, damping their vibrations, and isolating them from building supports.

A crystal goblet with weak damping can be broken by an intense sound wave at a frequency equal to or very nearly equal to the natural frequency of vibration of the goblet. The breaking of the goblet is often done in physics demonstrations using an audio oscillator, a loudspeaker and an amplifier.



Extended objects have more than one resonance frequency. When plucked, a guitar string transmits its energy to the body of the guitar. The body's oscillations, coupled to those of the air mass it encloses, produce the resonance patterns shown. *(Royal Swedish Academy of Music.)*

* MATHEMATICAL TREATMENT OF RESONANCE

We can treat a driven oscillator mathematically by assuming that, in addition to the restoring force and a damping force, the oscillator is subject to an external driving force that varies harmonically with time:

$$F_{\text{ext}} = F_0 \cos \omega t \qquad 14\text{-}52$$

where F_0 and ω are the amplitude and angular frequency of the driving force. This frequency is generally not related to the natural angular frequency of the system ω_0.

Newton's second law applied to an object that has a mass m attached to a spring that has a force constant k and subject to a damping force $-bv_x$ and an external force $f_0 \cos \omega t$ gives

$$\Sigma F_x = ma_x$$

$$-kx - bv_x + F_0 \cos \omega t = m\frac{d^2x}{dt^2}$$

where we have used $a_x = d^2x/dt^2$. Substituting $m\omega_0^2$ for k (Equation 14-8) and rearranging gives

$$m\frac{d^2x}{dt^2} + b\frac{dx}{dt} + m\omega_0^2 x = F_0 \cos \omega t \qquad 14\text{-}53$$

DIFFERENTIAL EQUATION FOR A DRIVEN OSCILLATOR

We now discuss the general solution of Equation 14-53 qualitatively. It consists of two parts, the **transient solution** and the **steady-state solution.** The transient part of the solution is identical to that for a damped oscillator given in Equation 14-39. The constants in this part of the solution depend on the initial conditions. Over time, this part of the solution becomes negligible because of the exponential decrease of the amplitude. We are then left with the steady-state solution, which can be written as

$$x = A\cos(\omega t - \delta) \qquad 14\text{-}54$$

POSITION FOR A DRIVEN OSCILLATOR

where the angular frequency ω is the same as that of the driving force. The amplitude A is given by

$$A = \frac{F_0}{\sqrt{m^2(\omega_0^2 - \omega^2)^2 + b^2\omega^2}} \qquad 14\text{-}55$$

AMPLITUDE FOR A DRIVEN OSCILLATOR

and the phase constant δ is given by

$$\tan\delta = \frac{b\omega}{m(\omega_0^2 - \omega^2)} \qquad 14\text{-}56$$

PHASE CONSTANT FOR A DRIVEN OSCILLATOR

Comparing Equations 14-52 and 14-54, we can see that the displacement and the driving force oscillate with the same frequency, but they differ in phase by δ. When the driving frequency ω approaches zero, δ approaches zero, as can be seen from Equation 14-56. At resonance, ω equals ω_0 and δ equals 90°, and when ω is much greater than ω_0, δ approaches 180°. At the beginning of this chapter, the displacement of a particle undergoing simple harmonic motion is written $x = A\cos(\omega t + \delta)$ (Equation 14-4). This equation is identical to Equation 14-54 except for the sign preceding the phase constant δ. The phase of a driven oscillator always lags behind the phase of the driving force. The negative sign in Equation 14-54 ensures that δ is always positive (rather than always negative).

In your simple experiment to drive a meterstick by moving your hand back and forth (see discussion immediately following Equation 14-51), you should note that at resonance the oscillation of your hand is neither in phase nor 180° out of phase with the oscillation of the stick. If you move your hand back and forth at a frequency several times the natural frequency of the pendulum, the stick's steady-state motion will be almost 180° out of phase with your hand.

The velocity of the object in the steady state is obtained by differentiating x with respect to t:

$$v_x = \frac{dx}{dt} = -\omega A\sin(\omega t - \delta)$$

At resonance, $\delta = \pi/2$, and the velocity is in phase with the driving force:

$$v_x = -\omega A\sin\left(\omega t - \frac{\pi}{2}\right) = +\omega A\cos\omega t$$

Thus, at resonance, the object is always moving in the direction of the driving force, as would be expected for maximum power input. The velocity amplitude ωA is maximum at $\omega = \omega_0$.

! At resonance, the object is always moving in the direction of the driving force, as would be expected for maximum power input.

Example 14-15 An Object on a Spring

Try It Yourself

An object of mass 1.5 kg on a spring that has a force constant equal to 600 N/m loses 3.0% of its energy in each cycle. The same system is driven by a sinusoidal force with a maximum value of $F_0 = 0.50$ N. (*a*) What is Q for this system? (*b*) What is the resonance (angular) frequency? (*c*) If the driving frequency is slowly varied through resonance, what is the width $\Delta\omega$ of the resonance? (*d*) What is the amplitude at resonance? (*e*) What is the amplitude if the driving frequency $\omega = 19$ rad/s?

PICTURE The energy loss per cycle is only 3.0%, so the damping is weak. We can find Q from $Q = 2\pi/(\Delta E/E)_{\text{cycle}}$ (Equation 14-47) and then use this result and $\Delta\omega/\omega_0 = 1/Q$ (Equation 14-51) to find the width $\Delta\omega$ of the resonance. The resonance frequency is the natural frequency. The amplitude both at resonance and off resonance can be found from Equation 14-55, with the damping constant calculated from Q using $Q = \omega_0\tau$ (Equation 14-45) and $\tau = m/b$ (Equation 14-42).

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
(*a*) The damping is weak. Relate Q to the fractional energy loss using $Q = 2\pi/(\Delta E/E)_{\text{cycle}}$ (Equation 14-47):	$Q \approx \dfrac{2\pi}{(\lvert\Delta E\rvert/E)_{\text{cycle}}} = \dfrac{2\pi}{0.030} = \boxed{210}$
(*b*) The resonance frequency is the natural frequency of the system:	$\omega_0 = \sqrt{\dfrac{k}{m}} = \boxed{20\text{ rad/s}}$
(*c*) Relate the width of the resonance $\Delta\omega$ to Q using $\Delta\omega/\omega_0 = 1/Q$ (Equation 14-51):	$\Delta\omega = \dfrac{\omega_0}{Q} = \boxed{0.096\text{ rad/s}}$
(*d*) 1. Write an expression for the amplitude A for any driving frequency ω (Equation 14-55):	$A(\omega) = \dfrac{F_0}{\sqrt{m^2(\omega_0^2 - \omega^2)^2 + b^2\omega^2}}$
2. Set ω equal to ω_0 to calculate A at resonance:	$A(\omega_0) = \dfrac{F_0}{b\omega_0}$
3. Use $Q = \omega_0\tau$ (Equation 14-45) and $\tau = m/b$ (Equation 14-42) to relate the damping constant b to Q:	$b = \dfrac{m\omega_0}{Q} = 0.144$ kg/s
4. Use the results of the previous two steps to calculate the amplitude at resonance:	$A(\omega_0) = \dfrac{F_0}{b\omega_0} = \boxed{17\text{ cm}}$
(*e*) Calculate the amplitude for $\omega = 19$ rad/s. (We omit the units to simplify the equation. Because all quantities are in SI units, A will be in meters.)	$A(19) = \dfrac{0.5}{\sqrt{1.5^2(20^2 - 19^2)^2 + 0.144^2(19)^2}} = \boxed{0.85\text{ cm}}$

CHECK At a frequency just 1 rad/s below the 20 rad/s resonance frequency, the amplitude drops by a factor of 20. This is not surprising, because the width $\Delta\omega$ of the resonance is only 0.096 rad/s.

TAKING IT FURTHER Off resonance the term $b^2\omega^2$ is negligible compared with the other term in the denominator of the expression for A. When $\omega - \omega_0$ is more than several times the width $\Delta\omega$, as it was in this example, we can neglect the $b^2\omega^2$ term and calculate A from $A \approx F_0/[m(\omega_0^2 - \omega^2)]$. Figure 14-26 shows the amplitude versus driving frequency ω. Note that the horizontal scale is over a small range of ω.

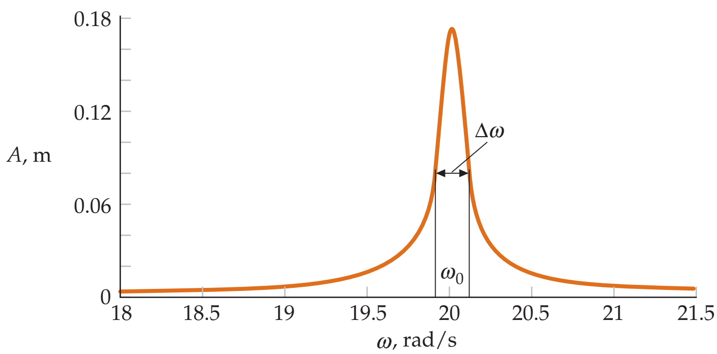


FIGURE 14-26

Physics Spotlight

Moving to the Beat: Millennium Bridge

Massive damped oscillators were attached under the walkway shortly after this suspension bridge opened. The oscillators were put there to prevent the excessive swaying that was driven by lateral forces exerted by the footsteps of the walkers. *(Alamy.)*

The three-span London Millennium footbridge opened in June of 2000. Between 80,000 and 100,000 people crossed the suspension bridge during the course of the day. As the bridge became crowded with up to 2000 people on it at any one time,[*] it began to sway from side to side. Soon the lateral swaying was so strong that many people had to hold onto the handrails.[†] The "Wobbly Bridge"[‡] was closed three days after its opening and did not reopen until February 2002. The footbridge was designed to withstand extremely strong winds, as well as hits from heavy barges on both piers. However, the lateral motion was a shock to the designers and engineers. After several months of study, researchers concluded that walking has a lateral component of force, as well as vertical and forward/backward components.

The typical cadence of a walking person is such that his or her left foot strikes the walkway at approximately one-second intervals. The same is true, of course, for the right foot. When someone steps forward onto his or her left foot, nearly 25 N of force is directed to the left; the force is directed to the right for the right foot.[#] At each step, a left or right lateral force is exerted on the walkway, so the lateral forces shake the walkway with a frequency of 1 Hz. Unfortunately, the two lowest natural frequencies of sideways motion for the 144-meter-long center span were 0.5 Hz and 1.0 Hz,[°] and the 100-meter-long southern span had a natural vibration mode at 0.8 Hz. The footsteps of the crowd drove the motion of the bridge. When the crowd was small, the combined force of the footsteps was not enough to cause motion. But after more than 200 people were on the bridge,[§] the natural damping of the bridge was not high enough to resist the combined force of the crowd's footsteps pushing the bridge sideways.

The swaying increased because of human reaction to the sideways motion. Calculations show that the maximum lateral acceleration was between 0.2g and 0.3g,[¶] enough to cause people to lose their balance. An instinctive method of regaining balance on a moving surface is to walk so that the timing of footsteps matches the motion of the surface. This resonant walking increased the amplitude of the motion.

Measurements were made of test crowds on the bridge, which led to the solution of a series of dampers. Eight tuned-mass dampers and 37 viscous dampers were installed to reduce the lateral swaying. The tuned-mass dampers are 2.5-ton steel blocks suspended on pendulums. They reduce lateral sway by vibrating 180° out of phase with the bridge.[**] The viscous dampers are similar to the shock absorbers used to dampen vertical oscillations in automobiles; they work by moving a piston back and forth through a viscous fluid. The main lateral damping is performed by 37 viscous dampers.[††] Additional mass dampers were installed to dampen any vertical oscillations. During the final tests before reopening, the peak measured accelerations on the bridge dropped by 97%, from 0.25g to 0.006g.[‡‡] The bridge has had no swaying problems since reopening.

Any[##] bridge with a lateral vibration mode below 1.3 Hz is susceptible to oscillation caused by the footsteps of a crowd.[°°] Several different types of bridges had exhibited lateral swaying under pedestrian loads, including a cable-stayed bridge in Japan[§§] and footbridges in Paris and Ottawa. Even highway bridges have shown the same behavior.[¶¶] Because of the London Millennium footbridge, engineers have been motivated to look at vibration in a new manner.

Summary

1. Simple harmonic motion occurs whenever the restoring force is proportional to the displacement from equilibrium. It has wide application in the study of oscillations, waves, electrical circuits, and molecular dynamics.
2. Resonance is an important phenomenon in many areas of physics. It occurs when the frequency of the driving force is close to the natural frequency of the oscillating system.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Simple Harmonic Motion	In simple harmonic motion, the acceleration (and thus the net force) is both proportional to, and oppositely directed from, the displacement from the equilibrium position. $F_x = -kx = ma_x$	14-1
Position function	$x = A\cos(\omega t + \delta)$	14-4
Angular frequency	$\omega = 2\pi f = \dfrac{2\pi}{T}$	14-11
Mechanical energy	$E = K + U = \frac{1}{2}kA^2$	14-17
Circular motion	If a particle moves in a circle with constant speed, the projection of the particle onto a diameter of the circle moves in simple harmonic motion.	
General motion near equilibrium	If an object is given a small displacement from a position of stable equilibrium, it typically oscillates about this position with simple harmonic motion.	
2. Natural Frequencies for Various Systems		
Mass on a spring	$\omega = \sqrt{\dfrac{k}{m}}$	14-8
Simple pendulum	$\omega = \sqrt{\dfrac{g}{L}}$	14-27
Torsional oscillator	$\omega = \sqrt{\dfrac{\kappa}{I}}$ where I is the moment of inertia and κ is the torsional constant. For small oscillations of a physical pendulum, $\kappa = MgD$, where D is the distance of the center of mass from the rotation axis.	14-33
3. Damped Oscillations	In the oscillations of real systems, the motion is damped because of dissipative forces. If the damping is greater than some critical value, the system does not oscillate when disturbed, but merely returns to its equilibrium position. The motion of a weakly damped system is nearly simple harmonic with an amplitude that decreases exponentially with time.	
Frequency	$\omega' = \omega_0\sqrt{1 - \dfrac{1}{4Q^2}}$	14-48
Energy	$E = E_0 e^{-t/\tau}$	14-44
Amplitude	$A = A_0 e^{-(1/2)t/\tau}$	14-41
Decay time	$\tau = \dfrac{m}{b}$	14-42
Q factor defined	$Q = \omega_0 \tau$	14-45
Q factor for weak damping	$Q \approx \dfrac{2\pi}{(\lvert\Delta E\rvert/E)_{\text{cycle}}} \quad \left(\dfrac{\lvert\Delta E\rvert}{E}\right)_{\text{cycle}} \ll 1$	14-47
4. Driven Oscillations	When an underdamped ($b < b_c$) system is driven by an external sinusoidal force $F_{\text{ext}} = F_0 \cos\omega t$, the system oscillates with a frequency ω equal to the driving frequency and an amplitude A that depends on the driving frequency.	

TOPIC	RELEVANT EQUATIONS AND REMARKS	
Resonance frequency	$\omega = \omega_0$	
Resonance width for weak damping	$\dfrac{\Delta\omega}{\omega_0} = \dfrac{1}{Q}$	14-51
*Position function	$x = A\cos(\omega t - \delta)$	14-54
*Amplitude	$A = \dfrac{F_0}{\sqrt{m^2(\omega_0^2 - \omega^2)^2 + b^2\omega^2}}$	14-55
*Phase constant	$\tan\delta = \dfrac{b\omega}{m(\omega_0^2 - \omega^2)}$	14-56

Answer to Concept Check

14-1 $\sqrt{L/g}$

Answers to Practice Problems

14-1 (*a*) $f = 3.6$ Hz, $T = 0.28$ s, (*b*) $f = 2.5$ Hz, $T = 0.40$ s

14-2 $\omega = 3.1$ rad/s, $v_{\text{max}} = 0.13$ m/s

14-3 (*a*) $E = \frac{1}{2}mv_{\text{max}}^2 = 0.0625$ J (*b*) $A = \sqrt{2E_{\text{total}}/k} = 5.59$ cm

14-4 24 cm

14-5 2.01 s

14-6 $g' = 10.3\ \text{m/s}^2$, $T = 1.96$ s

14-7 $T = \sqrt{\dfrac{2L}{3g}}$ for $x = L/6$ and for $x = L/2$

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

• Single-concept, single-step, relatively easy

•• Intermediate-level, may require synthesis of concepts

••• Challenging

SSM Solution is in the *Student Solutions Manual*

Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • True or false:

(*a*) For a simple harmonic oscillator, the period is proportional to the square of the amplitude.

(*b*) For a simple harmonic oscillator, the frequency does not depend on the amplitude.

(*c*) If the net force on a particle undergoing one-dimensional motion is proportional to, and oppositely directed from, the displacement from equilibrium, the motion is simple harmonic.

2 • If the amplitude of a simple harmonic oscillator is tripled, by what factor is the energy changed?

3 •• An object attached to a spring exhibits simple harmonic motion with an amplitude of 4.0 cm. When the object is 2.0 cm from the equilibrium position, what percentage of its total mechanical energy is in the form of potential energy? (*a*) one-quarter, (*b*) one-third, (*c*) one-half, (*d*) two-thirds, (*e*) three-quarters SSM

4 •• An object attached to a spring exhibits simple harmonic motion with an amplitude of 10.0 cm. How far from equilibrium will the object be when the system's potential energy is equal to its kinetic energy? (*a*) 5.00 cm, (*b*) 7.07 cm, (*c*) 9.00 cm, (*d*) The distance cannot be determined from the data given.

5 •• Two identical systems each consist of a spring with one end attached to a block and the other end attached to a wall. The springs are horizontal, and the blocks are supported from below by a frictionless horizontal table. The blocks are oscillating in simple harmonic motions such that the amplitude of the motion of block A is four times as large as the amplitude of the motion of block B. How do their maximum speeds compare? (*a*) $v_{\text{A max}} = v_{\text{B max}}$, (*b*) $v_{\text{A max}} = 2v_{\text{B max}}$, (*c*) $v_{\text{A max}} = 4v_{\text{B max}}$, (*d*) This comparison cannot be done by using the data given.

6 •• Two systems each consist of a spring with one end attached to a block and the other end attached to a wall. The springs are horizontal, and the blocks are supported from below by a frictionless horizontal table. The identical blocks are oscillating in simple harmonic motions with equal amplitudes. However, the force constant of spring A is four times as large as the force constant of spring B. How do their maximum speeds compare? (*a*) $v_{\text{A max}} = v_{\text{B max}}$, (*b*) $v_{\text{A max}} = 2v_{\text{B max}}$, (*c*) $v_{\text{A max}} = 4v_{\text{B max}}$, (*d*) This comparison cannot be done by using the data given.

7 •• Two systems each consist of a spring with one end attached to a block and the other end attached to a wall. The identical springs are horizontal, and the blocks are supported from below by a frictionless horizontal table. The blocks are oscillating in simple harmonic motions with equal amplitudes. However, the mass of block A is four times as large as the mass of block B. How do their maximum speeds compare? (*a*) $v_{\text{A max}} = v_{\text{B max}}$, (*b*) $v_{\text{A max}} = 2v_{\text{B max}}$, (*c*) $v_{\text{A max}} = \frac{1}{2}v_{\text{B max}}$, (*d*) This comparison cannot be done by using the data given. SSM

8 •• Two systems each consist of a spring with one end attached to a block and the other end attached to a wall. The identical springs are horizontal, and the blocks are supported from below by a frictionless horizontal table. The blocks are oscillating in simple harmonic motions with equal amplitudes. However, the mass of block A is four times as large as the mass of block B. How do the magnitudes of their maximum accelerations compare? (*a*) $a_{A\max} = a_{B\max}$, (*b*) $a_{A\max} = 2a_{B\max}$, (*c*) $a_{A\max} = \frac{1}{2}a_{B\max}$, (*d*) $a_{A\max} = \frac{1}{4}a_{B\max}$, (*e*) This comparison cannot be done by using the data given.

9 •• In general physics courses, the mass of the spring in simple harmonic motion is usually neglected because its mass is usually much smaller than the mass of the object attached to it. However, this is not always the case. If you neglect the mass of the spring when it is not negligible, how will your calculation of the system's period, frequency, and total energy compare to the actual values of these parameters? Explain. SSM

10 •• Two mass–spring systems oscillate with periods T_A and T_B. If $T_A = 2T_B$ and the systems' springs have identical force constants, it follows that the systems' masses are related by (*a*) $m_A = 4m_B$, (*b*) $m_A = m_B/\sqrt{2}$, (*c*) $m_A = m_B/2$, (*d*) $m_A = m_B/4$.

11 •• Two mass–spring systems oscillate at frequencies f_A and f_B. If $f_A = 2f_B$ and the systems' springs have identical force constants, it follows that the systems' masses are related by (*a*) $m_A = 4m_B$, (*b*) $m_A = m_B/\sqrt{2}$, (*c*) $m_A = m_B/2$, (*d*) $m_A = m_B/4$.

12 •• Two mass–spring systems *A* and *B* oscillate so that their total mechanical energies are equal. If $m_A = 2m_B$, which expression best relates their amplitudes? (*a*) $A_A = A_B/4$, (*b*) $A_A = A_B/\sqrt{2}$, (*c*) $A_A = A_B$, (*d*) Not enough information is given to determine the ratio of the amplitudes.

13 •• Two mass–spring systems *A* and *B* oscillate so that their total mechanical energies are equal. If the force constant of spring *A* is two times as large as the force constant of spring *B*, then which expression best relates their amplitudes? (*a*) $A_A = A_B/4$, (*b*) $A_A = A_B/\sqrt{2}$, (*c*) $A_A = A_B$, (*d*) Not enough information is given to determine the ratio of the amplitudes. SSM

14 •• The length of the string or wire supporting a pendulum bob increases slightly when the temperature of the string or wire increases. How does this affect a clock operated by a simple pendulum?

15 •• A lamp hanging from the ceiling of the club car in a train oscillates with period T_0 when the train is at rest. The period will be (match left and right columns)

1. greater than T_0 when	A. The train moves horizontally at constant velocity.
2. less than T_0 when	B. The train rounds a curve at constant speed.
3. equal to T_0 when	C. The train climbs a hill at constant speed.
	D. The train goes over the crest of a hill at constant speed.

16 •• Two simple pendulums are related as follows. Pendulum A has a length L_A and a bob of mass m_A; pendulum B has a length L_B and a bob of mass m_B. If the period of A is twice that of B, then (*a*) $L_A = 2L_B$ and $m_A = 2m_B$, (*b*) $L_A = 4L_B$ and $m_A = m_B$, (*c*) $L_A = 4L_B$, whatever the ratio m_A/m_B, (*d*) $L_A = \sqrt{2}L_B$, whatever the ratio m_A/m_B.

17 •• Two simple pendulums are related as follows. Pendulum A has a length L_A and a bob of mass m_A; pendulum B has a length L_B and a bob of mass m_B. If the frequency of A is one-third the frequency of B, then (*a*) $L_A = 3L_B$ and $m_A = 3m_B$, (*b*) $L_A = 9L_B$ and $m_A = m_B$, (*c*) $L_A = 9L_B$, regardless of the ratio m_A/m_B, (*d*) $L_A = \sqrt{3}L_B$ regardless of the ratio m_A/m_B. SSM

18 •• Two simple pendulums are related as follows. Pendulum A has a length L_A and a bob of mass m_A; pendulum B has a length L_B and a bob of mass m_B. They have the same period. If the only difference between their motions is that the amplitude of A's motion is twice the amplitude of B's motion, then (*a*) $L_A = L_B$ and $m_A = m_B$, (*b*) $L_A = 2L_B$ and $m_A = m_B$, (*c*) $L_A = L_B$ whatever the ratio m_A/m_B, (*d*) $L_A = \frac{1}{2}L_B$. whatever the ratio m_A/m_B.

19 •• True or false:

(*a*) The mechanical energy of a damped, undriven oscillator decreases exponentially with time.
(*b*) Resonance for a damped, driven oscillator occurs when the driving frequency exactly equals the natural frequency.
(*c*) If the *Q* factor of a damped oscillator is high, then its resonance curve will be narrow.
(*d*) The decay time τ for a spring-mass oscillator with linear damping is independent of its mass.
(*e*) The *Q* factor for a driven spring-mass oscillator with linear damping is independent of its mass.

20 •• Two damped spring-mass oscillating systems have identical spring and damping constants. However, system A's mass m_A is four times system B's mass m_B. How do their decay times compare? (*a*) $\tau_A = 4\tau_B$, (*b*) $\tau_A = 2\tau_B$, (*c*) $\tau_A = \tau_B$, (*d*) Their decay times cannot be compared, given the information provided.

21 •• Two damped spring-mass oscillating systems have identical spring constants and decay times. However, system A's mass m_A is twice system B's mass m_B. How do their damping constants, *b*, compare? (*a*) $b_A = 4b_B$, (*b*) $b_A = 2b_B$, (*c*) $b_A = b_B$, (*d*) $b_A = \frac{1}{2}b_B$, (*e*) Their decay times cannot be compared, given the information provided.

22 •• Two damped, driven spring-mass oscillating systems have identical driving forces as well as identical spring and damping constants. However, the mass of system A is four times the mass of system B. Assume both systems are very weakly damped. How do their resonant frequencies compare? (*a*) $\omega_A = \omega_B$ (*b*) $\omega_A = 2\omega_B$, (*c*) $\omega_A = \frac{1}{2}\omega_B$, (*d*) $\omega_A = \frac{1}{4}\omega_B$, (*e*) Their resonant frequencies cannot be compared, given the information provided.

23 •• Two damped, driven spring-mass oscillating systems have identical masses, driving forces, and damping constants. However, system A's force constant k_A is four times system B's force constant k_B. Assume they are both very weakly damped. How do their resonant frequencies compare? (*a*) $\omega_A = \omega_B$, (*b*) $\omega_A = 2\omega_B$, (*c*) $\omega_A = \frac{1}{2}\omega_B$, (*d*) $\omega_A = \frac{1}{4}\omega_B$, (*e*) Their resonant frequencies cannot be compared, given the information provided. SSM

24 •• Two damped, driven simple-pendulum systems have identical masses, driving forces, and damping constants. However, system A's length is four times system B's length. Assume they are both very weakly damped. How do their resonant frequencies compare? (*a*) $\omega_A = \omega_B$, (*b*) $\omega_A = 2\omega_B$, (*c*) $\omega_A = \frac{1}{2}\omega_B$, (*d*) $\omega_A = \frac{1}{4}\omega_B$, (*e*) Their resonant frequencies cannot be compared, given the information provided.

ESTIMATION AND APPROXIMATION

25 • Estimate the width of a typical grandfather clock's cabinet relative to the width of the pendulum bob, presuming the desired motion of the pendulum is simple harmonic. SSM

26 • A small punching bag for boxing workouts is approximately the size and weight of a person's head and is suspended from a very short rope or chain. Estimate the natural frequency of oscillations of such a punching bag.

27 •• For a child on a swing, the amplitude drops by a factor of $1/e$ in about eight periods if no additional mechanical energy is given to the system. Estimate the *Q* factor for this system.

28 •• (*a*) Estimate the natural period of oscillation for swinging your arms as you walk, when your hands are empty. (*b*) Now estimate the natural period of oscillation when you are carrying a heavy briefcase. (*c*) Observe other people while they walk. Do your estimates seem reasonable?

SIMPLE HARMONIC MOTION

Note: Unless otherwise specified, assume that all objects in this section are in simple harmonic motion.

29 • The position of a particle is given by $x = (7.0\text{ cm})\cos 6\pi t$, where t is in seconds. What are (*a*) the frequency, (*b*) the period, and (*c*) the amplitude of the particle's motion? (*d*) What is the first time after $t = 0$ that the particle is at its equilibrium position? In what direction is it moving at that time?

30 • What is the phase constant δ in $x = A\cos(\omega t + \delta)$ (Equation 14.4) if the position of the oscillating particle at time $t = 0$ is (*a*) 0, (*b*) $-A$, (*c*) A, and (*d*) $A/2$?

31 • A particle of mass m begins at rest from $x = +25$ cm and oscillates about its equilibrium position at $x = 0$ with a period of 1.5 s. Write expressions for (*a*) the position x as a function of t, (*b*) the velocity v_x as a function of t, and (*c*) the acceleration a_x as a function of t. SSM

32 •• Find (*a*) the maximum speed, and (*b*) the maximum acceleration of the particle in Problem 29. (*c*) What is the first time that the particle is at $x = 0$ and moving to the right?

33 •• Work Problem 31 for when the particle is initially at $x = 25$ cm and moving with velocity $v_0 = +50$ cm/s.

34 •• The period of a particle that is oscillating in simple harmonic motion is 8.0 s and its amplitude is 12 cm. At $t = 0$, it is at its equilibrium position. Find the distance the particle travels during the intervals (*a*) $t = 0$ to $t = 2.0$ s, (*b*) $t = 2.0$ s to $t = 4.0$ s, (*c*) $t = 0$ to $t = 1.0$ s, and (*d*) $t = 1.0$ s to $t = 2.0$ s.

35 •• The period of a particle oscillating in simple harmonic motion is 8.0 s. At $t = 0$, the particle is at rest at $x = A = 10$ cm. (*a*) Sketch x as a function of t. (*b*) Find the distance traveled in the first, second, third, and fourth second after $t = 0$.

36 •• **ENGINEERING APPLICATION, CONTEXT-RICH** Military specifications often call for electronic devices to be able to withstand accelerations of up to $10g$ ($10g = 98.1\text{ m/s}^2$). To make sure that your company's products meet this specification, your manager has told you to use a "shaking table," which can vibrate a device at controlled and adjustable frequencies and amplitudes. If a device is placed on the table and made to oscillate at an amplitude of 1.5 cm, what should you adjust the frequency to in order to test for compliance with the $10g$ military specification?

37 •• The position of a particle is given by $x = 2.5\cos\pi t$, where x is in meters and t is in seconds. (*a*) Find the maximum speed and maximum acceleration of the particle. (*b*) Find the speed and acceleration of the particle when $x = 1.5$ m. SSM

38 ••• (*a*) Show that $A_0\cos(\omega t + \delta)$ can be written as $A_s\sin(\omega t) + A_c\cos(\omega t)$, and determine A_s and A_c in terms of A_0 and δ. (*b*) Relate A_c and A_s to the initial position and velocity of a particle undergoing simple harmonic motion.

SIMPLE HARMONIC MOTION AS RELATED TO CIRCULAR MOTION

39 • A particle moves at a constant speed of 80 cm/s in a circle of radius 40 cm centered at the origin. (*a*) Find the frequency and period of the x component of its position. (*b*) Write an expression for the x component of the particle's position as a function of time t, assuming that the particle is located on the $+y$ axis at time $t = 0$. SSM

40 • A particle moves in a 15-cm-radius circle centered at the origin and completes 1.0 rev every 3.0 s. (*a*) Find the speed of the particle. (*b*) Find its angular speed ω. (*c*) Write an equation for the x component of the particle's position as a function of time t, assuming that the particle is on the $-x$ axis at time $t = 0$.

ENERGY IN SIMPLE HARMONIC MOTION

41 • A 2.4-kg object on a frictionless hoizontal surface is attached to one end of a horizontal spring of force constant $k = 4.5$ kN/m. The other end of the spring is held stationary. The spring is stretched 10 cm from equilibrium and released. Find the system's total mechanical energy.

42 • Find the total energy of a system consisting of a 3.0-kg object on a frictionless horizontal surface oscillating with an amplitude of 10 cm and a frequency of 2.4 Hz at the end of a horizontal spring.

43 • A 1.50-kg object on a frictionless horizontal surface oscillates at the end of a spring (force constant $k = 500$ N/m). The object's maximum speed is 70.0 cm/s. (*a*) What is the system's total mechanical energy? (*b*) What is the amplitude of the motion? SSM

44 • A 3.0-kg object on a frictionless horizontal surface oscillating at the end of a spring that has a force constant equal to 2.0 kN/m has a total mechanical energy of 0.90 J. (*a*) What is the amplitude of the motion? (*b*) What is the maximum speed?

45 • An object on a frictionless horizontal surface oscillates at the end of a spring with an amplitude of 4.5 cm. Its total mechanical energy is 1.4 J. What is the force constant of the spring?

46 •• A 3.0-kg object on a frictionless horizontal surface oscillates at the end of a spring with an amplitude of 8.0 cm. Its maximum acceleration is 3.5 m/s^2. Find the total mechanical energy.

SIMPLE HARMONIC MOTION AND SPRINGS

47 • A 2.4-kg object on a frictionless horizontal surface is attached to the end of a horizontal spring that has a force constant $k = 4.5$ kN/m. The spring is stretched 10 cm from equilibrium and released. What are (*a*) the frequency of the motion, (*b*) the period, (*c*) the amplitude, (*d*) the maximum speed, and (*e*) the maximum acceleration? (*f*) When does the object first reach its equilibrium position? What is its acceleration at this time?

48 • A 5.00-kg object on a frictionless horizontal surface is attached to one end of a horizontal spring that has a force constant $k = 700$ N/m. The spring is stretched 8.00 cm from equilibrium and released. What are (*a*) the frequency of the motion, (*b*) the period, (*c*) the amplitude, (*d*) the maximum speed, and (*e*) the maximum acceleration? (*f*) When does the object first reach its equilibrium position? What is its acceleration at this time?

49 • A 3.0-kg object on a frictionless horizonal surface is attached to one end of a horizontal spring and oscillates with an amplitude $A = 10$ cm and a frequency $f = 2.4$ Hz. (*a*) What is the force constant of the spring? (*b*) What is the period of the motion? (*c*) What is the maximum speed of the object? (*d*) What is the maximum acceleration of the object? SSM

50 • An 85.0-kg person steps into a car of mass 2400 kg, causing it to sink 2.35 cm on its springs. If started into vertical oscillation, and assuming no damping, at what frequency will the car and passenger vibrate on these springs?

51 • A 4.50-kg object oscillates on a horizontal spring with an amplitude of 3.80 cm. The object's maximum acceleration is 26.0 m/s^2. Find (*a*) the force constant of the spring, (*b*) the frequency of the object, and (*c*) the period of the motion of the object.

52 •• An object of mass m is suspended from a vertical spring of force constant 1800 N/m. When the object is pulled down 2.50 cm from equilibrium and released from rest, the object oscillates at 5.50 Hz. (*a*) Find m. (*b*) Find the amount the spring is stretched from its unstressed length when the object is in equilibrium. (*c*) Write expressions for the displacement x, the velocity v_x and the acceleration a_x as functions of time t.

53 •• An object is hung on the end of a vertical spring and is released from rest with the spring unstressed. If the object falls 3.42 cm before first coming to rest, find the period of the resulting oscillatory motion.

54 •• A suitcase of mass 20 kg is hung from two bungee cords, as shown in Figure 14-27. Each cord is stretched 5.0 cm when the suitcase is in equilibrium. If the suitcase is pulled down a little and released, what will be its oscillation frequency?

FIGURE 14-27 Problem 54

55 •• A 0.120-kg block is suspended from a spring. When a small pebble of mass 30 g is placed on the block, the spring stretches an additional 5.0 cm. With the pebble on the block, the block oscillates with an amplitude of 12 cm. (*a*) What is the frequency of the motion? (*b*) How long does the block take to travel from its lowest point to its highest point? (*c*) What is the net force on the pebble when it is at the point of maximum upward displacement?

56 •• Referring to Problem 55, find the maximum amplitude of oscillation at which the pebble will remain in contact with the block.

57 •• An object of mass 2.0 kg is attached to the top of a vertical spring that is anchored to the floor. The unstressed length of the spring is 8.0 cm and the length of the spring when the object is in equilibrium is 5.0 cm. When the object is resting at its equilibrium position, it is given a sharp downward blow with a hammer so that its initial speed is 0.30 m/s. (*a*) To what maximum height above the floor does the object eventually rise? (*b*) How long does it take for the object to reach its maximum height for the first time? (*c*) Does the spring ever become unstressed? What minimum initial velocity must be given to the object for the spring to be unstressed at some time?

58 ••• **Engineering Application** A winch cable has a cross-sectional area of 1.5 cm^2 and a length of 2.5 m. Young's modulus for the cable is 150 GN/m^2. A 950-kg engine block is hung from the end of the cable. (*a*) By what length does the cable stretch? (*b*) If we treat the cable as a simple spring, what is the oscillation frequency of the engine block at the end of the cable?

SIMPLE PENDULUM SYSTEMS

59 • Find the length of a simple pendulum if its frequency for small amplitudes is 0.75 Hz. SSM

60 • Find the length of a simple pendulum if its period for small amplitudes is 5.0 s.

61 • What would the period of the pendulum in Problem 60 be if the pendulum were on the moon, where the acceleration due to gravity is one-sixth that on Earth?

62 • If the period of a 70.0-cm-long simple pendulum is 1.68 s, what is the value of g at the location of the pendulum?

63 • A simple pendulum that is set up in the stairwell of a 10-story building consists of a heavy weight suspended on a 34.0-m-long wire. What is the period of oscillation?

64 •• Show that the total energy of a simple pendulum undergoing oscillations of small amplitude ϕ_0 (in radians) is $E \approx \frac{1}{2}mgL\phi_0^2$. *Hint: Use the approximation* $\cos\phi \approx 1 - \frac{1}{2}\phi^2$ *for small* ϕ.

65 ••• A simple pendulum of length L is attached to a massive cart that slides without friction down a plane inclined at angle θ with the horizontal, as shown in Figure 14-28. Find the period of oscillation for small oscillations of this pendulum. SSM

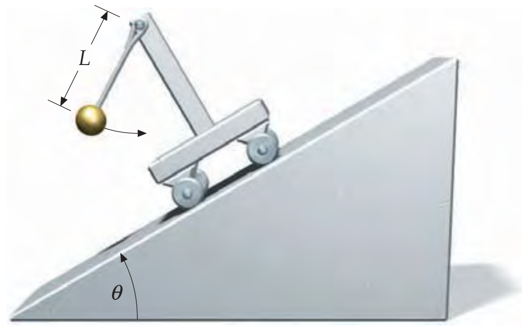

FIGURE 14-28 Problem 65

66 ••• The bob at the end of a simple pendulum of length L is released from rest from an angle ϕ_0. (*a*) Model the pendulum's motion as simple harmonic motion, and find its speed as it passes through $\phi = 0$ by using the small angle approximation. (*b*) Using the conservation of energy, find this speed exactly for any angle (not just small angles). (*c*) Show that your result from Part (*b*) agrees with the approximate answer in Part (*a*) when ϕ_0 is small. (*d*) Find the difference between the approximate and exact results for $\phi_0 = 0.20$ rad and $L = 1.0$ m. (*e*) Find the difference between the approximate and exact results for $\phi_0 = 1.20$ rad and $L = 1.0$ m.

* PHYSICAL PENDULUMS

67 • A thin 5.0-kg uniform disk with a 20-cm radius is free to rotate about a fixed horizontal axis perpendicular to the disk and passing through its rim. The disk is displaced slightly from equilibrium and released. Find the period of the subsequent simple harmonic motion. SSM

68 • A circular hoop that has a 50-cm radius is hung on a narrow horizontal rod and allowed to swing in the plane of the hoop. What is the period of its oscillation, assuming that the amplitude is small?

69 • A 3.0-kg plane figure is suspended at a point 10 cm from its center of mass. When it is oscillating with small amplitude, the period of oscillation is 2.6 s. Find the moment of inertia I about an axis perpendicular to the plane of the figure through the pivot point.

70 •• **Engineering Application, Context-Rich, Conceptual** You have designed a cat door that consists of a square piece of plywood that is 1.0 in. thick and 6.0 in. on a side, and is hinged at its top. To make sure the cat has enough time to get through it safely, the door should have a natural period of at least 1.0 s. Will your design work? If not, explain qualitatively what you would need to do to make it meet your requirements.

71 •• You are given a meterstick and asked to drill a small diameter hole through it so that, when the stick is pivoted about a horizontal axis through the hole, the period of the pendulum will be a minimum. Where should you drill the hole?

72 •• Figure 14-29 shows a uniform disk that has a radius $R = 0.80$ m, a mass of 6.00 kg, and a small hole a distance d from the disk's center that can serve as a pivot point. (*a*) What should be the distance d so that the period of this physical pendulum is 2.50 s? (*b*) What should be the distance d so that this physical pendulum will have the shortest possible period? What is this shortest possible period?

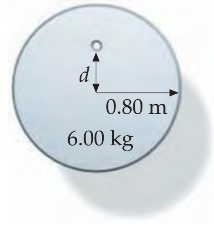

FIGURE 14-29 Problem 72

73 ••• Points P_1 and P_2 on a plane object (Figure 14-30), are distances h_1 and h_2 respectively, from the center of mass. The object oscillates with the same period T when it is free to rotate about an axis through P_1 and when it is free to rotate about an axis through P_2. Both of these axes are perpendicular to the plane of the object. Show that $h_1 + h_2 = gT^2/(4\pi^2)$, where $h_1 \neq h_2$. SSM

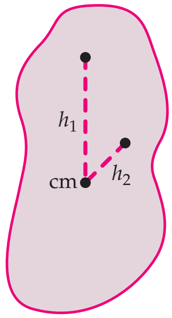

FIGURE 14-30 Problem 73

74 ••• A physical pendulum consists of a spherical bob of radius r and mass m suspended from a rigid rod of negligible mass, as in Figure 14-31. The distance from the center of the sphere to the point of support is L. When r is much less than L, such a pendulum is often treated as a simple pendulum of length L. (*a*) Show that the period for small oscillations is given by $T = T_0\sqrt{1 + (2r^2/5L^2)}$, where $T_0 = 2\pi\sqrt{L/g}$ is the period of a simple pendulum of length L. (*b*) Show that when r is smaller than L, the period can be approximated by $T \approx T_0(1 + r^2/5L^2)$. (*c*) If $L = 1.00$ m and $r = 2.00$ cm, find the error in the calculated value when the approximation $T = T_0$ is used for this period. How large must the radius of the bob be for the error to be 1.00 percent?

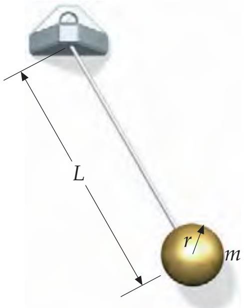

FIGURE 14-31 Problem 74

75 ••• Figure 14-32 shows the pendulum of a clock in your grandmother's house. The uniform rod of length $L = 2.00$ m has a mass $m = 0.800$ kg. Attached to the rod is a uniform disk of mass $M = 1.20$ kg and radius 0.150 m. The clock is constructed to keep perfect time if the period of the pendulum is exactly 3.50 s. (*a*) What should the distance d be so that the period of this pendulum is 2.50 s? (*b*) Suppose that the pendulum clock loses 5.00 min/d. To make sure your grandmother will not be late for her quilting parties, you decide to adjust the clock back to its proper period. How far and in what direction should you move the disk to ensure that the clock will keep perfect time?

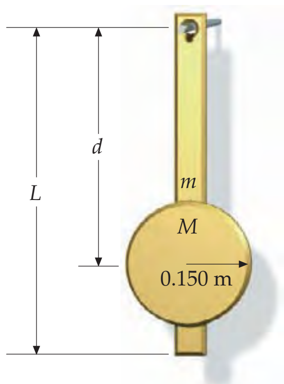

FIGURE 14-32 Problem 75

DAMPED OSCILLATIONS

76 • A 2.00-kg object oscillates on a spring with an initial amplitude of 3.00 cm. The force constant of the spring is 400 N/m. Find (*a*) the period, and (*b*) the total initial energy. (*c*) If the energy decreases by 1.00 percent per period, find the linear damping constant b and the Q factor.

77 •• Show that the ratio of the amplitudes for two successive oscillations is constant for a linearly damped oscillator. SSM

78 •• An oscillator has a period of 3.00 s. Its amplitude decreases by 5.00 percent during each cycle. (*a*) By how much does its mechanical energy decrease during each cycle? (*b*) What is the time constant τ? (*c*) What is the Q factor?

79 •• A linearly damped oscillator has a Q factor of 20. (*a*) By what fraction does the energy decrease during each cycle? (*b*) Use Equation 14-40 to find the percentage difference between ω' and ω_0. *Hint: Use the approximation* $(1 + x)^{1/2} \approx 1 + \frac{1}{2}x$ *for small* x.

80 •• A linearly damped mass-spring system oscillates at 200 Hz. The time constant of the system is 2.0 s. At $t = 0$, the amplitude of oscillation is 6.0 cm and the energy of the oscillating system is 60 J. (*a*) What are the amplitudes of oscillation at $t = 2.0$ s and $t = 4.0$ s? (*b*) How much energy is dissipated in the first 2-s interval and in the second 2-s interval?

81 •• **ENGINEERING APPLICATION** Seismologists and geophysicists have determined that the vibrating Earth has a resonance period of 54 min and a Q factor of about 400. After a large earthquake, Earth will "ring" (continue to vibrate) for up to 2 months. (*a*) Find the percentage of the energy of vibration lost to damping forces during each cycle. (*b*) Show that after n periods the vibrational energy is given by $E_n = (0.984)^n E_0$, where E_0, is the original energy. (*c*) If the original energy of vibration of an earthquake is E_0, what is the energy after 2.0 d? SSM

82 ••• A pendulum that is used in your physics laboratory experiment has a length of 75 cm and a compact bob with a mass equal to 15 g. To start the bob oscillating, you place a fan next to it that blows a horizontal stream of air on the bob. While the fan is on, the bob is in equilibrium when the pendulum is displaced by an angle of 5.0° from the vertical. The speed of the air from the fan is 7.0 m/s. You turn the fan off, and allow the pendulum to oscillate. (*a*) Assuming that the drag force due to the air is of the form $-bv$, predict the decay time constant τ for this pendulum. (*b*) How long will it take for the pendulum's amplitude to reach 1.0°?

83 ••• **ENGINEERING APPLICATION, CONTEXT-RICH** You are in charge of monitoring the viscosity of oils at a manufacturing plant and you determine the viscosity of an oil by using the following method: The viscosity of a fluid can be measured by determining the decay time of oscillations for an oscillator that has known properties and operates while immersed in the fluid. As long as the speed of the oscillator through the fluid is relatively small, so that turbulence is not a factor, the drag force of the fluid on a sphere is proportional to the sphere's speed v relative to the fluid: $F_d = 6\pi a\eta v$, where η is the viscosity of the fluid and a is the sphere's radius. Thus, the constant b is given by $6\pi a\eta$. Suppose your apparatus consists of a stiff spring that has a force constant equal to 350 N/cm and a gold sphere (radius 6.00 cm) hanging on the spring. (*a*) What viscosity of an oil do you measure if the decay time for this system is 2.80 s? (*b*) What is the Q factor for your system? SSM

DRIVEN OSCILLATIONS AND RESONANCE

84 • A linearly damped oscillator loses 2.00 percent of its energy during each cycle. (*a*) What is its Q factor? (*b*) If its resonance frequency is 300 Hz, what is the width of the resonance curve $\Delta\omega$ when the oscillator is driven?

85 • Find the resonance frequency for each of the three systems shown in Figure 14-33.

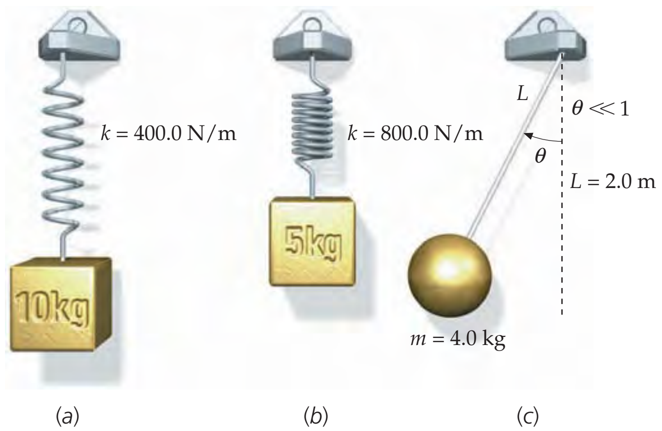

FIGURE 14-33 Problem 85

86 •• A damped oscillator loses 3.50 percent of its energy during each cycle. (*a*) How many cycles elapse before half of its original energy is dissipated? (*b*) What is its Q factor? (*c*) If the natural frequency is 100 Hz, what is the width of the resonance curve when the oscillator is driven by a sinusoidal force?

87 •• A 2.00-kg object oscillates on a spring that has a force constant equal to 400 N/m. The linear damping constant has a value of $b = 2.00$ kg/s. The system is driven by a sinusoidal force of maximum value 10.0 N and angular frequency $\omega = 10.0$ rad/s. (*a*) What is the amplitude of the oscillations? (*b*) If the driving frequency is varied, at what frequency will resonance occur? (*c*) What is the amplitude of oscillation at resonance? (*d*) What is the width of the resonance curve $\Delta\omega$? SSM

88 •• **ENGINEERING APPLICATION, CONTEXT-RICH** Suppose you have the same apparatus that is described in Problem 83 and the same gold sphere hanging from a weaker spring that has a force constant of only 35.0 N/cm. You have studied the viscosity of ethylene glycol with this device, and found that ethylene glycol has a viscosity value of 19.9 mPa·s. Now you decide to drive this system with an external oscillating force. (*a*) If the magnitude of the driving force for the device is 0.110 N and the device is driven at resonance, how large would be the amplitude of the resulting oscillation? (*b*) If the system were not driven, but were allowed to oscillate, what percentage of its energy would it lose per cycle?

GENERAL PROBLEMS

89 • **MULTISTEP** A particle's displacement from equilibrium is given by $x(t) = 0.40\cos(3.0t + \pi/4)$, where x is in meters and t is in seconds. (*a*) Find the frequency f and period T of its motion. (*b*) Find an expression for the velocity of the particle as a function of time. (*c*) What is its maximum speed?

90 • **ENGINEERING APPLICATION** An astronaut arrives at a new planet, and gets out his simple device to determine the gravitational acceleration there. Prior to his arrival, he noted that the radius of the planet was 7550 km. If his 0.500-m-long simple pendulum has a period of 1.0 s, what is the mass of the planet?

91 •• A pendulum clock keeps perfect time on Earth's surface. In which case will the error be greater: if the clock is placed in a mine of depth h, or if the clock is elevated to a height h? Prove your answer and assume that $h \ll R_E$.

92 •• Figure 14-34 shows a pendulum of length L with a bob of mass M. The bob is attached to a spring that has a force constant k, as shown. When the bob is directly below the pendulum support, the spring is unstressed. (*a*) Derive an expression for the period of this oscillating system for small-amplitude vibrations. (*b*) Suppose that $M = 1.00$ kg and L is such that in the absence of the spring the period is 2.00 s. What is the force constant k if the period of the oscillating system is 1.00 s?

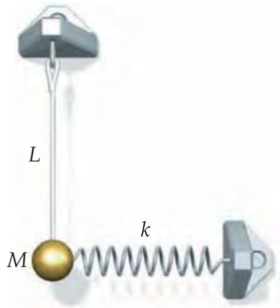

FIGURE 14-34 Problem 92

93 •• A block that has a mass equal to m_1 is supported from below by a frictionless horizontal surface. The block, which is attached to the end of a horizontal spring that has a force constant k, oscillates with an amplitude A. When the spring is at its greatest extension and the block is instantaneously at rest, a second block of mass m_2 is placed on top of it. (*a*) What is the smallest value for the coefficient of static friction μ_s such that the second object does not slip on the first? (*b*) Explain how the total mechanical energy E, the amplitude A, the angular frequency ω, and the period T of the system are affected by the placing of m_2 on m_1, assuming that the coefficient of friction is great enough to prevent slippage. SSM

94 •• A 100-kg box hangs from the ceiling of a room—suspended from a spring with a force constant of 500 N/m. The unstressed length of the spring is 0.500 m. (*a*) Find the equilibrium position of the box. (*b*) An identical spring is stretched and attached to the ceiling and the box, and is parallel with the first spring. Find the frequency of the oscillations when the box is released. (*c*) What is the new equilibrium position of the box once it comes to rest?

95 •• **ENGINEERING APPLICATION** The acceleration due to gravity g varies with geographical location because of Earth's rotation and because Earth is not exactly spherical. This was first discovered in the seventeenth century, when it was noted that a pendulum clock carefully adjusted to keep correct time in Paris lost about 90 s/d near the equator. (*a*) Show by using the differential approximation that a small change in the acceleration of gravity Δg produces a small change in the period ΔT of a pendulum given by $\Delta T/T \approx -\frac{1}{2}\Delta g/g$. (*b*) How large a change in g is needed to account for a 90-s/d change in the period?

96 •• A small block that has a mass equal to m_1 rests on a piston that is vibrating vertically with simple harmonic motion described by the formula $y = A\sin\omega t$. (*a*) Show that the block will leave the piston if $\omega^2 A > g$. (*b*) If $\omega^2 A = 3g$ and $A = 15$ cm, at what time will the block leave the piston?

97 •• Show that for the situations in Figure 14-35*a* and 14-35*b*, the object oscillates with a frequency $f = (1/2\pi)\sqrt{k_{eff}/m}$, where k_{eff} is given by (*a*) $k_{eff} = k_1 + k_2$, and (*b*) $1/k_{eff} = 1/k_1 + 1/k_2$. *Hint: Find the magnitude of the net force F on the object for a small displacement x and write $F = -k_{eff}x$. Note that in Part*(b) *the springs stretch by different amounts, the sum of which is x.* SSM

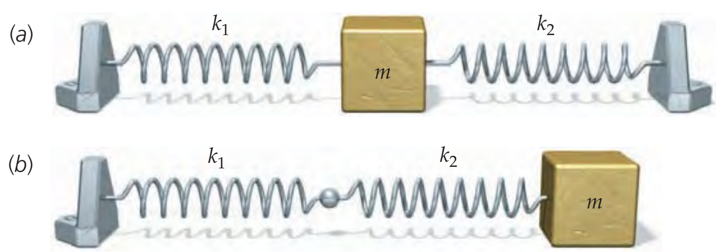

FIGURE 14-35 Problem 97

98 •• **CONTEXT-RICH** During an earthquake, a horizontal floor oscillates horizontally in approximately simple harmonic motion. Assume it oscillates at a single frequency with a period of 0.80 s. (*a*) After the earthquake, you are in charge of examining the video of the floor motion and discover that a box on the floor started to slip when the amplitude reached 10 cm. From your data, determine the coefficient of static friction between the box and the floor (*b*) If the coefficient of friction between the box and floor were 0.40, what would be the maximum amplitude of vibration before the box would slip?

99 •• If we attach two blocks that have masses m_1 and m_2 to either end of a spring that has a force constant k and set them into oscillation by releasing them from rest with the spring stretched, show that the oscillation frequency is given by $\omega = (k/\mu)^{1/2}$, where $\mu = m_1m_2/(m_1 + m_2)$ is the reduced mass of the system.

100 •• In one of your chemistry labs, you determine that one of the vibrational modes of the HCl molecule has a frequency of 8.969×10^{13} Hz. Using the result of Problem 99, find the "effective spring constant" between the H atom and the Cl atom in the HCl molecule.

101 •• If a hydrogen atom in HCl were replaced by a deuterium atom (forming DCl) in Problem 100, what would be the new vibration frequency of the molecule? Deuterium consists of 1 proton and 1 neutron.

102 ••• **SPREADSHEET** A block of mass m resting on a horizontal table is attached to a spring that has a force constant k, as shown in Figure 14-36. The coefficient of kinetic friction between the block and the table is μ_k. The spring is unstressed if the block is at the origin ($x = 0$), and the $+x$ direction is to the right. The spring is stretched a distance A, where $kA > \mu_k mg$, and the block is released. (*a*) Apply Newton's second law to the block to obtain an equation for its acceleration d^2x/dt^2 for the first half-cycle, during which the block is moving to the left. Show that the resulting equation can be written as $d^2x'/dt^2 = -\omega^2x'$, where $\omega = \sqrt{k/m}$ and $x' = x - x_0$, with $x_0 = \mu_k mg/k = \mu_k g/\omega^2$. (*b*) Repeat Part (*a*) for the second half-cycle as the block moves to the right, and show that $d^2x''/dt^2 = -\omega^2x''$, where $x'' = x + x_0$ and x_0 has the same value. (*c*) Use a **spreadsheet program** to graph the first five half-cycles for $A = 10x_0$. Describe the motion, if any, after the fifth half-cycle.

FIGURE 14-36 Problem 102

103 ••• Figure 14-37 shows a uniform solid half-cylinder of mass M and radius R resting on a horizontal surface. If one side of this cylinder is pushed down slightly and then released, the half-cylinder will oscillate about its equilibrium position. Determine the period of this oscillation. SSM

FIGURE 14-37 Problem 103

104 ••• A straight tunnel is dug through Earth, as shown in Figure 14-38. Assume that the walls of the tunnel are frictionless. (*a*) The gravitational force exerted by Earth on a particle of mass m at a distance r from the center of Earth when $r < R_E$ is $F_r = -(GmM_E/R_E^3)r$, where M_E is the mass of Earth and R_E is its radius. Show that the net force on a particle of mass m at a distance x from the middle of the tunnel is given by $F_x = -(GmM_E/R_E^3)x$ and that the motion of the particle is therefore simple harmonic motion. (*b*) Show that the period of the motion is independent of the length of the tunnel and is given by $T = 2\pi\sqrt{R_E/g}$ (c) Find its numerical value in minutes.

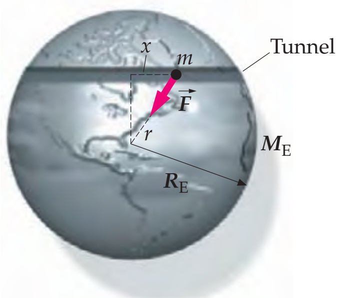

FIGURE 14-38 Problem 104

105 ••• **MULTISTEP** In this problem, derive the expression for the average power delivered by a driving force to a driven oscillator (Figure 14-39).

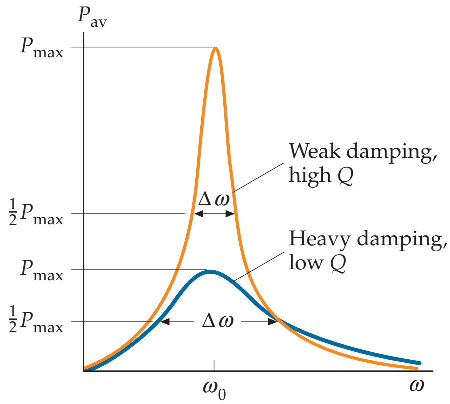

FIGURE 14-39 Problem 105

(*a*) Show that the instantaneous power input of the driving force is given by $P = Fv = -A\omega F_0 \cos \omega t \sin(\omega t - \delta)$.

(*b*) Use the identity $\sin(\theta_1 - \theta_2) = \sin\theta_1 \cos\theta_2 - \cos\theta_1 \sin\theta_2$ to show that the equation in Part (*a*) can be written as $P = A\omega F_0 \sin\delta \cos^2 \omega t \sin - A\omega F_0 \cos\delta \cos\omega t \sin\omega t$.

(*c*) Show that the average value of the second term in your result for Part (*b*) over one or more periods is zero, and that therefore $P_{av} = \frac{1}{2}A\omega F_0 \sin\delta$.

(*d*) From Equation 14-56 for $\tan\delta$, construct a right triangle in which the side opposite the angle δ is $b\omega$ and the side adjacent is $m(\omega_0^2 - \omega^2)$, and use this triangle to show that

$$\sin\delta = \frac{b\omega}{\sqrt{m^2(\omega_0^2 - \omega^2)^2 + b^2\omega^2}} = \frac{b\omega A}{F_0}$$ SSM

(*e*) Use your result for Part (*d*) to eliminate ωA from your result for Part (*c*), so that the average power input can be written as

$$P_{av} = \frac{1}{2}\frac{F_0^2}{b}\sin^2\delta = \frac{1}{2}\left[\frac{b\omega^2F_0^2}{m^2(\omega_0^2 - \omega^2)^2 + b^2\omega^2}\right]$$

106 ••• **MULTISTEP** In this problem, you are to use the result of Problem 105 to derive Equation 14-51. At resonance, the denominator of the fraction in brackets in Problem 105(*e*) is $b^2\omega_0^2$ and P_{av} has its maximum value. For a sharp resonance, the variation in ω in the numerator in this equation can be neglected. Then, the power input will be half its maximum value at the values of ω, for which the denominator is $2b^2\omega_0^2$.

(*a*) Show that ω then satisfies $m^2(\omega - \omega_0)^2(\omega + \omega_0)^2 \approx b^2\omega_0^2$.

(*b*) Using the approximation $\omega + \omega_2 \approx 2\omega_0$, show that $\omega - \omega_0 \approx \pm b/2m$.

(*c*) Express b in terms of Q.

(*d*) Combine the results of Part (*b*) and Part (*c*) to show that there are two values of ω for which the power input is half that at resonance and that they are given by

$$\omega_1 = \omega_0 - \frac{\omega_0}{2Q} \quad \text{and} \quad \omega_2 = \omega_0 - \frac{\omega_0}{2Q}$$

Therefore, $\omega_2 - \omega_1 = \Delta\omega = \omega_0/Q$, which is equivalent to Equation 14-51.

107 ••• **SPREADSHEET** The Morse potential, which is often used to model interatomic forces, can be written in the form $U(r) = D(1 - e^{-\beta(r-r_0)})^2$, where r is the distance between the two atomic nuclei. (*a*) Using a **spreadsheet program** or **graphing calculator,** make a graph of the Morse potential using $D = 5.00$ eV, $\beta = 0.20$ nm^{-1}, and $r_0 = 0.750$ nm. (*b*) Determine the equilibrium separation and "force constant" for small displacements from equilibrium for the Morse potential. (*c*) Determine an expression for the oscillation frequency for a *homonuclear* diatomic molecule (that is, two of the same atoms), where the atoms each have mass m.

CHAPTER 15

THE CREW OF AN NOAA (NATIONAL OCEANIC AND ATMOSPHERIC ADMINISTRATION) VESSEL DEPLOYS A DART (DEEP-OCEAN ASSESSMENT AND REPORTING OF TSUNAMIS) BUOY IN THE NORTH PACIFIC. THE DECEMBER 2004 INDIAN OCEAN EARTHQUAKE (ALSO KNOWN AS THE SUMATRA-ANDAMAN EARTHQUAKE) AND THE RESULTING TSUNAMI CAUSED THE LOSS OF HUNDREDS OF THOUSANDS OF LIVES. TSUNAMI DETECTION DEVICES SUCH AS THE DART CAN HELP PREVENT THIS TYPE OF CATASTROPHIC LOSS BY PREDICTING WHEN THE GIANT WAVES WILL HIT LAND. *(Courtesy of NOAA and the Harbor Branch Oceanographic Institution.)*

Traveling Waves

? Why do tsunami waves travel so much faster than ocean surface waves? (See Example 15-2.)

In Chapter 14, we looked at oscillatory motion and things that move with repeating patterns. In this chapter, we are still concerned with oscillation, but we explore the physics of waves. Waves travel through various media, such as water, air, and land, and travel through space where there is no medium in which to travel. Think of ocean waves, music, earthquakes, and sunlight. Waves *do* transport energy and momentum, but do *not* transport matter.

The study of wave motion has resulted in many fascinating inventions. Police radar guns and garage door openers both employ electromagnetic waves to achieve very different goals—determining the speed of motorists and opening doors from several meters away. Sonographic equipment, which uses ultrasonic waves, allows medical professionals to obtain remarkable images such as a fetus in its mother's uterus. An understanding of how waves act when confronted with obstacles helps performance-hall architects to create the best acoustic setting for concerts and symphonies.

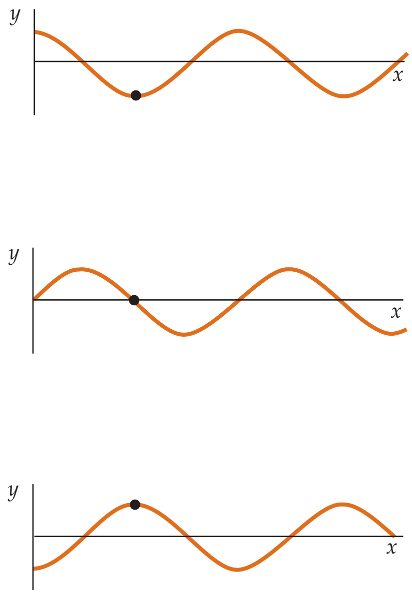
In this chapter, we discuss simple wave motion. We examine periodic waves, particularly harmonic waves. We also discuss how waves move in three dimensions and explore what happens when waves encounter obstacles. Finally, we look at the Doppler effect and discuss its relevance to the world around us.

15-1 SIMPLE WAVE MOTION

TRANSVERSE AND LONGITUDINAL WAVES

A mechanical wave is caused by a disturbance in a medium. For example, when a taut string is plucked, the disturbance produced travels along the string as a wave. The disturbance in this case is the change in shape of the string from its equilibrium shape. Its propagation arises from the interaction of each string segment with the adjacent segments. The segments of the string move in the direction transverse to (perpendicular to) the string as the pulses propagate back and forth along the string. Waves such as these, in which the motion of the medium (the string) perpendicular to the direction of propagation of the disturbance, are called **transverse** waves (Figure 15-1). Waves in which the motion of the medium is along (parallel to) the direction of propagation of the disturbance are called **longitudinal** waves (Figure 15-2). Sound waves are examples of longitudinal waves. When sound travels through a medium (a gas, a liquid, or a solid) the molecules of the medium oscillate (move back and forth) along the line of propagation, alternately compressing and rarefying (expanding) the medium.

(a)



(b)

FIGURE 15-1 (*a*) Transverse wave pulse on a spring. The motion of the propagating medium is perpendicular to the direction of motion disturbance. (*b*) Three successive drawings of a transverse wave on a string traveling to the right. An element of the string (the black dot) moves up and down as the wave crests and troughs travel to the right. *(Richard Menga/Fundamental Photographs.)*

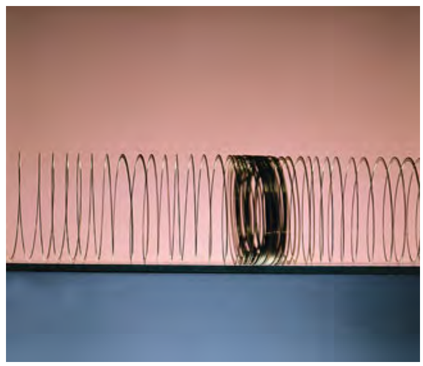


FIGURE 15-2 Longitudinal wave pulse on a spring. The disturbance is parallel with the direction of the motion of the wave. *(Richard Menga/Fundamental Photographs.)*

WAVE PULSES

Figure 15-3*a* shows a pulse on a string at time $t = 0$. The shape of the string at this instant can be represented by some function $y = f(x)$. At some later time (Figure 15-3*b*), the pulse is farther down the string. In a new coordinate system with origin O' that moves to the right with the same speed as the pulse, the pulse is stationary. The string is described in this frame by $f(x')$ for all times. The x coordinates of the two reference frames are related by

$$x' = x - vt$$

so $f(x') = f(x - vt)$. Thus, the shape of the string in the original frame is

$$y = f(x - vt) \qquad \text{wave moving in the } +x \text{ direction} \qquad 15\text{-}1$$

The same line of reasoning for a pulse moving to the left leads to

$$y = f(x + vt) \qquad \text{wave moving in the } -x \text{ direction} \qquad 15\text{-}2$$

(b)

FIGURE 15-3

In both expressions, v is the speed of propagation of the wave. (Because v is a speed and not a velocity, it is always a positive quantity.) The function $y = f(x - vt)$ is called a **wave function.** For waves on a string, the wave function represents the transverse displacement of the string. For sound waves in air, the wave function can be the longitudinal displacement of the air molecules, or the pressure of the air. These wave functions are solutions of a differential equation called the *wave equation,* which can be derived using Newton's laws.

SPEED OF WAVES

A general property of waves is that their speed relative to the medium depends on the properties of the medium, but is independent of the motion of the source of the waves. For example, the speed of a sound from a car horn depends only on the properties of air and not on the motion of the car.

For wave pulses on a rope, we can demonstrate that the greater the tension, the faster the propagation of the waves. Furthermore, waves propagate faster in a light rope than in a heavy rope under the same tension. If F_T is the tension (we use F_T rather than T for tension because we use T for the period) and μ is the linear mass density (mass per unit length), then the wave speed is

$$v = \sqrt{\frac{F_T}{\mu}} \qquad 15\text{-}3$$

SPEED OF WAVES ON A STRING

Example 15-1 Inchy Runs for His Life

Inchy, an inchworm, is inching along a cotton clothesline (Figure 15-4). The 25-m-long clothesline has a mass of 1.0 kg and is kept taut by a hanging object of mass 10 kg, as shown. Vivian is hanging up her swimsuit 5.0 m from one end when she sees Inchy 2.5 cm from the opposite end. She plucks the line sending a terrifying 3.0-cm-high pulse toward Inchy. If Inchy crawls at 1.0 in/s, will he get to the end of the clothesline before the pulse reaches him?

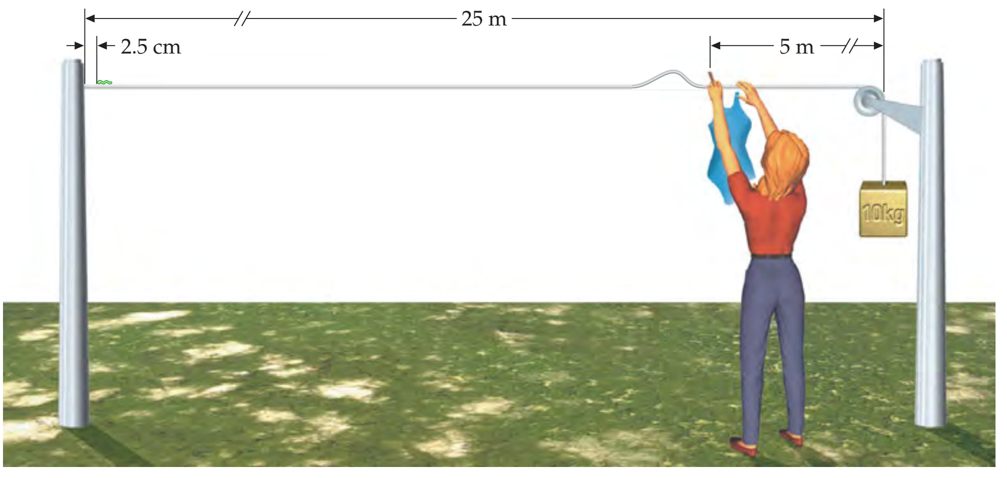

FIGURE 15-4

PICTURE We need to know how fast the wave travels. To find the wave speed we use the formula $v = \sqrt{F_T/\mu}$. Let $m_s = 0.25$ kg be the mass of the string and let $m = 10$ kg be the mass of the hanging object.

SOLVE

1. The speed of the pulse is related to the tension F_T and mass density μ:

$$v = \sqrt{\frac{F_T}{\mu}}$$

2. Express the mass density and tension in terms of the given parameters:

$$\mu = \frac{m_s}{L} \quad \text{and} \quad F_T = mg$$

3. Substitute these values to calculate the speed:

$$v = \sqrt{\frac{F_T}{\mu}} = \sqrt{\frac{mgL}{m_s}} = \sqrt{\frac{(10\text{ kg})(9.81\text{ m/s}^2)(25\text{ m})}{1.0\text{ kg}}}$$
$$= 49.5\text{ m/s}$$

4. Use this speed to find the time for the pulse to travel the 20 m to the far end:

$$\Delta t = \frac{\Delta x}{v} = \frac{20\text{ m}}{49.5\text{ s}} = 0.40\text{ s}$$

5. Find the time it takes Inchy to travel the 2.5 cm to the end traveling at 1.0 in/s:

$$\Delta t' = \frac{\Delta x'}{v'} = \frac{2.5\text{ cm}}{1\text{ in/s}} \times \frac{1\text{ in}}{2.54\text{ cm}} = 0.98\text{ s}$$

$\Delta t' > \Delta t$ Inchy does not beat the pulse.

CHECK The pulse travels at 49 m/s and Inchy travels at 1.0 in/s = 0.025 m/s. The pulse travels almost 2000 times faster than the inchworm. No wonder Inchy does not beat the pulse.

PRACTICE PROBLEM 15-1 Show that the units of $\sqrt{F_T/\mu}$ are m/s when F_T is in newtons and μ is in kg/m.

! While the wave pulse in Example 15-1 moves to the left at 49 m/s, the particles that make up the string do not. Instead, they move first up and then down as the pulse passes by them.

Example 15-2 The Speed of a Shallow Gravity Wave

Surface ocean waves are possible because of gravity and are called *gravity waves*. Gravity waves are called shallow waves if the water depth is less than half a wavelength. The wave speed for gravity waves depends on the depth and is given by $v = \sqrt{gh}$, where h is the depth. A gravity wave in the open ocean, where the depth is 5.0 km, has a wavelength of 100 km. (*a*) What is the wave speed of the wave? (*b*) Is the wave a shallow wave?

PICTURE Use $v = \sqrt{gh}$ to calculate the wave speed. Check to see if the depth is greater than half the specified wavelength.

SOLVE

(*a*) Using $v = \sqrt{gh}$, calculate the wave speed:

$$v = \sqrt{gh} = \sqrt{(9.81\text{ m/s}^2)(5000\text{ m})} = \boxed{221\text{ m/s} = 797\text{ km/h}}$$

(*b*) The wave is a shallow wave if the depth is less than half the specified wavelength:

$$\frac{h}{\lambda} = \frac{5\text{ km}}{100\text{ km}} = \frac{1}{20}$$

The depth is equal to one-twentieth of the wavelength, so the wave is $\boxed{\text{definitely a shallow wave.}}$

CHECK Tsunamis are known to travel at speeds of 800 km/h (~500 mi/h) in the open ocean, so our result is plausible.

TAKING IT FURTHER Suppose a tsunami is caused by an earthquake lifting a region of the ocean floor that is 50-km wide by a height of a meter or so. Such a tsunami would have a wavelength of ~100 km, and the height of the wave would be only a meter or so in the open ocean. Tsunamis travel so fast in the open ocean because they have wavelengths that are longer than the depth of the ocean. Typical ocean waves have wavelengths of a 100 m or less, which is much less then the depth of the open ocean. These waves are deep-water waves, and deep-water waves travel much more slowly than do shallow-water waves. In really shallow water, like the water very near the shore, other factors must be considered when calculating the speed of the waves.

For sound waves in a fluid such as air or water, the speed v is given by

$$v = \sqrt{\frac{B}{\rho}} \qquad 15\text{-}4$$

where ρ is the equilibrium density of the medium and B is the bulk modulus* (Equation 13-6). Comparing Equations 15-3 and 15-4, we can see that, in general, the speed of waves depends on an elastic property of the medium (the tension for string waves and the bulk modulus for sound waves) and on an inertial property of the medium (the linear mass density or the volume mass density).

* The bulk modulus is the negative ratio of the pressure change in volume (Chapter 13):

$$B = -\frac{\Delta P}{\Delta V/V}$$

For sound waves in a gas such as air, the bulk modulus* is proportional to the pressure, which in turn is proportional to the density ρ and to the absolute temperature T of the gas. The ratio B/ρ is thus independent of density and is merely proportional to the absolute temperature T. In Chapter 17, we show that, in this case, Equation 15-4 is equivalent to

$$v = \sqrt{\frac{\gamma RT}{M}} \qquad 15\text{-}5$$

SPEED OF SOUND IN A GAS

In this equation, T is the absolute temperature measured in kelvins (K), which is related to the Celsius temperature t_C by

$$T = t_C + 273.15 \qquad 15\text{-}6$$

The dimensionless constant γ depends on the kind of gas. For diatomic molecules, such as O_2 and N_2, γ has the value 7/5. Because O_2 and N_2 comprise 98 percent of the atmosphere, 7/5 is also the γ value for air. (For gases composed of monatomic molecules such as He, γ has the value 5/3.)† The constant R is the universal gas constant

$$R = 8.3145\ \text{J/(mol}\cdot\text{K)} \qquad 15\text{-}7$$

and M is the molar mass of the gas (that is, the mass of one mole of the gas), which for air is

$$M = 29.0 \times 10^{-3}\ \text{kg/mol}$$

Example 15-3 Speed of Sound in Air

Try It Yourself

The spring track season at a school in the Northeast starts in early April when air temperatures are around 13.0°C. By the end of the season, the weather has warmed and temperatures are then around 33.0°C. Calculate the speed of sound as it leaves the starter's pistol in air at (*a*) 13.0°C and (*b*) 33.0°C. Of course, runners should always leave the blocks at the sight of smoke from the pistol, instead of waiting for the sound of the shot to reach them.

PICTURE The speeds at the specified temperatures can be obtained using Equation 15-5, using 7/5 for the value of γ (for a diatomic gas), and using 29.0×10^{-3} kg/mol for M.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
(*a*) 1. Use Equation 15-5 ($v = \sqrt{\gamma RT/M}$) and given values to solve for the speed at 13.0°C. (Be sure to convert the temperature to kelvins.)	$v_a = \sqrt{\frac{\gamma RT_a}{M}} = \boxed{339\ \text{m/s}}$
(*b*) 1. From Equation 15-5, we can see that v is proportional to $\sqrt{T}$. Use this proportionality to express the ratio of the speed at 33.0°C to the speed at 13.0°C:	$\frac{v_b}{v_a} = \sqrt{\frac{T_b}{T_a}}$
2. Calculate v at 33.0°C:	$v_b = \boxed{351\ \text{m/s}}$

CHECK The Part (*b*) result is larger than the Part (*a*) result. This is what is expected because the speed of sound increases with increasing temperature.

TAKING IT FURTHER We see from this example that the speed of sound in air is about 343 m/s at 20°C. (This temperature is commonly referred to as room temperature.)

PRACTICE PROBLEM 15-2 For helium, $M = 4.00 \times 10^{-3}$ kg/mol and $\gamma = 5/3$. What is the speed of sound waves in helium gas at 20.0°C?

---

* The **isothermal bulk modulus,** which describes changes that occur at constant temperature, differs from the **adiabatic bulk modulus,** which describes changes that have no heat transfer. For sound waves at audible frequencies, the changes in the pressure occur too rapidly for appreciable heat transfer, so the appropriate bulk modulus is the adiabatic bulk modulus.

† These values of γ for monatomic and diatomic gases are established in Section 9 of Chapter 18.

Derivation of v for waves on a string Equation 15-3 ($v = \sqrt{F_T/\mu}$) can be obtained by applying the impulse-momentum theorem to the motion of a string. Suppose you are holding one end of a long taut string with tension F_T and uniform mass per unit length μ. (The other end of the string is attached to a distant wall.) Suddenly, you begin to move your hand upward at a constant speed u. After a short time, the string appears as shown in Figure 15-5, with the rightmost point of the inclined segment of the string moving to the right at the wave speed v and the entire inclined segment moving upward at speed u. By applying the impulse-momentum theorem ($\vec{F}_{av}\,\Delta t = \Delta\vec{p}$) to the string, we obtain

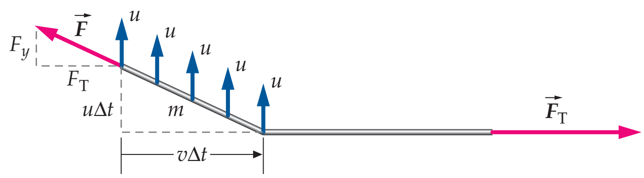

FIGURE 15-5 As the end of the string moves upward at constant speed u, the point where the string changes from horizontal to inclined moves to the right at the wave speed v.

$$F_y\,\Delta t = mu - 0 \qquad 15\text{-}8$$

where F_y is the upward component of the force of your hand on the string, m is the mass of the inclined segment, and Δt is the time that your hand has been moving upward. The two triangles in the figure are similar, so

$$\frac{F_y}{F_T} = \frac{u\,\Delta t}{v\,\Delta t} \quad \text{or} \quad F_y = \frac{u}{v}F_T$$

Substituting for F_y in Equation 15-8 gives

$$\frac{u}{v}F_T\,\Delta t = (\mu v\,\Delta t)u$$

where $\mu v\,\Delta t$ has been substituted for m. Solving for v gives

$$v = \sqrt{\frac{F_T}{\mu}}$$

which is the expression for the wave speed that is given in Equation 15-3.

In the following discussion we show that this result is true not only for a wave pulse shaped like that shown in Figure 15-5, but for pulses with a wide variety of shapes.

* THE WAVE EQUATION

We can apply Newton's second law to a segment of the string to derive a differential equation known as the wave equation, which relates the spatial derivatives of $y(x,t)$ to its time derivatives. Figure 15-6 shows one segment of a string. We consider only small angles θ_1 and θ_2. Then the length of the segment is approximately Δx and its mass is $m = \mu\,\Delta x$, where μ is the string's mass per unit length. First, we show that, for small vertical displacements, the net horizontal force on a segment is zero and the tension is uniform and constant. The net force in the horizontal direction is zero. That is,

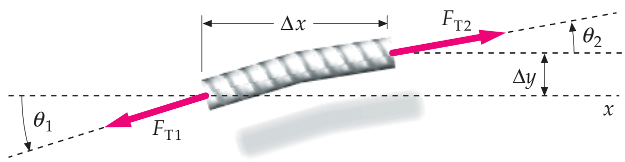

FIGURE 15-6 Segment of a stretched string used for the derivation of the wave equation. The net vertical force on the segment is $F_{T2}\sin\theta_2 - F_{T1}\sin\theta_1$, where F is the tension in the string. The wave equation is derived by applying Newton's second law to the segment.

$$\Sigma F_x = F_{T2}\cos\theta_2 - F_{T1}\cos\theta_1 = 0$$

where θ_2 and θ_1 are the angles shown and F_T is the tension in the string. Because the angles are assumed to be small, we may approximate $\cos\theta$ by 1 for each angle. Then, the net horizontal force on the segment can be written

$$\Sigma F_x = F_{T2} - F_{T1} = 0$$

Thus,

$$F_{T2} = F_{T1} = F_T$$

The segment moves vertically, and the net force in this direction is

$$\Sigma F_y = F_T\sin\theta_2 - F_T\sin\theta_1$$

Because the angles are assumed to be small, we may approximate $\sin\theta$ by $\tan\theta$ for each angle. Then the net vertical force on the string segment can be written

$$\sum F_y = F_T(\sin\theta_2 - \sin\theta_1) \approx F_T(\tan\theta_2 - \tan\theta_1)$$

The tangent of the angle made by the string with the horizontal is the slope of the line tangent to the string. The slope S is the first derivative of $y(x,t)$ with respect to x for constant t. A derivative of a function of two variables with respect to one of the variables with the other held constant is called a **partial derivative.** The partial derivative of y with respect to x is written $\partial y/\partial x$. Thus, we have

$$S = \tan\theta = \frac{\partial y}{\partial x}$$

Then

$$\sum F_y = F_T(S_2 - S_1) = F_T\,\Delta S$$

where S_1 and S_2 are the slopes of either end of the string segment and ΔS is the change in the slope. Setting this net force equal to the mass $\mu\,\Delta x$ times the acceleration $\partial^2 y/\partial t^2$ gives

$$F_T\,\Delta S = \mu\Delta x\frac{\partial^2 y}{\partial t^2} \quad \text{or} \quad F_T\frac{\Delta S}{\Delta x} = \mu\frac{\partial^2 y}{\partial t^2} \qquad \text{15-9}$$

In the limit as $\Delta x \rightarrow 0$, we have

$$\lim_{\Delta x\rightarrow 0}\frac{\Delta S}{\Delta x} = \frac{\partial S}{\partial x} = \frac{\partial}{\partial x}\frac{\partial y}{\partial x} = \frac{\partial^2 y}{\partial x^2}$$

Thus, in the limit as $\Delta x \rightarrow 0$, Equation 15-9 becomes

$$\frac{\partial^2 y}{\partial x^2} = \frac{\mu}{F_T}\frac{\partial^2 y}{\partial t^2} \qquad \text{15-10}a$$

Equation 15-10*a* is the **wave equation** for a taut string.

We now show that the wave equation is satisfied by any function $x - vt$. Let $\alpha = x - vt$ and consider any wave function

$$y = y(x - vt) = y(\alpha)$$

We use y' for the derivative of y with respect to α. Then, by the chain rule for derivatives,

$$\frac{\partial y}{\partial x} = \frac{dy}{d\alpha}\frac{\partial\alpha}{\partial x} = y'\frac{\partial\alpha}{\partial x} \quad \text{and} \quad \frac{\partial y}{\partial t} = \frac{dy}{d\alpha}\frac{\partial\alpha}{\partial t} = y'\frac{\partial\alpha}{\partial t}$$

Because

$$\frac{\partial\alpha}{\partial x} = \frac{\partial(x - vt)}{\partial x} = 1 \quad \text{and} \quad \frac{\partial\alpha}{\partial t} = \frac{\partial(x - vt)}{\partial t} = -v$$

we have

$$\frac{\partial y}{\partial x} = y' \quad \text{and} \quad \frac{\partial y}{\partial t} = -vy'$$

Taking the second derivatives, we obtain

$$\frac{\partial^2 y}{\partial x^2} = y'' \quad \text{and} \quad \frac{\partial^2 y}{\partial t^2} = -v\frac{\partial y'}{\partial t} = -v\frac{dy'}{d\alpha}\frac{\partial\alpha}{\partial t} = +v^2 y''$$

Thus,

$$\frac{\partial^2 y}{\partial x^2} = \frac{1}{v^2}\frac{\partial^2 y}{\partial t^2} \qquad \text{15-10}b$$

WAVE EQUATION

The same result (Equation 15-10*b*) can be obtained for any function of $x + vt$ as well. Comparing Equations 15-10*a* and 15-10*b*, we see that the speed of propagation of the wave is $v = \sqrt{F_T/\mu}$, which is Equation 15-3.

Example 15-4 Harmonic Wave Function

In the following section, harmonic waves are defined by the wave function $y(x,t) = A\sin(kx - \omega t)$, where $v = \omega/k$. Show that this wave function satisfies Equation 15-10*b* by explicitly calculating the second derivatives.

PICTURE We can show this by explicitly calculating $\partial^2 y/\partial x^2$ and $\partial^2 y/\partial t^2$, where $y = A\sin(kx - \omega t)$, and substituting into Equation 15-10*b*.

SOLVE

1. Calculate the second partial derivative of y with respect to x:

$$\frac{\partial y}{\partial x} = \frac{\partial}{\partial x}[A\sin(kx-\omega t)] = A\cos(kx-\omega t)\frac{\partial(kx-\omega t)}{\partial x} = kA\cos(kx-\omega t)$$

$$\frac{\partial^2 y}{\partial x^2} = \frac{\partial}{\partial x}\frac{\partial y}{\partial x} = \frac{\partial}{\partial x}kA\cos(kx-\omega t) = -kA\sin(kx-\omega t)\frac{\partial(kx-\omega t)}{\partial x}$$

$$= -k^2A\sin(kx-\omega t)$$

2. Similarly, calculate the second partial derivative of y with respect to t:

$$\frac{\partial y}{\partial t} = \frac{\partial}{\partial t}[A\sin(kx-\omega t)] = A\cos(kx-\omega t)\frac{\partial(kx-\omega t)}{\partial t} = -\omega A\cos(kx-\omega t)$$

$$\frac{\partial^2 y}{\partial t^2} = \omega A\sin(kx-\omega t)\frac{\partial y(kx-\omega t)}{\partial t} = -\omega^2A\sin(kx-\omega t)$$

3. Substituting these results in Equation 15-10*b* gives:

$$-k^2A\sin(kx-\omega t) = \frac{1}{v^2}[-\omega^2A\sin(kx-\omega t)]$$

$$\text{or}\quad A\sin(kx-\omega t) = \frac{\omega^2/k^2}{v^2}A\sin(kx-\omega t)$$

4. The two sides of the step-3 result are equal to each other, provided $(\omega^2/k^2)/v^2 = 1$:

$$\boxed{\text{$A\sin(kx-\omega t)$ is a solution to the wave equation (Equation 15-9b), provided $(\omega^2/k^2)/v^2 = 1$. That is, provided $v = \omega/k$.}}$$

CHECK Any function of the form $y(x - vt)$ satisfies the wave equation (Equation 15-10*b*). The function $y = A\sin(kx - \omega t)$ is of the form $y(x - vt)$ provided $v = \omega/k$. To show that this function is in the proper form, we substitute kv for ω to obtain

$$y = A\sin(kx-\omega t) = A\sin(kx - kvt) = A\sin(k[x - vt])$$

which is of the form $y(x - vt)$.

PRACTICE PROBLEM 15-3 Show that any function $y(kx + \omega(t)$ satisfies Equation 15-10*b*, provided $v = \omega/k$.

Derivation of v for sound waves The speed of sound is given by $v = \sqrt{B/\rho}$ (Equation 15-4), where B and ρ are the bulk modulus and density of the medium, respectively. This equation can be obtained by applying the impulse-momentum theorem to the motion of the air in a long cylinder (Figure 15-7) with a piston at one end and with the other end open to the atmosphere. Suddenly, you begin to move the piston to the right at constant speed u. After a short time, Δt, the piston has moved a distance $u\,\Delta t$ and all the air within distance $v\,\Delta t$ from the initial position of the piston is moving to the right with speed u. By applying the impulse-momentum theorem ($\vec{F}_{av}\,\Delta t = \Delta\vec{p}$) to the air in the cylinder we obtain

$$F\,\Delta t = mu - 0 \qquad 15\text{-}11$$

where m is the mass of the air moving with speed u and F is the net force on the air in the cylinder. The air was initially at rest. The net force F is related to the pressure increase ΔP of the air near the moving piston by

$$F = A\,\Delta P$$

where A is the cross-sectional area of the cylinder.

The bulk modulus of the air is given by

$$B = -\frac{\Delta P}{\Delta V/V} \qquad \text{so} \qquad \Delta P = -B\frac{\Delta V}{V} = -B\frac{-Au\,\Delta t}{Av\,\Delta t} = B\frac{u}{v}$$

where $Au\Delta t$ is the volume swept out by the piston and $Av\Delta t$ is the initial volume of the air that is now moving with speed u. Substituting for F in Equation 15-11 gives

$$A\Delta P\Delta t = mu \qquad \text{or} \qquad AB\frac{u}{v}\Delta t = (\rho A v \Delta t)u$$

where $\rho Av\,\Delta t$ has been substituted for m. Solving for v gives

$$v = \sqrt{\frac{B}{\rho}}$$

which is the same as the expression for v in Equation 15-4.

A wave equation for sound waves can be derived using Newton's laws. In one dimension, this equation is

$$\frac{\partial^2 s}{\partial x^2} = \frac{1}{v_s^2}\frac{\partial^2 s}{\partial t^2}$$

where s is the displacement of the medium in the x direction and v_s is the speed of sound in the medium.

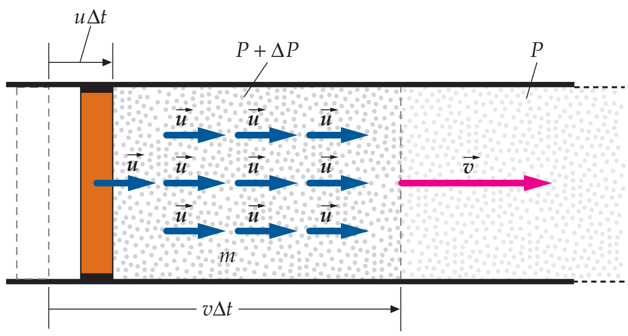

FIGURE 15-7 The air near the piston is moving to the right at the same constant speed u as the piston. The right edge of this pressure pulse moves to the right with the wave speed v. The pressure in the pulse is higher than the pressure in the rest of the cylinder by ΔP.

15-2 PERIODIC WAVES

If one end of a long taut string is shaken back and forth in periodic motion, then a **periodic wave** is generated. If a periodic wave is traveling along a taut string or any other medium, each point along the medium oscillates with the same period.

HARMONIC WAVES

Harmonic waves are the most basic type of periodic waves. All waves, whether they are periodic or not, can be modeled as a superposition of harmonic waves. Consequently, an understanding of harmonic wave motion can be generalized to form an understanding of any type of wave motion. If a **harmonic wave** is traveling through a medium, each point of the medium oscillates in simple harmonic motion.

If one end of a string is attached to a vibrating tuning fork that is moving up and down with simple harmonic motion, a sinusoidal wave train propagates along the string. This wave train is a harmonic wave. As shown in Figure 15-8, the shape of the string is that of a sinusoidal function. The minimum distance after which the wave repeats (the distance between crests, for example) in this figure is called the **wavelength** λ.

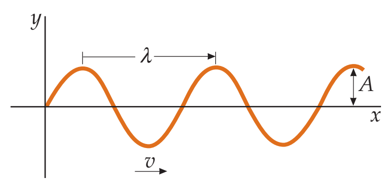

FIGURE 15-8 Harmonic wave at some instant in time. A is the amplitude and λ is the wavelength. For a wave on a string, this figure can be obtained by taking a high-speed photographic snapshot of the string.

As the wave propagates along the string, each point on the string moves up and down—perpendicular to the direction of propagation—in simple harmonic motion with the frequency f of the tuning fork. During one period T of this motion the wave moves a distance of one wavelength, so its speed is given by

$$v = \frac{\lambda}{T} = f\lambda \qquad \text{15-12}$$

where we have used the relation $T = 1/f$.

Because the relation $v = f\lambda$ arises only from the definitions of wavelength and frequency, it applies to all periodic waves.

The sine function that describes the displacements in Figure 15-8 is

$$y(x) = A\sin\left(2\pi\frac{x}{\lambda} + \delta\right)$$

where A is the amplitude, λ is the wavelength, and δ is a phase constant that depends on the choice of the origin (where $x = 0$). This equation is expressed more simply as

$$y(x) = A\sin(kx + \delta) \qquad 15\text{-}13$$

where k, called the **wave number,** is given by

$$k = \frac{2\pi}{\lambda} \qquad 15\text{-}14$$

Note that k has dimensions of m^{-1}. (Because the angle must be in radians, we sometimes write the units of k as rad/m.) When dealing with a single harmonic wave we usually choose the location of the origin so that $\delta = 0$.

For a wave traveling in the direction of increasing x with speed v, replace x in Equation 15-13 with $x - vt$ (see "Wave Pulses" in Section 15-1). With δ equal to zero, this gives

$$y(x,t) = A\sin k(x - vt) = A\sin(kx - kvt)$$

or

$$y(x,t) = A\sin(kx - \omega t) \qquad 15\text{-}15$$

HARMONIC WAVE FUNCTION

where

$$\omega = kv \qquad 15\text{-}16$$

is the angular frequency, and the argument of the sine function, $(kx - \omega t)$, is called the **phase.** The angular frequency is related to the frequency f and period T by

$$\omega = 2\pi f = \frac{2\pi}{T} \qquad 15\text{-}17$$

Substituting $\omega = 2\pi f$ into Equation 15-16 and using $k = 2\pi/\lambda$, we obtain

$$2\pi f = kv = \frac{2\pi}{\lambda}v$$

or $v = f\lambda$, which is Equation 15-12.

If a harmonic wave traveling along a string is described by $y(x,t) = A\sin(kx - \omega t)$, the velocity of a point on the string at a fixed value of x is

$$v_y = \frac{\partial y}{\partial t} = \frac{\partial}{\partial t}[A\sin(kx - \omega t)] = -\omega A\cos(kx - \omega t) \qquad 15\text{-}18$$

TRANSVERSE VELOCITY

The acceleration of this point is given by $\partial^2 y/\partial t^2$.

Example 15-5 A Harmonic Wave on a String

The wave function $y(x,t) = (0.030\text{ m}) \times \sin[(2.2\text{ m}^{-1})x - (3.5\text{ s}^{-1})t]$ is for a harmonic wave on a string. (*a*) In what direction does this wave travel and what is its speed? (*b*) Find the wavelength, frequency, and period of this wave. (*c*) What is the maximum displacement of any point on the string? (*d*) What is the maximum speed of any point on the string?

PICTURE (*a*) To find the direction of travel, express $y(x,t)$ as either a function of $(x - vt)$ or as a function of $(x + vt)$ and use Equations 15-1 and 15-2. To find the wave speed, use $\omega = kv$ (Equation 15-16). (*b*) The wavelength, frequency, and period can be found from the wave number k and the angular frequency ω. (*c*) The maximum displacement of a point on the string is the amplitude A. (*d*) The velocity of a point on the string is $\partial y/\partial t$.

SOLVE

(*a*) 1. The given wave function is of the form $y(x,t) = A\sin(kx - \omega t)$. Using $\omega = kv$ (Equation 15-16), write the wave function as a function of $x - vt$. Then, use Equations 15-1 and 15-2 to find the direction of travel:

$y(x,t) = A\sin(kx - \omega t)$ and $\omega = kv$

so $y(x,t) = A\sin(kx - kvt) = A\sin[k(x - vt)]$

The wave travels in the $\boxed{+x \text{ direction.}}$

2. Because the form is $y = A\sin(kx - \omega t)$, we know A as well as both ω and k. Use these to calculate the speed:

$$v = \frac{\lambda}{T} = \frac{\lambda}{2\pi}\frac{2\pi}{T} = \frac{\omega}{k} = \frac{3.5\text{ s}^{-1}}{2.2\text{ m}^{-1}} = 1.59\text{ m/s}$$
$$= \boxed{1.6\text{ m/s}}$$

(*b*) The wavelength λ is related to the wave number k, and the period T and frequency f are related to ω:

$$\lambda = \frac{2\pi}{k} = \frac{2\pi}{2.2\text{ m}^{-1}} = 2.86\text{ m} = \boxed{2.9\text{ m}}$$
$$T = \frac{2\pi}{\omega} = \frac{2\pi}{3.5\text{ s}^{-1}} = 1.80\text{ s} = \boxed{1.8\text{ s}}$$
$$f = \frac{1}{T} = \frac{1}{1.80\text{ s}} = 0.557\text{ Hz} = \boxed{0.56\text{ Hz}}$$

(*c*) The maximum displacement of a string segment is the amplitude A:

$$A = \boxed{0.030\text{ m}}$$

(*d*) 1. Compute $\partial y/\partial t$ to find the velocity of a point on the string:

$$v_y = \frac{\partial y}{\partial t} = (0.030\text{ m})\frac{\partial[\sin(2.2\text{ m}^{-1}x - 3.5\text{ s}^{-1}t)]}{\partial t}$$
$$= (0.030\text{ m})(-3.5\text{ s}^{-1})\cos(2.2\text{ m}^{-1}x - 3.5\text{ s}^{-1}t)$$
$$= -(0.105\text{ m/s})\cos(2.2\text{ m}^{-1}x - 3.5\text{ s}^{-1}t)$$

2. The maximum transverse speed occurs when the cosine function has the value of ± 1:

$$v_{y,\max} = 0.105\text{ m/s} = \boxed{0.11\text{ m/s}}$$

CHECK We have included the units explicitly to show how they work out. They serve as a plausibility check. Often we will omit the units for brevity.

Energy transfer via waves on a string Consider again a string attached to a tuning fork. As the fork vibrates, it transfers energy to the segment of the string attached to it. For example, as the fork moves upward from its equilibrium position it stretches the adjacent string segment slightly—increasing its elastic potential energy. In addition, the fork slows as it moves upward from it equilibrium, so it slows the string segment closest to it. This decreases the kinetic energy of the segment. As a wave moves along the string, energy is transferred from one segment to the next in a similar manner.

Power is the rate of energy transfer. We can calculate the power by considering work done by the force that one segment of the string exerts on a neighboring segment. The rate of work done by this force is the power. Figure 15-9 shows a harmonic wave moving to the right along a string segment. That is, we assume a wave function of the form

$$y(x,t) = A\sin(kx - \omega t) \qquad 15\text{-}19$$

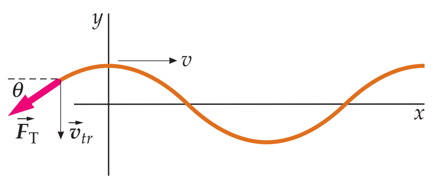

FIGURE 15-9 The tension force $\vec{F}_T$ has a component in the direction of the transverse velocity $\vec{v}_{tr}$, so at this instant the force is doing work on the end of the string that has a positive value.

The tension force $\vec{F}_T$ on the left end of the segment is directed tangent to the string, as shown. To calculate the power transferred by this force, we use the formula $P = \vec{F}_T \cdot \vec{v}_{tr}$ (Equation 6-16), where F_T is the tension and $\vec{v}_{tr}$, the transverse velocity, is the velocity of the end of the segment. To obtain an expression for the power, we first express the vectors in component form. That is, $\vec{F}_T = F_{Tx}\hat{i} + F_{Ty}\hat{j}$ and $\vec{v}_{tr} = v_y\hat{j}$. Taking the scalar product gives $P = F_{Ty}v_y$. We obtain v_y by differentiating Equation 15-18. From the figure, we see that $F_{Ty} = -F_T \sin\theta \approx -F_T \tan\theta$, where we have used the small angle approximation sin $\approx$ $\tan\theta$. Because $\tan\theta$ is the slope of line tangent to the string, we have $\tan\theta = \partial y/\partial x$. Thus

$$P = F_{Ty}v_y \approx -F_T v_y \tan\theta = -F_T \frac{\partial y}{\partial t}\frac{\partial y}{\partial x} \qquad \text{15-20}$$

Applying Equation 15-20 to a harmonic wave (by taking derivatives of Equation 15-19) gives

$$P = -F_T[-\omega A\cos(kx - \omega t)][kA\cos(kx - \omega t)] = F_T\omega k A^2\cos^2(kx - \omega t)$$

Using $v = \sqrt{F_T/\mu}$ (Equation 15-3) and $v = \omega/k$ (Equation 15-16), we substitute for F_T and the leading k to obtain

$$P = \mu v\omega^2 A^2\cos^2(kx - \omega t) \qquad \text{15-21}$$

where v is the wave speed. The average power at any location x is then

$$P_{av} = \tfrac{1}{2}\mu v\omega^2 A^2 \qquad \text{15-22}$$

because the average value of $\cos^2(kx - \omega t)$ is $\frac{1}{2}$. This average is taken over an entire period T of the motion with x held constant.

The energy travels along a taut string at an average speed equal to the wave speed v, so the average energy $(\Delta E)_{av}$ flowing past point P_1 during time Δt (Figure 15-10*a* and Figure 15-10*b*) is

$$(\Delta E)_{av} = P_{av}\,\Delta t = \tfrac{1}{2}\mu v\omega^2 A^2\Delta t$$

This energy is distributed over a length $\Delta x = v\,\Delta t$, so the average energy in length Δx is

$$(\Delta E)_{av} = \tfrac{1}{2}\mu\omega^2 A^2\,\Delta x \qquad \text{15-23}$$

Note that like the average power, the average energy per unit length is proportional to the square of the amplitude of the wave.

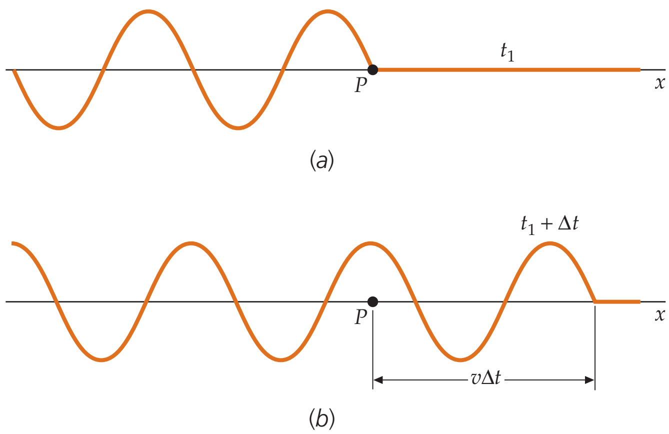

FIGURE 15-10 The wave has reached point P at time t_1. During time Δt, the wave advanced past point P a distance $v\,\Delta t$.

Example 15-6 Average Total Energy of a Wave on a String

A harmonic wave of wavelength 25 cm and amplitude 1.2 cm moves along a 15-m-long segment of a 60-m-long string that has a mass of 320 g and a tension of 12 N. (*a*) What is the speed and angular frequency of the wave? (*b*) What is the average total energy of the wave?

PICTURE The wave speed is $v = \sqrt{F_T/\mu}$, where F_T is given and $\mu = m/L$. We find ω from $\omega = 2\pi f$, where $f = v/\lambda$. The energy is found using $(\Delta E)_{av} = \frac{1}{2}\mu\omega^2 A^2\,\Delta x$ (Equation 15-23).

SOLVE

(*a*) 1. The speed is related to the tension and mass density: $v = \sqrt{\dfrac{F_T}{\mu}}$ and $\mu = \dfrac{m}{L}$

2. Calculate the wave speed: $v = \sqrt{\dfrac{F_T L}{m}} = \sqrt{\dfrac{(12\text{ N})(60\text{ m})}{(0.32\text{ kg})}} = 47.4\text{ m/s} = \boxed{47\text{ m/s}}$

3. The angular frequency is found from the frequency, which is found from the speed and wavelength:

$$\omega = 2\pi f \quad \text{and} \quad v = f\lambda,$$

$$\text{so} \quad \omega = 2\pi\frac{v}{\lambda} = 2\pi\frac{47.4\text{ m/s}}{0.25\text{ m}} = 1190\text{ rad/s}$$

$$= \boxed{1200\text{ rad/s}}$$

(*b*) The average total energy of a harmonic wave on the string is given by $(\Delta E)_{\text{av}} = \frac{1}{2}\mu\omega^2A^2\Delta x$ (Equation 15-23):

$$(\Delta E)_{\text{av}} = \frac{1}{2}\mu\omega^2A^2\,\Delta x = \frac{1}{2}\frac{m}{L}\omega^2A^2\,\Delta x$$

$$= \frac{1}{2}\frac{0.32\text{ kg}}{60\text{ m}}(1190\text{ s}^{-1})^2(0.012\text{ m})^2(15\text{ m})$$

$$= 8.19\text{ J} = \boxed{8.2\text{ J}}$$

CHECK The units for the average energy in the Part-(*b*) result are given by

$$1\frac{\text{kg}\cdot\text{s}^{-2}\,\text{m}^3}{\text{m}} = 1\frac{\text{kg}\cdot\text{m}^2}{s^2} = 1\text{ N}\cdot\text{m} = 1\text{ J}$$

where we have used that $1\text{ N} = 1\text{ kg}\cdot\text{m/s}^2$. The units work out, so the Part-(*b*) result is plausible.

PRACTICE PROBLEM 15-4 Calculate the average rate at which energy is transmitted along the string.

HARMONIC SOUND WAVES

Harmonic sound waves can be generated by a tuning fork or loudspeaker that is vibrating with simple harmonic motion. The vibrating source causes the air molecules next to it to oscillate with simple harmonic motion about their equilibrium positions. These molecules collide with neighboring molecules, causing them to oscillate, which in turn collide with their neighboring molecules, causing them to oscillate, and so forth, thereby propagating the sound wave. Equation 15-15 describes a harmonic sound wave if the wave function $y(x,t)$ is replaced by $s(x,t)$, which represents the displacements of the molecules from their equilibrium positions. Thus,

$$s(x,t) = s_0\sin(kx - \omega t) \qquad 15\text{-}24$$

These displacements are along the direction of propagation of the wave, and lead to variations in the density and pressure of the air. Figure 15-11 shows the displacement of air molecules and the density changes caused by a sound wave at some fixed time. Because the pressure in a gas is proportional to its density, the pressure is maximum

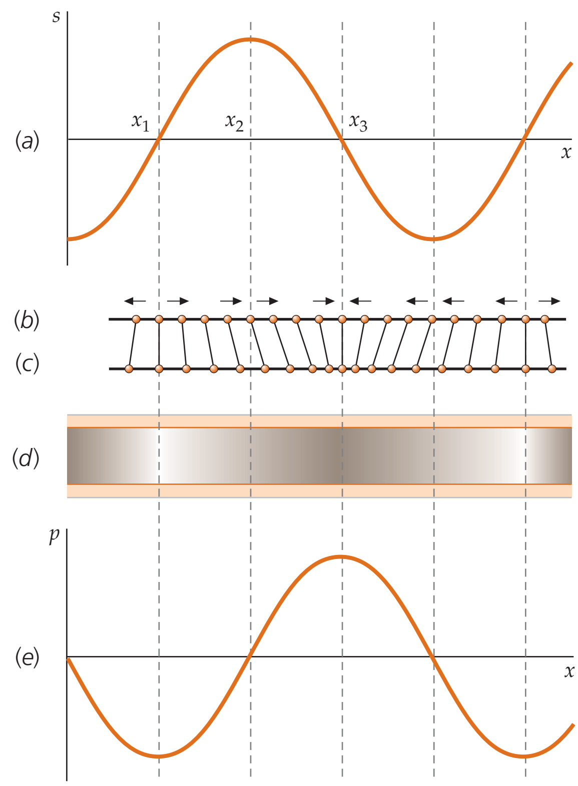

FIGURE 15-11 (*a*) Displacement from equilibrium of air molecules in a harmonic sound wave versus position at some instant. Points x_1 and x_3 are points of zero displacement. (*b*) Some representative molecules equally spaced at their equilibrium positions 1/4 cycle earlier. The arrows indicate the directions of their velocities at that instant. (*c*) Molecules near points x_1, x_2, and x_3 after the sound wave arrives. Just to the left of x_1, the displacement is negative, indicating that the gas molecules are displaced to the left, away from point x_1, at this time. Just to the right of x_1, the displacement is positive, indicating that the molecules are displaced to the right, which is again away from point x_1. So at point x_1, the density is a minimum because the gas molecules on both sides are displaced away from that point. At point x_3, the density is a maximum because the molecules on both sides of that point are displaced toward point x_3. At point x_2, the density does not change because the gas molecules on both sides of that point have equal displacements in the same direction. (*d*) Density of the air at this instant. The density is maximum at x_3 and minimum at x_1, which are both points of zero displacement. It is equal to the equilibrium value at point x_2, which is a maximum in displacement. (*e*) Pressure change, which is proportional to the density change, versus position. The pressure change and displacement (position change) are 90° out of phase.

where the density is maximum. We see from this figure that the density wave, and thus the pressure wave, is 90° out of phase with the displacement wave. (In the arguments of sine or cosine functions, we will always express phase angles in radians. However, in verbal descriptions, we usually say that "two waves are 90° out of phase" rather than "two waves are out of phase by $\pi/2$ rad.") Where the displacement s is zero, the density, and thus the pressure, is either maximum or minimum, and where the displacement is a maximum or a minimum, the density, and thus the pressure, is zero. A displacement wave given by Equation 15-24 thus implies a pressure wave given by

$$p = p_0 \sin\left(kx - \omega t - \frac{\pi}{2}\right) = -p_0 \cos(kx - \omega t) \qquad 15\text{-}25$$

where p stands for the pressure minus the local equilibrium pressure, and p_0, the maximum value of p, is called the pressure amplitude. It can be shown that the pressure amplitude p_0 is related to the displacement amplitude s_0 by

$$p_0 = \rho\omega v s_0 \qquad 15\text{-}26$$

where v is the speed of propagation and ρ is the equilibrium density of the gas. Thus, as a harmonic sound wave travels through air, the displacement of air molecules, the pressure, and the density all vary sinusoidally with the frequency of the vibrating source.

PRACTICE PROBLEM 15-5

Sound of frequencies from about 20 Hz to about 20,000 Hz are audible to humans (although many people have rather limited hearing above 15,000 Hz). If the speed of sound in air is 343 m/s, what are the wavelengths that correspond to the highest and lowest audible frequencies?

Energy of sound waves The average energy of a harmonic sound wave in a volume element ΔV is given by Equation 15-23 with A replaced by s_0 and $\mu\,\Delta x$, replaced by $\rho\,\Delta V$, where ρ is the equilibrium density of the medium.

$$(\Delta E)_{av} = \tfrac{1}{2}\rho\omega^2 s_0^2\,\Delta V \qquad 15\text{-}27$$

The energy per unit volume is the average energy density η_{av}:

$$\eta_{av} = \frac{\Delta E_{av}}{\Delta V} = \frac{1}{2}\rho\omega^2 s_0^2 \qquad 15\text{-}28$$

where η is the lowercase Greek letter eta.

ELECTROMAGNETIC WAVES

Electromagnetic waves include light, radio waves, X rays, gamma rays, and microwaves, among others. The various types of electromagnetic waves differ only in wavelength and frequency. Unlike mechanical waves, electromagnetic waves do not require a medium for propagation. They travel through a vacuum with speed c, which is a universal constant, $c \approx 3.00 \times 10^8$ m/s. The wave function for electromagnetic waves is an electric field $\vec{E}(x,t)$ associated with the wave. (Electric fields are introduced in Chapter 21. A wave equation, similar to those for string waves and sound waves, is derived from the laws of electricity and magnetism in Chapter 30.) The electric field is perpendicular to the direction of propagation, so electromagnetic waves are transverse waves.

Electromagnetic waves are produced when free electric charges accelerate or when electrons bound to atoms and molecules make transitions to lower energy states. Radio waves, which have frequencies of about 1 MHz for AM and 100 MHz for FM, are produced by macroscopic electric currents oscillating in radio antennas. The frequency of the emitted waves equals the frequency of oscillation of the charges. Light waves, which have frequencies of the order of 10^{14} Hz, are generally produced by atomic or molecular transitions involving bound electrons. The spectrum of electromagnetic waves is discussed in Chapter 31.

(David Sacks/ The Image Bank/ Getty.)

15-3 WAVES IN THREE DIMENSIONS

Figure 15-12 shows two-dimensional circular waves on the surface of water in a ripple tank. These waves are generated by drops of water striking the surface. The wave crests form concentric circles called **wavefronts.** For a point source of sound, the waves move out in three dimensions, and the wavefronts are concentric spherical surfaces.

FIGURE 15-12 Circular wavefronts diverging from a point source in a ripple tank. *(PhotoDisc/Getty Images.)*

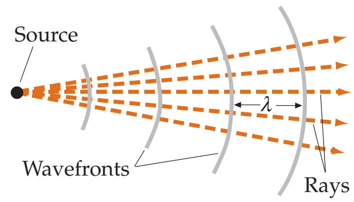

FIGURE 15-13 The motion of wavefronts can be represented by rays drawn perpendicular to the wavefronts. For a point source, the rays are radial lines diverging from the source.

The motion of any set of wavefronts can be indicated by rays, which are directed lines perpendicular to the wavefronts (Figure 15-13). For circular or spherical waves, the rays are radial lines.

In a homogeneous medium, such as air at constant density, the wavefronts travels in straight lines in the direction of the rays, much like a beam of particles. At a great distance from a point source, a sufficiently small section of the wavefront can be approximated by a flat surface (a plane), and the rays are approximately parallel lines; such a wave is called a **plane wave** (Figure 15-14). The two-dimensional analog of a plane wave is a *line wave,* which is a small part of a circular wavefront at a great distance from the source. Line waves can also be produced in a ripple tank by a line source, as in Figure 15-15.

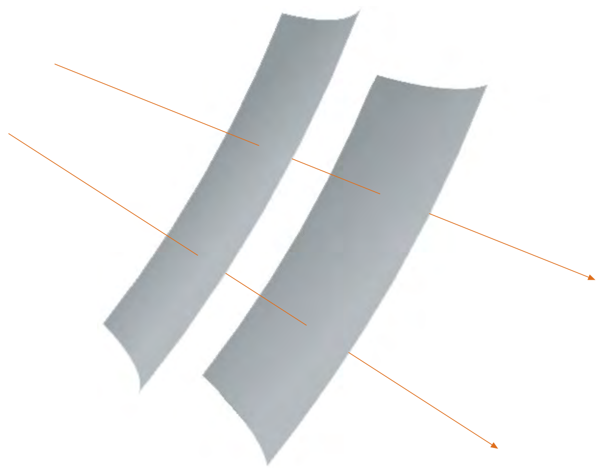

FIGURE 15-14 Plane waves. At great distances from a point source, the wavefronts are approximately parallel planes, and the rays are approximately parallel lines perpendicular to the wavefronts.

FIGURE 15-15 A two-dimensional analog of a plane wave can be generated in a ripple tank by a flat board that oscillates up and down in the water to produce the wavefronts, which are straight lines.

WAVE INTENSITY

If a point source emits waves uniformly in all directions, then the energy at a distance r from the source is distributed uniformly on a spherical surface of radius r and area $A = 4\pi r^2$. If P_{av} is the average power emitted by the source, then the average power per unit area at a distance r from the source is $P_{av}/(4\pi r^2)$. The average power per unit area that is incident perpendicular to the direction of propagation is called the **intensity:**

$$I = \frac{P_{av}}{A} \qquad 15\text{-}29$$

INTENSITY DEFINED

The SI units of intensity are watts per square meter (W/m²). At a distance r from a point source, the intensity is

$$I = \frac{P_{av}}{4\pi r^2} \qquad 15\text{-}30$$

INTENSITY DUE TO A POINT SOURCE

The intensity of a three-dimensional wave varies inversely with the square of the distance from a point source.

There is a simple relation between the intensity of a wave and the energy density in the medium through which it propagates. Figure 15-16 shows a spherical wave that has just reached the radius r_1. The volume inside the radius r_1 contains energy because the particles in that region are oscillating. The region outside r_1 contains no energy because the wave has not yet reached it. After a short time Δt, the wave moves out a short distance $\Delta r = v\,\Delta t$ past r_1. The average energy in the spherical shell of surface area A, thickness $v\,\Delta t$, and volume $\Delta V = A\,\Delta r = Av\,\Delta t$ is

$$(\Delta E)_{av} = \eta_{av}\,\Delta V = \eta_{av} Av\,\Delta t$$

The rate of transfer of energy is the power passing into the shell. The average incident power is

$$P_{av} = \frac{(\Delta E)_{av}}{\Delta t} = \eta_{av} Av$$

and the intensity of the wave is

$$I = \frac{P_{av}}{A} = \eta_{av} v \qquad 15\text{-}31$$

Thus, the intensity equals the product of the wave speed v and the average energy density η_{av}. Substituting $\eta_{av} = \frac{1}{2}\rho\omega^2 s_0^2$ from Equation 15-28 for the energy density in a harmonic sound wave, we obtain

$$I = \eta_{av} v = \frac{1}{2}\rho\omega^2 s_0^2 v = \frac{1}{2}\frac{p_0^2}{\rho v} \qquad 15\text{-}32$$

where we have used $s_0 = p_0/(\rho\omega v)$ from Equation 15-26. This result—that the intensity of a sound wave is proportional to the square of the amplitude—is a general property of harmonic waves.

The human ear can accommodate a large range of sound-wave intensities, from about 10^{-12} W/m² (which is usually taken to be the threshold of hearing) to about 1 W/m² (an intensity great enough to stimulate pain in most people). The pressure

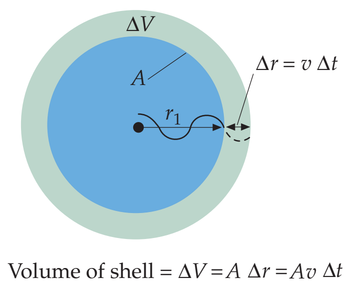

FIGURE 15-16

Sound waves from a telephone handset spreading out in the air. The waves have been made visible by sweeping out the space in front of the handset with a light source whose brightness is controlled by a microphone. *(From Winston E. Kock, Lasers and Holography, 1978, Dover Publications, New York.)*

amplitudes that correspond to these extreme intensities are about 3×10^{-5} Pa for the hearing threshold and 30 Pa for the pain threshold. (Recall that a pascal is a newton per square meter.) These very small pressure variations add to or subtract from the normal atmospheric pressure of about 101.3 kPa.

Example 15-7 A Loudspeaker

A loudspeaker diaphragm 30 cm in diameter is vibrating at 1.0 kHz with an amplitude of 0.020 mm. Assuming that the air molecules in the vicinity have the same amplitude of vibration, find (*a*) the pressure amplitude immediately in front of the diaphragm, (*b*) the sound intensity immediately in front of the diaphragm, and (*c*) the acoustic power being radiated. (*d*) If the sound is radiated uniformly into the forward hemisphere, find the intensity at 5.0 m from the loudspeaker.

PICTURE (*a*) and (*b*) The pressure amplitude is calculated directly from $p_0 = \rho\omega v s_0$ (Equation 15-26), and the intensity from $I = \frac{1}{2}\rho\omega^2 s_0^2 v$ (Equation 15-32). (*c*) The power radiated is the intensity times the area of the diaphragm. (*d*) The area of a hemisphere of radius r is $2\pi r^2$. We can use Equation 15-29 with $A = 2\pi r^2$.

SOLVE

(*a*) Equation 15-26 relates the pressure amplitude to the displacement amplitude, frequency, wave velocity, and air density:

$$p_0 = \rho\omega v s_0 = (1.29\ \text{kg/m}^3)2\pi(10^3\ \text{Hz})(343\ \text{m/s})(2.0 \times 10^{-5}\ \text{m})$$
$$= 55.6\ \text{N/m}^2 = \boxed{56\ \text{Pa}}$$

(*b*) Equation 15-32 relates the intensity to these same known quantities:

$$I = \tfrac{1}{2}\rho\omega^2 s_0^2 v = \tfrac{1}{2}(1.29\ \text{kg/m}^3)[2\pi(1.0\ \text{kHz})]^2(2.0 \times 10^{-5}\ \text{m})^2(343\ \text{m/s})$$
$$= 3.494\ \text{W/m}^2 = \boxed{3.5\ \text{W/m}^2}$$

(c) The power is the intensity times the area of the diaphragm:

$$P_{\text{av}} = IA = (3.494\ \text{W/m}^2)\pi(0.15\ \text{m})^2 = 0.247\ \text{W} = \boxed{0.25\ \text{W}}$$

(*d*) Calculate the intensity at $r = 5.0$ m, assuming uniform radiation into the forward hemisphere:

$$I = \frac{P_{\text{av}}}{A} = \frac{0.247\ \text{W}}{2\pi(5.0\ \text{m})^2} = 1.57\ \times 10^{-3}\ \text{W/m}^2 = \boxed{1.6\ \text{mW/m}^2}$$

CHECK The Part-(*d*) result is smaller than the Part-(*b*) result, as expected. (We expect the intensity to be greatest immediately in front of the diaphragm.)

TAKING IT FURTHER The assumption of uniform radiation in the forward hemisphere is not a very good one because the wavelength in this case $[\lambda = v/f = (343\ \text{m/s})/(1000\ \text{s}^{-1}) = 34.3\ \text{cm}]$ is not large compared with the speaker diameter. There is also some radiation in the backward direction, as can be observed if you stand behind a loudspeaker.

Loudspeakers at a rock concert may put out more than 100 times as much power as the speaker in this example.

* ***Intensity level and loudness*** Our perception of loudness is not proportional to the intensity. However, our perception of loudness varies logarithmically with intensity to a good approximation. We therefore use a logarithmic scale to describe the **intensity level** β of a sound wave, which is measured in **decibels** (dB) and defined by

$$\beta = (10\ \text{dB}) \log \frac{I}{I_0} \qquad 15\text{-}33$$

DEFINITION—INTENSITY LEVEL IN dB

where *log* refers to a base-10 logarithm. The decibel is a dimensionless number, like the radian. Typically, we write Equation 15-33 without explicitly writing the units. That is, we write it as $\beta = 10 \log(I/I_0)$. Here I is the intensity of the sound and I_0 is

See **Math Tutorial** *for more information on* **Exponents and Logarithms**

a reference level, which usually is taken to be the threshold of hearing:

$$I_0 = 10^{-12}\ \text{W/m}^2 \qquad 15\text{-}34$$

THRESHOLD OF HEARING

On this scale, the threshold of hearing ($I = 10^{-12}$ W/m^2) corresponds to an intensity level of $\beta = 10 \log(10^{-12}/10^{-12}) = 0$ dB and the pain threshold ($I = 1$ W/m^2) corresponds to $\beta = 10 \log(1/10^{-12}) = 10 \log 10^{12} = 120$ dB. Thus, the range of sound intensities from 10^{-12} W/m^2 to 1 W/m^2 corresponds to intensity levels from 0 dB to 120 dB. Table 15-1 lists the intensity levels of some common sounds.

Table 15-1 Intensity and Intensity Level of Some Common Sounds

Source	I/I_0	dB	Description
	10^0	0	Hearing threshold
Normal breathing	10^1	10	Barely audible
Rustling leaves	10^2	20	
Soft whisper (at 5 m)	10^3	30	Very quiet
Library	10^4	40	
Quiet office	10^5	50	Quiet
Normal conversation (at 1 m)	10^6	60	
Busy traffic	10^7	70	
Noisy office with machines; average factory	10^8	80	
Heavy truck (at 15 m); Niagara Falls	10^9	90	Constant exposure endangers hearing
Old subway train	10^{10}	100	
Construction noise (at 3 m)	10^{11}	110	
Rock concert with amplifiers (at 2 m); jet takeoff (at 60 m)	10^{12}	120	Pain threshold
Pneumatic riveter; machine gun	10^{13}	130	
Jet takeoff (nearby)	10^{15}	150	
Large rocket engine (nearby)	10^{18}	180	

Example 15-8 Soundproofing

A sound absorber attenuates the sound *intensity level* by 30 dB. By what factor is the *intensity* changed?

PICTURE Inspect Table 15-1 to see the change in intensity for every 10-dB change in intensity level. Can you discern the pattern?

SOLVE

1. From Table 15-1, we can see that for every 10-dB decrease in the intensity level, the intensity changes by a factor of 1/10.

Thus, if the sound level decreases by 30 dB, then the intensity changes by a factor of $10^{-1} \times 10^{-1} \times 10^{-1} = \boxed{10^{-3}.}$

CHECK We can compare this result with the result gotten by directly using Equation 15-33. That is, $\beta_2 - \beta_1 = 10 \log(I_2/I_0) - 10 \log(I_1/I_0) = 10 \log(I_2/I_1)$. Solving for I_2 gives $I_2 = 10^{(\beta_2-\beta_1)/10} I_1$. Substituting -30 for $\beta_2 - \beta_1$ gives $I_2 = 10^{-3} I_1$, thus verifying our previous result.

CONCEPT CHECK 15-1

When his radio breaks, Chuck purchases a new one that produces twice as much acoustic power as the old one. His expectation is that his new radio will sound twice as loud as his old radio. Will he be disappointed? Explain.

The sensation of loudness depends on the frequency as well as the intensity of a sound. Figure 15-17 is a plot of intensity level versus frequency for sounds of equal loudness to the human ear. (In this figure, the frequency is plotted on a logarithmic scale to display the wide range of frequencies from 20 Hz to 10 kHz.) We observe from this plot that the human ear is most sensitive at about 4 kHz for all intensity levels.

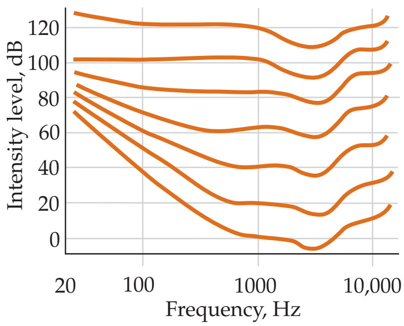

FIGURE 15-17 Intensity level versus frequency for sounds perceived to be of equal loudness. The lowest curve is below the threshold for hearing of all but about one percent of the population. The second lowest curve is approximately the hearing threshold for about 50 percent of the population.

Example 15-9 Barking Dogs

A barking dog delivers about 1.0 mW of acoustic power. (*a*) If this power is uniformly distributed in all directions, what is the sound intensity level at a distance of 5.0 m? (*b*) What would be the intensity level of two dogs, each 5.0 m away, barking at the same time if each delivered 1.0 mW of power?

PICTURE The intensity level is found from the intensity, which is found from $I = P_{\text{av}}/(4\pi r^2)$. For two dogs, the intensities are added.

SOLVE

(*a*) 1. The intensity level β is related to the intensity I. Thus, we must first calculate the intensity I:

$$\beta = 10\log\frac{I}{I_0}$$

2. Using $I = P_{\text{av}}/(4\pi r^2)$, calculate the intensity at $r = 5.0$ m:

$$I_1 = \frac{P_{1\,\text{av}}}{4\pi r^2} = \frac{1.0\times10^{-3}\text{ W}}{4\pi(5.0\text{ m})^2} = 3.18\times10^{-6}\text{ W/m}^2$$

3. Use your result to find the intensity level at 5 m:

$$\beta_1 = 10\log\frac{I_1}{I_0} = 10\log\frac{3.18\times10^{-6}}{1\times10^{-12}} = \boxed{65.0\text{ dB}}$$

(*b*) If I_1 is the intensity for one dog barking, the intensity for two dogs barking is $I_2 = 2I_1$:

$$\beta_2 = 10\log\frac{I_2}{I_0} = 10\log\frac{2I_1}{I_0} = 10\left(\log 2 + \log\frac{I_1}{I_0}\right)$$

$$= 10\log 2 + \beta_1 = 3.01 + 65.0 = \boxed{68.0\text{ dB}}$$

CHECK If the Part-(*b*) result is correct then whenever the intensity is doubled, the intensity level increases by ~3 dB. To see if this checks out we divide 65 dB by 3 dB to get 21.7, so doubling the threshold intensity 21.7 times should give an intensity of $I_1 \approx 3\times10^{-6}$ W/m². That is, $2^{21.7}I_0$ should equal about 3×10^{-6} W/m². Multiplying 1×10^{-12} W/m² by $2^{21.7}$ gives 3.4×10^{-6} W/m², so our Part-(*b*) result is plausible.

15-4 WAVES ENCOUNTERING BARRIERS

REFLECTION, TRANSMISSION, AND REFRACTION

When a wave is incident on a boundary that separates two regions of differing wave speed, part of the wave is reflected and part is transmitted. Figure 15-18*a* shows a pulse on a light string that is attached to a heavier string (one with a slower wave speed). In this case, the pulse reflected at the boundary is inverted. If the second string is lighter than the first (Figure 15-18*b*), then the reflected pulse is upright. (By upright we mean

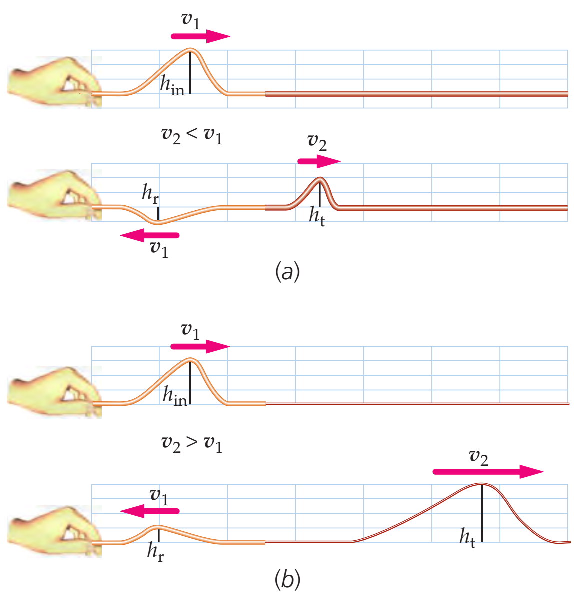

FIGURE 15-18 The leading edges of the pulses are steeper than the trailing edges because the end of the string was raised more quickly than it was lowered. (*a*) A wave pulse traveling on a string attached to a more massive string in which the wave speed is half as large. The reflected pulse is inverted, whereas the transmitted pulse is not. (*b*) A wave pulse traveling on a string attached to a less massive string in which the wave speed is twice as large. In this case, the reflected pulse is not inverted.

it has the same orientation as the incident pulse.) The pulse transmitted to the second string is always upright. A string attached to a fixed point is equivalent to a string being attached to a second string with an extremely large mass per unit length, so for an incident pulse on a string attached to a fixed point the reflected pulse is inverted. Conversely, if the string is tied to a string of negligible mass per unit length, the reflected pulse is upright. The heights of the incident, transmitted, and reflected pulses, shown in Figure 15-18, are h_{in}, h_t, and h_r, respectively. The **reflection coefficient** r is the height of the reflected pulse divided by the height of the incident pulse, and the **transmission coefficient** τ is the height of the transmitted pulse divided by the height of the incident pulse. That is, $r = h_r/h_i$ and $\tau = h_t/h_{in}$, where heights h_i, h_{in}, and h_t are shown in Figure 15-18. The expressions for r and τ, are

$$r = \frac{v_2 - v_1}{v_2 + v_1} \quad \text{and} \quad \tau = \frac{2v_2}{v_2 + v_1} \qquad \text{15-35}$$

REFLECTION AND TRANSMISSION COEFFICIENTS

These expressions for the reflection and transmission coefficients r and τ are known as the *Fresnel relations.* They can be derived by requiring that the tension, the height of the string and the slope of the string all remain continuous at the point where the mass per unit length is discontinuous. (Newton's third law requires that the slope be continuous.) Note that τ is never negative and that r is negative if $v_2 < v_1$. This implies the transmitted pulse is never inverted and the reflected pulse is inverted if $v_2 < v_1$.

Example 15-10 Two Soldered Wires

Two wires of different linear mass densities are soldered together end-to-end and then stretched under a tension F_T (the tension is the same in both wires). The wave speed in the first wire is twice that in the second. A harmonic wave traveling in the first wire is incident on the junction of the wires. (*a*) If the amplitude of the incident wave is A, what are the amplitudes of the reflected and transmitted waves? (*b*) What is the ratio μ_2/μ_1 of the mass densities of the wires? (*c*) What fraction of the incident average power is reflected at the junction and what fraction is transmitted?

PICTURE To calculate the amplitudes of the reflected and transmitted waves, use $A_r = rA$ and $A_t = \tau A$, where A_r and A_t are the amplitudes of the reflected and transmitted waves, respectively, and r and τ are the reflection and transmission coefficients given in Equation 15-35. Each power is expressed using $P_{av} = \frac{1}{2}\mu v\omega^2 A^2$ (Equation 15-22). The incident, reflected and transmitted waves all share the same frequency. Because the reflected wave and incident wave are in the same medium, they have the same wave speed v_1. We are given that the wave speed v_2 in the second wire is $\frac{1}{2}v_1$ (Figure 15-19).

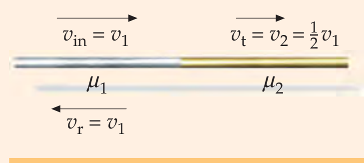

FIGURE 15-19

SOLVE

(*a*) 1. Express the reflected and transmitted amplitudes in terms of the incident amplitude and the reflection and transmission coefficients (Equation 15-35):

$$A_r = rA \quad \text{and} \quad A_t = \tau A$$

2. Use the given relation $v_1 = 2v_2$ to solve for the reflection and transmission coefficients:

$$r = \frac{v_2 - v_1}{v_2 + v_1} = \frac{v_2 - 2v_2}{v_2 + 2v_2} = -\frac{1}{3}$$

$$\tau = \frac{2v_2}{v_2 + v_1} = \frac{2v_2}{v_2 + 2v_2} = \frac{2}{3}$$

$$\text{so} \quad A_r = \boxed{-\frac{1}{3}A} \quad \text{and} \quad A_t = \boxed{\frac{2}{3}A}$$

(*b*) 1. The formula relating the mass density with the wave speed is $v = \sqrt{F_T/\mu}$ (Equation 15-3). F_T is the same on either side of the junction. Solve for μ_2 and μ_1:

$$v_1^2 = \frac{F_T}{\mu_1} \quad \text{and} \quad v_2^2 = \frac{F_T}{\mu_2}$$

$$\text{so} \quad \mu_1 = \frac{F_T}{v_1^2} \quad \text{and} \quad \mu_2 = \frac{F_T}{v_2^2}$$

2. Divide μ_2 by μ_1 and use the given information that $v_1 = 2v_2$:

$$\frac{\mu_2}{\mu_1} = \frac{v_1^2}{v_2^2} = \frac{(2v_2)^2}{v_2^2} = \boxed{4}$$

(*c*) 1. Write expressions for the incident, reflected, and transmitted power using $P_{av} = \frac{1}{2}\mu v \omega^2 A^2$ (Equation 15-22):

$$P_{\text{in av}} = \tfrac{1}{2}\mu_1\omega^2 A^2 v_1$$
$$P_{\text{r av}} = \tfrac{1}{2}\mu_1\omega^2 A_r^2 v_1$$
$$P_{\text{t av}} = \tfrac{1}{2}\mu_2\omega^2 A_t^2 v_2$$

2. Substitute the Part-(*a*) results into the expressions for the reflected and transmitted power:

$$P_{\text{r av}} = \tfrac{1}{2}\mu_1\omega^2\left(-\frac{1}{3}A\right)^2 v_1 = \frac{1}{18}\mu_1\omega^2 A^2 v_1$$
$$P_{\text{t av}} = \tfrac{1}{2}\mu_2\omega^2\left(\frac{2}{3}A\right)^2 v_2 = \frac{2}{9}\mu_2\omega^2 A^2 v_2$$

3. Obtain expressions for P_r/P_{in} and for P_t/P_{in}:

$$\frac{P_{\text{r av}}}{P_{\text{in av}}} = \frac{\frac{1}{18}\mu_1\omega^2 A^2 v_1}{\frac{1}{2}\mu_1\omega^2 A^2 v_1} = \boxed{\frac{1}{9}}$$
$$\frac{P_{\text{t av}}}{P_{\text{in av}}} = \frac{\frac{2}{9}\mu_2\omega^2 A^2 v_2}{\frac{1}{2}\mu_1\omega^2 A^2 v_1} = \frac{4}{9}\frac{\mu_2}{\mu_1}\frac{v_2}{v_1}$$

4. Simplify using the Part-(*b*) result and the given relation $v_1 = 2v_2$:

$$\frac{P_{\text{t av}}}{P_{\text{in av}}} = \frac{4}{9}4\frac{v_2}{2v_2} = \boxed{\frac{8}{9}}$$

CHECK The fractional power reflected plus the fractional power transmitted equals one, as one would expect.

TAKING IT FURTHER The reflected wave is inverted relative to the incident wave, so it is 180° out of phase with it. A negative amplitude corresponds to a phase shift of 180°.

PRACTICE PROBLEM 15-6 Repeat Example 15-10 except with $v_2 = 2v_1$.

Energy conservation gives another relation between the reflection and transmission coefficients. This relation, established in Problem 15-70 is given by

$$1 = r^2 + \frac{v_1}{v_2}\tau^2 \qquad 15\text{-}36$$

where r^2 is the fraction of the incident power that is reflected and $(v_1/v_2)\tau^2$ is the fraction that is transmitted.

PRACTICE PROBLEM 15-7

Show that the values of r and τ for the wires in Example 15-10 satisfy Equation 15-36.

In three dimensions, a boundary between two regions of differing wave speed is a surface. Figure 15-20 shows a ray incident on such a boundary surface. This example could be a sound wave in air striking a solid or liquid surface. The reflected ray makes an angle with the normal to the surface equal to that of the incident ray, as shown.

The transmitted ray is bent toward or away from the normal—depending on whether the wave speed in the second medium is less or greater than that in the incident medium. The bending of the transmitted ray is called **refraction.** When the wave speed in the second medium is greater than that in the incident medium (as occurs when a light wave in glass or water is refracted into the air), the ray

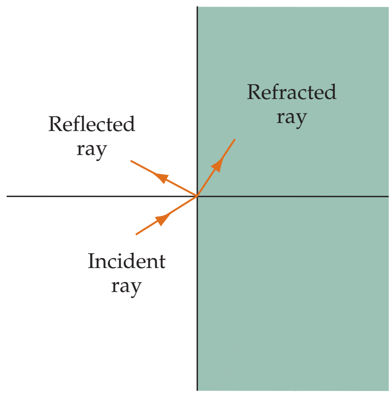

FIGURE 15-20 A wave striking a boundary surface between two media in which the wave speed differs. Part of the wave is reflected and part is transmitted. The change in direction of the transmitted (refracted) ray is called refraction.

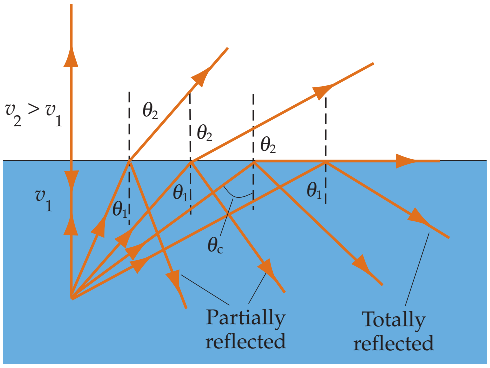

FIGURE 15-21 Light from a source in the water is bent away from the normal when it enters the air. For angles of incidence above a critical angle θ_C, there is no transmitted ray, a condition known as total internal reflection.

describing the direction of propagation is bent away from the normal, as shown in Figure 15-21. As the angle of incidence is increased, the angle of refraction increases, until a critical angle of incidence is reached for which the angle of refraction is 90°. For incident angles greater than the critical angle, there is no refracted ray, a phenomenon known as **total internal reflection.**

The amount of energy reflected from a surface depends on the surface. Rigid flat walls, floors, and ceilings make good reflectors for sound waves, whereas porous and less rigid materials, such as cloth in draperies and furniture coverings, absorb much of the incident sound. The reflection of sound waves plays an important role in the design of a lecture hall, a library, or a music auditorium. If a lecture hall has many flat reflecting surfaces, speech is difficult to understand because of the many echoes that simultaneously arrive at the listener's ear. Absorbent material is often placed on the walls and ceiling to reduce such reflections. In a concert hall, a reflecting shell is placed behind the orchestra, and reflecting panels are hung from the ceiling to reflect and direct the sound back toward the listeners.

(Courtesy of Davies Symphony Hall.)

Example 15-11 Balloon Hearing Aid — *Conceptual*

A popular physics demonstration uses a weather balloon filled with carbon dioxide. If you place the balloon between yourself and a sound source, the sound gets louder. Why is that?

PICTURE The molar mass of carbon dioxide is greater than the effective molar mass of air. Thus, sound travels faster in air than it does in carbon dioxide at atmospheric pressure. To "see" why the sound gets louder when the balloon is between you and the source of the sound, draw a diagram of the rays of sound as they pass through the balloon. The rays will refract (bend) when they are transmitted through a surface where the speed of sound changes.

SOLVE

1. Trace a ray from the source of the sound through the top half of the balloon (Figure 15-22*a*). The ray will refract toward the normal as it enters the balloon, and away from the normal as it exits the balloon:
2. Repeat step 1 for four or five additional rays, including some that go through the lower half of the balloon (Figure 15-22*b*).
3. Use the diagram to explain why the sound is louder when the balloon is between you and the source of sound: The sound is loudest in the region where the rays intersect.

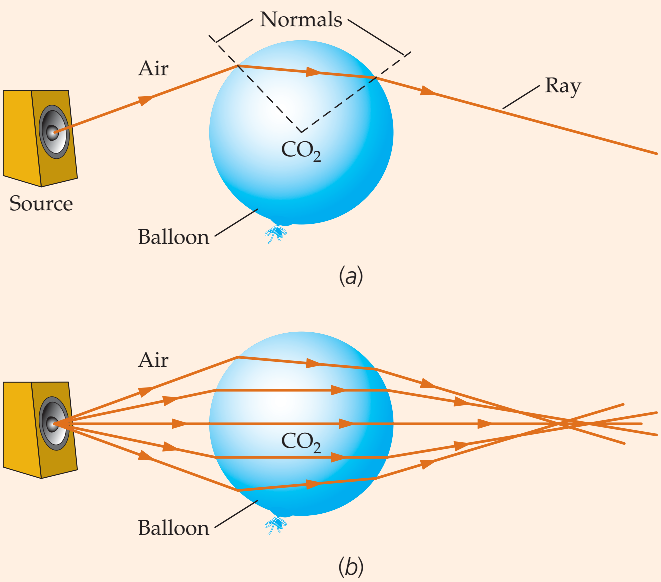

FIGURE 15-22

CHECK The balloon is to sound as a magnifying glass is to light. In glass, light travels more slowly than it does in air, just as in CO_2 sound travels more slowly than it does in air.

DIFFRACTION

If a wavefront is partially blocked by an obstacle, the unblocked part of the wavefront bends behind the obstacle. This bending of the wavefronts is called **diffraction.** Almost all of the diffraction occurs for that part of the wavefront that passes within a few wavelengths of the edge of the obstacle. For the parts of the wavefront that pass farther than a few wavelengths from the edge, diffraction is negligible and the wave propagates in straight lines in the direction of the incident rays. When wavefronts encounter a barrier with an aperture (hole) only a few wavelengths across, the part of the wavefronts passing through the aperture all pass within a few wavelengths of an edge. Thus, flat wavefronts bend and spread out and become spherical or circular (Figure 15-23). In contrast, for a beam of *particles* falling upon a barrier with an aperture, the part of the beam passing through the aperture does so with no change in the direction of the particles (Figure 15-24). Diffraction is one of the key characteristics that distinguish waves from particles. We will discuss how diffraction arises when we study the interference and diffraction of light in Chapter 35.

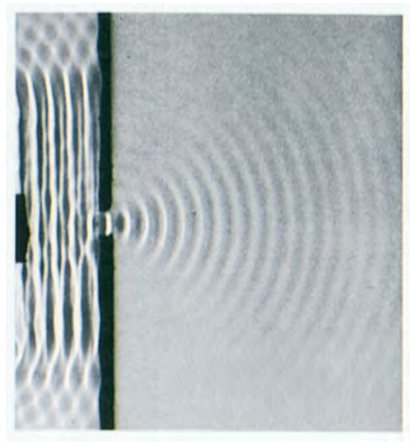

FIGURE 15-23 Plane waves in a ripple tank meeting a barrier with an opening that is only a few wavelengths wide. Beyond the barrier are circular waves that are concentric about the opening, much as if there were a point source at the opening. *(Fundamental Photographers.)*

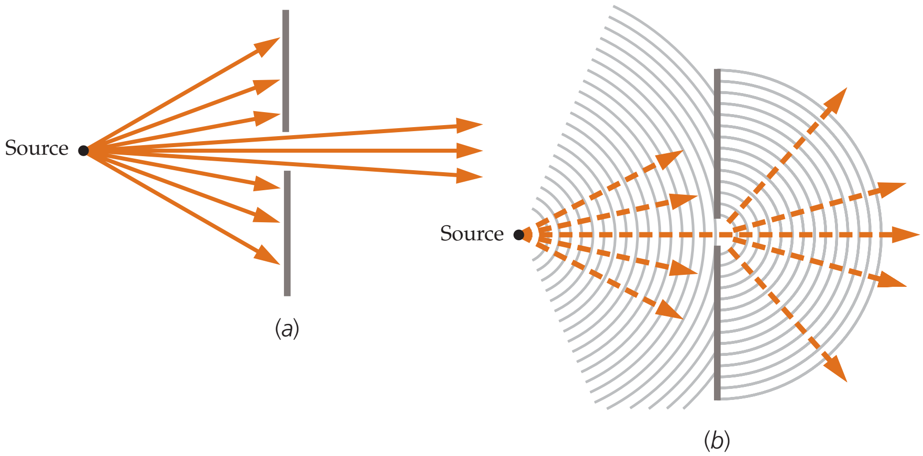

FIGURE 15-24 Comparison of particles and waves passing through a narrow opening in a barrier. (*a*) Transmitted particles are confined to a narrow-angle beam. (*b*) Transmitted waves spread out (radiate widely) from the aperture, which acts like a point source of circular waves.

Although waves passing through an aperture always bend, or diffract, to some extent, the amount of diffraction depends on whether the wavelength is small or large relative to the size of the aperture. If the wavelength is large relative to the aperture, as in Figure 15-25, the diffraction effects are large, and the waves spread out as they pass through the aperture—as if the waves were originating from a point source. On the other hand, if the wavelength is small relative to the aperture, the effect of diffraction is small, as shown in Figure 15-23. Near the edges of the aperture the wavefronts are distorted and the waves appear to bend slightly. For the most part, however, the wavefronts are not affected and the waves propagate in straight lines, much like a beam of particles. The approximation that waves propagate in straight lines in the direction of the rays with no diffraction is known as the **ray approximation.** Wavefronts are distorted *near* the edges of any obstacle blocking part of the wavefronts. By *near* we mean within a few wavelengths of the edges.

Because the wavelengths of audible sound (which range from a few centimeters to several meters) are generally large compared with apertures and obstacles (doors or windows, and people, for example), diffraction of sound waves is a phenomenon that is regularly observed. On the other hand, the wavelengths of visible light 4×10^{-7} to 7×10^{-7} m) are so small compared with the size of ordinary objects and apertures that the diffraction of light is not easily noticed; light appears to travel in straight lines. Nevertheless, the diffraction of light is an important phenomenon, one we study in detail in Chapter 35.

Diffraction places a limitation on how accurately small objects can be located by reflecting waves off them and on how well details of the objects can be resolved. Waves are not reflected appreciably from objects smaller than the wavelength, so detail cannot be observed on a scale smaller than the wavelength used. If waves of wavelength λ are used to locate an object, then its position can be known only to within an uncertainty of one wavelength.

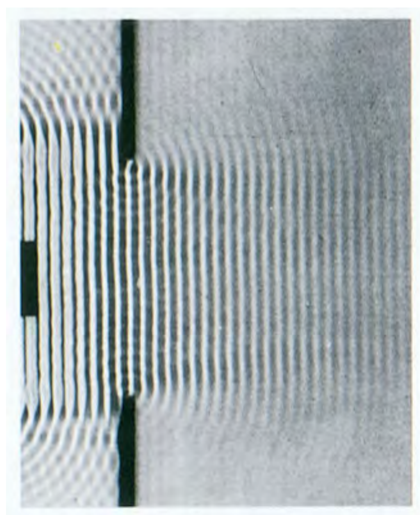

FIGURE 15-25 Plane waves in a ripple tank meeting a barrier with an opening width that is large compared to λ. The wave continues in the forward direction, with only a small amount of spreading into the regions to either side of the opening. *(Fundamental Photographers.)*

Sound waves with frequencies above 20,000 Hz are called **ultrasonic waves.** Because of their very small wavelengths, narrow beams of ultrasonic waves can be sent out and reflected from small objects. Bats can emit and detect frequencies up to about 120 kHz, corresponding to a wavelength of 2.8 mm, which they use to locate small prey such as moths. Echolocation systems, called sonar (from *so*und and *na*vigation *r*anging), are used to detect the outlines of submerged objects with sound waves. The frequency used by commercially available fish finders ranges from about 25 to 200 kHz, and porpoises produce echolocation clicks in the same frequency range. In medicine, ultrasonic waves are used for diagnostic purposes. Ultrasonic waves are passed through the human body and information about the frequency and intensity of the transmitted and reflected waves is processed to construct a three-dimensional picture of the body's interior, called a sonogram.

(GE Medical Systems/Photo Researchers, Inc.)

15-5 THE DOPPLER EFFECT

If a wave source and a receiver are moving relative to each other, the received frequency is not the same as the frequency of the source. If they are moving closer together, the received frequency is greater than the source frequency; and if they are moving farther apart, the received frequency is less than the source frequency. This is called the **Doppler effect.** A familiar example is the drop in pitch of the sound of the horn of an approaching car as the car passes by—and then recedes.

In the following discussion, all motions are relative to the medium. Consider the source moving with speed u_s, shown in Figure 15-26*a* and *b*, and a stationary receiver. The source has frequency f_s (and period $T_s = 1/f_s$). The received frequency f_r, the number of wave crests passing the receiver per unit time, is related to the wavelength λ (the distance between successive crests) and wave speed relative v by

$$f_r\lambda = v \quad \text{(stationary receiver)} \qquad 15\text{-}37$$

A wave crest leaves the source at time t_1 (Figure15-26*c*) and the next wave crest leaves the source at time t_2. The time between these two events is $T_s = t_2 - t_1$, and during this time the source and the crest leaving the source at time t_1 travel distances u_sT_s and vT_s, respectively. Consequently, at time t_2, the distance between the source and the crest leaving at time t_1 equals the wavelength λ. Behind the source $\lambda = \lambda_b = (v + u_s)T_s$, and in front of the source $\lambda = \lambda_f = (v - u_s)T_s$, provided $u_s < v$. (If $u_s \geq v$, no wavefronts reach the region ahead of the source.) We can express both λ_b and λ_f as

$$\lambda = (v \pm u_s)T_s = \frac{v \pm u_s}{f_s} \qquad 15\text{-}38$$

where the minus sign is used if $\lambda = \lambda_f$ and the plus sign is used if $\lambda = \lambda_b$. We have substituted $1/f_s$ for T_s. Substituting for λ in Equation 15-37 and rearranging gives

$$f_r = \frac{v}{\lambda} = \frac{v}{v \pm u_s} f_s \quad \text{(stationary receiver)} \qquad 15\text{-}39$$

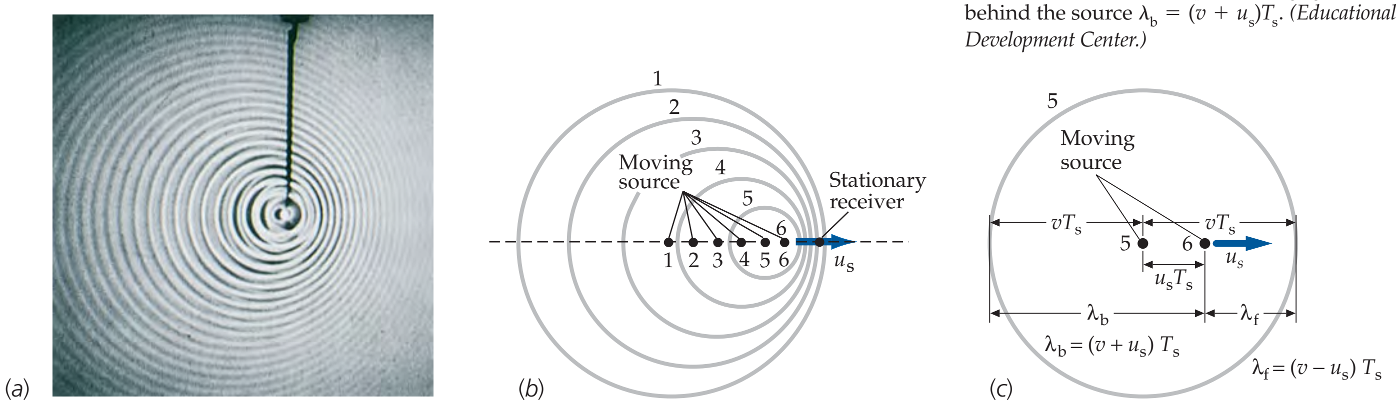

FIGURE 15-26 (*a*) Waves in a ripple tank produced by a point source moving to the right. The wavefronts are closer together in front of the source and farther apart behind the source. (*b*) Successive wavefronts emitted by a point source moving with speed u_s to the right. The numbers of the wavefronts correspond to the positions of the source when the wave was emitted. (*c*) The source vibrates one cycle in time T_s. During time T_s the source moves a distance u_sT_s and the fifth wavefront travels a distance vT_s. In front of the source the wavelength $\lambda_f = (v - u_s)T_s$, while behind the source $\lambda_b = (v + u_s)T_s$. *(Educational Development Center.)*

When the receiver moves relative to the medium, the received frequency is different simply because the receiver moves past more or fewer wave crests in a given time. Let T_r denote the time between arrivals of successive crests for a receiver moving with speed u_r. Then, during the time between the arrivals of two successive crests, each crest will have traveled a distance vT_r, and during the same time the receiver will have traveled a distance u_rT_r. If the receiver moves in the direction opposite to that of the wave (Figure 15-27), then during time T_r, the distance a crest moves plus the distance the receiver moves equals the wavelength. That is, $vT_r + u_rT_r = \lambda$, or $T_r = \lambda/(v + u_r)$. [If the receiver moves in the same direction as the wave, then $vT_r - \lambda = u_rT_r$, so $T_r = \lambda/(v - u_r)$]. Because $f_r = \lambda/T_r$, we have

$$f_r = \frac{1}{T_r} = \frac{v \pm u_r}{\lambda} \qquad \text{15-40}$$

where, if the receiver moves in the same direction as the wave, the received frequency is lower, so we choose the negative sign. If the receiver moves in the direction opposite to that of the wave, the frequency is higher, so we choose the positive sign. Substituting for λ from Equation 15-38, we obtain

$$f_r = \frac{v \pm u_r}{v \pm u_s} f_s \qquad \text{15-41}a$$

The correct choices for the plus or minus signs are most easily determined by remembering that the frequency tends to increase both when the source moves toward the receiver and when the receiver moves toward the source. For example, if the receiver is moving toward the source, the plus sign is selected in the numerator, which tends to increase the received frequency; if the source is moving away from the receiver, the plus sign is selected in the denominator, which tends to decrease the received frequency. Equation 15-41*a* appears more symmetric, and thus is easier to remember, if expressed in the form

$$\frac{f_r}{v \pm u_r} = \frac{f_s}{v \pm u_s} \qquad \text{15-41}b$$

It can be shown (see Problem 83) that if both u_s and u_r are much smaller than the wave speed v, then the shift in frequency $\Delta f = f_r - f_s$ is given approximately by

$$\frac{\Delta f}{f_s} \approx \pm\frac{u}{v} \qquad (u \ll v) \qquad \text{15-42}$$

where $u = u_s \pm u_r$ is the speed of the source relative to the receiver.

In a reference frame in which the medium is moving (for example, the reference frame of the ground if air is the medium and if there is a wind blowing), the wave speed v is replaced by $v' = v \pm u_w$, where u_w is the speed of the wind relative to the ground.

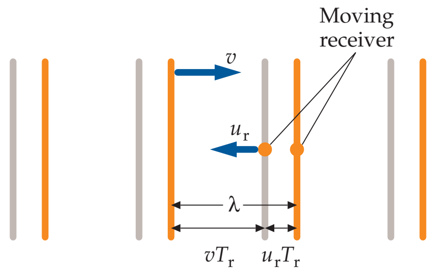

FIGURE 15-27 The time between arrivals of wave crests at the receiver is T_r. The wave crests are represented by orange lines when a wave crest reaches the receiver, and they are represented by grey lines when the next crest reaches the receiver. During time T_r the receiver travels the distance u_rT_r, while the wave crest travels the distance vT_r.

! Equations 15-37 through 15-42 are valid only in the reference frame of the propagating medium.

PROBLEM-SOLVING STRATEGY

Solving Problems Involving Doppler Shift

PICTURE Solving problems involving the Doppler shift means using the equation

$$f_r = \frac{v \pm u_r}{v \pm u_s} f_s$$

(Equation 15-41*a*).

SOLVE

1. Find the speed of the source u_s and of the receiver u_r in the reference frame of the propagating medium.
2. Find the directions of the motions of the source and receiver in the same reference frame.
3. Substitute values into Equation 15-41*a*. Both the source moving toward the receiver and the receiver moving toward the source tend to increase the received frequency. Thus, if the source is moving toward the receiver,

choose the minus sign in the denominator, and if the receiver is moving toward the source, choose the plus sign in the numerator.

4. If the wave bounces off a reflector before reaching the receiver, treat the reflector first as a receiver and apply Equation 15-41*a*, then treat the reflector as a source and apply Equation 15-41*a* once again.

CHECK If the distance between a source and receiver is decreasing, then the received frequency f_r is higher than the source frequency f_s. If this distance is increasing, then f_r is lower than f_s.

Example 15-12 Sounding the Horn

The frequency of a car horn is 400 Hz. If the horn is honked as the car moves with a speed $u_s = 34$ m/s (about 122 km/h) through still air toward a stationary receiver, find (*a*) the wavelength of the sound passing the receiver, and (*b*) the frequency received. Take the speed of sound in air to be 343 m/s. (*c*) Find the wavelength of the sound passing the receiver and find the frequency received if the car is stationary as the horn is honked and a receiver moves with a speed $u_r = 34$ m/s toward the car.

PICTURE (*a*) The waves in front of the source are compressed, so we use the minus sign in $\lambda = (v \pm u_s)/f_s$ (Equation 15-38). (*b*) We calculate the received frequency using $f_r = [(v \pm u_r)/(v \pm u_s)]f_s$ (Equation 15-41*a*). (*c*) For a moving receiver, we use the same equations as in Parts (*a*) and (*b*).

SOLVE

(*a*) Using Equation 15-38, calculate the wavelength in front of the car. In front of the source the wavelength is shorter, so choose the sign accordingly:

$$\lambda = \frac{v - u_s}{f_s} = \frac{343\text{ m/s} - 34\text{ m/s}}{400\text{ Hz}} = 0.758\text{ m} = \boxed{0.76\text{ m}}$$

(*b*) Using Equation 15-41*a* with $u_r = 0$, solve for the received frequency:

$$f_r = \frac{v \pm u_r}{v \pm u_s} f_s = \frac{v}{v - u_s} f_s = \left(\frac{343}{343 - 34}\right)(400\text{ Hz}) = 453\text{ Hz} = \boxed{450\text{ Hz}}$$

(*c*) 1. Using Equation 15-38 with $u_s = 0$, calculate the wavelength in front of the source:

$$\lambda = \frac{v \pm u_s}{f_s} = \frac{343\text{ m/s}}{400\text{ Hz}} = 0.858\text{ m} = \boxed{0.86\text{ m}}$$

2. The received frequency is given by Equation 15-41*a* with $u_s = 0$. The source is approaching the receiver, so the frequency is shifted upward. Choose the sign accordingly:

$$f_r = \frac{v \pm u_r}{v \pm u_s} f_s = \frac{v + u_r}{v} f_s = \left(1 + \frac{u_r}{v}\right) f_s = \left(1 + \frac{34}{343}\right)(400\text{ Hz}) = \boxed{440\text{ Hz}}$$

CHECK The receiver is moving at about 10% of the speed of sound and the frequency received is about 10% higher than the frequency of the source, which is plausible. (Caution, though, this works only if the source is at rest.)

TAKING IT FURTHER The frequency f_r can also be obtained using Equation 15-40.

PRACTICE PROBLEM 15-8 As a train moving at 90 km/h is approaching a stationary listener on a windless day, it sounds its horn, which has a frequency of 630 Hz. (*a*) What is the wavelength of the sound waves in front of the train? (*b*) What frequency is heard by the listener? (Use 343 m/s for the speed of sound.)

Example 15-13 The Speed of the Wave — *Context-Rich*

You work for an insurance company. An asteroid crashing into the ocean generates a tsunami. When the waves strikes land a 10-m-high wave does a lot of damage. Your boss wants to know how fast the big waves were moving. Knowing that you took a physics course, he asks you to find out. All you have to go on is the audio from a tape recorder that was found in a tree after the waves receded. The audio on the tape has a siren in the background, and in between blasts from the local warning siren is a faint echo of the siren. You measure the frequencies of the sound produced by the siren and its echo and find the siren had a frequency of 4000 Hz, but the echo had a frequency of 4080 Hz. How fast was the big wave approaching?

PICTURE You check with the weather service and find there was no wind at the time the tsunami hit. In addition, the reported temperature is 20°C, so the speed of sound was 343 m/s. First, apply the Doppler-effect equation (Equation 15-41*a*) to calculate the frequency of the sound received by the tsunami in terms of the speed u of the big wave. Apply the equation again, this time considering the big wave as the source of the sound and the tape recorder as the receiver. Assume that the tape recorder was not moving.

SOLVE

1. Apply the Doppler-effect equation with $u_s = 0$ to relate the frequency f_r received by the big wave to the speed u of the big wave:

$$f_r = \frac{v \pm u_r}{v \pm u_s} f_s = \frac{v+u}{v} f_s \qquad f_r = \frac{v+u}{v} f_s$$

2. Apply the Doppler-effect equation, this time with $u_r = 0$, to relate the frequency f_r' received by the tape recorder to the speed of the big wave. Use the step-1 result f_r as the frequency of the big wave as a source of sound:

$$f_r' = \frac{v \pm u_r}{v \pm u_s} f_s' = \frac{v}{v-u} f_r \qquad f_r' = \frac{v}{v-u} f_r$$

3. We now have two equations and two unknowns. Substitute the step-1 result into the step-2 result and simplify:

$$f_r' = \frac{v}{v-u} f_r = \frac{v}{v-u}\,\frac{v+u}{v} f_s \qquad f_r' = \frac{v+u}{v-u} f_s$$

4. Solve for the speed u:

$$u = \frac{f_r' - f_s}{f_r' - f_s} v = \frac{4400\text{ Hz} - 4000\text{ Hz}}{4400\text{ Hz} + 4000\text{ Hz}} 343\text{ m/s} = \boxed{16.3\text{ m/s}}$$

CHECK Sixteen meters per second is about twice as fast as a person can sprint under ideal conditions. Having seen video of tsunamis striking the shore, this seems like a plausible speed.

Another familiar example of the Doppler effect is the radar used by police to measure the speed of a car. Electromagnetic waves emitted by the radar transmitter strike the moving car. The car acts as both a moving receiver and a moving source as the waves reflect off it back to the radar receiver. Equation 15-41a is not valid for electromagnetic waves. Electromagnetic waves require the use of the relativistic Doppler-effect formula. (The relativistic Doppler effect is discussed following Example 15-14.) It turns out that if $u \ll c$, where c is the speed of light, Equation 15-42 is valid for electromagnetic waves.

Example 15-14 Police Radar

Try It Yourself

The radar unit in a police car sends out electromagnetic waves that travel at the speed of light c. The electric current in the antenna of the radar unit oscillates at frequency f_s. The waves reflect from a speeding car moving away from the police car at speed u relative to the police car. There is a frequency difference of Δf between f_s and f_x', the frequency received at the police car. Find u in terms of f_s and Δf.

PICTURE The radar wave strikes the speeding car at frequency f_r. This frequency is less than f_s because the car is moving away from the source. The frequency shift is given by $\Delta f/f = \pm u/v$ (Equation 15-42) with $v = c$. The car then acts as a moving source emitting waves of frequency f_r. The police unit detects waves of frequency $f_x' < f_r$ because the source (the speeding car) is moving away from the police car. The frequency difference is $f_x' - f_s$.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. The radar unit must be able to determine the speed based only on what it transmits and what it detects.	The radar unit must determine u in terms of f_s and f_r'. We solve $\Delta f/f = \pm u/v$ (Equation 15-42) for u in terms of f_s and $\Delta f = f_r' - f_s$.
2. The frequency difference Δf is the frequency difference $\Delta f_1 = f_r - f_s$ plus the frequency difference $\Delta f_2 = f - f_r$.	$\Delta f = \Delta f_1 + \Delta f_2$
3. Using Equation 15-42 with $v = c$, substitute for the frequency differences in step 2.	$\Delta f = -\frac{u}{c} f_s - \frac{u}{c} f_r = -\frac{u}{c}(f_s + f_r)$
4. Again using Equation 15-42, solve for f_r in terms of f_s.	$\frac{\Delta f_1}{f_s} = -\frac{u}{c}$ so $f_r = \left(1 - \frac{u}{c}\right) f_s$

5. Substitute your step-4 result into your step-3 result and simplify.
$$\Delta f = -\frac{u}{c}\left(2 - \frac{u}{c}\right)f_s$$

6. Compared to 2, u/c is negligible. Use this to simplify the step-5 result and solve for u in terms of Δf and f_s.
$$\Delta f \approx -2\frac{u}{c}f_s \quad \text{so} \quad u = -\frac{\Delta f}{2f_s}c = \boxed{\frac{|\Delta f|}{2f_s}c}$$

CHECK The step-6 result is a dimensionless ratio times the speed of light, so it has the correct dimensions for a speed. Thus, the dimensions of the step-6 result are plausible.

TAKING IT FURTHER The difference in frequency between two waves of nearly equal frequency is easy to detect because the two waves interfere to produce a wave whose amplitude oscillates with frequency $|\Delta f|$, which is called the beat frequency. Interference and beats are discussed in Chapter 16.

PRACTICE PROBLEM 15-9 Calculate Δf if $f_s = 1.50 \times 10^9$ Hz, $c = 3.00 \times 10^8$ m/s, and $u = 50.0$ m/s.

The Doppler shift and relativity We see from Example 15-12 (and Equations 15-39, 15-40, and 15-41) that the magnitude of the Doppler shift in frequency depends on whether it is the source or the receiver that is moving relative to the medium. For sound, these two situations are physically different. For example, if you move relative to still air, you feel air rushing past you. In your reference frame, there is a wind. For sound waves in air, therefore, we can tell whether the source or receiver is moving by noting if there is a wind in the reference frame of the source or the receiver. However, light and other electromagnetic waves propagate through empty space in which there is no propagating medium. There is no "wind" to tell us whether the source or receiver is moving. According to Einstein's theory of relativity, absolute motion cannot be detected, and all observers measure the same speed c for light, independent of their motion relative to the source. Thus Equation 15-41 cannot be correct for the Doppler shift for light. Two modifications must be made in calculating the relativistic Doppler effect for light. First, the speed of waves passing a receiver is c, which is independent of the motion of the receiver. Second, the time interval between the emission of successive wave crests, which is $T_s = 1/f_s$ in the reference frame of the source, is different in the reference frame of the receiver when the two reference frames are in relative motion, because of relativistic time dilation and length contraction (Equations R-9 and R-3). (We discuss the relativistic Doppler effect in Chapter 39.) The result is that the frequency received depends only on the relative speed of approach (or recession) u, and is related to the frequency emitted by

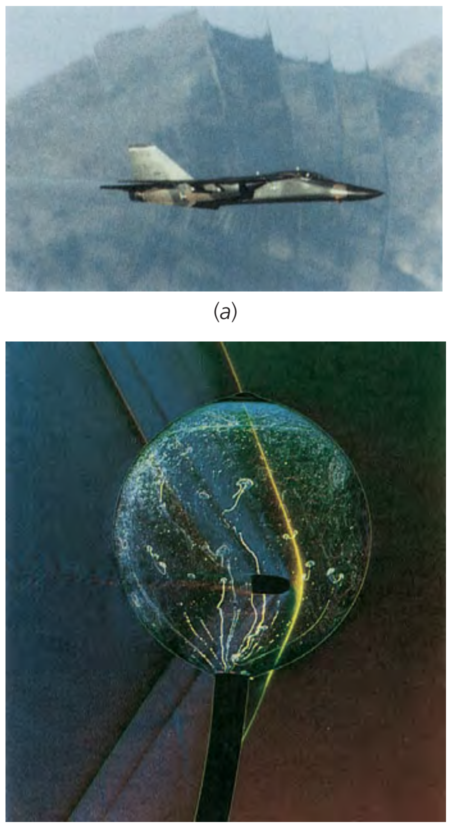
$$f_r = \sqrt{\frac{c \pm u}{c \pm u}}f_s \qquad 15\text{-}43$$

Choose the signs that give an up-shift in frequency when the source and receiver are approaching, and vice versa. Again, when $u \ll c$, $\Delta f/f_s \approx \pm u/c$, as given by Equation 15-42.

SHOCK WAVES

During our derivations of the Doppler-shift expressions, we assumed that the speed u of the source was less than the wave speed v. If a source moves with speed greater than the wave speed, then there will be no waves in front of the source. Instead, the waves pile up behind the source to form a shock wave. In the case of sound waves, this shock wave is heard as a sonic boom when it arrives at the receiver.

Figure 15-28 shows a source originally at point P_1 moving to the right with speed u. After some time t, the wave emitted from point P_1 has traveled a distance vt. The source has traveled a distance ut and will be at point P_2. The line from



(*a*)

(*b*)

(*a*) Shock waves from a supersonic airplane. *(Sandia National Laboratory.)* (*b*) Shock waves produced by a bullet traversing a helium balloon. *(Estate of Harold E. Edgerton/ Palm Press Inc.)*

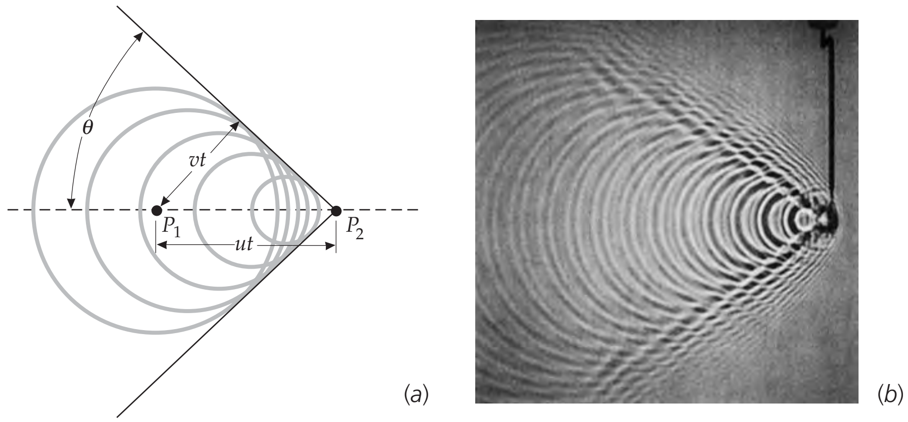


FIGURE 15-28 (*a*) Source moving with a speed u that is greater than the wave speed v. The envelope of the wavefronts forms a cone with the source at the apex. (*b*) Waves in a ripple tank produced by a source moving with a speed $u > v$. *(Educational Development Center.)*

this new position of the source to the wavefront emitted when the source was at P_1 makes an angle θ, called the **Mach angle,** with the path of the source, given by

$$\sin\theta = \frac{vt}{ut} = \frac{v}{u} \qquad \text{15-44}$$

Thus, the shock wave is confined to a cone that narrows as u increases. The ratio of the source speed u to the wave speed v is called the **Mach number:**

$$\text{Mach number} = \frac{u}{v} \qquad \text{15-45}$$

Equation 15-44 also applies to the electromagnetic radiation called *Cerenkov radiation*, which is given off when a charged particle moves in a medium with speed u that is greater than the speed of light v in that medium. (According to the special theory of relativity, it is impossible for a particle to move faster than c, the speed of light in vacuum. In a medium such as glass however, electrons and other particles can move faster than the speed of light in that medium.) The blue glow surrounding the fuel elements of a nuclear reactor is an example of Cerenkov radiation.

Example 15-15 A Sonic Boom

Try It Yourself

A supersonic plane flying due east at an altitude of 15 km passes directly over point P. The sonic boom is heard at point P when the plane is 22 km east of point P. What is the speed of the supersonic plane?

PICTURE The speed of the plane is related to the sine of the Mach angle (Equation 15-2). Draw a picture so the sine of the Mach angle can be calculated.

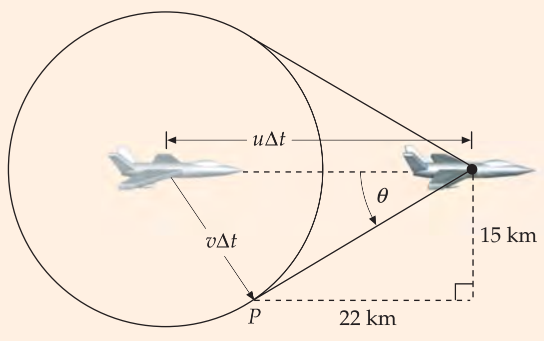

FIGURE 15-29 In the time that the plane moves distance $u\,\Delta t$, the sound moves distance $v\,\Delta t$.

SOLVE

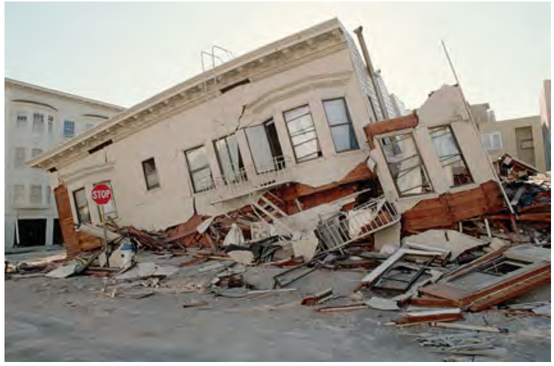
Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. Sketch the position of the plane (Figure 15-29) both at the instant the sonic boom is heard at point P and at the instant that sound was produced. Label the distance the sound travels $v\,\Delta t$, and the distance the plane travels $u\,\Delta t$.	
2. From your sketch and Equation 15-44, calculate u:	$\tan\theta = \dfrac{15\text{ km}}{22\text{ km}}$ so $\theta = 34.3°$ $\sin\theta = \dfrac{v\,\Delta t}{u\,\Delta t} = \dfrac{v}{u}$ so $u = \dfrac{v}{\sin\theta} = 609\text{ m/s} = \boxed{610\text{ m/s}}$

CHECK The speed of sound is 343 m/s, so 610 m/s is plausible for a supersonic speed.

Physics Spotlight

All Shook Up: Sediment Basins and Earthquake Resonance



The damage to buildings constructed on water-logged loose gravel, sand, dirt and clay is greater than the damage to those constructed on hard rock. *(Roger Ressmeyer/CORBIS.)*

On April 18, 1906, the city of San Francisco was devastated by a powerful earthquake. All the buildings in the lowest area collapsed. These buildings were built on water-logged *unconsolidated sediments* —loose gravel, sand, dirt, and clay. Some buildings even sank one or more stories into the ground as the shaking liquefied the loose sediment. Buildings up on rocky Nob Hill and Russian Hill fared better.

Cities located on unconsolidated sediments and near major faults are more vulnerable to earthquake damage than those that are not. If they are partly surrounded by rocky hills or mountains, the danger increases. Vulnerable cities include Seattle,[*, †] Istanbul,[‡] Rome,[#] Los Angeles,[°] San Francisco,[§] and Taipei.[¶]

Unconsolidated sediments are at much greater risk for seismic shaking than rock. When an earthquake occurs, some of the earthquake's energy is sent forth in seismic waves. These waves cause the ground to vibrate over a wide range of frequencies. In solid rock, the waves vibrate and have relatively small amplitudes. The looser the rock or sediment, the more the propagation speed decreases and the amplitude increases.[**] In loose gravel, the waves vibrate more slowly and have greater amplitude. In water-logged sediments, the waves vibrate still more slowly and have much greater amplitude. If you tap a bowl of gelatin sharply on the side, you can hear the sound of tapping the bowl. If it is a metal or glass bowl, the sound will have a frequency of hundreds of hertz. But the gelatin attenuates and scatters the higher frequencies, and resonates at lower frequencies. The same principle underlies the vulnerability of many cities to earthquakes.[††]

Unfortunately, the resonance frequencies of most buildings are closer to the resonance frequencies of the seismic waves in loose sediments.[‡‡] Thus, not only do the sediments vibrate with greater amplitude, but they vibrate most strongly at frequencies that are closer to the resonance frequencies of buildings. This problem was clearly recognized in the State report on the San Francisco earthquake of 1906.[##] Buildings located in areas of unconsolidated sediment were far more damaged than those that were located on higher, firmer ground.

The situation is worst for those cities that are built on sediments that are partially surrounded by areas of hard rock. There the waves resonate within the basin of sediments with large amplitudes. This was true in 1906, when the town of Santa Rosa sustained great damage, even though it was farther from the epicenter of the quake than other, less damaged towns. Santa Rosa is located within its own sediment basin, surrounded by rock.[°°] The basin resonance causes the sediments to vibrate with still greater amplitude. This greater amplitude creates greater damage. Usually, the damage is from the horizontal acceleration caused by the seismic waves. Until the stringent earthquake codes of the 1970s, buildings were not built to withstand horizontal forces. In most cities, well over half the buildings date from before the stringent codes were adopted.

Geophysicists use models of these basins and their sediments to predict areas that are likely to sustain high damage from earthquakes.[§§] These predictions are used to improve codes or to require that bridges,[¶¶] breakwaters,[***] and buildings[†††] are designed and constructed according to current best practices for hazard reduction. The next time you shake a bowl of gelatin, think of sediment basins and seismic damage.

Summary

1. In wave motion, energy and momentum are transported from one point in space to another without the transport of matter.
2. The relation $v = f\lambda$ holds for all harmonic waves.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Transverse and Longitudinal Waves	In transverse waves, such as waves on a string, the disturbance is perpendicular to the direction of propagation. In longitudinal waves, such as sound waves, the disturbance is along the direction of propagation.	
2. Speed of Waves	The wave speed v is independent of the motion of the wave source. The speed of a wave relative to the medium depends on the density and elastic properties of the medium.	
Waves on a string	$v = \sqrt{F_T/\mu}$	15-3
Sound waves	$v = \sqrt{B/\rho}$	15-4
Sound waves in a gas	$v = \sqrt{\gamma RT/M}$	15-5
	where T is the absolute temperature,	
	$T = t_C + 273.15$	15-6
	R is the universal gas constant,	
	$R = 8.314\ \mathrm{J/(mol \cdot K)}$	15-7
	M is the molar mass of the gas, which for air is 29.0×10^{-3} kg/mol, and γ is a constant that depends on the kind of gas. For a diatomic gas such as air, $\gamma = 7/5$. For a monatomic gas such as helium, $\gamma = 5/3$.	
Electromagnetic waves	The speed of electromagnetic waves in vacuum is a universal constant $c = 3.00 \times 10^8$ m/s	
***3. Wave Equation**	$\frac{\partial^2 y}{\partial x^2} = \frac{1}{v^2}\frac{\partial^2 y}{\partial t^2}$	15-10*b*
4. Harmonic Waves		
Wave function	$y(x,t) = A\sin(kx \pm \omega t)$	15-15
	where A is the amplitude, k is the wave number, and ω is the angular frequency. Use the minus sign for a wave traveling in the $+x$ direction, and the plus sign for a wave traveling in the $-x$ direction.	
Wave number	$k = \frac{2\pi}{\lambda}$	15-14
Angular frequency	$\omega = 2\pi f = \frac{2\pi}{T}$	15-17
Speed	$v = f\lambda = \omega/k$	15-12, 15-16
Energy	The energy in a harmonic wave is proportional to the square of the amplitude.	
Power for harmonic waves on a string	$P_{av} = \frac{1}{2}\mu v \omega^2 A^2$	15-22
5. Harmonic Sound Waves	Sound waves can be considered to be either displacement waves or pressure waves. The human ear is sensitive to sound waves of frequencies from about 20 Hz to 20 kHz. In a harmonic sound wave, the pressure and displacement are 90° out of phase.	
Amplitudes	The pressure and displacement amplitudes are related by	
	$p_0 = \rho\omega v s_0$	15-26
	where ρ is the density of the medium.	
Energy density	$\eta_{av} = \frac{(\Delta E)_{av}}{\Delta V} = \frac{1}{2}\rho\omega^2 s_0^2$	15-28

TOPIC	RELEVANT EQUATIONS AND REMARKS	
6. Intensity	The intensity of a wave is the average power per unit area. $$I = \frac{P_{\text{av}}}{A}$$	15-29
Average intensity I of a sound wave	$$I = \eta_{\text{av}} v = \frac{1}{2}\rho\omega^2 s_0^2 v = \frac{1}{2}\frac{p_0^2}{\rho v}$$	15-32
*Intensity level β in dB	Sound intensity levels are measured on a logarithmic scale. $$\beta = (10\text{ dB})\log\frac{I}{I_0}$$ where $I_0 = 10^{-12}\text{ W/m}^2$ is taken as the threshold of hearing.	15-33
7. Reflection and Refraction	When a wave is incident on a boundary surface that separates two regions of differing wave speed, part of the wave is reflected and part is transmitted.	
	The reflection and transmission coefficients are $$r = \frac{v_2 - v_1}{v_2 + v_1} \quad \text{and} \quad \tau = \frac{2v_2}{v_2 + v_1}$$	15-35
8. Diffraction	If a wavefront is partially blocked by an obstacle, the unblocked part of the wavefront diffracts (bends) into the region behind the obstacle.	
Ray approximation	If a wavefront is partially blocked by an obstacle, almost all of the diffraction occurs for that part of the wavefront that passes within a few wavelengths of the edge. For those parts of the wavefront that pass farther from the edge than a few wavelengths, diffraction is negligible and the wave propagates in straight lines in the direction of the incident rays.	
9. Doppler Effect	When a sound source and receiver are in relative motion, the received frequency f_r is higher than the frequency of the source f_s if their separation is decreasing, and lower if their separation is increasing.	
Moving source	$$\lambda = \frac{v \pm u_s}{f_s}$$	15-38[4]
Moving receiver	$$f_r = \frac{v \pm u_r}{\lambda}$$	15-40[3]
Either source or receiver moving	$$f_r = \frac{v \pm u_r}{v \pm u_s} f_s \quad \text{or} \quad \frac{f_r}{v \pm u_r} = \frac{f_s}{v \pm u_s}$$ Choose the signs that give an up-shift in frequency for an approaching source or receiver, and vice versa.	15-41[3]
Small speeds of source or receiver	$$\frac{\Delta f}{f_s} \approx \pm\frac{u}{v} \qquad (u \ll v)$$	15-42[3]
Relativistic Doppler shift	$$f_r = \sqrt{\frac{c \pm u}{c \pm u}}\, f_s$$ Choose the signs that give an up-shift in frequency for an approaching source or receiver, and vice versa.	15-43
10. Shock Waves	When the source speed is greater than the wave speed, the waves behind the source are confined to a cone of angle θ given by	
Mach angle	$$\sin\theta = \frac{u}{v}$$	15-44
Mach number	$$\text{Mach number} = \frac{u}{v}$$	15-45

Answer to Concept Check

15-1 Chuck will be disappointed. Twice the acoustic power will produce twice the *intensity* a given distance from the radio, not twice the *intensity level*.

Answers to Practice Problems

15-1 $\sqrt{\dfrac{\text{N}}{\text{kg/m}}} = \sqrt{\dfrac{\text{kg}\cdot\text{m/s}^2}{\text{kg/m}}} = \sqrt{\dfrac{\text{kg}\cdot\text{m}^2/\text{s}^2}{\text{kg}}} = \sqrt{\text{m}^2/\text{s}^2} = \text{m/s}$

15-2 1.01 km/s

15-3 $\dfrac{\partial^2 y}{\partial x^2} = k^2\dfrac{d^2y}{d^2\beta}$ and $\dfrac{\partial^2 y}{\partial t^2} = \omega^2\dfrac{d^2y}{d^2\beta}$, where $\beta = kx + \omega t$. Thus

$k^2 = \dfrac{\omega^2}{v^2} \Rightarrow \omega = kv$

15-4 26 W

15-5 $\lambda = 17$ m at 20 Hz, 17 mm at 20,000 Hz

15-6 (*a*) $A_r = +\frac{1}{3}A$ and $A_r = \frac{4}{3}A$, (*b*) $P_r/P_{in} = 1/3$ and $P_r/P_{in} = 8/9$

15-7 $1 = \left(-\dfrac{1}{3}\right)^2 + 2\left(\dfrac{2}{3}\right)^2 = \dfrac{1}{9} + 2\dfrac{4}{9} = 1$

15-8 (*a*) $\lambda = 0.5$ m, (*b*) $f_r = 680$ Hz

15-9 $\Delta f = 500$ Hz

Problems

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

Use 343 m/s as the speed of sound for air, unless otherwise indicated.

In intensity level problems involving the hearing threshold, the reference intensity is exactly 1×10^{-12} W/m² by convention. It is assumed to be accurate to an infinite number of significant figures. Therefore, the number of significant figures in the answers is determined only by those of the data.

• Single-concept, single-step, relatively easy

•• Intermediate-level, may require synthesis of concepts

••• Challenging

SSM Solution is in the *Student Solutions Manual*

Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • A rope hangs vertically from the ceiling. A pulse is sent up the rope. Does the pulse travel faster, slower, or at a constant speed as it moves toward the ceiling? Explain your answer. SSM

2 • A pulse on a horizontal taut string travels to the right. If the rope's mass per unit length decreases to the right, what happens to the speed of the pulse as it travels to the right? (*a*) It slows down. (*b*) It speeds up. (*c*) Its speed is constant. (*d*) You cannot tell from the information given.

3 • As a sinusoidal wave travels past a point on a taut string the arrival time between successive crests is measured to be 0.20 s. Which of the following is true? (*a*) The wavelength of the wave is 5.0 m. (*b*) The frequency of the wave is 5.0 Hz. (*c*) The velocity of propagation of the wave is 5.0 m/s. (*d*) The wavelength of the wave is 0.20 m. (*e*) There is not enough information to justify any of these statements.

4 • Two harmonic waves on identical strings differ only in amplitude. Wave A has an amplitude that is twice the amplitude of wave B. How do the energies of these waves compare? (*a*) $E_A = E_B$, (*b*) $E_A = 2E_B$, (*c*) $E_A = 4E_B$, (*d*) There is not enough information to compare their energies.

5 •• **ENGINEERING APPLICATION** To keep all of the lengths of the treble strings (unwrapped steel wires) in a piano about the same order of magnitude, wires of different linear mass densities are employed. Explain how this allows a piano manufacturer to use wires with lengths that are the same order of magnitude. SSM

6 • Musical instruments produce sounds of widely varying frequencies. Which sound waves have the longer wavelengths? (*a*) The lower frequencies. (*b*) The higher frequencies. (*c*) All frequencies have the same wavelength. (*d*) There is not enough information to compare the wavelengths of the different frequency sounds.

7 • In Problem 6, which sound waves have the larger speeds? (*a*) The lower frequency sounds. (*b*) The higher frequency sounds. (*c*) All frequencies have the same wave speed. (*d*) There is not enough information to compare their speeds.

8 • Sound travels at 343 m/s in air and 1500 m/s in water. A sound of 256 Hz is made under water, but you hear the sound while walking along the side of the pool. In the air, the frequency is (*a*) the same, but the wavelength of the sound is shorter, (*b*) higher, but the wavelength of the sound stays the same, (*c*) lower, but the wavelength of the sound is longer, (*d*) lower, and the wavelength of the sound is shorter, (*e*) the same, and the wavelength of the sound stays the same.

9 • While out on patrol, the battleship *Rodger Young* hits a mine, begins to burn, and ultimately explodes. Sailor Abel jumps into the water and begins swimming away from the doomed ship, while Sailor Baker gets into a life raft. Comparing their experiences later, Abel tells Baker, "I was swimming underwater, and heard a big explosion from the ship. When I surfaced, I heard a second explosion. What do you think it could be?" Baker says, "I think it was your imagination—I only heard one explosion." Explain why Baker only heard one explosion, while Abel heard two.

10 • True or false: A 60-dB sound has twice the intensity of a 30-dB sound.

11 • At a given location, two harmonic sound waves have the same amplitude, but the frequency of sound A is twice the frequency of sound B. How do their average energy densities compare? (*a*) The average energy density of A is twice the average energy density of B. (*b*) The average energy density of A is four times the average energy density of B. (*c*) The average energy density of A is 16 times the average energy density of B. (*d*) You cannot compare the average energy densities from the data given. SSM

12 • At a given location, two harmonic sound waves have the same frequency, but the amplitude of sound A is twice the amplitude of sound B. How do their average energy densities compare? (*a*) The average energy density of A is twice the average energy density of B. (*b*) The average energy density of A is four times the average energy density of B. (*c*) The average energy density of A is 16 times the average energy density of B. (*d*) You cannot compare the average energy densities from the data given.

13 • What is the ratio of the intensity of normal conversation to the sound intensity of a soft whisper (at a distance of 5.0 m)? (*a*) 10^3, (*b*) 2, (*c*) 10^{-3}, (*d*) 1/2 *Hint: See Table 15-1.*

14 • What is the ratio of the intensity level of normal conversation to the sound intensity level of a soft whisper (at a distance of 5.0 m)? (*a*) 10^3, (*b*) 2, (*c*) 10^{-3}, (*d*) 1/2 *Hint: See Table 15-1.*

15 • To increase the sound intensity level by 20 dB requires the sound intensity to increase by what factor? (*a*) 10, (*b*) 100, (*c*) 1000, (*d*) 2

16 • You are using a hand-held sound level meter to measure the intensity level of the roars produced by a lion prowling in the high grass. To decrease the measured sound intensity level by 20 dB requires the lion move away from you until its distance from you has increased by what factor? (*a*) 10, (*b*) 100, (*c*) 1000, (*d*) You cannot tell the required distance from the data given.

17 • One end of a very light (but strong) thread is attached to an end of a thicker and denser cord. The other end of the thread is fastened to a sturdy post and you pull the other end of the cord so the thread and cord are taut. A pulse is sent down the thicker, denser cord. True or false:

(*a*) The pulse that is reflected back from the thread-cord attachment point is inverted compared to the initial incoming pulse.
(*b*) The pulse that continues past the thread-cord attachment point is not inverted compared to the initial incoming pulse.
(*c*) The pulse that continues past the thread-cord attachment point has an amplitude that is smaller than the pulse that is reflected.

18 • Light traveling in air strikes a glass surface at a 45° incident angle. True or false:

(*a*) The angle between the reflected light ray and the incident ray is 90°.
(*b*) The angle between the reflected light ray and the refracted light ray is less than 90°.

19 • Sound waves in air encounter an open 1.0-m-wide door into a classroom. Due to the effects of diffraction, the sound of which frequency is least likely to be heard by all the students in the room–assuming the room is full? (*a*) 600 Hz, (*b*) 300 Hz, (*c*) 100 Hz, (*d*) All of the sounds are equally likely to be heard in the room. (*e*) Diffraction depends on wavelength not frequency, so you cannot tell from the data given. SSM

20 • Microwave radiation in modern microwave ovens has a wavelength on the order of centimeters. Would you expect significant diffraction if this radiation was aimed at a 1.0-m-wide door? Explain.

21 •• Stars often occur in pairs revolving around their common center of mass. If one of the stars is a black hole, it is invisible. Explain how the existence of such a black hole might be inferred by measuring the Doppler frequency shift of the light observed from the other, visible star. SSM

22 •• Figure 15-30 shows a wave pulse at time $t = 0$ moving to the right. (*a*) At this particular time, which segments of the string are moving up? (*b*) Which segments are moving down? (*c*) Is there any segment of the string at the pulse that is instantaneously at rest? Answer these questions by sketching the pulse at a slightly later time and a slightly earlier time to see how the segments of the string are moving.

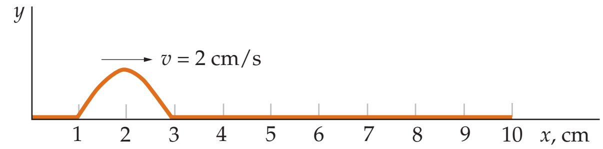

FIGURE 15-30 Problems 22, 23

23 •• Make a sketch of the velocity of each string segment versus position for the pulse shown in Figure 15-30.

24 •• An object of mass m hangs on a very light rope that is connected to the ceiling. You pluck the rope just above the object, and a wave pulse travels up to the ceiling and back. Compare the round-trip time for such a wave pulse to the round-trip time of a wave pulse on the same rope if an object of mass $9m$ is hung on the rope instead. (Assume that the rope does not stretch, that is, that the mass-to-ceiling distance is the same in each case.)

25 •• The explosion of a depth charge beneath the surface of a body of water is recorded by a helicopter hovering above the water's surface, as shown in Figure 15-31. Along which path—A, B, or C—will the sound wave take the least time to reach the helicopter? Explain why you chose the path you did.

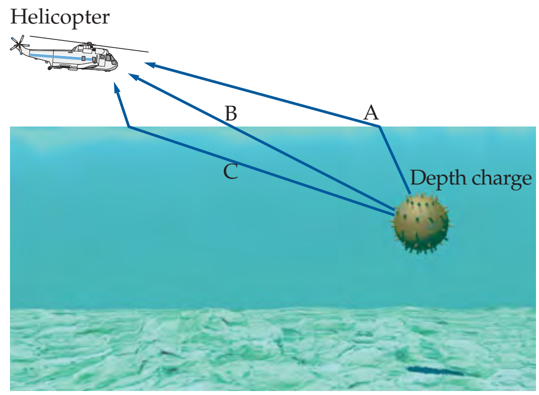

FIGURE 15-31 Problem 25

26 •• Does a speed of Mach 2 at an altitude 60,000 feet mean the same as a speed of Mach 2 near ground level? Explain clearly.

ESTIMATION AND APPROXIMATION

27 •• Many years ago, Olympic 100-m dashes were started by the sound from a starter's pistol, with the starter positioned several meters down the track, just on the inside of the track. (Today, the pistol that is used is often only a trigger, which is used to electronically activate speakers behind each sprinter's starting blocks. This method avoids the problem of one runner hearing the sound before the other runners.) Estimate the time advantage the runner at the inside lane (relative to the runner at the outside lane of 8 runners) would have if all runners started when they heard the sound from the starter's pistol.

28 •• Estimate the speed of the bullet as it passes through the helium balloon in Figure 15-32. *Hint: A protractor would be beneficial.*

FIGURE 15-32 Problem 28 *(Estate of Harold E. Edgerton/Palm Press Inc.)*

29 •• The new student townhouses at a local college are in the form of a semicircle half-enclosing the track field. To estimate the speed of sound in air, an ambitious physics student stood at the center of the semicircle and clapped his hands rhythmically at a frequency at which he could not hear the echo of the clap, because the echo reached him at the same time as his next clap. This frequency was about 2.5 claps/s. Once he established this frequency, he paced off the distance to the townhouses, which was 30 double strides. Assuming that the length of each stride is equal to half his height (5 ft 11 in.), estimate the speed of sound in air using these data. How far off is your estimation from the commonly accepted value of 343 m/s?

SPEED OF WAVES

30 • (*a*) The bulk modulus of water is $2.00 \times 10^9\ \mathrm{N/m^2}$. Use this value to find the speed of sound in water. (*b*) The speed of sound in mercury is 1410 m/s. What is the bulk modulus of mercury ($\rho = 13.6 \times 10^3\ \mathrm{kg/m^3}$)?

31 • Calculate the speed of sound waves in hydrogen gas ($M = 2.00$ g/mol and $\gamma = 1.40$) at $T = 300$ K.

32 • A 7.00-m-long guitar string has a mass of 100 g and is under a tension of 900 N. What is the speed of a transverse wave pulse on this string?

33 •• (*a*) Compute the derivative of the speed of a wave on a string with respect to the tension dv/dF_T and show that the differentials dv and dF_T obey $dv/v = \frac{1}{2}\, dF_T/F_T$. (*b*) A wave moves with a speed of 300 m/s on a string that is under a tension of 500 N. Using the differential approximation, estimate how much the tension must be changed to increase the speed to 312 m/s. (*c*) Calculate ΔF_T exactly and compare it to the differential approximation result in Part (*b*). Assume that the string does not stretch with the increase in tension. SSM

34 •• (*a*) Compute the derivative of the speed of sound in air with respect to the absolute temperature, and show that the differentials dv and dT obey $dv/v = \frac{1}{2}\, dT/T$. (*b*) Use this result to estimate the percentage change in the speed of sound when the temperature changes from 0°C to 27°C. (*c*) If the speed of sound is 331 m/s at 0°C, estimate its value at 27°C using the differential approximation. (*d*) How does this approximation compare with the result of an exact calculation?

35 ••• Derive a convenient formula for the speed of sound in air at temperature t in degrees Celsius. Begin by writing the temperature as $T = T_0 + \Delta T$, where $T_0 = 273$ K and corresponds to 0°C and $\Delta T = t$, which is the Celsius temperature. The speed of sound is a function of T, $v(T)$. To a first-order approximation, you can write $v(T) \approx v(T_0) + (dv/dT)_{T_0}\, \Delta T$, where $(dv/dT)_{T_0}$ is the derivative evaluated at $T = T_0$. Compute this derivative, and show that the result leads to

$$v = (331\ \mathrm{m/s})(1 + (t/2T_0)) = (331 + 0.606t)\ \mathrm{m/s}$$

THE WAVE EQUATION

36 • Show explicitly that the following functions satisfy the wave equations $\partial^2 y/\partial x^2 = (1/v^2)\, \partial^2 y/\partial t^2$: (*a*) $y(x,t) = k(x + vt)^3$, (*b*) $y(x,t) = Ae^{ik(x - vt)}$, where A and k are constants and $i = \sqrt{-1}$, and (*c*) $y(x,t) = \ln[k(x - vt)]$.

37 • Show that the function $y = A \sin kx \cos \omega t$ satisfies the wave equation.

HARMONIC WAVES ON A STRING

38 • One end of a 6.0-m-long string is moved up and down with simple harmonic motion at a frequency of 60 Hz. If the wave crests travel the length of the string in 0.50 s, find the wavelength of the waves on the string.

39 • A harmonic wave on a string that has a mass per unit length of 0.050 kg/m and a tension of 80 N has an amplitude of 5.0 cm. Each point on the string moves with simple harmonic motion at a frequency of 10 Hz. What is the power carried by the wave propagating along the string? SSM

40 • A 2.00-m-long rope has a mass of 0.100 kg. The tension is 60.0 N. An oscillator at one end sends a harmonic wave with an amplitude of 1.00 cm down the rope. The other end of the rope is terminated so all of the energy of the wave is absorbed and none is reflected. What is the frequency of the oscillator if the power transmitted is 100 W?

41 •• The wave function for a harmonic wave on a string is $y(x,t) = (1.00\ \mathrm{mm}) \sin(62.8\ \mathrm{m^{-1}}x + 314\ \mathrm{s^{-1}}t)$. (*a*) In what direction does this wave travel, and what is the wave's speed? (*b*) Find the wavelength, frequency, and period of this wave. (*c*) What is the maximum speed of any point on the string?

42 •• A harmonic wave on a string with a frequency of 80 Hz and an amplitude of 0.025 m travels in the $+x$ direction with a speed of 12 m/s. (*a*) Write a suitable wave function for this wave. (*b*) Find the maximum speed of a point on the string. (*c*) Find the maximum acceleration of a point on the string.

43 •• A 200-Hz harmonic wave with an amplitude equal to 1.2 cm moves along a 40-m-long string that has a mass of 0.120 kg and a tension of 50 N. (*a*) What is the average total energy of the waves on a 20-m-long segment of string? (*b*) What is the power transmitted past a given point on the string?

44 •• On a real string, some of the energy of a wave dissipates as the wave travels down the string. Such a situation can be described by a wave function whose amplitude $A(x)$ depends on x: $y = A(x) \sin(kx - \omega t)$, where $A(x) = A_0 e^{-bx}$. What is the power transported by the wave as a function of x, where $x > 0$?

45 •• Power is to be transmitted along a taut string by means of transverse harmonic waves. The wave speed is 10 m/s and the linear mass density of the string is 0.010 kg/m. The power source oscillates with an amplitude of 0.50 mm. (*a*) What average power is transmitted along the string if the frequency is 400 Hz? (*b*) The power transmitted can be increased by increasing the tension in the string, the frequency of the source, or the amplitude of the waves. By how much would each of these quantities have to increase to cause an increase in power by a factor of 100 if it is the only quantity changed? SSM

46 ••• Two very long strings are tied together at the point $x = 0$. In the region $x < 0$, the wave speed is v_1, while in the region $x > 0$, the speed is v_2. A sinusoidal wave is incident on the knot from the left ($x < 0$); part of the wave is reflected and part is transmitted. For $x < 0$, the displacement of the wave is described by $y(x,t) = A \sin(k_1 x - \omega t) + B \sin(k_1 x + \omega t)$, while for $x > 0$, $y(x,t) = C \sin(k_2 x - \omega t)$, where $\omega/k_1 = v_1$ and $\omega/k_2 = v_2$. (*a*) If we assume that both the wave function y and its first spatial derivative $\partial y/\partial x$ must be continuous at $x = 0$, show that $C/A = 2v_2/(v_1 + v_2)$, and that $B/A = (v_1 - v_2)/(v_1 + v_2)$. (*b*) Show that $B^2 + (v_1/v_2)C^2 = A^2$.

HARMONIC SOUND WAVES

47 • A sound wave in air produces a pressure variation given by $p(x,t) = 0.75 \cos\left[\frac{\pi}{2}(x - 343t)\right]$, where p is in pascals, x is in meters, and t is in seconds. Find (*a*) the pressure amplitude, (*b*) the wavelength, (*c*) the frequency, and (*d*) the wave speed.

48 • (*a*) Middle C on the musical scale has a frequency of 262 Hz. What is the wavelength of this note in air? (*b*) The frequency of the C an octave above middle C is twice that of middle C. What is the wavelength of this note in air?

49 • (*a*) What is the displacement amplitude for a sound wave with a frequency of 100 Hz and a pressure amplitude of 1.00×10^{-4} atm? (*b*) The displacement amplitude of a sound wave of frequency 300 Hz is 1.00×10^{-7} m. Assuming the density of air is $1.29\ \mathrm{kg/m^3}$, what is the pressure amplitude of this wave? SSM

50 • (*a*) What is the displacement amplitude of a sound wave that has a frequency of 500 Hz at the pain-threshold pressure amplitude of 29.0 Pa? (*b*) Assuming the density of air is $1.29\ \mathrm{kg/m^3}$, what is the displacement amplitude of a sound wave that has the same pressure amplitude as the wave in Part (*a*), but has a frequency of 1.00 kHz?

51 • A typical loud sound wave that has a frequency of 1.00 kHz has a pressure amplitude of about 1.00×10^{-4} atm. (*a*) At $t = 0$, the pressure is a maximum at some point x_1. What is the displacement at that point at $t = 0$? (*b*) Assuming the density of air is $1.29\ \mathrm{kg/m^3}$, what is the maximum value of the displacement at any time and place?

52 • An octave represents a change in frequency by a factor of 2. Over how many octaves can a typical person hear?

53 •• **Biological Application** In the oceans, whales communicate by sound transmission through the water. A whale emits a sound of 50.0 Hz to tell a wayward calf to catch up to the pod. The speed of sound in water is about 1500 m/s. (*a*) How long does it take the sound to reach the calf if he is 1.20 km away? (*b*) What is the wavelength of this sound in the water? (*c*) If the whales are close to the surface, some of the sound energy might refract out into the air. What would be the frequency and wavelength of the sound in the air?

WAVES IN THREE DIMENSIONS: INTENSITY

54 • A spherical sinusoidal source radiates sound uniformly in all directions. At a distance of 10.0 m, the sound intensity level is $1.00 \times 10^{-4}\ \mathrm{W/m^2}$. (*a*) At what distance from the source is the intensity $1.00 \times 10^{-6}\ \mathrm{W/m^2}$? (*b*) What power is radiated by this source?

55 • **Engineering Application** A loudspeaker at a rock concert generates a sound that has an intensity level equal to $1.00 \times 10^{-2}\ \mathrm{W/m^2}$ at 20.0 m and has a frequency of 1.00 kHz Assume that the speaker spreads its energy uniformly in three dimensions. (*a*) What is the total acoustic power output of the speaker? (*b*) At what distance will the sound intensity be at the pain threshold of $1.00\ \mathrm{W/m^2}$? (*c*) What is the sound intensity at 30.0 m? SSM

56 •• When a pin of mass 0.100 g is dropped from a height of 1.00 m, 0.050 percent of its energy is converted into a sound pulse that has a duration of 0.100 s. (*a*) Estimate how far away the dropped pin can be heard if the minimum audible intensity is $1.00 \times 10^{-11}\ \mathrm{W/m^2}$. (*b*) Your result in Part (*a*) is much too large in practice, because of background noise. If you assume the intensity must be at least $1.00 \times 10^{-8}\ \mathrm{W/m^2}$ for the sound to be heard, estimate how far away the dropped pin can be heard. (In both parts, assume that the intensity is $P/4\pi r^2$.)

*INTENSITY LEVEL

57 • What is the intensity level in decibels of a sound wave that has an intensity equal to (*a*) $1.00 \times 10^{-10}\ \mathrm{W/m^2}$ and (*b*) $1.00 \times 10^{-2}\ \mathrm{W/m^2}$? SSM

58 • What is the intensity of a sound wave if, at a particular location, the intensity level is (*a*) $\beta = 10$ dB and (*b*) $\beta = 3.0$ dB?

59 • At a certain distance, the sound intensity level of a dog's bark is 50 dB. At that same distance, the sound intensity level of a rock concert is 10,000 times that of the dog's bark. What is the sound intensity level of the rock concert?

60 • What fraction of the acoustic power of a noise would have to be eliminated to lower its sound intensity level from 90 to 70 dB?

61 •• A spherical source radiates sound uniformly in all directions. At a distance of 10 m, the sound intensity level is 80 dB. (*a*) At what distance from the source is the intensity level 60 dB? (*b*) What power is radiated by this source?

62 •• Harry and Sally are sitting on opposite sides of a circus tent when an elephant trumpets a loud blast. If Harry experiences a sound intensity level of 65 dB and Sally experiences only 55 dB, what is the ratio of the distance between Sally and the elephant to the distance between Harry and the elephant?

63 •• Three noise sources produce intensity levels of 70 dB, 73 dB, and 80 dB, when acting separately. When the sources act together, the resultant intensity is the sum of the individual intensities. (*a*) Find the sound intensity level in decibels when the three sources act at the same time. (*b*) Discuss the effectiveness of eliminating the two less intense sources in reducing the intensity level of the noise.

64 •• Show that if two people are different distances away from a sound source, the difference $\Delta\beta$ between the intensity levels reaching the people, in decibels, will always be the same, no matter the power radiated by the source.

65 ••• Everyone at a party is talking equally loudly. One person is talking to you and the sound intensity level at your location is 72 dB. Assuming that all 38 people at the party are at the same distance from you as the person who you are talking to, find the sound intensity level at your location.

66 ••• When a violinist pulls the bow across a string, the force with which the bow is pulled is fairly small, about 0.60 N. Suppose the bow travels across the A string, which vibrates at 440 Hz, at 0.50 m/s. A listener 35 m from the performer hears a sound of 60-dB intensity. Assuming that the sound radiates uniformly in all directions, with what efficiency is the mechanical energy of bowing converted to sound energy?

67 ••• The noise intensity level at some location in an empty classroom is 40 dB. When 100 students are writing during an exam, the noise level at that location increases to 60 dB. Assuming that the noise produced by each student contributes an equal amount of acoustic power, find the noise intensity level in the room after 50 students have left. SSM

STRING WAVES EXPERIENCING SPEED CHANGES

68 • A 3.00-m-long piece of string, with a mass of 25.0 g, is tied to 4.00 m of heavy twine with a mass of 75.0 g, and the combination is put under a tension of 100 N. If a transverse pulse is sent down the less dense string, determine the reflection and transmission coefficients at the junction point.

69 • Consider a taut string, with a mass per unit length μ_1, carrying transverse wave pulses that are incident upon a point where the string connects to a second string, with a mass per unit length μ_2. (*a*) Show that if $\mu_2 = \mu_1$, then the reflection coefficient r equals zero and the transmission coefficient τ equals $+1$. (*b*) Show that if $\mu_2 \gg \mu_1$, then $r \approx -1$ and $\tau \approx 0$. (*c*) Show that if $\mu_2 \ll \mu_1$, then $r \approx +1$ and $\tau \approx +2$. SSM

70 •• Verify the validity of $1 = r^2 + (v_1/v_2)\tau^2$ (Equation 15-36) by substituting the expressions for r and τ into it.

71 ••• Consider a taut string that has a mass per unit length μ_1 carrying transverse wave pulses of the form $y = f(x - v_1 t)$ that are incident upon a point P where the string connects to a second string with mass per unit length μ_2. Derive $1 = r^2 + (v_1/v_2)\tau^2$ by equating the power incident on point P to the power reflected at P plus the power transmitted at P.

THE DOPPLER EFFECT

In Problems 72 through 77, assume that the source emits sound at a frequency of 200 Hz. Assume also that the sound travels through still air at 343 m/s.

72 • A sound source is moving at 80 m/s toward a stationary listener that is standing in still air. (*a*) Find the wavelength of the sound in the region between the source and the listener. (*b*) Find the frequency heard by the listener.

73 • Consider the situation described in Problem 72 from the reference frame of the source. In this frame, the listener and the air are moving toward the source at 80 m/s and the source is at rest. (*a*) At what speed, relative to the source, is the sound traveling in the region between the source and the listener? (*b*) Find the wavelength of the sound in the region between the source and the listener. (*c*) Find the frequency heard by the listener.

74 • A sound source is moving away from the stationary listener at 80 m/s. (*a*) Find the wavelength of the sound waves in the region between the source and the listener. (*b*) Find the frequency heard by the listener.

75 • The listener is moving at 80 m/s away from the stationary source that is at rest relative to the air. Find the frequency heard by the listener.

76 •• CONTEXT-RICH You have made the trek to observe a Space Shuttle landing. Near the end of its descent, the ship is traveling at Mach 2.50 at an altitude of 5000 m. (*a*) What is the angle that the shock wave makes with the line of flight of the shuttle? (*b*) How far are you from the shuttle by the time you hear its shock wave, assuming the shuttle maintains both a constant heading and a constant 5000-m altitude after flying directly over your head?

77 •• ENGINEERING APPLICATION The SuperKamiokande neutrino detector of Japan is a water tank the size of a 14-story building. When neutrinos collide with electrons in the water, most of their energy is transferred to the electrons. As a consequence, the electrons then fly off at speeds that approach *c*. The neutrino is counted by detecting the shock wave, called Cerenkov radiation, that is produced when the high-speed electrons travel through the water at speeds greater than the speed of light in water. If the maximum angle of the Cerenkov shock-wave cone is 48.75°, what is the speed of light in water?

78 •• ENGINEERING APPLICATION, CONTEXT-RICH You are in charge of calibrating the radar guns for a local police department. One such device emits microwaves at a frequency of 2.00 GHz. During the trials, these waves are reflected from a car moving directly away from the stationary emitter. You detect a frequency difference (between the received microwaves and the ones sent out) of 293 Hz. Find the speed of the car.

79 •• ENGINEERING APPLICATION, CONTEXT-RICH The Doppler effect is routinely used to measure the speed of winds in storm systems. As the manager of a weather monitoring station in the Midwest, you are using a Doppler radar system that has a frequency of 625 MHz to bounce a radar pulse off of the raindrops in a swirling thunderstorm system 50 km away. You measure the reflected radar pulse to be up-shifted in frequency by 325 Hz. Assuming the wind is headed directly toward you, how fast are the winds in the storm system moving? *Hint: The radar system can only measure the component of the wind velocity along its "line of sight."* SSM

80 •• ENGINEERING APPLICATION A stationary destroyer is equipped with sonar that sends out 40 MHz pulses of sound. The destroyer receives reflected pulses back from a submarine directly below with a time delay of 80 ms at a frequency of 39.958 MHz. If the speed of sound in seawater is 1.54 km/s, (*a*) what is the depth of the submarine? (*b*) What is its vertical speed?

81 •• A police radar unit transmits microwaves of frequency 3.00×10^{10} Hz, and their speed in air is 3.00×10^{8} m/s. Suppose a car is receding from the stationary police car at a speed of 140 km/h. (*a*) What is the frequency difference between the transmitted signal and the signal received from the receding car? (*b*) Suppose the police car is, instead, moving at a speed of 60 km/h in the same direction as the other vehicle. What is the difference in frequency between the emitted and the reflected signals?

82 •• BIOLOGICAL APPLICATION, CONTEXT-RICH In modern medicine, the Doppler effect is routinely used to measure the rate and direction of blood flow in arteries and veins. High-frequency "ultrasound" (sound at frequencies above the human hearing range) is typically employed. Suppose you are in charge of measuring the blood flow in a vein (located in the lower leg of an older patient) that returns blood upward to the heart. Her varicose veins indicate that perhaps the one-way valves in the vein are not working properly and that the blood is "pooling" in the veins and perhaps even that the blood flow is backward toward her feet. Employing sound that has a frequency of 50.0 kHz, you point the sound source from above her thigh region down toward her feet and measure the sound reflected from that vein area to be lower than 50.0 kHz. (*a*) Was your diagnosis of the valve condition correct? If so, explain. (*b*) Estimate the instrument's frequency difference capability to enable you to measure speeds down to 1.00 mm/s. Take the speed of sound in flesh to be the same as that in water, 1500 m/s.

83 •• A sound source of frequency f_s moves with speed u_s relative to still air toward a receiver who is moving away from the source with speed u_r relative to still air. (*a*) Write an expression for the received frequency f_r'. (*b*) Use the result that $(1 - x)^{-1} \approx 1 + x$ to show that if both u_s and u_r are small compared to v, then the received frequency is approximately

$$f_r' = \left(1 + \frac{u_{rel}}{v}\right) f_s$$

where $u_{rel} = u_s - u_r$ is the velocity of the source relative to the receiver. SSM

84 •• To study the Doppler shift on your own, you take an electronic tone generating device that is set to a frequency of middle C (262 Hz) to a campus wishing well known as "The Abyss." When you hold the device at arm's length (1.0 m), you measure its intensity level to be 80.0 dB. You then drop the tuner down the hole, listening to its sound as it falls. (*a*) After the tuner has fallen for 5.50 s, what frequency do you hear? (*b*) Estimate the time at which you can no longer hear the tuner.

85 •• You are in a hot-air balloon carried along by a 36-km/h wind and have a sound source with you that emits a sound of 800 Hz as it approaches a tall building. (*a*) What is the frequency of the sound heard by an observer at the window of this building? (*b*) What is the frequency of the reflected sound heard by you?

86 •• A car is approaching a reflecting wall. A stationary observer behind the car hears a sound of frequency 745 Hz from the car horn and a sound of frequency 863 Hz from the wall. (*a*) How fast is the car traveling? (*b*) What is the frequency of the car horn? (*c*) What frequency does the car driver hear reflected from the wall?

87 •• The driver of a car traveling at 100 km/h toward a vertical wall briefly sounds the horn. Exactly 1.00 s later she hears the echo and notes that its frequency is 840 Hz. How far from the wall was the car when the driver sounded the horn and what is the frequency of the horn?

88 •• You are on a transatlantic flight traveling due west at 800 km/h. An experimental plane flying at Mach 1.6 and 3.0 km to the north of your plane is also on an east-to-west course. What is the distance between the two planes when you hear the sonic boom from the experimental plane?

89 ••• The Hubble space telescope has been used to determine the existence of planets orbiting distant stars. A planet orbiting a star will cause the star to "wobble" with the same period as the planet's orbit. Because of this wobble, light from the star will be Doppler-shifted up and down periodically. Estimate the maximum and minimum wavelengths of light of nominal wavelength 500 nm emitted by the Sun that is Doppler-shifted by the motion of the Sun due to the planet Jupiter.

GENERAL PROBLEMS

90 • At time $t = 0$, the shape of a wave pulse on a string is given by the function $y(x,0) = 0.120\ \mathrm{m}^3/((2.00\ \mathrm{m})^2 + x^2)$, where x is in meters. (*a*) Sketch $y(x, 0)$ versus x. (*b*) Give the wave function $y(x,t)$ at a general time t if the pulse is moving in the $+x$ direction with a speed of 10.0 m/s and if the pulse is moving in the $-x$ direction with a speed of 10.0 m/s.

91 • A whistle that has a frequency of 500 Hz moves in a circle of radius 1.00 m at 3.00 rev/s. What are the maximum and minimum frequencies heard by a stationary listener in the plane of the circle and 5.00 m away from its center? SSM

92 • Ocean waves move toward the beach with a speed of 8.90 m/s and a crest-to-crest separation of 15.0 m. You are in a small boat anchored off shore. (*a*) At what frequency do the wave crests reach your boat? (*b*) You now lift anchor and head out to sea at a speed of 15.0 m/s. At what frequency do the wave crests reach your boat now?

93 •• A 12.0-m-long wire that has an 85.0-g mass is under a tension of 180 N. A pulse is generated at the left end of the wire, and 25.0 ms later a second pulse is generated at the right end of the wire. Where do the pulses first meet?

94 •• You are parked on the shoulder of a highway. Find the speed of a car in which the tone of the car's horn drops by 10 percent as it passes you. (In other words, the total drop in frequency between the "approach" value and the "recession" value is 10%.)

95 •• A loudspeaker driver 20.0 cm in diameter is vibrating at 800 Hz with an amplitude of 0.0250 mm. Assuming that the air molecules in the vicinity have the same amplitude of vibration, find (*a*) the pressure amplitude immediately in front of the driver, (*b*) the sound intensity, and (*c*) the acoustic power being radiated by the front surface of the driver. SSM

96 •• A plane, harmonic, sound wave in air has an amplitude of 1.00 μm has an intensity of 10.0 m W/m^2. What is the frequency of the wave?

97 •• Water flows at 7.0 m/s in a pipe of radius 5.0 cm. A plate with area equal to the cross-sectional area of the pipe is suddenly inserted to stop the flow. Find the force exerted on the plate. Take the speed of sound in water to be 1.4 km/s. *Hint: When the plate is inserted, a pressure wave propagates through the water at the speed of sound, v_s. The mass of water brought to a stop in time Δt is the water in a length of pipe equal to $v_s\ \Delta t$.*

98 •• A high-speed flash photography setup meant to capture a picture of a bullet exploding a soap bubble is shown in Figure 15-33. The shock wave from the bullet is to be detected by a microphone that will trigger the flash. The microphone is placed on a track that is parallel to and 0.350 m below the path of the bullet. The track is used to adjust the position of the microphone. If the bullet is traveling at 1.25 times the speed of sound, and the distance between the lab bench and the track is 0.350 m, how far back from the soap bubble must the microphone be set to trigger the flash? (Assume that the flash itself is instantaneous once the microphone is triggered.)

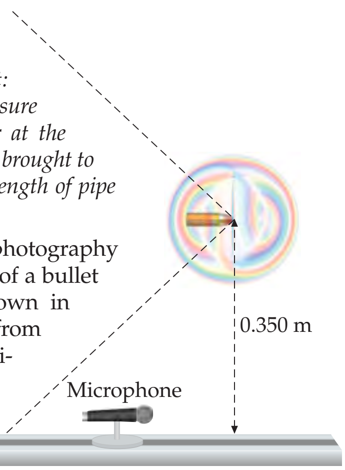

FIGURE 15-33 Problem 98

99 •• A column of precision marchers keeps in step by listening to the band positioned at the head of the column. The beat of the music is for 100 paces/min. A television camera shows that only the marchers at the front and the rear of the column are actually in step. The marchers in the middle section are striding forward with the left foot when those at the front and rear are striding forward with the right foot. The marchers are so well trained, however, that they are all certain that they are in proper step with the music. How long is the column?

100 •• **BIOLOGICAL APPLICATION** A bat flying toward a stationary obstacle at 12.0 m/s emits brief, high-frequency sound pulses at a repetition frequency of 80.0 Hz. What is the interval between the arrival times of the reflected pulses heard by the bat?

101 •• Laser ranging to the moon is done routinely to accurately determine the Earth-moon distance. However, to determine the distance accurately, corrections must be made for the average speed of light in Earth's atmosphere, which is 99.997 percent of the speed of light in vacuum. Assuming that Earth's atmosphere is 8.00 km high, estimate the length of the correction.

102 •• A tuning fork attached to a taut string generates transverse waves. The vibration of the fork is perpendicular to the string. Its frequency is 400 Hz and the amplitude of its oscillation is 0.50 mm. The string has a linear mass density of 0.010 kg/m and is under a tension of 1.0 kN. Assume that there are no waves reflected at the far end of the string. (*a*) What are the period and frequency of waves on the string? (*b*) What is the speed of the waves? (*c*) What are the wavelength and wave number? (*d*) What is a suitable wave function for the waves on the string? (*e*) What is the maximum speed and acceleration of a point on the string? (*f*) At what minimum average rate must energy be supplied to the fork to keep it oscillating at a steady amplitude?

103 ••• A long rope with a mass per unit length of 0.100 kg/m is under a constant tension of 10.0 N. A motor drives one end of the rope with transverse simple harmonic motion at 5.00 cycles per second and an amplitude of 40.0 mm. (*a*) What is the wave speed? What is the wavelength? (*c*) What is the maximum transverse linear momentum of a 1.00-mm segment of the rope? (*d*) What is the maximum net force on a 1.00-mm segment of the rope?

104 ••• In this problem, you will derive an expression for the potential energy of a segment of a string carrying a traveling wave (Figure 15-34). The potential energy of a segment equals the work done by the tension in stretching the string, which is $\Delta U = F_T(\Delta\ell - \Delta x)$, where F_T is the tension, $\Delta\ell$ is the length of the stretched segment, and Δx is its original length. (*a*) Use the binomial expansion to show that $\Delta\ell - \Delta x \approx \frac{1}{2}(\Delta y/\Delta x)^2\,\Delta x$, and therefore $\Delta U \approx \frac{1}{2}F_T(\Delta y/\Delta x)^2\,\Delta x$. (*b*) Compute $\partial y/\partial x$ from the wave function $y(x, t) = A\sin(kx - \omega t)$ (Equation 15-15) and show that $\Delta U \approx \frac{1}{2}F_T k^2 A^2\cos^2(kx - \omega t)\,\Delta x$.

$$\Delta\ell = \sqrt{(\Delta x)^2 + (\Delta y)^2} = \Delta x[1 + (\Delta y/\Delta x)^2]^{1/2}.$$

CHAPTER 16

COMPOSED OF OVER 6134 PIPES OF WIDELY VARYING SIZES, THIS ORGAN IS CAPABLE OF NOTES RANGING FROM A C THAT IS BELOW THE LOWEST C ON A PIANO AND HAS A FREQUENCY OF ONLY 16 Hz TO A NOTE THAT IS A FULL OCTAVE AND A THIRD HIGHER THAN A PIANO'S HIGHEST NOTE AND HAS A FREQUENCY OF 10,548 Hz. *(Ted Soqui/Corbis.)*

Superposition and Standing Waves

? What is the length of the organ pipe that produces the 16-Hz note? (See Example 16-9.)

To get a clear understanding of simple wave motion, in Chapter 15 we examined the movement of a sequence of disturbances through a medium. However, if you have been to the ocean, perhaps you have observed what happens when these disturbances collide and cut across each other. When two or more waves overlap in space, their individual disturbances superimpose, adding algebraically, to create a resultant wave. For the case of harmonic waves, overlapping waves of the same frequency produce sustained wave patterns in space.

The Walt Disney Concert Hall in Los Angeles, California, which houses the pipe organ shown here, is an engineering and acoustic marvel. Structural and civil engineers worked to establish structural integrity of the Frank Gehry–designed organ and to ensure that the organ is strong enough to withstand earthquakes. Acoustical engineers created models for acoustic testing. One such model, scaled to one-tenth actual size, even included felt-covered lead figures to represent audience members. (Sound waves at 10 times the normal frequency—and one-tenth of the normal wavelength—were used to test the design.)

Our study of waves does not end with this chapter, though. We will continue our examination of waves in Chapter 34 where the wave nature of electrons and other material objects are integral to our understanding of quantum physics.

In this chapter, we begin with the superposition of wave pulses on a string and then consider the superposition and interference of harmonic waves. We examine the phenomenon of beats and study standing waves, which occur when harmonic waves are confined in space. Finally, we consider the analysis of complex musical tones.

16-1 SUPERPOSITION OF WAVES

Figure 16-1*a* shows two small-amplitude wave pulses of different durations moving in opposite directions on a string. The shape of the string when they overlap can be found by adding the displacements that would be produced by each pulse separately. The **principle of superposition** is a property of wave motion, which states:

> When two or more waves overlap, the resultant wave is the algebraic sum of the individual waves.
>
> PRINCIPLE OF SUPERPOSITION

That is, when there are two pulses on the string, the total wave function is the algebraic sum of the individual wave functions. While the principle of superposition holds for many waves, it does not hold for all waves. For example, the principle of superposition does not hold if the sum of two displacements exceeds the proportional limit* of the medium. Throughout the discussions that follow, we assume that the principle of superposition holds.

In the special case of two pulses that are identical except that one is inverted relative to the other, as in Figure 16-1*b*, there is an instant when the pulses exactly overlap and add to zero. At this instant the string is horizontal. A short time later the individual pulses emerge, each continuing in its original direction. That is, they exit the overlap region looking exactly as they did prior to entering the overlap region.

! After two wave pulses traveling in opposite directions "collide," they each continue moving with the same speed, size, and shape that they had before the "collision."

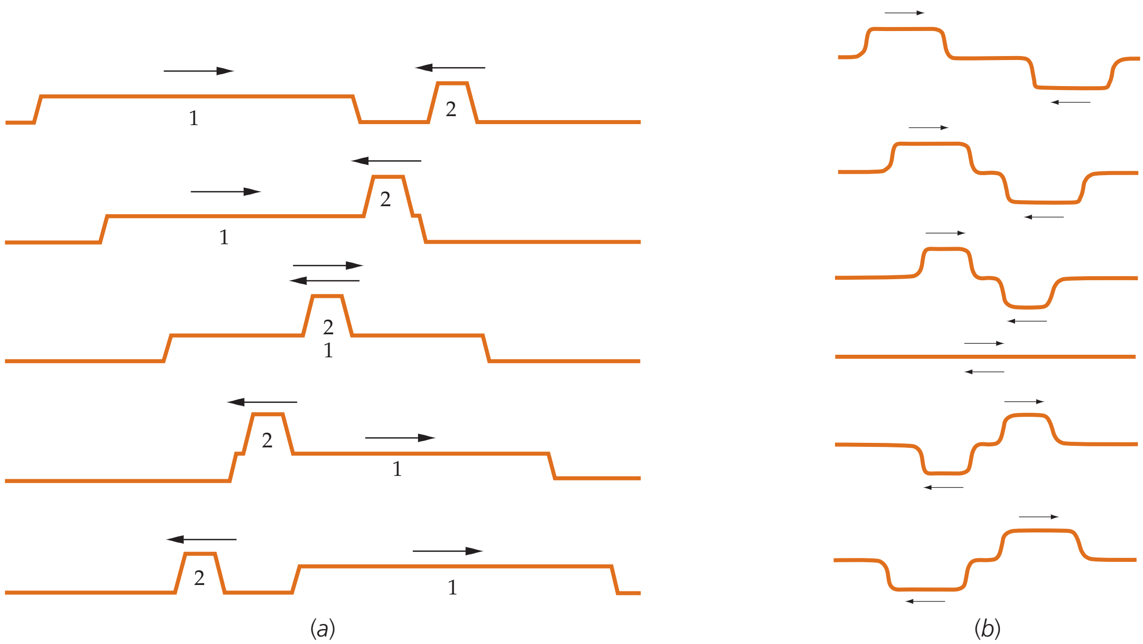

FIGURE 16-1 Wave pulses moving in opposite directions on a string. The shape of the string when the pulses overlap is found by adding the displacements due to each separate pulse. (*a*) Superposition of two pulses having displacements in the same direction (upward). The figure shows the shape of the string at equal time intervals of duration Δt. Each pulse travels the length of pulse 2 during time Δt. (*b*) Superposition of two pulses having equal displacements in opposite directions. Here the algebraic addition of the displacement amounts to the subtraction of the magnitudes.

* The proportional limit of an elastic material is the maximum strain for which stress is proportional to strain. Stress and strain are discussed in Section 8 of Chapter 12.

Example 16-1 Colliding Pulses *Conceptual*

An upright pulse on a taut string moves to the right, while an inverted pulse of the same size and shape moves to the left. When these pulses overlap there is an instant when the string is flat and no pulses can be seen. This is all in accord with the principle of superposition. The question is, why do the pulses reappear and continue on following the collision?

PICTURE The displacement of each point on the string is zero at the instant the string is flat, but is the velocity of each point zero at that instant? For an upright pulse, the string in the leading edge of the pulse is moving upward and the string in the trailing edge is moving downward. For an inverted pulse the opposite is true: the string in the leading edge is moving downward and the string in the trailing edge is moving upward.

SOLVE

1. Plot both the position and the velocity of the string versus the position along the string before the pulses overlap (Figure 16-2). For an upright pulse, the string in the leading edge is moving upward and the string in the trailing edge is moving downward. For an inverted pulse, the opposite is true; the string in the leading edge is moving downward and the string in the trailing edge is moving upward.

2. This time plot both the position and the velocity of the string versus the position along the string at the instant the pulses completely overlap (Figure 16-3).

3. Is the velocity zero at all points on the string at the instant the string is flat? In step 1, the velocity profiles of the string are identical for the two pulses, so when the two pulses overlap, the displacements add to zero, but the velocities do not add to zero. The pulses reform after they overlap because the string is moving and has inertia. Thus, it does not stay flat.

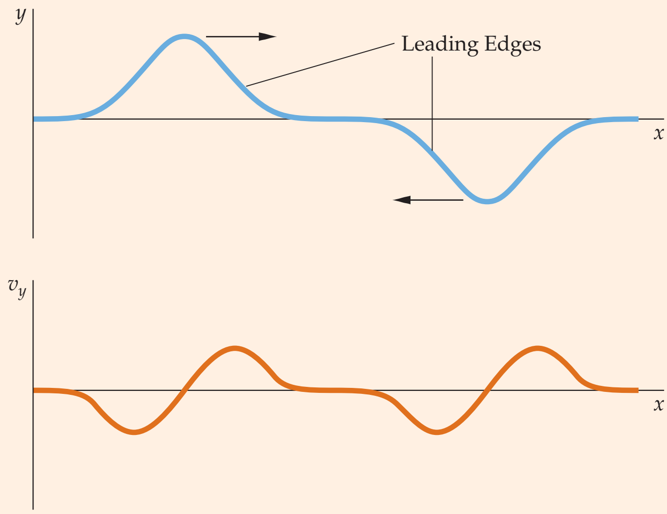

FIGURE 16-2

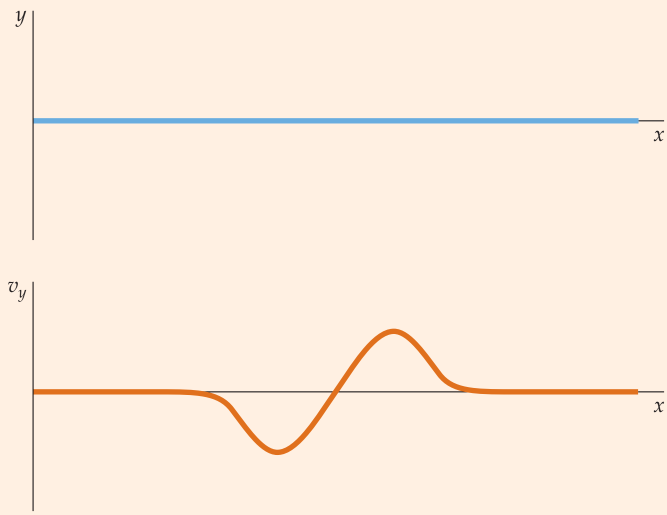

FIGURE 16-3

* SUPERPOSITION AND THE WAVE EQUATION

The principle of superposition follows from the fact that the wave equation (Equation 15-10*b*) is linear for small transverse displacements. That is, the function $y(x, t)$ and its derivatives occur only to the first power. The defining property of a linear equation is that if y_1 and y_2 are two solutions of the equation, then the linear combination

$$y_3 = C_1 y_1 + C_2 y_2 \qquad \text{16-1}$$

where C_1 and C_2 are any constants, is also a solution. The linearity of the wave equation can be shown by the direct substitution of y_3 into the wave equation. The result is the mathematical statement of the principle of superposition. If any two waves satisfy a wave equation, then their algebraic sum also satisfies the same wave equation.

Example 16-2 Superposition and the Wave Equation

Show that if functions y_1 and y_2 both satisfy wave equation

$$\frac{\partial^2 y}{\partial x^2} = \frac{1}{v^2}\frac{\partial^2 y}{\partial t^2} \qquad \text{(Equation 15-10}b\text{)}$$

then the function y_3 given by Equation 16-1 also satisfies the wave equation.

PICTURE Substitute y_3 into the wave equation, assume that y_1 and y_2 each satisfy the wave equation, and show that, as a consequence, the linear combination $C_1y_1 + C_2y_2$ satisfies the wave equation.

SOLVE

1. Substitute the expression for y_3 in Equation 16-1 into the left side of the wave equation, then break it into separate terms for y_1 and y_2:

$$\frac{\partial^2 y_3}{\partial x^2} = \frac{\partial^2}{\partial x^2}(C_1y_1 + C_2y_2) = C_1\frac{\partial^2 y_1}{\partial x^2} + C_2\frac{\partial^2 y_2}{\partial x^2}$$

2. Both y_1 and y_2 satisfy the wave function. Write the wave equation for both y_1 and y_2:

$$\frac{\partial^2 y_1}{\partial x^2} = \frac{1}{v^2}\frac{\partial^2 y_1}{\partial t^2} \quad \text{and} \quad \frac{\partial^2 y_2}{\partial x^2} = \frac{1}{v^2}\frac{\partial^2 y_2}{\partial t^2}$$

3. Substitute the step-2 results into the step-1 result and factor out any common terms:

$$\frac{\partial^2 y_3}{\partial x^2} = C_1\frac{1}{v^2}\frac{\partial^2 y_1}{\partial t^2} + C_2\frac{1}{v^2}\frac{\partial^2 y_2}{\partial t^2} = \frac{1}{v^2}\left(C_1\frac{\partial^2 y_1}{\partial t^2} + C_2\frac{\partial^2 y_2}{\partial t^2}\right)$$

4. Move the constants inside the arguments of the derivatives and express the sum of the derivatives as the derivative of the sum:

$$\frac{\partial^2 y_3}{\partial x^2} = \frac{1}{v^2}\left(\frac{\partial^2 C_1y_1}{\partial t^2} + \frac{\partial^2 C_2y_2}{\partial t^2}\right) = \frac{1}{v^2}\frac{\partial^2}{\partial t^2}(C_1y_1 + C_2y_2)$$

5. The argument of the time derivative in step 4 is y_3:

$$\therefore \boxed{\frac{\partial^2 y_3}{\partial x^2} = \frac{1}{v^2}\frac{\partial^2 y_3}{\partial t^2}}$$

CHECK The step-5 result is dimensionally consistent. The term on the left has dimensions of $[L]/[L]^2 = [L]^{-1}$ and the term on the right has dimensions of $\{[T]^2/[L]^2\}\{[L]/[T]^2\} = [L]^{-1}$.

INTERFERENCE OF HARMONIC WAVES

The result of the superposition of two harmonic waves of the same frequency depends on the phase difference δ between the waves. Let $y_1(x, t)$ be the wave function for a harmonic wave traveling to the right with amplitude A, angular frequency ω, and wave number k:

$$y_1 = A\sin(kx - \omega t) \qquad 16\text{-}2$$

For this wave function, we have chosen the phase constant to be zero.* If we have another harmonic wave also traveling to the right with the same amplitude, frequency, and wave number, then the general equation for its wave function can be written

$$y_2 = A\sin(kx - \omega t + \delta) \qquad 16\text{-}3$$

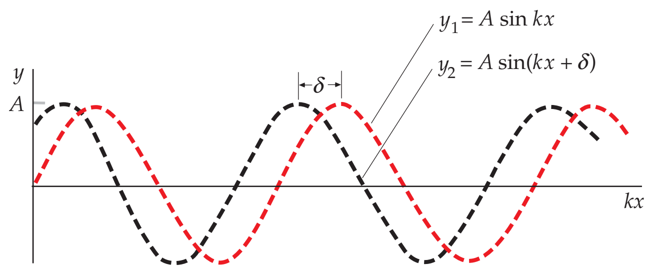

FIGURE 16-4 Displacement versus position at (a given instant) for two harmonic waves having the same amplitude, frequency, and wavelength, but differing in phase by δ.

where δ is the phase constant. The two waves described by Equations 16-2 and 16-3 differ in phase by δ. Figure 16-4 shows a plot of the two wave functions versus position at time $t = 0$. The resultant wave is the sum

$$y_1 + y_2 = A\sin(kx - \omega t) + A\sin(kx - \omega t + \delta) \qquad 16\text{-}4$$

We can simplify Equation 16-4 by using the trigonometric identity

$$\sin\theta_1 + \sin\theta_2 = 2\cos\tfrac{1}{2}(\theta_1 - \theta_2)\sin\tfrac{1}{2}(\theta_1 + \theta_2) \qquad 16\text{-}5$$

See **Math Tutorial** *for more information on* **Trigonometry**

* This choice is convenient but not mandatory. If, for example, we chose $t = 0$ when the displacement was maximum at $x = 0$, we would write $y_1 = A\cos(kx - \omega t) = A\sin(kx - \omega t + \frac{1}{2}\pi)$.

For this case, $\theta_1 = kx - \omega t$ and $\theta_2 = kx - \omega t + \delta$, so that

$$\tfrac{1}{2}(\theta_1 - \theta_2) = -\tfrac{1}{2}\delta$$

and

$$\tfrac{1}{2}(\theta_1 + \theta_2) = kx - \omega t + \tfrac{1}{2}\delta$$

Thus, Equation 16-4 becomes

$$y_1 + y_2 = [2A\cos\tfrac{1}{2}\delta]\sin(kx - \omega t + \tfrac{1}{2}\delta) \qquad 16\text{-}6$$

SUPERPOSITION OF TWO WAVES OF THE SAME AMPLITUDE AND FREQUENCY

where we have used $\cos(-\tfrac{1}{2}\delta) = \cos\tfrac{1}{2}\delta$. We see that the result of the superposition of two harmonic waves having the same wave number k and frequency ω is a harmonic wave having wave number k and frequency ω. The resultant wave has amplitude $2A\cos\tfrac{1}{2}\delta$ and a phase equal to half the difference between the phases of the original waves. The phenomenon of two or more waves of the same, or almost the same, frequency superposing to produce an observable pattern in the intensity is called **interference.** In this example, the intensity, which is proportional to the square of the amplitude, is uniform. If the two waves are in phase, then $\delta = 0$, $\cos 0 = 1$, and the amplitude of the resultant wave is $2A$. The interference of two waves in phase is called **constructive interference** (Figure 16-5). If the two waves are 180° out of phase, then $\delta = \pi$, $\cos(\tfrac{1}{2}\delta) = 0$, and the amplitude of the resultant wave is zero. The interference of two waves 180° out of phase is called **destructive interference** (Figure 16-6).

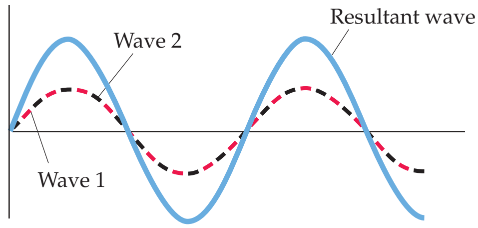

FIGURE 16-5 Constructive interference. If two harmonic waves of the same frequency are in phase, the amplitude of the resultant wave is the sum of the amplitudes of the individual waves. Waves 1 and 2 are identical, so they appear as a single harmonic wave. Wave 1 is shown as a red dashed curve and Wave 2 is shown as a black dashed curve.

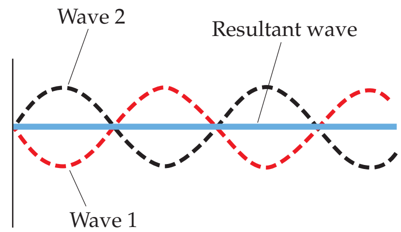

FIGURE 16-6 Destructive interference. If two harmonic waves of the same frequency differ in phase by 180°, the amplitude of the resultant wave is the difference between the amplitudes of the individual waves. If the original waves have equal amplitudes, they cancel completely.

PRACTICE PROBLEM 16-1

Two waves with the same frequency, wavelength, and amplitude are traveling in the same direction. (*a*) If they differ in phase by 90.0° and each has an amplitude of 4.00 cm, what is the amplitude of the resultant wave? (*b*) For what phase difference δ will the resultant amplitude be equal to 4.0 cm?

Beats The interference of two sound waves with slightly different frequencies produces the interesting phenomenon known as **beats.** Consider two sound waves that have angular frequencies of ω_1 and ω_2 and the same pressure amplitude p_0. What do we hear? At a fixed point, the spatial dependence of the wave merely contributes a phase constant, so we can neglect it. The pressure at the ear due to either wave acting alone will be a simple harmonic function of the type

$$p_1 = p_0 \sin\omega_1 t$$

and

$$p_2 = p_0 \sin\omega_2 t$$

where we have chosen sine functions, rather than cosine functions for convenience, and have assumed that the waves are in phase at time $t = 0$. Using the trigonometry identity

$$\sin\theta_1 + \sin\theta_2 = 2\cos\tfrac{1}{2}(\theta_1 - \theta_2)\sin\tfrac{1}{2}(\theta_1 + \theta_2)$$

for the sum of two sine functions, we obtain for the resultant wave

$$p = p_0\sin\omega_1 t + p_0\sin\omega_2 t = 2p_0\cos\tfrac{1}{2}(\omega_1 - \omega_2)t\,\sin\tfrac{1}{2}(\omega_1 + \omega_2)t$$

If we write $\omega_{av} = (\omega_1 + \omega_2)/2$ for the average angular frequency and $\Delta\omega = \omega_1 - \omega_2$ for the difference in angular frequencies, the resultant wave function is

$$p = 2p_0\cos(\tfrac{1}{2}\Delta\omega t)\sin\omega_{av}t = 2p_0\cos(2\pi\tfrac{1}{2}\Delta f t)\sin 2\pi f_{av}t \qquad 16\text{-}7$$

where $\Delta f = \Delta\omega/(2\pi)$ and $f_{av} = \omega_{av}/(2\pi)$.

Figure 16-7 shows a plot of pressure variations as a function of time. The waves are initially in phase. Thus, they add constructively at time $t = 0$. Because their frequencies differ, the waves gradually become out of phase, and at time t_1 they are 180° out of phase and interfere destructively.* An equal time interval later (time t_2 in the figure), the two waves are again in phase and interfere constructively. The greater the difference in the frequencies of the two waves, the more rapidly they oscillate in and out of phase.

When two tuning forks vibrate with equal amplitudes and with almost equal frequencies f_1 and f_2, the tone that we hear has a frequency of $f_{av} = (f_1 + f_2)/2$ and an amplitude of $2p_0 \cos(2\pi \frac{1}{2} \Delta f\, t)$. (For some values of t the amplitude is negative. Because $-\cos\theta = \cos(\theta + \pi)$, a change in the sign of the amplitude is equivalent to a 180° phase change.) The amplitude oscillates with the frequency $\frac{1}{2}\Delta f$. Because the sound intensity is proportional to the square of the amplitude, the sound is loud whenever the amplitude function is either a maximum or a minimum. Thus, the frequency of this variation in intensity, called the **beat frequency,** is twice $\frac{1}{2}\Delta f$:

$$f_{beat} = \Delta f \qquad 16\text{-}8$$

BEAT FREQUENCY

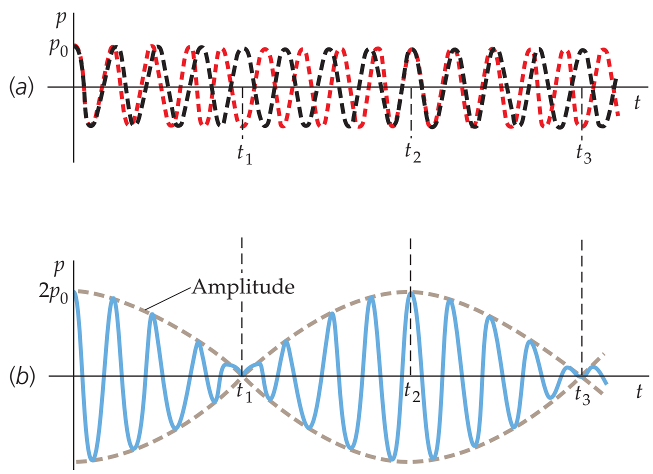

FIGURE 16-7 Beats. (*a*) Two harmonic waves of different but nearly equal frequencies that are in phase at $t = 0$ are 180° out of phase at some later time t_1. At a still later time, t_2, they are back in phase. (*b*) The resultant of the two waves shown in (*a*). The frequency of the resultant wave is about the same as the frequencies of the original waves, but the amplitude is modulated as indicated. The intensity is maximum at times 0 and t_2, and zero at times t_1 and t_3.

The beat frequency equals the difference in the individual frequencies of the two waves. If we simultaneously strike two tuning forks having the frequencies 241 Hz and 243 Hz, we will hear a pulsating tone at the average frequency of 242 Hz that has a maximum intensity at half-second intervals; that is, the beat frequency is 2 Hz. The ear can detect beats with beat frequencies of up to about 15 to 20 per second. Above this frequency, the fluctuations in loudness are too rapid to be distinguished.

The phenomenon of beats is often used to compare an unknown frequency with a known frequency, as when a tuning fork is used to tune a piano string. Pianos are tuned by simultaneously ringing the tuning fork and striking a key, while at the same time adjusting the tension of the piano string until the beats are far apart, indicating that the difference in frequency of the two sound generators is very small.

Example 16-3 Tuning a Guitar

When a 440-Hz (concert A) tuning fork is struck simultaneously with the playing of the A string of a slightly out-of-tune guitar, 3.00 beats per second are heard. The guitar string is tightened a little to increase its frequency. As the guitar string is slowly tightened, you hear the beat frequency slowly increase. What was the initial frequency of the guitar string (the frequency before it was tightened)?

PICTURE Because 3.00 beats per second were heard initially, the initial frequency of the guitar string was either 437 Hz or 443 Hz. The greater the difference between the frequency of the string and the frequency of the tuning fork, the greater the beat frequency. The frequency of the string increases with an increase in the tension.

SOLVE

1. Because the beat frequency increases as the tension increases, the initial frequency must have been 443 Hz: $f = f_A + f_{beat} = 440\text{ Hz} + 3.00\text{ Hz} = \boxed{443\text{ Hz}}$

CHECK The answer has the correct number of significant figures.

The tuning fork has been struck and a string has been plucked. Listening to the beats the man is tightening (or loosening) the string in order to bring the beat frequency to zero. As the beat frequency approaches zero the string frequency approaches the tuning-fork frequency. *(Ray Malace Photography.)*

* Complete cancellation occurs only when the pressure amplitudes of the two waves are equal.

Phase difference due to path difference A common cause of a phase difference between two waves is different path lengths between the sources of the waves and the point where the interference occurs. Suppose that two sources oscillate in phase (positive crests leave the sources at the same time) and emit harmonic waves of the same frequency and wavelength. Now consider a point in space for which the path lengths to the two sources differ. If the path difference is one wavelength, as is the case in Figure 16-8*a*, or any other integral number of wavelengths, the interference is constructive. If the path difference is one-half of a wavelength or an odd number of half wavelengths, as in Figure 16-8*b*, the maximum of one wave at the same time as the minimum of the other and the interference is destructive.

The wave functions for waves from two sources oscillating in phase can be written

$$p_1 = p_0 \sin(kx_1 - \omega t)$$

and

$$p_2 = p_0 \sin(kx_2 - \omega t)$$

The phase difference for these two wave functions is

$$\delta = (kx_2 - \omega t) - (kx_1 - \omega t) = k(x_2 - x_1) = k\,\Delta x$$

Using $k = 2\pi/\lambda$, we have

$$\delta = k\,\Delta x = 2\pi\frac{\Delta x}{\lambda} \qquad 16\text{-}9$$

PHASE DIFFERENCE DUE TO PATH DIFFERENCE

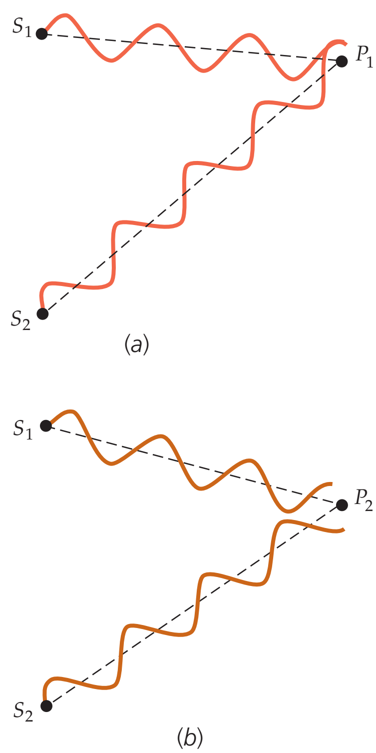

FIGURE 16-8 Waves from two sources S_1 and S_2 are in phase when they meet at a point P_1. (*a*) When the path difference is one wavelength λ, the waves are in phase at P_1 and therefore interfere constructively. (*b*) When the path difference is $\frac{1}{2}\lambda$, the waves at P_2 are out of phase by 180° and therefore interfere destructively. If the waves are of equal amplitude at P_2, they will cancel completely at this point.

Example 16-4 A Resultant Sound Wave

Two identical loudspeakers are driven in phase by a common audio oscillator. At a point 5.00 m from one speaker cone and 5.17 m from the other, the amplitude of the sound from each is p_0. Find the amplitude of the resultant wave at that point if the frequency of the sound waves is (*a*) 1000 Hz, (*b*) 2000 Hz, and (*c*) 500 Hz. (Use 340 m/s for the speed of sound.)

PICTURE The amplitude of the resultant wave due to superposition of two waves differing in phase by δ is given by $A = 2p_0 \cos\frac{1}{2}\delta$ (Equation 16-6), where p_0 is the amplitude of either wave and $\delta = 2\pi\,\Delta x/\lambda$ (Equation 16-9) is the phase difference. We are given the path difference, $\Delta x = 5.17\text{ m} - 5.00\text{ m} = 0.17\text{ m}$, so all that is needed is the wavelength λ.

SOLVE

(*a*) 1. The wavelength equals the speed divided by the frequency. Calculate λ for $f = 1000$ Hz:

$$\lambda = \frac{v}{f} = \frac{340\text{ m/s}}{1000\text{ Hz}} = 0.340\text{ m}$$

2. For $\lambda = 0.340$ m, the given path difference ($\Delta x = 0.17$ m) is $\frac{1}{2}\lambda$, so we expect destructive interference. Use this value of λ and $A = 2p_0 \cos\frac{1}{2}\delta$ (Equation 16-6), to calculate the phase difference δ, and then use δ to calculate the amplitude A:

$$\delta = 2\pi\frac{\Delta x}{\lambda} = 2\pi\frac{0.17\text{ m}}{0.340\text{ m}} = \pi$$

$$\text{so} \quad A = 2p_0 \cos\frac{1}{2}\delta = 2p_0 \cos\frac{\pi}{2} = \boxed{0.0\text{ m}}$$

(*b*) 1. Calculate λ for $f = 2000$ Hz:

$$\lambda = \frac{v}{f} = \frac{340\text{ m/s}}{2000\text{ Hz}} = 0.170\text{ m}$$

2. For $\lambda = 0.170$ m, the path difference equals λ, so we expect constructive interference. Calculate the phase difference and amplitude:

$$\delta = 2\pi\frac{\Delta x}{\lambda} = 2\pi\frac{0.170\text{ m}}{0.17\text{ m}} = 2\pi$$

$$\text{so} \quad A = 2p_0 \cos\tfrac{1}{2}\delta = 2p_0 \cos\pi = \boxed{-2p_0}$$

(*c*) 1. Calculate λ for $f = 500$ Hz: $\lambda = \frac{v}{f} = \frac{340\text{ m/s}}{500\text{ Hz}} = 0.680\text{ m}$

2. Calculate the phase difference and amplitude: $\delta = 2\pi\frac{\Delta x}{\lambda} = 2\pi\frac{0.17\text{ m}}{0.680\text{ m}} = \frac{\pi}{2}$

so $A = 2p_0\cos\frac{1}{2}\delta = 2p_0\cos\frac{\pi}{4} = \boxed{\sqrt{2}\,p_0}$

CHECK Each of the three answers is between $-2p_0$ and $+2p_0$, so the answers are within the expected range.

TAKING IT FURTHER In Part (*b*), A is found to be negative. Equation 16-6 can be written $y_1 + y_2 = A'\sin\left(kx - \omega t + \frac{\delta}{2}\right)$, which can also be written $y_1 + y_2 = -A'\sin\left(kx - \omega t + \frac{\delta}{2} + \pi\right)$. A phase shift of $\pi = 180°$ is equivalent to multiplying by -1.

Example 16-5 Sound Intensity of Two Loudspeakers

The two identical loudspeakers in Example 16-4 are now turned to face each other at a distance of 180 cm. In addition, they are now driven at 686 Hz. Locate the points between the speakers along a line joining them for which the sound intensity is (*a*) maximum, and (*b*) minimum. (Neglect the variation in intensity with distance from either speaker, and use 343 m/s for the speed of sound.)

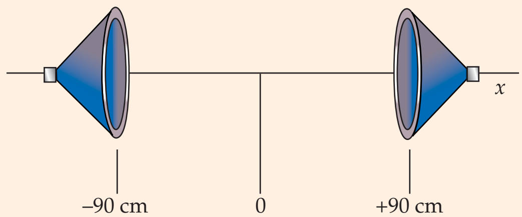

FIGURE 16-9 The two loudspeakers are on the x axis with $x = 0$ midway between them.

PICTURE We choose the origin to be at the midpoint between the speakers (Figure 16-9). Because the origin is equidistant from the speakers, it is a point of maximum intensity. When we move a distance x from the origin toward one of the speakers, the path difference between us and the two speakers is $2x$. The intensity will be maximum at points where $2x = 0, \lambda, 2\lambda, 3\lambda, \ldots$, and minimum where $2x = \frac{1}{2}\lambda, \frac{3}{2}\lambda, \frac{5}{2}\lambda, \ldots$.

SOLVE

(*a*) 1. The intensity will be maximum when $2x$ equals an integral number of wavelengths: $2x = 0, \pm\lambda, \pm 2\lambda, \pm 3\lambda, \ldots$

2. Calculate the wavelength: $\lambda = \frac{v}{f} = \frac{343\text{ m/s}}{686\text{ Hz}} = 0.500\text{ m} = 50.0\text{ cm}$

3. Solve for x using the calculated wavelength: $x = 0, \pm\frac{1}{2}\lambda, \pm\lambda, \pm\frac{3}{2}\lambda, \ldots = \boxed{0, \pm 25.0\text{ cm}, \pm 50.0\text{ cm}, \pm 75.0\text{ cm}}$

(*b*) 1. The intensity will be minimum when $2x$ equals an odd number of half wavelengths: $2x = \pm\frac{1}{2}\lambda, \pm\frac{3}{2}\lambda, \pm\frac{5}{2}\lambda, \ldots$

2. Solve for x using the calculated wavelength: $x = \pm\frac{1}{4}\lambda, \pm\frac{3}{4}\lambda, \pm\frac{5}{4}\lambda, \ldots = \boxed{\pm 12.5\text{ cm}, \pm 37.5\text{ cm}, \pm 62.5\text{ cm}, \pm 87.5\text{ cm}}$

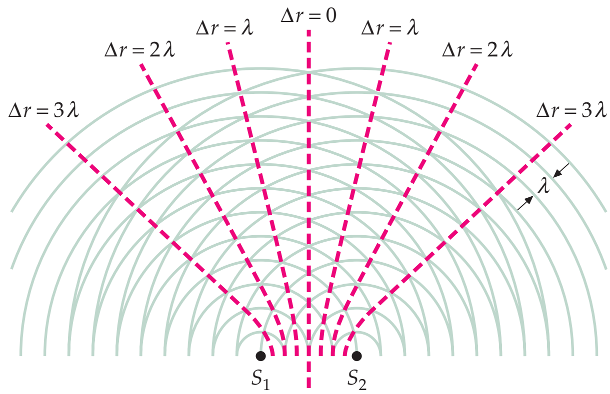
CHECK The answers for Parts (*a*) and (*b*) complement each other, with the intensity minima located halfway between the intensity maxima, as expected.

TAKING IT FURTHER The maxima and minima will be relative maxima and relative minima, because at each maxima (and minima) the amplitude from the nearer speaker will be slightly greater than that from the farther speaker. Only seven terms were used for the maxima and only eight terms for the minima, because any additional terms would not be in the region between the two speakers.

Figure 16-10*a* shows the wave pattern in a ripple tank produced by two point sources that are oscillating in phase. Each source produces waves with circular wavefronts. The circular wavefronts shown all have the same phase (they are all crests) and are separated by one wavelength. We can construct a similar pattern with a compass by drawing circular arcs representing the wave crests from each source at some particular instant of time (Figure 16-10*b*). Where the crests from each source overlap, the waves interfere constructively. At these points, the path lengths from the two sources are either equal or they differ by an integral number of wavelengths. The dashed lines indicate the points that are both equidistant from the sources or whose path differences from the sources are one wavelength, two wavelengths, or three wavelengths. At each point along any of these lines the interference is constructive, so these are lines of interference maxima. Between the lines of interference maxima are lines of interference minima. On a line of interference minima, the path length from any point on the line to each of the two sources differs by an odd number of half wavelengths. Throughout the region where the two waves are superposed, the amplitude of the resultant wave is given by $A = 2p_0 \cos\frac{1}{2}\delta$, where p_0 is the amplitude of each wave separately and δ is related to the path difference Δr by $\delta = 2\pi\, \Delta r/\lambda$ (Equation 16-9).

Figure 16-11 shows the intensity I of the resultant wave from two sources as a function of path difference Δx. At points where the interference is constructive, the amplitude of the resultant wave is twice that of either wave alone, and because the intensity is proportional to the square of the amplitude, the intensity is $4I_0$, where I_0 is the intensity due to either source alone. At points of destructive interference, the intensity is zero. The average intensity, shown by the dashed line at $2I_0$ in the figure, is twice the intensity due to either source alone, a result required by the conservation of energy. The interference of the waves from the two sources thus redistributes the energy in space. The interference of two sound sources can be demonstrated by driving two separated speakers with the same amplifier (so that they are always in phase) fed by an audio-signal generator. Moving about the room, one can detect by ear the positions of constructive and destructive interference.* This demonstration is best done in a room called an *anechoic chamber,* where reflections (echoes) off the walls of the room are minimized.

(*a*)



(*b*)

FIGURE 16-10 (*a*) Water waves in a ripple tank produced by two sources oscillating in phase. (*b*) Drawing of wave crests for the sources in (*a*). The dashed lines indicate points for which the path difference is an integral number of wavelengths. *(Part (a) Berenice Abbott, 8J 1328/Photo Researchers.)*

Coherence Two sources need not be in phase to produce an interference pattern. Consider two sources that are 180° out of phase. (Two speakers that are in phase can be made to be out of phase by 180° merely by switching the leads to one of the speakers.) The intensity pattern is the same as that in Figure 16-11, except that the locations of the maxima and minima are interchanged. At points for which the distance differs by an integral number of wavelengths, the interference is destructive because the waves are 180° out of phase. At points where the path difference is an odd number of half wavelengths, the waves are now in phase because the 180° phase difference of the sources is offset by the 180° phase difference due to the path difference.

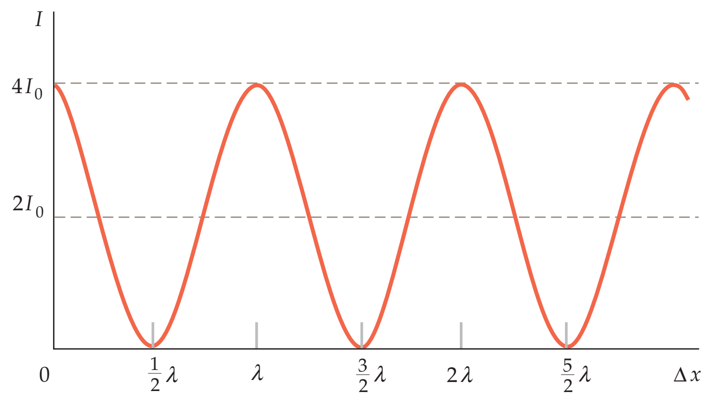


FIGURE 16-11 Intensity versus path difference for two sources that are in phase. I_0 is the intensity due to each source individually.

Similar interference patterns will be produced by any two sources whose phase difference remains constant. Two sources that remain in phase or maintain a constant phase difference are said to be **coherent.** Coherent sources of water waves in a ripple tank are easy to produce by driving both sources with the same motor. Coherent sound sources are obtained by driving two speakers with the same signal source and amplifier.

Wave sources whose difference in phase is not constant, but varies randomly, are said to be **incoherent sources.** There are many examples of incoherent sources, such as two speakers driven by different amplifiers or two violins played by

* In this demonstration, the sound intensity will be not quite zero at the points of destructive interference because of sound reflections from the walls or objects in the room.

different violinists. For incoherent sources, the interference at a particular point varies rapidly back and forth from constructive to destructive, and no interference pattern is sustained long enough to be observed. The resultant intensity of waves from two or more incoherent sources is simply the sum of the intensities due to the individual sources.

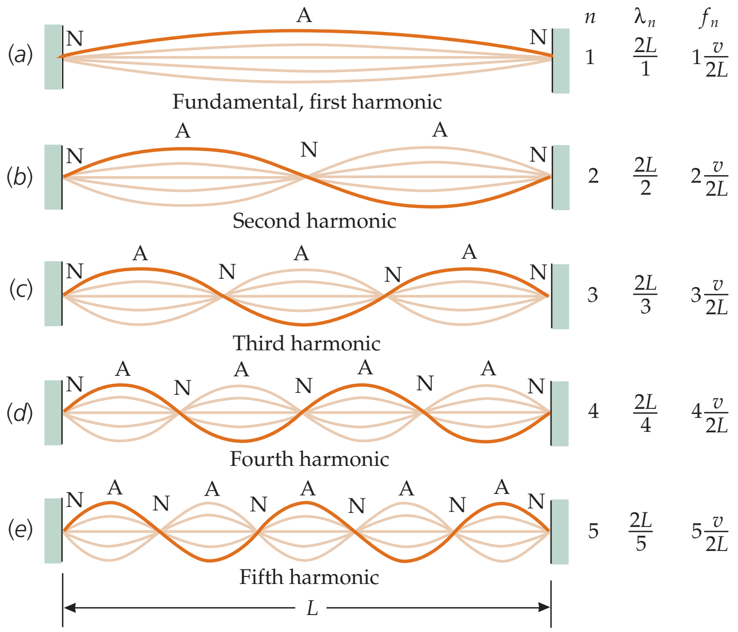

FIGURE 16-12 Standing waves on a string that is fixed at both ends. Antinodes are labeled A and nodes are labeled N. The nth harmonic has n antinodes, where $n = 1, 2, 3, \ldots$.

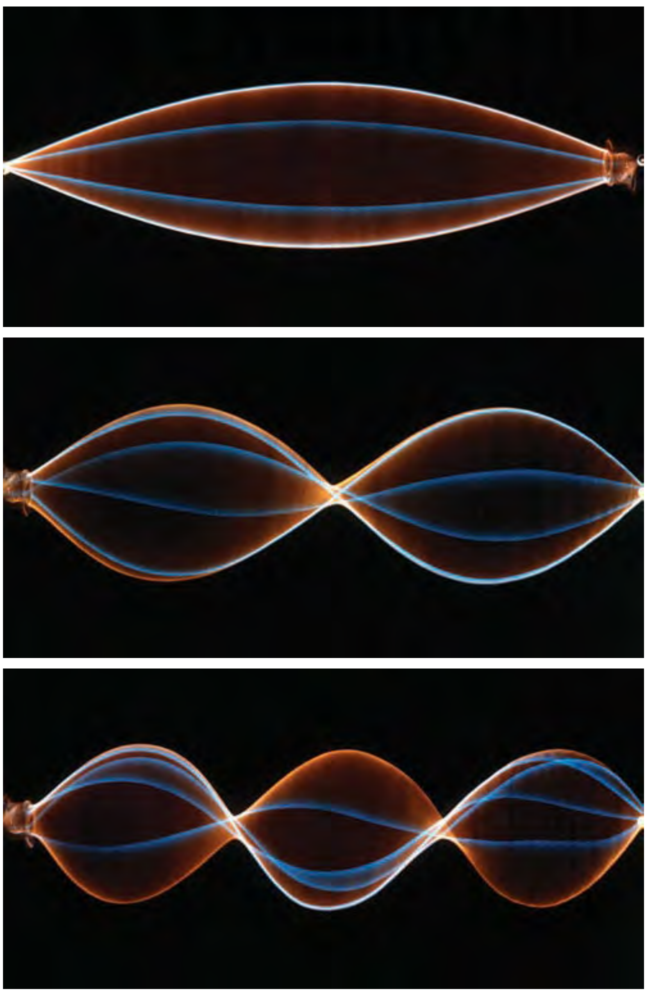
16-2 STANDING WAVES

If waves are confined in space, like the waves on a piano string, sound waves in an organ pipe, or light waves in a laser, reflections at both ends cause the waves to travel in both directions. These superposing waves interfere in accordance with the principle of superposition. For a given string or pipe, there are certain frequencies for which superposition results in a stationary vibration pattern called a **standing wave.** Standing waves have important applications in musical instruments and in quantum theory.

STANDING WAVES ON STRINGS

String fixed at both ends If we fix one end of a taut flexible string and move the other end of the string up and down with simple harmonic motion of small amplitude, we find that at certain frequencies, standing-wave patterns such as those shown in Figure 16-12 are produced. The frequencies that produce these patterns are called the **resonance frequencies** of the string system. Each such frequency, with its accompanying wave function, is called a **mode of vibration.** The lowest resonance frequency is called the **fundamental** frequency f_1. It produces the standing-wave pattern shown in Figure 16-12*a*, which is called the **fundamental mode** of vibration or the **first harmonic.** The second lowest frequency f_2 produces the pattern shown in Figure 16-12*b*. This mode of vibration has a frequency twice that of the fundamental frequency and is called the second harmonic. The third lowest frequency f_3 is three times the fundamental frequency, and it produces the third harmonic pattern shown in Figure 16-12*c*. The set of all resonant frequencies is called the **resonant frequency spectrum** of the string.

Many systems that support standing waves have resonant frequency spectra in which the resonant frequencies are not integral multiples of the lowest frequency. In all resonant frequency spectra, the lowest resonant frequency is called the fundamental frequency (or just the fundamental), the next lowest resonant frequency is called the first **overtone,** the next lowest the second overtone, and so forth. This terminology has its roots in music. Only if each resonant frequency is an integral multiple of the fundamental frequency are they referred to as harmonics.



Standing waves on a string made to oscillate by a vibrator attached to the left end of the string. These standing waves occur only at specific frequencies. *(Richard Megna/Fundamental Photographs, New York.)*

We note from Figure 16-12 that for each harmonic there are certain points on the string (the midpoint in Figure 16-12*b*, for example) that do not move. Such points are called **nodes.** Midway between each adjacent pair of nodes is a point of maximum amplitude of vibration called an **antinode.** A fixed end of the string is, of course, a node. (If one end is attached to a tuning fork or other vibrator rather than being fixed, it will still be approximately a node because the amplitude of the vibration at that end is so much smaller than the amplitude at the antinodes.) We note that the first harmonic has one antinode, the second harmonic has two antinodes, and so on.

! Not all resonant frequencies are called harmonics. Only frequencies that are a part of a resonant frequency spectrum that is composed of integral multiples of the fundamental (lowest) frequency are referred to as harmonics.

We can relate the resonance frequencies to the wave speed in the string and the length of the string. The distance between a node and the nearest antinode is one-fourth of the wavelength. Therefore, the length of the string L equals one-half the wavelength in the fundamental mode of vibration (Figure 16-13) and, as Figure 16-12 reveals, L equals two half-wavelengths for the second harmonic, three half-wavelengths for the third harmonic, and so forth. In general, if λ_n is the wavelength of the nth harmonic, we have

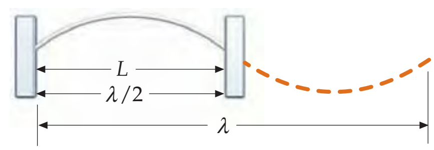


FIGURE 16-13 For the first harmonic of a taut string fixed at both ends, $\lambda = 2L$.

$$L = n\frac{\lambda_n}{2} \qquad n = 1, 2, 3, \ldots \tag{16-10}$$

STANDING-WAVE CONDITION, BOTH ENDS FIXED

This result is known as the **standing-wave condition.** We can find the frequency of the nth harmonic from the fact that the wave speed v equals the frequency f_n times the wavelength. Thus,

$$f_n = \frac{v}{\lambda_n} = \frac{v}{2L/n} \qquad n = 1, 2, 3, \ldots$$

or

$$f_n = n\frac{v}{2L} = nf_1 \qquad n = 1, 2, 3, \ldots \tag{16-11}$$

RESONANCE FREQUENCIES, BOTH ENDS FIXED

where $f_1 = v/(2L)$ is the fundamental frequency.

We can understand standing waves in terms of resonance. Consider a string of length L that is attached at one end to a vibrator (Figure 16-14) and is fixed at the other end. The first wave crest sent out by the vibrator travels down the string a distance L to the fixed end, where it is reflected and inverted. It then travels back a distance L and is again reflected and inverted at the vibrator. The total time for the round-trip is $2L/v$. If this time equals the period of the vibrator, the twice-reflected wave crest exactly overlaps the second wave crest produced by the vibrator, and the two crests interfere constructively, producing a crest with twice the original amplitude. The combined wave crest travels down the string and back and is added to by the third crest produced by the vibrator, increasing the amplitude threefold, and so on. Thus, the vibrator is in resonance with the string. The wavelength is equal to $2L$ and the frequency is equal to $v/(2L)$.

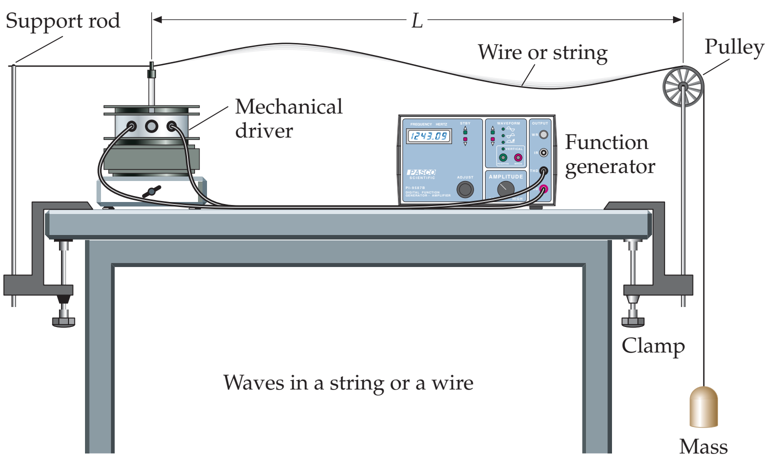

FIGURE 16-14 The mechanical driver sends waves down the string. The waves reflect off the pulley.

Resonance also occurs at other vibrator frequencies. The vibrator is in resonance with the string if the time it takes for the first wave crest to travel the distance $2L$ is any integer n times the period T of the vibrator. That is, if $2L/v = nT_n$, where $2L/v$ is the round-trip time for a wave crest. Thus,

$$f_n = \frac{1}{T_n} = n\frac{v}{2L} \qquad n = 1, 2, 3, \ldots$$

is the condition for resonance. This result is the same result we found by fitting an integral number of half-wavelengths into the distance L. Various damping effects, such as the loss of energy during reflection and air drag on the string, put a limit on the maximum amplitude that can be reached.

The resonance frequencies given by Equation 16-11 are also called the **natural frequencies** of the string. When the frequency of the vibrator is not one of the natural frequencies of the vibrating string, standing waves are not produced. After the first wave travels the distance $2L$ and is reflected from the fork, it differs in phase from the wave being generated at the vibrator (Figure 16-15). When this resultant wave has traveled the distance $2L$ and is again reflected at the vibrator, it will differ in phase from the next wave generated. In some cases, the new resultant wave will superpose with the previous wave to produce a wave of greater amplitude, in other cases the new amplitude will be less. On the average, the amplitude will neither increase nor decrease, but will remain on the order of the amplitude of the first wave generated, which is the amplitude of the vibrator. This amplitude is very small compared with the amplitudes attained at resonance frequencies.

The resonance of standing waves is analogous to the resonance of a simple harmonic oscillator with a harmonic driving force. However, a vibrating string does not have just one natural frequency, but a sequence of natural frequencies that are integral multiples of the fundamental frequency. This sequence is called a **harmonic series.**

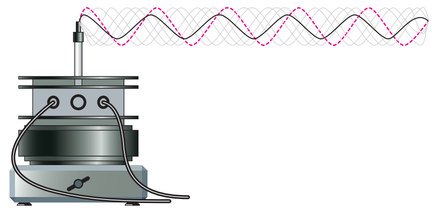

FIGURE 16-15 Waves on a string produced by a mechanical wave driver whose frequency is not in resonance with the natural frequencies of the string. The wave leaving the wave driver for the first time (dashed red line) is not in phase with the waves that have been reflected two or more times (gray lines), and these waves are not in phase with each other, so there is no buildup in amplitude. The resultant wave (black line) has about the same amplitude as the individual waves, which is about the amplitude of the driver.

PROBLEM-SOLVING STRATEGY

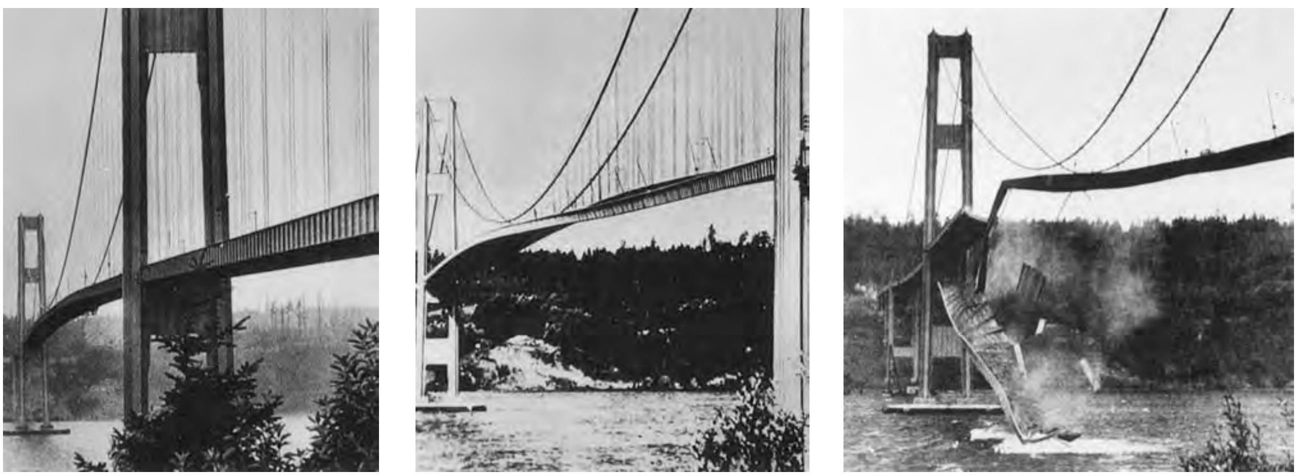
Using the Standing-Wave Condition to Solve Problems

PICTURE You should not bother to memorize Equation 16-11. Just sketch Figure 16-12 to remind yourself of the standing-wave condition, $\lambda_n = 2L/n$, and then use $v = f_n\lambda_n$.

SOLVE

1. Reconstruct Figure 16-12 for the first few harmonics (not the expression on the right of the figure, just the pictures of the string). At each end of the string there is a node, and the distance between a node and an adjacent antinode is invariably $\frac{1}{4}\lambda$.
2. Relate the wave speed to the frequency using $v = f\lambda$.
3. Relate the wave speed to the tension using $v = \sqrt{F_T/\mu}$.

CHECK Verify that your results are dimensionally correct.



Standing waves generated by 45 mi/h winds generated standing waves in the Tacoma Narrows suspension bridge, leading to its collapse on November 7, 1940, just four months after it had been opened for traffic. *(University of Washington.)*

Example 16-6 Give Me an A

A string is stretched between two fixed supports 0.700 m apart and the tension is adjusted until the fundamental frequency of the string is concert A, 440 Hz. What is the speed of transverse waves on the string?

PICTURE The wave speed equals the frequency times the wavelength. For a string fixed at both ends, in the fundamental mode there is a single antinode in the middle of the string. Thus, the length of the string equals one-half wavelength.

SOLVE

1. The wave speed is related to the frequency and wavelength We are given the fundamental frequency f_1: $v = f_1\lambda_1$
2. Use Figure 16-12 to relate the wavelength of the fundamental to the length of the string: $\lambda_1 = 2L$
3. Use this wavelength and the given frequency to find the speed: $v = f_1\lambda_1 = f_1 2L = 2f_1 L = 2(440\text{ Hz})(0.700\text{ m}) = \boxed{616\text{ m/s}}$

CHECK To check the plausibility of this answer, we check the units. The unit for frequency is the hertz, where 1 Hz = 1 cy/s, or just 1 s^{-1} (because a cycle is dimensionless). Thus, 1 Hz times 1 m equals 1 m/s, which are the correct units for speed.

PRACTICE PROBLEM 16-2 The speed of transverse waves on a stretched string is 200 m/s. If the string is 5.0 m long, find the frequencies of the fundamental and the second and third harmonics.

Example 16-7 Testing Piano Wire *Context-Rich*

You have a summer job at a music shop, helping the owner build instruments. He asks you to test a new wire for possible use in pianos. He tells you that the 3.00-m-long wire has a linear mass density of 0.00250 kg/m, and he has found two adjacent resonant frequencies at 252 Hz and at 336 Hz. He wants you to determine the fundamental frequency of the wire and determine whether or not the wire is a good choice for piano strings. You know that safety issues start to arise if the tension in the wire gets above 700 N.

A technician uses a micrometer to measure the diameter of a piano wire. *(Courtesy of Buck Rogers/Craftsmen Piano Rebuilders North Attleboro, MA.)*

PICTURE The tension F_T is found from $v = \sqrt{F_T/\mu}$, where the speed v can be found from $v = f\lambda$ using any harmonic. The wavelength for the fundamental is twice the length of the wire. To find the fundamental frequency let 252 Hz be the frequency of the nth harmonic. Then $f_n = nf_1$ and $f_{n+1} = (n+1)f_1$, where $f_{n+1} = 336$ Hz. We can solve these two equations for f_1.

SOLVE

1. The tension is related to the wave speed: $v = \sqrt{F_T/\mu}$ so $F_T = \mu v^2$
2. The wave speed is related to the wavelength and frequency: $v = f\lambda$
3. Use Figure 16-12 to relate the wavelength of the fundamental to the length of the wire: $\lambda_1 = 2L$
4. Use the step-2 and step-3 results to relate the speed v to the fundamental frequency f_1: $v = f_1\lambda_1 = f_1 \times 2L = 2f_1L$
5. Substitute into the step-1 result to find the tension: $F_T = \mu v^2 = 4\mu f_1^2 L^2$
6. The consecutive harmonics f_n and f_{n+1} are related to the fundamental frequency f_1: $nf_1 = 252$ Hz; $(n+1)f_1 = 336$ Hz
7. Dividing these equations eliminates f_1 and allows us to determine n: $\dfrac{n}{n+1} = \dfrac{252\text{ Hz}}{336\text{ Hz}} = 0.750 \Rightarrow n = 3$
8. Solve for f_1: $f_n = nf_1$ so $f_1 = \dfrac{f_n}{n} = \dfrac{f_3}{3} = \dfrac{252\text{ Hz}}{3} = 84.0\text{ Hz}$
9. Using the step-5 result, solve for F_T: $F_T = 4\mu f_1^2 L^2 = 4(0.00250\text{ kg/m})(84.0\text{ Hz})^2(3.00\text{ m})^2 = 635\text{ N}$
10. Is the tension safe? $\boxed{\text{The tension is less than the 700-N safety limit. The wire is safe to use.}}$

CHECK That the tension is the same order of magnitude as the safety limit makes the answer plausible.

String fixed at one end, free at the other Figure 16-16 shows a string that has one end fixed and one end attached to a ring that is free to slide up and down on a friction-free pole. The vertical motion of the ring is driven by the vertical component of the tension force (we are neglecting any effects of gravity). Ideally, we let the mass of the ring approach zero. Then the vertical motion of the end of the string that is attached to the ring is unconstrained, so it is said to be a *free end.* Any finite vertical force by the string on the massless ring would give the ring an infinite acceleration. However, the acceleration of the ring will remain finite as long as the tangent to the string at the point where it attaches to the ring remains parallel to the string's equilibrium position. For a string oscillating in a standing wave, the antinodes are the only points where the tangent to the string remains parallel to the string's equilibrium position. It follows that there is an antinode at the end of the string attached to the ring.

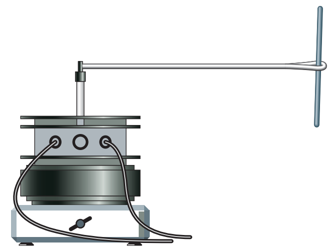


FIGURE 16-16 An approximation of a string fixed at one end and free at the other end can be produced by connecting the "free" end of the string to a ring that is free to move on a post. The end attached to the mechanical wave driver is approximately fixed because the amplitude of the driver is very small.

In the fundamental mode of vibration for a string fixed at one end and free at the other, there is a node at the fixed end and an antinode at the free end, so $L = \frac{1}{4}\lambda$ (Figure 16-17). (Recall that distance from a node to an adjacent antinode is equal to one-quarter wavelength.)

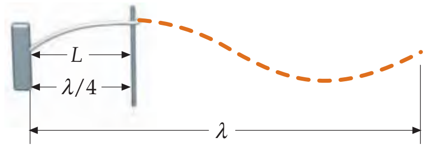

FIGURE 16-17 For the first harmonic of a taut string fixed at one end and free at the other end, $\lambda = 4L$.

In each mode of vibration shown in Figure 16-18 there is an odd number of quarter-wavelengths in the length L. That is, $L = n\frac{1}{4}\lambda_n$, where $n = 1, 3, 5, \ldots$. The standing-wave condition can thus be written

$$L = n\frac{\lambda_n}{4} \qquad n = 1, 3, 5, \ldots \qquad \text{16-12}$$

STANDING-WAVE CONDITION, ONE END FREE

so $\lambda_n = 4L/n$. The resonance frequencies are therefore given by

$$f_n = \frac{v}{\lambda_n} = n\frac{v}{4L} = nf_1 \qquad n = 1, 3, 5, \ldots \qquad \text{16-13}$$

RESONANCE FREQUENCIES, ONE END FREE

where

$$f_1 = \frac{v}{4L} \qquad \text{16-14}$$

is the fundamental frequency. The natural frequencies of this system occur in the ratios 1:3:5:7: . . . , which means that all the even harmonics are missing.

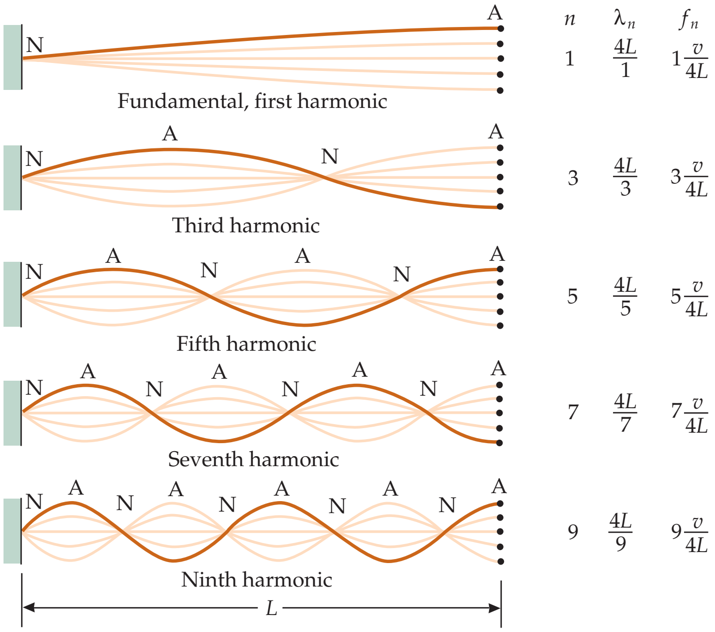

FIGURE 16-18 Standing waves on a string fixed at only one end. An antinode exists at the free end.

Wave functions for standing waves If a string vibrates in its nth mode, each point on the string moves with simple harmonic motion. Its displacement $y_n(x, t)$ is given by

$$y_n(x, t) = A_n(x)\cos(\omega_n t + \delta_n)$$

where ω_n is the angular frequency, δ_n is the phase constant, which depends on the initial conditions, and $A_n(x)$ is the amplitude, which depends on the position x of the point. The function $A_n(x)$ is the shape of the string when $\cos(\omega_n t + \delta_n) = 1$ (the instant that the vibration has its maximum displacement). The amplitude of a string vibrating in its nth mode is described by

$$A_n(x) = A_n \sin k_n x \qquad \text{16-15}$$

where $k_n = 2\pi/\lambda_n$ is the wave number. The wave function for a standing wave in the nth harmonic can thus be written

$$y_n(x, t) = A_n \sin(k_n x) \cos(\omega_n t + \delta_n) \qquad \text{16-16}$$

It is useful to remember the two conditions necessary for standing-wave motion, which are as follows:

1. Each point on the string either remains at rest or oscillates in simple harmonic motion. (Those points remaining at rest are the nodes.)
2. Any two oscillating points on the string oscillate either in phase or 180° out of phase.

NECESSARY CONDITIONS FOR A STANDING-WAVE MOTION ON A LENGTH OF STRING

Example 16-8 Standing Waves

Try It Yourself

(*a*) The wave functions for two waves that have equal amplitude, frequency, and wavelength, but that travel in opposite directions, are given by $y_1 = y_0 \sin(kx - \omega t)$ and $y_2 = y_0 \sin(kx + \omega t)$. Show that the superposition of these two waves is a standing wave. (*b*) A standing wave on a string that is fixed at both ends is given by $y(x, t) = (0.024 \text{ m}) \sin(52.3 \text{ m}^{-1} x) \cos(480 \text{ s}^{-1} t)$. Find the speed of waves on the string and find the distance between adjacent nodes for the standing waves.

PICTURE To show that the superposition of the two given waves is a standing wave is to show that the algebraic sum of y_1 and y_2 can be written in the form of $y_n(x, t) = A_n \sin(k_n x) \cos(\omega_n t + \delta_n)$ (Equation 16-16). To find the wave speed and the wavelength, we compare the given wave function with Equation 16-16 and identify the wave number and angular frequency. Knowing these, we can determine the wavelength and wave speed.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
(*a*) 1. Write Equation 16-16. If the sum of y_1 and y_2 can be written in this form, then the superposition of the two traveling waves is a standing wave:	$y(x, t) = A \sin kx \cos \omega t$
2. Add the two wave functions and use the trigonometric identity $\sin\theta_1 + \sin\theta_2 = 2 \sin\frac{1}{2}(\theta_1 + \theta_2) \cos\frac{1}{2}(\theta_1 - \theta_2)$.	$y = y_0 \sin(kx - \omega t) + y_0 \sin(kx + \omega t)$ $= 2y_0 \sin kx \cos \omega t$ This is of the form given by Equation 16-16 (with $A = 2y_0$), so $\boxed{\text{the superposition is a standing wave.}}$
(*b*) 1. Identify the wave number and the angular frequency:	$k = \boxed{52.3 \text{ m}^{-1}}$, $\omega = \boxed{480 \text{ s}^{-1}}$
2. Calculate the speed from $v = \omega/k$:	$v = \boxed{9.18 \text{ m/s}}$
3. Find the wavelength $\lambda = 2\pi/k$, and use it to find the distance between adjacent nodes:	$\frac{\lambda}{2} = \boxed{6.01 \text{ cm}}$

CHECK Anyone would expect that the superposition of a wave traveling to the right and an otherwise identical wave traveling to the left would not be a traveling wave. (If it were a traveling wave, which way would it be traveling?) Thus, we are not surprised that the superposition of the two traveling waves is a standing wave.

STANDING SOUND WAVES

An organ pipe is a familiar example of the use of standing waves in air columns. In the flue-type organ pipe, a stream of air is directed against the sharp edge of an opening (point A in Figure 16-19). The complicated swirling motion of the air near the edge sets up vibrations in the air column. The resonance frequencies of the pipe depend on the length of the pipe and on whether the top is stopped (closed) or open.

In an open organ pipe, the pressure does not vary appreciably near each open end. (It remains at atmospheric pressure.) Because the pressure just beyond the ends does not vary appreciably, there is a pressure node near each end. If the sound wave in the tube is a one-dimensional wave, which is largely correct if the tube diameter is much smaller than the wavelength, then the pressure node is extremely close to the open end of the tube. In practice, however, the pressure node lies slightly beyond the open end of the tube. The effective length of the pipe is $L_{\text{eff}} = L + \Delta L$, where ΔL is the end correction, which is somewhat smaller than the tube diameter. The standing-wave condition for this system is the same as that for a string fixed at both ends, where L is replaced by L_{eff} (the effective length of the tube), and all the same equations apply.

In a stopped organ pipe (open at one end, closed at the other), there is a pressure node near the opening (point A in Figure 16-19) and a pressure antinode at the closed end. The standing-wave condition for this system is the same as that for a string with one end fixed and one end free. The effective length of the tube is equal to an odd integer times $\lambda/4$. That is, the wavelength of the fundamental mode is four times the effective length of the tube, and only the odd harmonics are present.

As we saw in Chapter 15, a sound wave can be thought of as either a pressure wave or a displacement wave. The pressure and displacement variations in a sound wave are 90° out of phase. Thus, in a standing sound wave, the pressure nodes are displacement antinodes and vice versa. Near the open end of an organ pipe there is a pressure node and a displacement antinode, whereas at a stopped end there is a pressure antinode and a displacement node.

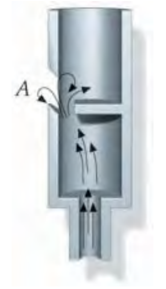

FIGURE 16-19 Cutaway view of a section of a flue-type organ pipe. Air is blown against the edge, causing a swirling motion of the air near point A that excites standing waves in the pipe. There is a pressure node near point A, which is open to the atmosphere.

Example 16-9 Standing Sound Waves in an Air Column: I — *Try It Yourself*

An unstopped (open at both ends) organ pipe has an effective length equal to 1.00 m. (*a*) If the speed of sound is 343 m/s, what are the allowed frequencies and wavelengths for standing sound waves in this pipe? (*b*) The speed of sound in helium is 975 m/s. What are the allowed frequencies for standing sound waves in this pipe if it is filled with and surrounded by helium?

PICTURE There is a displacement antinode (and a pressure node) at each end. Therefore, the effective length of the pipe is equal to an integral number of half-wavelengths.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
(*a*) 1. Using Figure 16-12, determine the wavelength of the fundamental mode:	$\lambda_1 = 2L_{\text{eff}} = 2.00\text{ m}$
2. Use $v = f\lambda$ to calculate the fundamental frequency f_1:	$f_1 = \dfrac{v}{\lambda_1} = 172\text{ Hz}$
3. Write expressions for the frequencies f_n and wavelengths λ_n of the other harmonics in terms of n:	$f_n = nf_1 = \boxed{n(172\text{ Hz}) \quad n = 1, 2, 3, \ldots}$ $\lambda_n = \dfrac{2L}{n} = \boxed{(2.00\text{ m})/n \quad n = 1, 2, 3, \ldots}$
(*b*) 1. Repeat Part (*a*) to calculate the resonant frequency spectrum of the helium-filled organ pipe:	$f_n = nf_1 = n\dfrac{v}{\lambda_1} = n\dfrac{v}{2L} = n\dfrac{975\text{ m/s}}{2.00\text{ m}}$ $= \boxed{n(488\text{ Hz}) \quad n = 1, 2, 3, \ldots}$

CHECK The product of the two Part-(*a*) step-3 results does not depend on n. (The n's cancel when you take the product.) This is as expected because the product is equal to the wave speed, which does not depend on frequency or wavelength.

PRACTICE PROBLEM 16-3 The longest organ pipe is the one with a fundamental frequency that is equal to 16 Hz, the lowest frequency audible to humans. What is the length of an unstopped organ pipe that has a fundamental frequency of 16.0 Hz?

CONCEPT CHECK 16-1

Why does your voice change pitch when you speak after inhaling the contents of a helium-filled balloon?

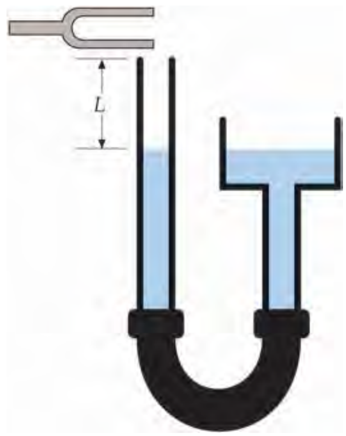

FIGURE 16-20 The length of the air column in the cylinder on the left is varied by moving the reservoir on the right up or down. The two cylinders are connected by a flexible hose.

Example 16-10 Standing Sound Waves in an Air Column: II

When a tuning fork of frequency 500 Hz is held above a tube that is partly filled with water, as in Figure 16-20, resonances are found when the water level is at distances $L = 16.0$, 50.5, 85.0, and 119.5 cm from the top of the tube. (*a*) What is the speed of sound in air? (*b*) How far from the open end of the tube is the displacement antinode?

PICTURE Standing sound waves of frequency 500 Hz are excited in the air column whose length L can be adjusted (by adjusting the water level). The air column is stopped at one end, open at the other. Thus, at resonance, the number of quarter-wavelengths in the effective length L_{eff} of the tube is equal to an odd integer (Figure 16-21). A displacement node exists at the surface of the water and a displacement antinode exists a short distance ΔL above the open end of the tube. Because the frequency is fixed, so is the wavelength. The speed is then found from $v = f\lambda$, where f is 500 Hz.

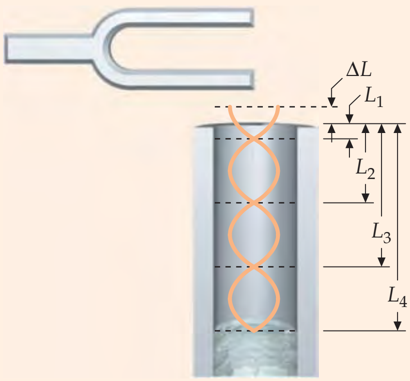

FIGURE 16-21 A displacement node exists at the surface of the water and a displacement antinode exists a distance ΔL above the top of the cylinder.

SOLVE

(*a*) 1. The speed of sound in air is related to the frequency and wavelength: $v = f\lambda$

2. Resonance occurs each time the water level is at the location of a displacement node (see Figure 16-21). That is, when the length L changes by half a wavelength: $L_{n+1} = L_n + \frac{\lambda}{2} \qquad n = 1, 2, 3, 4$

3. The distance between successive levels is found from the data given in the problem: $L_{n+1} - L_n = L_4 - L_3 = 119.5\text{ cm} - 85.0\text{ cm} = 34.5\text{ cm}$

so $\lambda = 2(34.5\text{ cm}) = 69.0\text{ cm} = 0.690\text{ m}$

4. Substitute the values of f and λ to determine v: $v = f\lambda = (500\text{ Hz})(0.690\text{ m}) = \boxed{345\text{ m/s}}$

(*b*) There will be a displacement antinode one-quarter wavelength above the displacement node at the surface of the water. Thus, the distance from the highest water level supporting resonance and the displacement antinode above the opening of the tube is one-quarter wavelength:

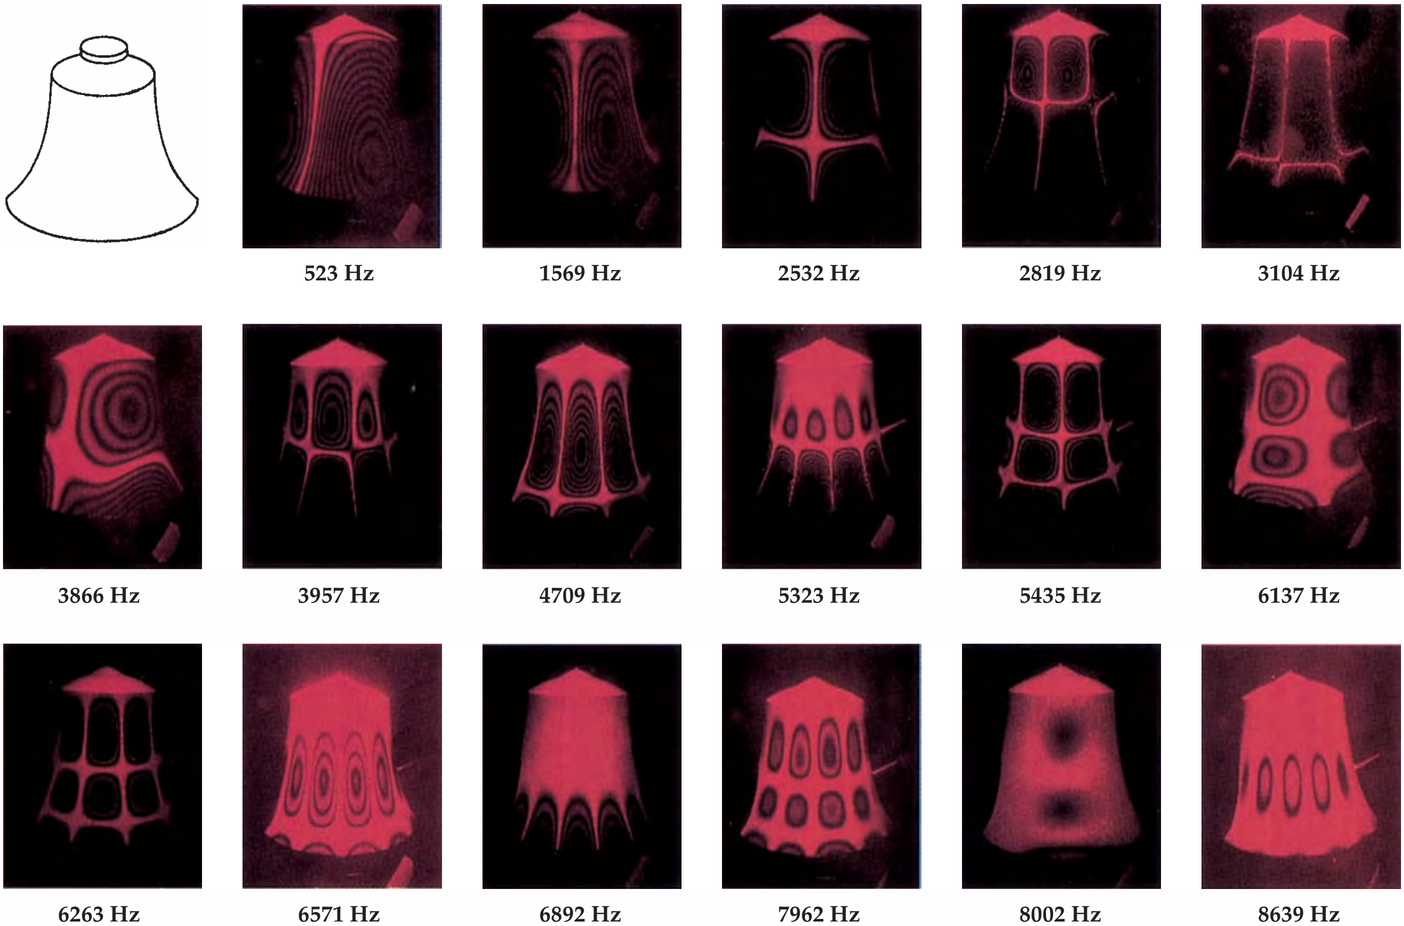
$\frac{1}{4}\lambda = L_1 + \Delta L$

so $\Delta L = \frac{1}{4}\lambda - L_1 = \frac{1}{4}(69.0\text{ cm}) - (16.0\text{ cm})$

$= \boxed{1.25\text{ cm}}$

CHECK As expected, the wave speed (step 4) is approximately equal to the speed of sound in air at room temperature.

Most musical wind instruments are much more complicated than simple cylindrical tubes. The conical tube, which is the basis for the oboe, bassoon, English horn, and saxophone, has a complete harmonic series with its fundamental wavelength equal to twice the length of the cone. Brass instruments are combinations of cones and cylinders. The analysis of these instruments is extremely complex. The fact that they have nearly harmonic series is a triumph of educated trial and error rather than mathematical calculation.



Holographic interferograms showing standing waves in a handbell. The "bull's eyes" locate the antinodes. *(Professor Thomas D. Rossing, Northern Illinois University, DeKalb.)*

* 16-3 ADDITIONAL TOPICS

THE SUPERPOSITION OF STANDING WAVES

As we saw in the preceding section, there is a set of natural resonance frequencies that produce standing waves for sound waves in air columns or vibrating strings that are fixed at one or both ends. For example, for a string fixed at both ends, the frequency of the fundamental mode of vibration is $f_1 = v/(2L)$, where L is the length of the string and v is the wave speed and the wave function is Equation 16-16:

$$y_1(x, t) = A_1 \sin k_1 x \cos(\omega_1 t + \delta_1)$$

In general, a vibrating system does not vibrate in a single harmonic mode. Instead, the motion consists of a superposition of several of the allowed harmonics. The wave function is a linear combination of the harmonic wave functions:

$$y(x, t) = \sum_n A_n \sin(k_n x) \cos(\omega_n t + \delta_n) \qquad \text{16-17}$$

where $k_n = 2\pi/\lambda_n$, $\omega_n = 2\pi f_n$, and A_n and δ_n are constants. The constants A_n and δ_n depend on the initial positions and velocities of the points on the string. If a harp string, for example, is plucked at the center and released, as in Figure 16-22, the

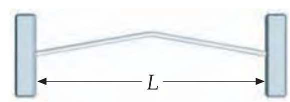


FIGURE 16-22 A string plucked at the center. When it is released, its vibration is a linear superposition of standing waves.

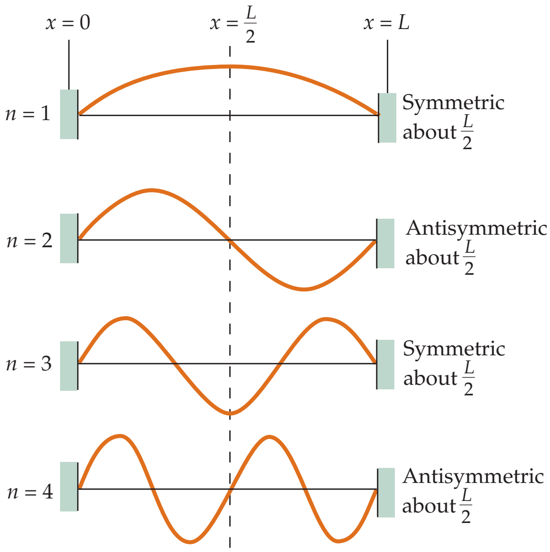

FIGURE 16-23 The first four harmonics for a string fixed at both ends. The odd harmonics are symmetrical about the center of the string, whereas the even harmonics are not. When a string is plucked at the center, it vibrates only in its odd harmonics.

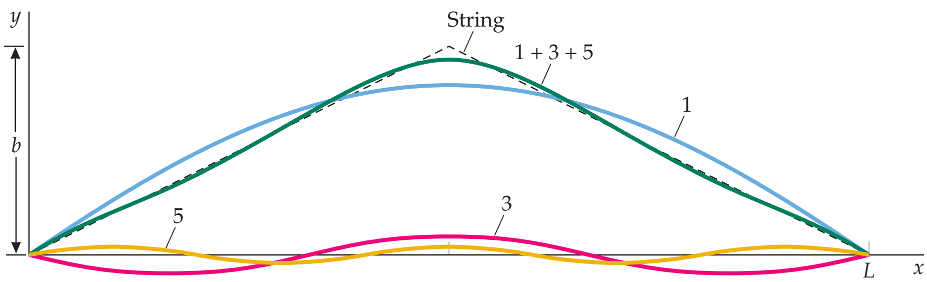

FIGURE 16-24 Approximating the shape of a string plucked at the center, as in Figure 16-22, using harmonics. The green line is an approximation of the original shape of the string based on the first three odd harmonics. The height of the string is exaggerated in this drawing to show the relative amplitudes of the harmonics. Most of the energy is associated with the fundamental, but there is some energy in the third, fifth, and other odd harmonics.

initial shape of the string is symmetric about the point $x = \frac{1}{2}L$ and the initial velocity is zero throughout the length of the string. The motion of the string after it has been released will remain symmetric about $x = \frac{1}{2}L$. Only the odd harmonics, which are also symmetric about $x = \frac{1}{2}L$, will be excited. The even harmonics, which are antisymmetric about $x = \frac{1}{2}L$, are not excited; that is, the constant A_n is zero for all even values of n. The shapes of the first four harmonics are shown in Figure 16-23. Most of the energy of the plucked string is associated with the fundamental, but small amounts of energy are associated with the third, fifth, and other odd harmonic modes. Figure 16-24 shows an approximation to the initial shape of the string using the superposition of only the first three odd harmonics.

(Corbis.)

HARMONIC ANALYSIS AND SYNTHESIS

When a clarinet and an oboe play the same note, say, concert A, they sound quite different. Both notes have the same **pitch,** a physiological sensation of the highness or lowness of the note that is strongly correlated with frequency. However, the notes differ in what is called **tone quality.** The principal reason for the difference in tone quality is that, although both the clarinet and oboe are producing vibrations at the same fundamental frequency, each instrument is also producing harmonics whose relative intensities depend on the instrument and how it is played. If the sound produced by each instrument were entirely at the fundamental frequency of the instrument, they would sound identical.

Figure 16-25 shows plots of the pressure variations versus time for the sound from a tuning fork, a clarinet, and an oboe, each playing the same note. These patterns are called **waveforms.** The waveform for the sound from the tuning fork is nearly a pure sine wave, but those from the clarinet and the oboe are clearly more complex.

Waveforms can be analyzed in terms of the harmonics that constitute them by means of **harmonic analysis.** (Harmonic analysis is also called **Fourier analysis** after the French mathematician J.B.J. Fourier, who developed the

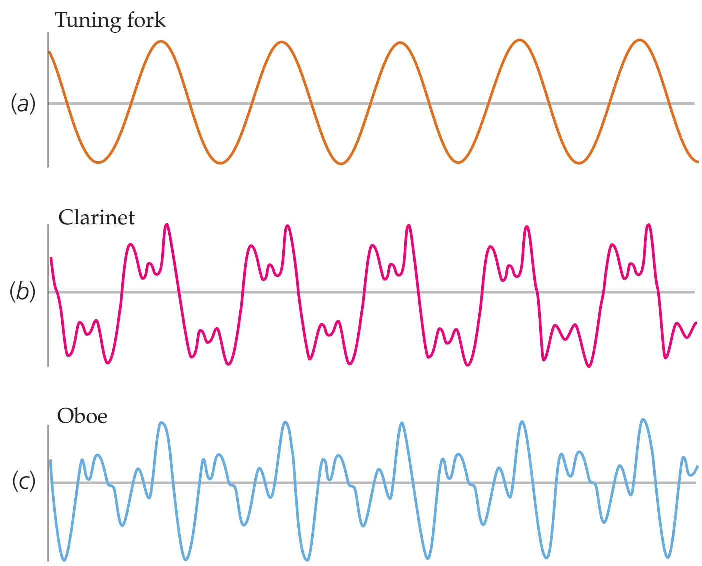

FIGURE 16-25 Waveforms of (*a*) a tuning fork, (*b*) a clarinet, and (*c*) an oboe, each at a fundamental frequency of 440 Hz and at approximately the same intensity.

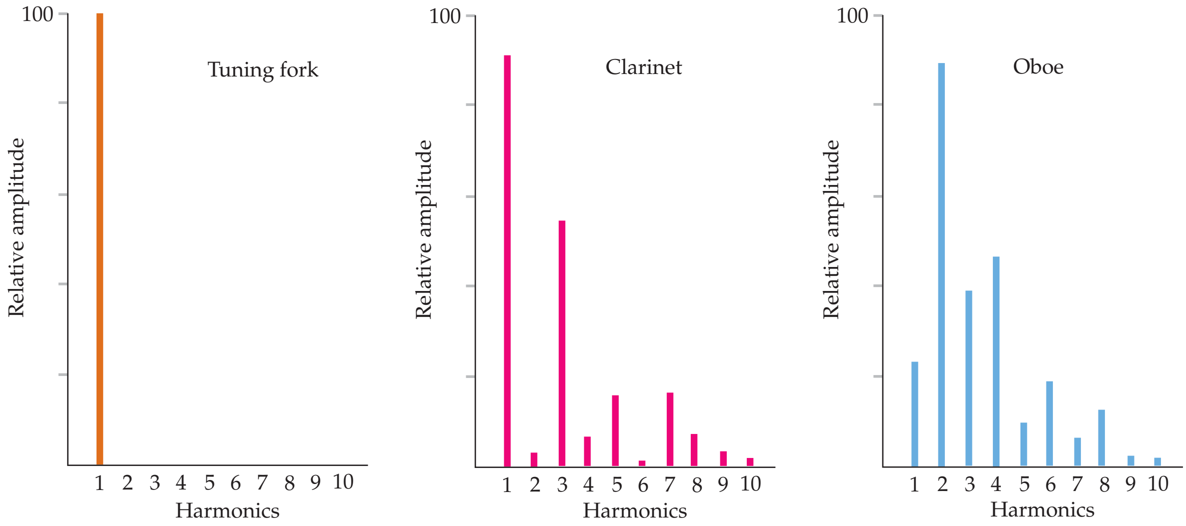

FIGURE 16-26 Relative intensities of the harmonics in the waveforms shown in Figure 16-25 for (*a*) the tuning fork, (*b*) the clarinet, and (*c*) the oboe.

techniques for analyzing periodic functions.) Figure 16-26 shows a plot of the relative intensities of the harmonics of the waveforms in Figure 16-25. The waveform of the sound from the tuning fork contains only the fundamental frequency. The waveform for the sound from the clarinet contains the fundamental, large amounts of the third, fifth, and seventh harmonics, and lesser amounts of the second, fourth, and sixth harmonics. For the sound from the oboe, there is more intensity in the second, third and fourth harmonics than in the fundamental.

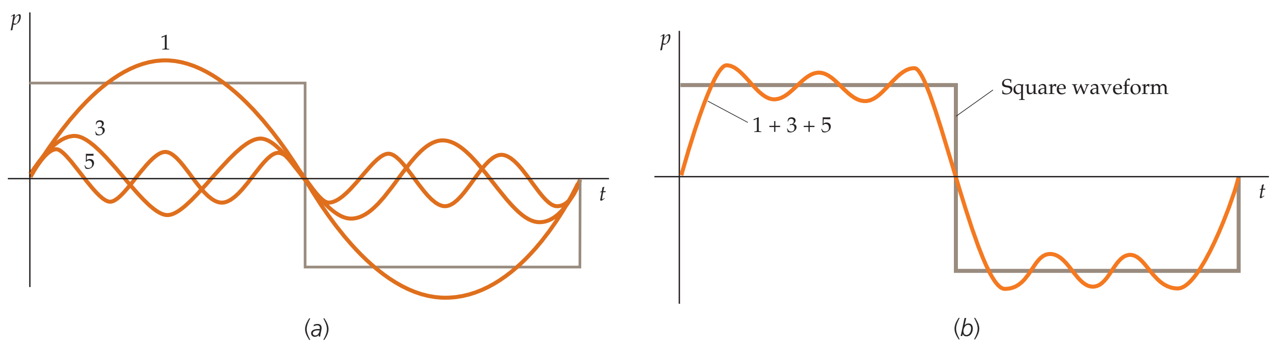

FIGURE 16-27 (a) The first three odd harmonics used to synthesize a square wave. (*b*) The approximation of a square wave that results from summing the first three odd harmonics in (*a*).

The inverse of harmonic analysis is **harmonic synthesis,** which is the construction of a periodic wave from harmonic components. Figure 16-27*a* shows the first three odd harmonics used to synthesize a square wave, and Figure 16-27*b* shows the square wave that results from the sum of the three harmonics. The more harmonics used in a synthesis, the closer the approximation will be to the actual waveform (the gray line in Figure 16-27*b*). The relative amplitudes of the harmonics needed to synthesize the square wave are shown in Figure 16-28.

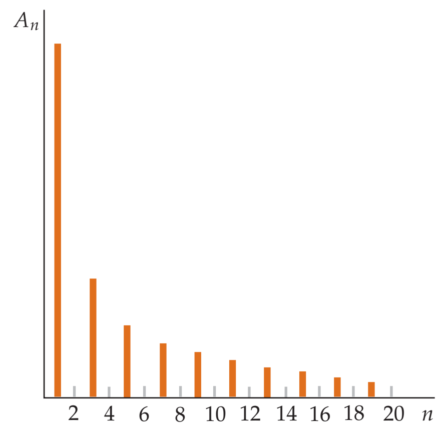

FIGURE 16-28 Relative amplitudes A_n of the first 10 harmonics needed to synthesize a square wave. The more harmonics that are used, the closer the approximation is to the square wave.

WAVE PACKETS AND DISPERSION

The waveforms previously discussed in this Section 16-3 are periodic in time. Pulses, which are not periodic, can also be represented by a group of harmonic waves of different frequencies. However, the synthesis of an isolated pulse requires a continuous distribution of frequencies rather than a discrete set of harmonics, as in Figure 16-28. Such a group is called a **wave packet.** The characteristic feature of a wave pulse is that it has a beginning and an end, whereas a harmonic wave repeats over and over. If the duration Δt of the pulse is very short, the range of frequencies $\Delta\omega$ needed to describe the pulse is very large. The general relation between Δt and $\Delta\omega$ is

$$\Delta\omega\,\Delta t \sim 1 \qquad \text{16-18}$$

where the tilde (~) means "of the order of magnitude of."

The exact value of this product depends on just how the quantities $\Delta\omega$ and Δt are defined. For any reasonable definitions, $\Delta\omega$ and $1/\Delta t$ have the same order of magnitude. A wave pulse produced by a source of short duration Δt, like the crack of a bat on a ball, has a narrow width in space $\Delta x = v\,\Delta t$, where v is the wave speed. Each harmonic wave of frequency ω has a wave number $k = \omega/v$. A range of frequencies $\Delta\omega$ implies a range of wave numbers $\Delta k = \Delta\omega/v$. Substituting $v\,\Delta k$ for $\Delta\omega$ in Equation 16-18 gives $v\,\Delta k\,\Delta t \sim 1$, or

$$\Delta k\,\Delta x \sim 1 \qquad \text{16-19}$$

Example 16-11 Estimating $\Delta\omega$ and Δk

In Example 15-1 a wave pulse on a long clothesline is moving at 100 /m. (*a*) If the width of the pulse is 1.00 m, what is the duration of the pulse? That is, how long does it take for the pulse to travel past a point on the clothesline? (*b*) The pulse can be considered as a superposition of harmonic waves. What is the range of frequencies of these harmonic waves? (*c*) What is the range of wave numbers?

PICTURE To find the duration of the pulse, we use distance equals speed times the time. To find the range of frequencies and the range of wave numbers, we use $\Delta\omega\,\Delta t \sim 1$ and $\Delta k\,\Delta x \sim 1$ (Equations 16-18 and 16-19).

SOLVE

(*a*) The duration of the pulse is the time it takes to pass a point on the clothesline:

$$L = v\,\Delta t \quad \text{so} \quad \Delta t = \frac{L}{v} = \frac{1.00\text{ m}}{100\text{ m/s}} = \boxed{0.0100\text{ s}}$$

(*b*) To find the range of frequencies, we use $\Delta\omega\,\Delta t \sim 1$ (Equation 16-18):

$$\Delta\omega\,\Delta t \sim 1 \quad \text{so} \quad \Delta\omega \sim \frac{1}{\Delta t} = \frac{1}{0.0100\text{ s}} = \boxed{100\text{ s}^{-1}}$$

(*c*) To find the range of wave numbers, we use $\Delta k\,\Delta x \sim 1$ (Equation 16-19):

$$\Delta k\,\Delta x \sim 1 \quad \text{so} \quad \Delta k \sim \frac{1}{\Delta x} = \frac{1}{1.00\text{ m}} = \boxed{1.00\text{ m}^{-1}}$$

CHECK We know that $k = \omega/v$, so a range of frequencies $\Delta\omega$ implies a range of wave numbers $\Delta k = \Delta\omega/v$. Dividing our Part-(*b*) result by the wave speed v, we obtain $(100\text{ s}^{-1})/(100\text{ m/s}) = 1\text{ m}^{-1}$. This value is our Part-(*c*) result.

If a wave packet is to maintain its shape as it travels, all of the component harmonic waves that make up the packet must travel with the same speed. This occurs if the speed of the component waves in a given medium is independent of frequency or wavelength. Such a medium is called a **nondispersive medium.** Air is, to an excellent approximation, a nondispersive medium for sound waves, but solids and liquids are not. (Probably the most familiar example of dispersion is the formation of a rainbow, which is due to the fact that the velocity of light waves in water depends slightly on the frequency of the light, so the different colors, corresponding to different frequencies, have slightly different angles of refraction.)

When the wave speed in a dispersive medium depends only slightly on the frequency (or wavelength), a wave packet changes shape very slowly as it travels, and it covers a considerable distance as a recognizable entity. But the speed of the packet, called the **group velocity,** is not the same as the (average) speed of the individual component harmonic waves, called the **phase velocity.** (By the speed of an individual harmonic wave we mean the speed of its wavefronts. Because wavefronts are lines or surfaces of constant phase, their speed is called the phase velocity of the wave.)

Physics Spotlight

Echoes of Silence: Acoustical Architecture

Architectural acoustics deals with the ways that sound energy reflects, reverberates, and absorbs within a venue. Computer modeling of spaces has allowed acoustic engineers to design flexible spaces,[*,†] while taking into account the different needs for listening to lectures, theater, and several types of music. In general, the goal is to make the sound uniform, audible, and intelligible at each seat.

The baffles hanging from the ceiling and attached to the walls above the doorways are there to absorb sound. Their surfaces are made of acoustically dead material, like felt. *(Courtesy of Perdue Acoustics.)*

There should not be any whole-room standing waves in the listening room.[‡] Whole-room standing waves make certain frequencies harder to hear for people in the seats near nodes, and key frequencies too loud for people seated near the antinodes. Rooms that are designed so that whole-room standing waves are reduced have long walls that are not parallel to each other, and ceilings and floors that are also nonparallel.

If listeners are seated an average of 50 feet from the main sound source, well under one percent of the sound energy can go directly into their ears,[#] and nearly all the sound energy that reaches listeners will be reflected sound. The reflections must be clean and energetic enough to give the listener a reasonable total volume. Timing the reflections is also important. If a reflection up to 15 decibels below the source level reaches a listener's ear more than 60 milliseconds after the source sound, it will be perceived as an echo.[°,§] If reflections louder than the source occur in the first 30 milliseconds, they may also be perceived as echoes. Echoes detract from the intelligibility of speech, and make music sound fuzzy. Late reflections arriving 50 ms or more after the source should be avoided.

Reflectors should be closer than 50 feet to each listener. This is a problem for open-air venues surrounded by tall buildings.[¶] Many older venues have nonstructural plaster work. These structures provide early reflections to listeners. Newer venues often use multiple speakers along the walls and ceiling. Chandeliers and panels suspended from high ceilings also reflect sound. Vaulted and detailed ceilings disperse the sound into many small, unenergetic reflections.

Acoustic absorbers are used to lower the ambient noise energy within a room. The materials for both the reflective structures and the absorbent structures are carefully tailored to the venue, because most materials have different *absorption coefficients* at different frequencies.[**] The absorption coefficient is a measure of the fraction of the sound energy that is absorbed, rather than reflected or transmitted. Window glass, for instance, has absorption coefficients of 0.35 at 125 Hz and 0.04 at 4 kHz. Indoor/outdoor carpet has absorption coefficients of 0.01 at 125 Hz and 0.65 at 4 kHz. Different materials must be used for both absorption and reflection to give a full-spectrum response at each seat.

Too much absorption gives rooms a dead feeling, and gives people claustrophobia.[††] Reverberation, or chaotic sound energy, gives rooms a warm feeling. Reverberation time, the measure of how quickly chaotic noise dissipates, is used as a measure of how lively a room sounds. Reverberation times of venues vary according to the purpose of the venue.

Summary

1. The principle of superposition, which holds for all electromagnetic waves in empty space, for waves on a flexible taut string in the small-angle approximation, and for sound waves of small amplitude, follows from the linearity of the corresponding wave equations.
2. Interference is an important wave phenomenon that applies to all coherent superposing waves. It follows from the principle of superposition. Diffraction and interference distinguish wave motion from particle motion.
3. The standing-wave conditions can be recalled by sketching a string or tube and drawing waves that have displacement nodes at a fixed or stopped end, and displacement antinodes at a free or open end.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Superposition and Interference	The superposition of two harmonic waves of equal amplitude, wave number, and frequency but phase difference δ, results in a harmonic wave of the same wave number and frequency, but differing in phase and amplitude from each of the two waves $$y = y_1 + y_2 = y_0 \sin(kx - \omega t) + y_0 \sin(k - \omega t + \delta) = [2y_0 \cos\tfrac{1}{2}\delta] \sin(kx - \omega t + \tfrac{1}{2}\delta)$$	16-6
Constructive interference	If waves are in phase or differ in phase by an integer times 2π, then the amplitudes of the waves add and the interference is constructive.	
Destructive interference	If waves differ in phase by π or by an odd integer times π, then the amplitudes subtract and the interference is destructive.	
Beats	Beats are the result of the interference of two waves of slightly different frequencies. The beat frequency equals the difference in the frequencies of the two waves: $$f_{\text{beat}} = \Delta f$$	16-8
Phase difference δ due to path difference Δx	$$\delta = k\,\Delta x = 2\pi \frac{\Delta x}{\lambda}$$	16-9
2. Standing Waves	Standing waves occur for certain frequencies and wavelengths when waves are confined in space. If they occur, then each point of the system oscillates in simple harmonic motion and any two points not at nodes move either in phase or 180° out of phase.	
Wavelength	The distance between a node and an adjacent antinode is a quarter-wavelength.	
String fixed at both ends	For a string fixed at both ends, there is a node at each end so that an integral number of half-wavelengths must fit into the length of the string. The standing-wave condition in this case is $$L = n\frac{\lambda_n}{2} \qquad n = 1, 2, 3, \ldots$$	16-10
Standing-wave function for a string fixed at both ends	The allowed waves form a harmonic series, with the frequencies given by $$f_n = \frac{v}{\lambda_n} = n\frac{v}{\lambda_1} = n\frac{v}{2L} = nf_1 \qquad n = 1, 2, 3, \ldots$$ where $f_1 = v/2L$ is the lowest frequency, called the fundamental.	16-18
Organ pipe open at both ends	Standing sound waves in the air in a pipe that is open at both ends have a pressure node (and a displacement antinode) near each end so that the standing-wave condition is the same as for a string fixed at both ends.	
String fixed at one end and free at the other	For a string with one end fixed and one end free, there is a node at the fixed end and an antinode at the free end, so that an integral number of quarter-wavelengths must fit into the length of the string. The standing-wave condition in this case is $$L = n\frac{\lambda_n}{4} \qquad n = 1, 3, 5, \ldots$$ (16-12) Only the odd harmonics are present. Their frequencies are given by $$f_n = \frac{v}{\lambda_n} = n\frac{v}{\lambda_1} = n\frac{v}{4L} = nf_1 \qquad n = 1, 3, 5, \ldots$$ where $f_1 = v/4L$.	16-12, 16-13

TOPIC	RELEVANT EQUATIONS AND REMARKS	
Organ pipe open at one end and stopped at the other	Standing sound waves in a pipe that is open at one end and stopped at the other end have a displacement antinode at the open end and a displacement node at the stopped end. The standing wave condition is the same as for a string fixed at one end.	
Wave Functions for Standing Waves	$y_n(x, t) = A_n \sin(k_n x) \cos(\omega_n t + \delta_n)$ where $k_n = 2\pi/\lambda_n$ and $\omega_n = 2\pi f_n$. The necessary conditions for standing waves on a string are 1. Each point on the string either remains at rest or oscillates with simple harmonic motion. (Those points remaining at rest are nodes.) 2. The motions of any two points on the string that are not nodes oscillate either in phase or 180° out of phase.	16-16
***3. Superposition of Standing Waves**	A vibrating system typically does not vibrate in a single harmonic mode, but in a superposition of the allowed harmonic modes.	
***4. Harmonic Analysis and Synthesis**	Sounds of different tone quality contain different mixtures of harmonics. The analysis of a particular tone in terms of its harmonic content is called harmonic analysis. Harmonic synthesis is the construction of a tone by the addition of harmonics.	
***5. Wave Packets**	A wave pulse can be represented by a continuous distribution of harmonic waves. The range of frequencies $\Delta\omega$ is related to the width in time Δt, and the range of wave numbers Δk is related to the width in space Δx.	
Frequency and time ranges	$\Delta\omega\, \Delta t \sim 1$	16-18
Wave number and space ranges	$\Delta k\, \Delta x \sim 1$	16-19
***6. Dispersion**	In a nondispersive medium, the phase velocity is independent of frequency, and a pulse (wave packet) travels without change in shape. In a dispersive medium, the phase velocity varies with frequency, and the pulse changes shape as it moves. The pulse moves with a velocity called the group velocity of the packet.	

Answer to Concept Check

16-1 Your voice changes pitch because the fundamental frequency of your throat and mouth cavity is increased, just like the resonant frequency of the organ pipe in Example 16-9 increased when it was filled with helium.

Answers to Practice Problems

16-1 (*a*) 5.66 cm, (*b*) 120° or 240°

16-2 $f_1 = 20$ Hz, $f_2 = 40$ Hz, $f_3 = 60$ Hz

16-3 About 10.7 m ≈ 35 ft

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

Use 343 m/s as the speed of sound for air, unless otherwise indicated.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • Two rectangular wave pulses are traveling in opposite directions along a string. At $t = 0$, the two pulses are as shown in Figure 16-29. Sketch the wave functions for $t = 1.0$, 2.0, and 3.0 s. SSM

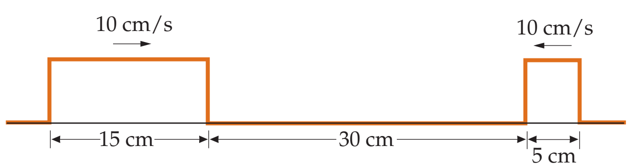

FIGURE 16-29 Problems 1, 2

2 • Repeat Problem 1 for the case in which the pulse on the right is inverted.

3 • Beats are produced by the superposition of two harmonic waves if (*a*) their amplitudes and frequencies are equal, (*b*) their amplitudes are the same but their frequencies differ slightly, (*c*) their frequencies are equal but their amplitudes differ slightly.

4 • Two tuning forks are struck and the sounds from each reach your ears at the same time. One sound has a frequency of 256 Hz, and the second sound has a frequency of 258 Hz. The underlying "hum" frequency that you hear is (*a*) 2 Hz, (*b*) 256 Hz, (*c*) 258 Hz, (*d*) 257 Hz.

5 • In Problem 4, the beat frequency is (*a*) 2 Hz, (*b*) 256 Hz, (*c*) 258 Hz, (*d*) 257 Hz.

6 • **CONTEXT-RICH** As a graduate student, you are teaching your first physics lecture while the professor is away. To demonstrate interference of sound waves, you have set up two speakers that are driven coherently and in phase by the same frequency generator on the front desk. Each speaker generates sound with a 2.4-m wavelength. One student in the front row says she hears a very low volume (loudness) of the sound from the speakers compared to the volume of the sound she hears when only one speaker is generating sound. What could be the difference in the distance between her and each of the two speakers? (*a*) 1.2 m, (*b*) 2.4 m, (*c*) 4.8 m, (*d*) You cannot determine the difference in distances from the data given.

7 • In Problem 6, determine the longest wavelength for which a student would hear "extra loud" sound due to constructive interference, assuming this student is located so that one speaker is 3.0 m farther from her than the other speaker.

8 • Consider standing waves in an organ pipe. True or false:
(*a*) In a pipe open at both ends, the frequency of the third harmonic is three times that of the first harmonic.
(*b*) In a pipe open at both ends, the frequency of the fifth harmonic is five times that of the fundamental.
(*c*) In a pipe that is open at one end and stopped at the other, the even harmonics are not excited.

Explain your choices.

9 • Standing waves result from the superposition of two waves that have (*a*) the same amplitude, frequency, and direction of propagation, (*b*) the same amplitude and frequency and opposite directions of propagation, (*c*) the same amplitude, slightly different frequencies, and the same direction of propagation, (*d*) the same amplitude, slightly different frequencies, and opposite directions of propagation.

10 • If you blow air over the top of a fairly large drinking straw you can hear a fundamental frequency due to a standing wave being set up in the straw. What happens to the fundamental frequency, (*a*) if while blowing, you cover the bottom of the straw with your fingertip? (*b*) if while blowing you cut the straw in half with a pair of scissors? (*c*) Explain your answers to Parts (*a*) and (*b*).

11 • An organ pipe that is open at both ends has a fundamental frequency of 400 Hz. If one end of this pipe is now stopped, the fundamental frequency is (*a*) 200 Hz, (*b*) 400 Hz, (*c*) 546 Hz, (*d*) 800 Hz. SSM

12 •• A string fixed at both ends resonates at a fundamental frequency of 180 Hz. Which of the following will reduce the fundamental frequency to 90 Hz? (*a*) Double the tension and double the length. (*b*) Halve the tension and keep the length and the mass per unit length fixed. (*c*) Keep the tension and the mass per unit length fixed and double the length. (*d*) Keep the tension and the mass per unit length fixed and halve the length.

13 •• **ENGINEERING APPLICATION** Explain how you might use the resonance frequencies of an organ pipe to estimate the temperature of the air in the pipe. SSM

14 •• In the fundamental standing-wave pattern of an organ pipe stopped at one end, what happens to the wavelength, frequency, and speed of the sound needed to create the pattern if the air in the pipe becomes significantly colder? Explain your reasoning.

15 •• (*a*) When a guitar string is vibrating in its fundamental mode, is the wavelength of the sound it produces in air typically the same as the wavelength of the standing wave on the string? Explain. (*b*) When an organ pipe is in any one of its standing-wave modes, is the wavelength of the traveling sound wave it produces in air typically the same as the wavelength of the standing sound wave in the pipe? Explain. SSM

16 •• Figure 16-30 is a photograph of two pieces of very finely woven silk placed one on top of the other. Where the pieces overlap, a series of light and dark lines are seen. This moiré pattern can also be seen when a scanner is used to copy photos from a book or newspaper. What causes the moiré pattern, and how is it similar to the phenomenon of interference?

FIGURE 16-30 **Problem 16** *(Courtesy of Chuck Adler.)*

17 •• When a musical instrument consisting of drinking glasses, each partially filled to a different height with water, is struck with a small mallet, each glass produces a different frequency of sound wave. Explain how this instrument works.

18 •• **ENGINEERING APPLICATION** During an organ recital, the air compressor that drives the organ pipes suddenly fails. An enterprising physics student in the audience tries to help by replacing the compressor with a pressurized tank of nitrogen gas. What effect, if any, will the nitrogen gas have on the frequency output of the organ pipes? What effect, if any, would helium gas have on the frequency output of the organ pipes?

19 •• The constant γ for helium (and all monatomic gases) is 1.67. If a man inhales helium and then speaks, his voice has a high pitch and becomes cartoon-like. Why?

ESTIMATION AND APPROXIMATION

20 • It is said that a powerful opera singer can hit a high note with sufficient intensity to shatter an empty wine glass by causing the air in it to resonate at the frequency of her voice. Estimate the frequency necessary to obtain a standing wave in an 8.0-cm-high glass. (The 8.0 cm does not include the height of the stem.) Approximately how many octaves above middle C (262 Hz) is this? *Hint: To go up one octave means to double the frequency.*

21 • Estimate how accurately you can tune a piano string to a tuning fork of known frequency using only your ears, the tuning fork, and a wrench. Explain your answer.

22 •• The shortest pipes used in organs are 7.5 cm long. (*a*) Estimate the fundamental frequency of a pipe this long that is open at both ends. (*b*) For such a pipe, estimate the harmonic number n of the highest-frequency harmonic that is within the audible range. (The audible range of human hearing is about 20 to 20,000 Hz.)

23 •• **BIOLOGICAL APPLICATION** Estimate the resonant frequencies that are in the audible range of human hearing of the human ear canal. Treat the canal as an air column open at one end, stopped at the other end, and with a length of 1.00 in. How many resonant frequencies lie in this range? Human hearing has been found experimentally to be the most sensitive at frequencies of about 3, 9, and 15 kHz. How do these frequencies compare to your calculations?

SUPERPOSITION AND INTERFERENCE

24 • Two harmonic waves traveling on a string in the same direction both have a frequency of 100 Hz, a wavelength of 2.0 cm, and an amplitude of 0.020 m. In addition, they overlap each other. What is the amplitude of the resultant wave if the original waves differ in phase by (*a*) $\pi/6$, and (*b*) $\pi/3$?

25 • Two harmonic waves having the same frequency, wave speed, and amplitude are traveling in the same direction and in the same propagating medium. In addition, they overlap each other. If they differ in phase by $\pi/2$ and each has an amplitude of 0.050 m, what is the amplitude of the resultant wave? SSM

26 • Two audio speakers facing in the same direction oscillate in phase at the same frequency. They are separated by a distance equal to one-third of a wavelength. Point P is in front of both speakers, on the line that passes through their centers. The amplitude of the sound at P due to either speaker acting alone is A. What is the amplitude (in terms of A) of the resultant wave at point P?

27 • Two compact sources of sound oscillate in phase with a frequency of 100 Hz. At a point 5.00 m from one source and 5.85 m from the other, the amplitude of the sound from each source separately is A. (*a*) What is the phase difference of the two waves at that point? (*b*) What is the amplitude (in terms of A) of the resultant wave at that point?

28 • With a drawing program or a compass, draw circular arcs of radius 1 cm, 2 cm, 3 cm, 4 cm, 5 cm, 6 cm, and 7 cm centered at each of two points (P_1 and P_2) a distance $d = 3.0$ cm apart. Draw smooth curves through the intersections corresponding to points N centimeters farther from P_1 than from P_2 for $N = +2, +1, 0, -1$, and -2, and label each curve with the corresponding value of N. There are two additional such curves you can draw, one for $N = +3$ and one for $N = -3$. If identical sources of coherent in-phase 1.0-cm-wavelength waves were placed at points P_1 and P_2, the waves would interfere constructively along each of the smooth curves.

29 • Two speakers separated by some distance emit sound waves of the same frequency. At some point P, the intensity due to each speaker separately is I_0. The distance from P to one of the speakers is $\frac{1}{2}\lambda$ longer than that from P to the other speaker. What is the intensity at P if (*a*) the speakers are coherent and in phase, (*b*) the speakers are incoherent, and (*c*) the speakers are coherent and 180° out of phase? SSM

30 • Two speakers separated by some distance emit sound waves of the same frequency. At some point P' the intensity due to each speaker separately is I_0. The distance from P' to one of the speakers is one wavelength longer than that from P' to the other speaker. What is the intensity at P' if (*a*) the speakers are coherent and in phase, (*b*) the speakers are incoherent, and (*c*) the speakers are coherent and out of phase?

31 •• A transverse harmonic wave with a frequency equal to 40.0 Hz propagates along a taut string. Two points 5.00 cm apart are out of phase by $\pi/6$. (*a*) What is the wavelength of the wave? (*b*) At a given point on the string, how much does the phase change in 5.00 ms? (*c*) What is the wave speed?

32 •• **BIOLOGICAL APPLICATION** It is thought that the brain determines the direction of the source of a sound by sensing the phase difference between the sound waves striking the eardrums. A distant source emits sound of frequency 680 Hz. When you are directly facing a sound source there is no phase difference. Estimate the phase difference between the sounds received by your ears when you are facing 90° away from the direction of the source.

33 •• Sound source A is located at $x = 0, y = 0$, and sound source B is located at $x = 0, y = 2.4$ m. The two sources radiate coherently and in phase. An observer at $x = 15$ m, $y = 0$ notes that as he takes a few steps from $y = 0$ in either the $+y$ or $-y$ direction, the sound intensity diminishes. What is the lowest frequency, and the next to lowest frequency of the sources that can account for that observation? SSM

34 •• Suppose that the observer in Problem 33 finds himself at a point of minimum intensity at $x = 15$ m, $y = 0$. What is then the lowest frequency and next to lowest frequency of the sources that can account for this observation?

35 ••• **SPREADSHEET** Two harmonic water waves of equal amplitudes but different frequencies, wave numbers, and speeds are traveling in the same direction. In addition, they are superposed on each other. The total displacement of the wave can be written as $y(x, t) = A[\cos(k_1x - \omega_1t) + \cos(k_2x - \omega_2t)]$, where $\omega_1/k_1 = v_1$ (the speed of the first wave) and $\omega_2/k_2 = v_2$ (the speed of the second wave). (*a*) Show that $y(x, t)$ can be written in the form $y(x, t) = Y(x, t)\cos(k_{av}x - \omega_{av}t)$, where $\omega_{av} = (\omega_1 + \omega_2)/2$, $k_{av} = (k_1 + k_2)/2$, $Y(x, t) = 2A\cos[(\Delta k/2)x - (\Delta\omega/2)t]$, $\Delta\omega = \omega_1 - \omega_2$, and $\Delta k = k_1 - k_2$. The factor $Y(x, t)$ is called the *envelope* of the wave. (*b*) Let $A = 1.00$ cm, $\omega_1 = 1.00$ rad/s, $k_1 = 1.00\ \mathrm{m^{-1}}$, $\omega_2 = 0.900$ rad/s, and $k_2 = 0.800\ \mathrm{m^{-1}}$. Using a **spreadsheet program** or **graphing calculator,** make a plot of $y(x, t)$ versus x at $t = 0.00$ s for $0 < x < 5.00$ m. (*c*) Using a **spreadsheet program** or **graphing calculator,** make three plots of $Y(x, t)$ versus x for $-5.00\text{ m} < x < 5.00$ m on the same graph. Make one plot for $t = 0.00$ s, the second for $t = 5.00$ s, and the third for $t = 10.00$ s. Estimate the speed at which the envelope moves from the three plots, and compare this estimate with the speed obtained using $v_{envelope} = \Delta\omega/\Delta k$. SSM

36 ••• Two coherent point sources are in phase and are separated by a distance d. An interference pattern is detected along a line parallel to the line through the sources and a large distance D from the sources, as shown in Figure 16-31. (*a*) Show that the path difference Δs from the two sources to some point on the line at an angle θ is given, approximately, by $\Delta s \approx d\sin\theta$. *Hint: Assume that* $D \gg d$, *so the lines from the sources to* P *are approximately parallel* (Figure 16-31*b*). (*b*) Show that the two waves interfere constructively at P if $\Delta s = m\lambda$, where $m = 0, 1, 2, \ldots$. (That is, show there is an interference maximum at P if $\Delta s = m\lambda$, where $m = 0, 1, 2, \ldots$.) (*c*) Show that the distance y_m from the central maximum (at $y = 0$) to the mth interference maximum at P is given by $y_m = D\tan\theta_m$, where $d\sin\theta_m = m\lambda$.

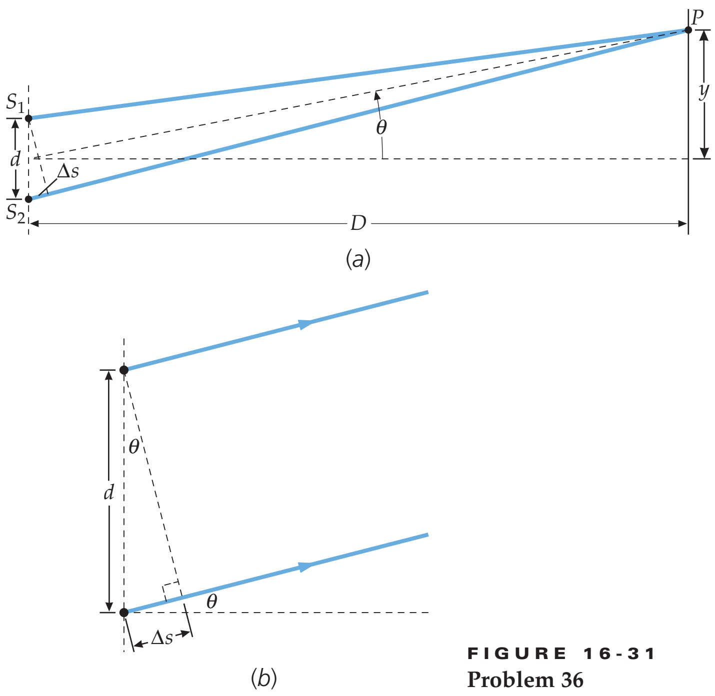

FIGURE 16-31
Problem 36

37 •• Two sound sources radiating in phase at a frequency of 480 Hz interfere such that maxima are heard at angles of 0° and 23° from a line perpendicular to that joining the two sources. The listener is at a large distance from the line through both sources, and no additional maxima are heard at angles in the range $0° < \theta < 23°$. Find the separation d between the two sources, and any other angles at which intensity maxima will be heard. (Use the result of Problem 36.)

38 •• Two loudspeakers are driven in phase by an audio amplifier at a frequency of 600 Hz. The speakers are on the y axis, one at $y = +1.00$ m and the other at $y = -1.00$ m. A listener, starting at $(x, y) = (D, 0)$, where $D \gg 2.00$ m, walks in the $+y$ direction along the line $x = D$. (See Problem 36.) (*a*) At what angle θ will she first hear a minimum in the sound intensity? (θ is the angle between the positive x axis and the line from the origin to the listener.) (*b*) At what angle will she first hear a maximum in the sound intensity (after $\theta = 0$)? (*c*) How many maxima can she possibly hear if she keeps walking in the same direction?

39 ••• Two sound sources driven in phase by the same amplifier are 2.00 m apart on the y axis, one at $y = +1.00$ m and the other at $y = -1.00$ m. At points large distances from the y axis, constructive interference is heard at angles with the x axis of $\theta_0 = 0.000$ rad, $\theta_1 = 0.140$ rad, and $\theta_2 = 0.283$ rad, and at no angles in between (see Figure 16-31). (*a*) What is the wavelength of the sound waves from the sources? (*b*) What is the frequency of the sources? (*c*) At what other angles is constructive interference heard? (*d*) What is the smallest angle for which the sound waves cancel? SSM

40 ••• The two sound sources from Problem 39 are now driven 90° out-of-phase, but at the same frequency as in Problem 39. At what angles are constructive and destructive interference heard?

41 •• ENGINEERING APPLICATION An astronomical radio telescope consists of two antennas separated by a distance of 200 m. Both antennas are tuned to the frequency of 20 MHz. The signals from each antenna are fed into a common amplifier, but one signal first passes through a phase selector that delays its phase by a chosen amount so that the telescope can "look" in different directions (Figure 16-32). When the phase delay is zero, plane radio waves that are incident vertically on the antennas produce signals that add constructively at the amplifier. What should the phase delay be so that signals coming from an angle $\theta = 10°$ with the vertical (in the plane formed by the vertical and the line joining the antennas) will add constructively at the amplifier? *Hint: Radio waves travel at* 3.00×10^8 *m/s.*

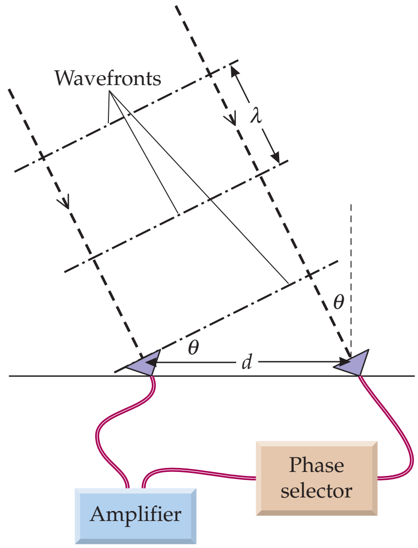

FIGURE 16-32
Problem 41

BEATS

42 • When two tuning forks are struck simultaneously, 4.0 beats per second are heard. The frequency of one fork is 500 Hz. (*a*) What are the possible values for the frequency of the other fork? (*b*) A piece of wax is placed on the 500-Hz fork to lower its frequency slightly. Explain how the measurement of the new beat frequency can be used to determine which of your answers to Part (*a*) is the correct frequency of the second fork.

43 ••• ENGINEERING APPLICATION A stationary police radar gun emits microwaves at 5.00 GHz. When the gun is aimed at a car, it superposes the transmitted and reflected waves. Because the frequencies of these two waves differ, beats are generated, with the speed of the car proportional to the beat frequency. The speed of the car, 83 mi/h, appears on the display of the radar gun. Assuming the car is moving along the line-of-sight of the police officer, and using the Doppler-shift equations, (*a*) show that, for a fixed radar-gun frequency, the beat frequency is proportional to the speed of the car. *Hint: Car speeds are tiny compared to the speed of light.* (*b*) What is the beat frequency in this case? (*c*) What is the calibration factor for this radar gun? That is, what is the beat frequency generated per mi/h of speed? SSM

STANDING WAVES

44 • A string fixed at both ends is 3.00 m long. It resonates in its second harmonic at a frequency of 60.0 Hz. What is the speed of transverse waves on the string?

45 • A string 3.00 m long and fixed at both ends is vibrating in its third harmonic. The maximum displacement of any point on the string is 4.00 mm. The speed of transverse waves on this string is 50.0 m/s. (*a*) What are the wavelength and frequency of this standing wave? (*b*) Write the wave function for this standing wave.

46 • Calculate the fundamental frequency for an organ pipe, with an effective length equal to 10 m, that is (*a*) open at both ends, and (*b*) stopped at one end.

47 • A 5.00-g, 1.40-m-long flexible wire has a tension of 968 N and is fixed at both ends. (*a*) Find the speed of transverse waves on the wire. (*b*) Find the wavelength and frequency of the fundamental. (*c*) Find the frequencies of the second and third harmonics. SSM

48 • A taut, 4.00-m-long rope has one end fixed and the other end free. (The free end is attached to a long, light string.) The speed of waves on the rope is 20.0 m/s. (*a*) Find the frequency of the fundamental. (*b*) Find the second harmonic. (*c*) Find the third harmonic.

49 • A steel piano wire without windings has a fundamental frequency of 200 Hz. When it is wound with copper wire, its linear mass density is doubled. What is its new fundamental frequency, assuming that the tension is unchanged?

50 • What is the greatest length that an organ pipe can have in order that its fundamental note be in the audible range (20 to 20,000 Hz) if (*a*) the pipe is stopped at one end, and (*b*) it is open at both ends?

51 •• The wave function $y(x, t)$ for a certain standing wave on a string that is fixed at both ends is given by $y(x, t) = 4.20 \sin(0.200\, x) \cos(300t)$, where y and x are in centimeters and t is in seconds. A standing wave can be considered as the superposition of two traveling waves. (*a*) What are the wavelength and frequency of the two traveling waves that make up the specified standing wave? (*b*) What is the speed of these waves on this string? (*c*) If the string is vibrating in its fourth harmonic, how long is it? SSM

52 •• The wave function $y(x, t)$ for a certain standing wave on a string that is fixed at both ends is given by $y(x, t) = (0.0500\text{ m}) \sin(2.50\text{ m}^{-1}\, x) \cos(500\text{ s}^{-1}\, t)$. A standing wave can be considered as the superposition of two traveling waves. (*a*) What are the speed and amplitude of the two traveling waves that result in the specified standing wave? (*b*) What is the distance between successive nodes on the string? (*c*) What is the shortest possible length of the string?

53 •• A 1.20-m-long pipe is stopped at one end. Near the open end, there is a loudspeaker that is driven by an audio oscillator whose frequency can be varied from 10.0 to 5000 Hz. (Neglect any end corrections.) (*a*) What is the lowest frequency of the oscillator that will produce resonance within the tube? (*b*) What is the highest frequency of the oscillator that will produce resonance within the tube? (*c*) How many different frequencies of the oscillator will produce resonance within the tube?

54 •• A 460-Hz tuning fork causes resonance in the tube depicted in Figure 16-33 when the length L of the air column above the water is 18.3 and 55.8 cm. (*a*) Find the speed of sound in air. (*b*) What is the end correction to adjust for the fact that the antinode does not occur exactly at the open end of the tube?

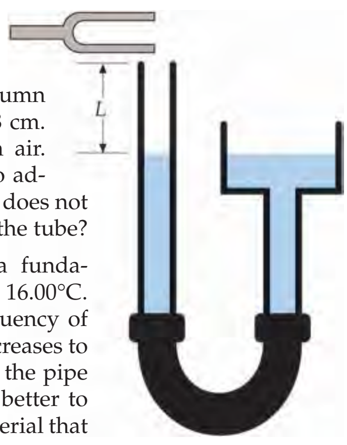

FIGURE 16-33 Problem 54

55 •• An organ pipe has a fundamental frequency of 440.0 Hz at 16.00°C. What will the fundamental frequency of the pipe be if the temperature increases to 32.00°C (assuming the length of the pipe remains constant)? Would it be better to construct organ pipes from a material that expands substantially as the temperature increases, or should the pipes be made of material that maintains the same length at all normal temperatures? SSM

56 •• According to theory, the end correction for a pipe is approximately $\Delta L = 0.3186D$, where D is the pipe diameter. Find the actual length of a pipe open at both ends that will produce a middle C (256 Hz) as its fundamental mode for pipes of diameter $D = 1.00$ cm, 10.0 cm, and 30.0 cm.

57 •• Assume a 40.0-cm-long violin string has a mass of 1.20 g and is vibrating in its fundamental mode* at a frequency of 500 Hz. (*a*) What is the wavelength of the standing wave on the string? (*b*) What is the tension in the string? (*c*) Where should you place your finger to increase the fundamental frequency to 650 Hz?

* A bowed string does not vibrate in a single mode. Thus, the conditions described in this problem statement are not completely accurate.

58 •• The G string on a violin is 30.0 cm long. When played without fingering, it vibrates in its fundamental mode* at a frequency of 196 Hz. The next higher notes on its C-major scale are A (220 Hz), B (247 Hz), C (262 Hz), and D (294 Hz). How far from the end of the string must a finger be placed to play each of these notes?

59 •• A string that has a linear mass density of 4.00×10^{-3} kg/m is under a tension of 360 N and is fixed at both ends. One of its resonance frequencies is 375 Hz. The next higher resonance frequency is 450 Hz. (*a*) What is the fundamental frequency of this string? (*b*) Which harmonics have the given frequencies? (*c*) What is the length of the string?

60 •• A string fixed at both ends has successive resonances with wavelengths of 0.54 m for the nth harmonic and 0.48 m for the $(n + 1)$th harmonic. (*a*) Which harmonics are these? (*b*) What is the length of the string?

61 •• The strings of a violin are tuned to the tones G, D, A, and E, which are separated by a fifth from one another. That is, $f(\text{D}) = 1.5f(\text{G})$, $f(\text{A}) = 1.5f(\text{D}) = 440$ Hz, and $f(\text{E}) = 1.5f(\text{A})$. The distance between the bridge at the scroll and the bridge over the body, the two fixed points on each string, is 30.0 cm. The tension on the E string is 90.0 N. (*a*) What is the linear mass density of the E string? (*b*) To prevent distortion of the instrument over time, it is important that the tension on all strings be the same. Find the linear mass densities of the other strings. SSM

62 •• On a cello, like most other stringed instruments, the positioning of the fingers by the player determines the fundamental frequencies of the strings. Suppose that one of the strings on a cello is tuned to play a middle C (262 Hz) when played at its full length. By what fraction must that string be shortened in order to play a note that is the interval of a third higher (namely, an E (330 Hz)? How about a fifth higher or a G (392 Hz)?

63 •• To tune your violin, you first tune the A string to the correct pitch of 440 Hz, and then you bow both it and an adjoining string simultaneously, all the while listening for beats. While bowing the A and E strings, you hear a beat frequency of 3.00 Hz and note that the beat frequency increases as the tension on the E string is increased. (The E string is to be tuned to 660 Hz.) (*a*) Why are beats produced by these two strings when bowed simultaneously? (*b*) What is the frequency of the E string vibration when the beat frequency is 3.00 Hz?

64 •• A 2.00-m-long string fixed at one end and free at the other end (the free end is fastened to the end of a long, light thread) is vibrating in its third harmonic with a maximum amplitude of 3.00 cm and a frequency 100 Hz. (*a*) Write the wave function for this vibration. (*b*) Write a function for the kinetic energy of a segment of the string of length dx, at a point a distance x from the fixed end, as a function of time t. At what times is this kinetic energy maximum? What is the shape of the string at these times? (*c*) Find the maximum kinetic energy of the string by integrating your expression for Part (*b*) over the total length of the string.

65 •• **CONTEXT-RICH** A commonly used physics experiment that examines resonances of transverse waves on a string is shown in Figure 16-34. A weight is attached to the end of a string draped over a pulley; the other end of the string is attached to a mechanical oscillator that moves up and down at a frequency f that remains fixed throughout the demonstration. The length L between the oscillator and the pulley is fixed, and the tension is equal to the gravitational force on the weight. For certain values of the tension, the string resonates. Assume the string does not stretch or shrink as the tension is varied. You are in charge of setting up this apparatus for a lecture demonstration. (*a*) Explain why only certain discrete values of the tension result in standing waves on the string. (*b*) Do you need to increase or decrease the tension to produce a standing wave with an additional antinode? Explain. (*c*) Prove your reasoning in Part (*b*) by showing that the values for the tension $F_{\text{T}n}$ for the nth

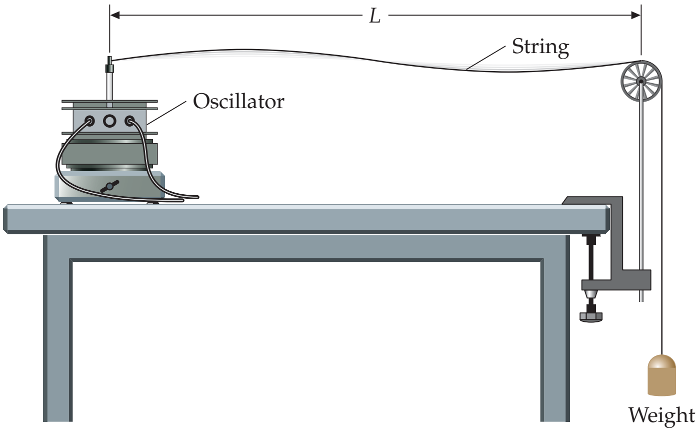

FIGURE 16-34 Problem 65

standing-wave mode are given by $F_{Tn} = 4L^2f^2\mu/n^2$, and thus the F_{Tn} is inversely proportional to n^2. (*d*) For your particular setup to fit onto the lecture table, you chose $L = 1.00$ m, $f = 80.0$ Hz, and $\mu = 0.750$ g/m. Calculate how much tension is needed to produce each of the first three modes (standing waves) of the string. SSM

* HARMONIC ANALYSIS

66 • A guitar string is given a light pluck at its midpoint. A microphone on your computer detects the sound and a program on the computer determines that most of the subsequent sound consists of a 100-Hz tone accompanied by a bit of sound with a 300-Hz tone. What are the two dominant standing-wave modes on the string?

* WAVE PACKETS

67 •• A tuning fork with natural frequency f_0 begins vibrating at time $t = 0$ and is stopped after a time interval, Δt. The waveform of the sound at some later time is shown (Figure 16-35) as a function of x. Let N be an estimate of the number of cycles in this waveform. (*a*) If Δx is the length in space of this wave packet, what is the range in wave numbers Δk of the packet? (*b*) Estimate the average value of the wavelength λ in terms of N and Δx. (*c*) Estimate the average wave number k in terms of N and Δx. (*d*) If Δt is the time it takes the wave packet to pass a point in space, what is the range in angular frequencies $\Delta\omega$ of the packet? (*e*) Express f_0 in terms of N and Δt. (*f*) The number N is uncertain by about ± 1 cycle. Use Figure 16-35 to explain why. (*g*) Show that the uncertainty in the wave number due to the uncertainty in N is $2\pi/\Delta x$. SSM

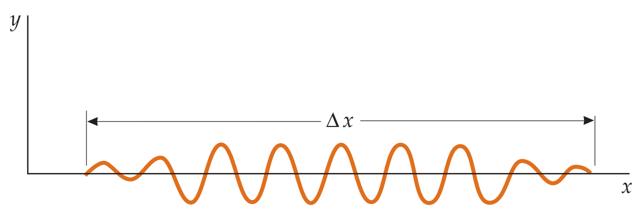

FIGURE 16-35 Problem 67

GENERAL PROBLEMS

68 •• A 35-m-long string has a linear mass density of 0.0085 kg/m and is under a tension of 18 N. Find the frequencies of the lowest four harmonics (*a*) if the string is fixed at both ends, and (*b*) if the string is fixed at one end and free at the other. (That is, if the free end is attached to a long string of negligible mass.)

69 •• CONTEXT-RICH, ENGINEERING APPLICATION Working for a small gold mining company, you stumble across an abandoned mine shaft that, because of decaying wood shoring, looks too dangerous to explore in person. To measure its depth, you employ an audio oscillator of variable frequency. You determine that successive resonances are produced at frequencies of 63.58 and 89.25 Hz. Estimate the depth of the shaft.

70 •• A 5.00-m-long string that is fixed at one end and attached to a long string of negligible mass at the other end is vibrating in its fifth harmonic, which has a frequency of 400 Hz. The amplitude of the motion at each antinode is 3.00 cm. (*a*) What is the wavelength of this wave? (*b*) What is the wave number? (*c*) What is the angular frequency? (*d*) Write the wave function for this standing wave.

71 •• The wave function for a standing wave on a string is described by $y(x, t) = (0.020)\sin(4\pi x)\cos(60\pi t)$, where y and x are in meters and t is in seconds. Determine the maximum displacement and maximum speed of a point on the string at (*a*) $x = 0.10$ m, (*b*) $x = 0.25$ m, (*c*) $x = 0.30$ m, and (*d*) $x = 0.50$ m. SSM

72 •• A 2.5-m-long string that has a mass of 0.10 kg is fixed at both ends and is under a tension of 30 N. When the nth harmonic is excited, there is a node 0.50 m from one end. (*a*) What is n? (*b*) What are the frequencies of the first three harmonics of this string?

73 •• An organ pipe is such that under normal conditions its fundamental frequency is 220 Hz. It is placed in an atmosphere of sulfur hexafluoride (SF_6) at the same temperature and pressure. The molar mass of air is 29.0×10^{-3} kg/mol and the molar mass of SF_6 is 146×10^{-3} kg/mol. What is the fundamental frequency of the organ pipe when it is in an atmosphere of SF_6?

74 •• During a lecture demonstration of standing waves, one end of a string is attached to a device that vibrates at 60 Hz and produces transverse waves of that frequency on the string. The other end of the string passes over a pulley, and the tension is varied by attaching weights to that end. The string has approximate nodes next to both the vibrating device and the pulley. (*a*) If the string has a linear mass density of 8.0 g/m and is 2.5 m long from the vibrating device to the pulley, what must be the tension for the string to vibrate in its fundamental mode? (*b*) Find the tension necessary for the string to vibrate in its second, third, and fourth harmonics.

75 •• Three successive resonance frequencies in an organ pipe are 1310, 1834, and 2358 Hz. (*a*) Is the pipe closed at one end or open at both ends? (*b*) What is the fundamental frequency? (*c*) What is the effective length of the pipe? SSM

76 •• During an experiment studying the speed of sound in air using an audio oscillator and a tube that is open at one end and stopped at the other end, a particular resonant frequency is found to have nodes roughly 6.94 cm apart. The oscillator's frequency is increased, and the next resonant frequency found has nodes 5.40 cm apart. (*a*) What are the two resonant frequencies? (*b*) What is the fundamental frequency? (*c*) Which harmonics are these two modes? The speed of sound is 343 m/s.

77 •• A standing wave on a rope is represented by the wave function $y(x, t) = (0.020)\sin(\frac{1}{2}\pi x)\cos(40\pi t)$, where x and y are in meters and t is in seconds. (*a*) Write wave functions for two traveling waves that, when superimposed, produce this standing-wave pattern. (*b*) What is the distance between the nodes of the standing wave? (*c*) What is the maximum speed of the rope at $x = 1.0$ m? (*d*) What is the maximum acceleration of the rope at $x = 1.0$ m?

78 •• SPREADSHEET Two traveling-wave pulses on a string are represented by the wave functions

$$y_1(x, t) = \frac{0.020}{2.0 + (x - 2.0t)^2} \quad \text{and} \quad y_2(x, t) = \frac{-0.020}{2.0 + (x + 2.0t)^2}$$

where x is in meters and t is in seconds. (*a*) Using a **spreadsheet program** or **graphing calculator,** make a separate graph of each wave function as a function of x at $t = 0$ and again at $t = 1.0$ s, and describe the behavior of each as time increases. For each graph make your plot for $-5.0\text{ m} < x < +5.0\text{ m}$. (*b*) Graph the resultant wave function at $t = -1.0$ s, at $t = 0.0$ s, and at $t = 1.0$ s.

79 ••• Three waves that have the same frequency, wavelength, and amplitude are traveling along the x axis. The three waves are described by the following wave functions: $y_1(x, t) = (5.00\text{ cm}) \sin(kx - \omega t - \frac{1}{3}\pi)$, $y_2(x, t) = (5.00\text{ cm}) \sin(kx - \omega t)$, and $y_3(x, t) = (5.00\text{ cm}) \sin(kx - \omega t + \frac{1}{3}\pi)$, where x is in meters and t is in seconds. The resultant wave function is given by $y_3(x, t) = A \sin(kx - \omega t + \delta)$. What are the values of A and δ?

80 ••• A harmonic pressure wave produced by a distant source is traveling through your vicinity, and the wavefronts that travel through your vicinity are vertical planes. Let the $+x$ direction be to the east and the $+y$ direction be toward the north. The wave function for the wave is $p(x, y, t) = A\cos(k_x x + k_y y - \omega t)$. Show that the direction in which the wave is traveling makes an angle $\theta = \tan^{-1}(k_y/k_x)$ with the $+x$ direction and that the wave speed is $v = \omega\sqrt{k_x^2 + k_y^2}$.

81 •• The speed of sound in air is proportional to the square root of the absolute temperature T (Equation 15-5). (*a*) Show that if the air temperature changes by a small amount, the fractional change in the fundamental frequency of an organ pipe is approximately equal to half the fractional change in the absolute temperature. That is, show that $\Delta f/f \approx \frac{1}{2}\Delta T/T$, where f is the frequency at absolute temperature T and Δf is the change in frequency when the temperature changes by ΔT. (Ignore any change in the length of the pipe due to thermal expansion.) (*b*) Suppose that an organ pipe that is stopped at one end has a fundamental frequency of 200.0 Hz when the temperature is 20.00°C. Use the approximate result from Part (*a*) to determine the pipe's fundamental frequency when the temperature is 30.00°C. (*c*) Compare your Part (*b*) result to what you would get using exact calculations. (Ignore any change in the length of the pipe due to thermal expansion.) SSM

82 •• The pipe in Figure 16-36 is kept filled with natural gas [methane (CH_4)]. The pipe is punctured by a line of small holes 1.00 cm apart down its entire 2.20-m length. A speaker forms the closure on one end of the pipe, and a solid piece of metal closes the other end. What frequency is being played in this picture? The speed of sound in low-pressure methane at room temperature is about 460 m/s.

FIGURE 16-36 Problem 82 *(University of Michigan Demonstration Laboratory.)*

83 •• **CONTEXT-RICH** Assume that your clarinet is entirely filled with helium and that before you start to play you fill your lungs with helium. You pick up the clarinet and play it as though you were trying to play a B-flat, which has a frequency of 277 Hz. The frequency of 277 Hz is the natural resonance frequency of this clarinet with all finger holes closed and when filled with air. What frequency do you actually hear?

84 ••• A 2.00-m-long wire that is fixed at both ends is vibrating in its fundamental mode. The tension in the wire is 40.0 N and the mass of the wire is 0.100 kg. At the midpoint of the wire, the amplitude is 2.00 cm. (*a*) Find the maximum kinetic energy of the wire. (*b*) What is the kinetic energy of the wire at the instant the transverse displacement is given by $y = 0.0200 \sin(\frac{\pi}{2}x)$, where y is in meters if x is in meters, for $0.00\text{ m} \le x \le 2.00\text{ m}$? (*c*) For what value of x is the average value of the kinetic energy per unit length the greatest? (*d*) For what value of x does the elastic potential energy per unit length have its maximum value?

85 ••• **SPREADSHEET** In principle, a wave with almost any arbitrary shape can be expressed as a sum of harmonic waves of different frequencies. (*a*) Consider the function defined by

$$f(x) = \frac{4}{\pi}\left(\frac{\cos x}{1} - \frac{\cos 3x}{3} + \frac{\cos 5x}{5} - \cdots\right)$$
$$= \frac{4}{\pi}\sum_{n=0}^{\infty}(-1)^n\frac{\cos[(2n+1)x]}{2n+1}$$

Write a **spreadsheet program** to calculate this series using a finite number of terms, and make three graphs of the function in the range $x = 0$ to $x = 4\pi$. To create the first graph, for each value of x that you plot, approximate the sum from $n = 0$ to $n = \infty$ with the first term of the sum. To create the second and third graphs, use only the first five terms and the first ten terms, respectively. This function is sometimes called the *square wave*. (*b*) What is the relation between this function and Leibnitz's series for π,

$$\frac{\pi}{4} = 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \cdots$$ SSM

86 ••• **SPREADSHEET** Write a **spreadsheet program** to calculate and graph the function

$$y(x) = \frac{4}{\pi}\left(\sin x - \frac{\sin 3x}{9} + \frac{\sin 5x}{25} - \cdots\right)$$
$$= \frac{4}{\pi}\sum_{n}\frac{(-1)^n \sin(2n+1)x}{(2n+1)^2}$$

for $0 \le x \le 4\pi$. Use only the first 25 terms in the sum for each value of x that you plot.

87 ••• **SPREADSHEET** If you clap your hands at the end of a long, cylindrical tube, the echo you hear back will not sound like the handclap; instead, you will hear what sounds like a whistle, initially at a very high frequency, but descending rapidly down to almost nothing. This "culvert whistler" is easily explained if you think of the sound from the clap as a single compression radiating outward from the hands. The echoes of the handclap arriving at your ear have traveled along different paths through the tube, as shown in Figure 16-37. The first echo to arrive travels straight down and straight back along the tube, while the second echo reflects once off of the center of the tube going out, and again going back, the third echo reflects twice at points 1/4 and 3/4 of the distance, and so on. The tone of the sound you hear reflects the frequency at which these echoes reach your ears. (*a*) Show that the time delay between the nth echo and the $(n + 1)$th echo is

$$\Delta t_n = \frac{2}{v}\left(\sqrt{(2n)^2r^2 + L^2} - \sqrt{[2(n-1)]^2r^2 + L^2}\right)$$

where v is the speed of sound, L is the length of the tube, and r is the tube's radius. (*b*) Using a **spreadsheet program** or **graphing calculator**, graph Δt_n versus n for $L = 90.0$ m, $r = 1.00$ m. (These values are the approximate length and radius of the long tube in the San Francisco Exploratorium.) Go to at least $n = 100$. (*c*) From your graph, explain why the frequency decreases over time. What are the highest and lowest frequencies you will hear in the whistler?

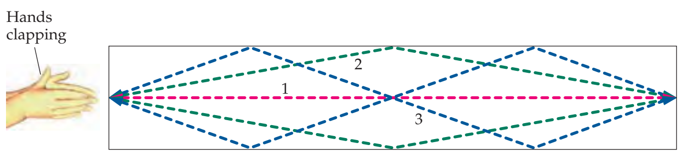

FIGURE 16-37 Problem 87

CHAPTER 17

WHEN BEN FRANKLIN WENT TO PARIS, HE SAW THE FIRST KNOWN MANNED HOT-AIR BALLOON FLIGHT. PEOPLE HAVE BEEN FLYING HOT-AIR BALLOONS EVER SINCE. *(Corbis.)*

Temperature and Kinetic Theory of Gases

? Why does the balloon rise when the air inside it is heated?
(See Example 17-7.)

Even very small children have a basic understanding of hot and cold, but what is temperature? What is it a measurement of? In Chapter 17, we begin our study of temperature.

A pilot, a hot air balloonist, and a scuba diver must all have a good working understanding of air and water temperatures as they plan their flights and dives. Pilots and balloonists need to be aware of how changes in air temperature affect air density as well as wind patterns. Scuba divers know that changes in body temperature affect how much air they will use over the course of a dive. They also understand the importance of equalizing the pressure on their bodies and the gases within their bodies. For the diver, the pilot, and the balloonist, the importance of how gases behave in relation to temperature is vital. Thus, we begin our study of thermodynamics with a discussion of temperature and an examination of the ideal-gas law.

In this chapter, we show that a consistent temperature scale can be defined in terms of the properties of gases that have low densities, and that temperature is a measure of the average internal molecular kinetic energy of an object.

17-1 THERMAL EQUILIBRIUM AND TEMPERATURE

Our sense of touch can usually tell us if an object is hot or cold. We know that to make a cold object warmer, we can place it in contact with a hot object, and to make a hot object cooler, we can place it in contact with a cold object.

When an object is heated or cooled, some of its physical properties change. If a solid or liquid is heated, its volume usually increases. If a gas is heated and its pressure is kept constant, its volume increases. However, if a gas is heated and its volume is kept constant, its pressure increases. If an electrical conductor is heated, its electrical resistance changes. (This property is discussed in Chapter 25.) A physical property that changes with temperature is called a **thermometric property.** A change in a thermometric property indicates a change in the temperature of the object.

Suppose that we place a warm copper bar in close contact with a cold iron bar so that the copper bar cools and the iron bar warms. We say that the two bars are in **thermal contact.** The copper bar contracts slightly as it cools, and the iron bar expands slightly as it warms. This process eventually stops and the lengths of the bars remain constant. The two bars are then in **thermal equilibrium** with each other.

Suppose instead that we place the warm copper bar in a cool running stream of water. The bar cools until it stops contracting, at the point at which the bar and the water are in thermal equilibrium. Next, we place a cold iron bar in the stream, near but not touching the copper bar. The iron bar will warm until the iron bar and the water are also in thermal equilibrium. If we remove the bars and place them in thermal contact with each other, we find that their lengths do not change. They are in thermal equilibrium with each other. Although it is common sense, there is no logical way to deduce this fact, which is called the **zeroth law of thermodynamics** (Figure 17-1):

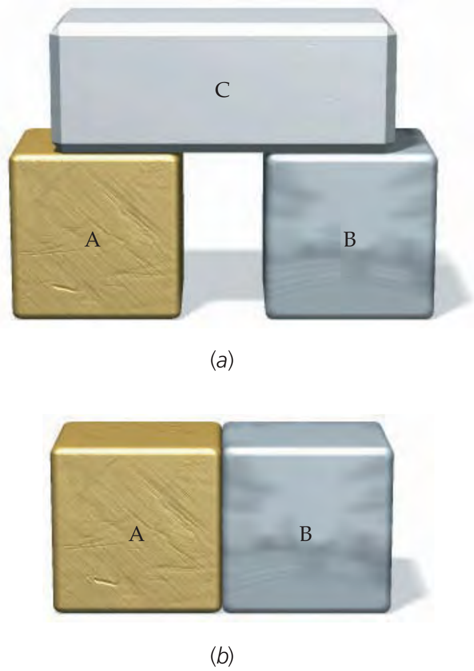

FIGURE 17-1 The zeroth law of thermodynamics. (*a*) Systems A and B are in thermal contact with system C, but not with each other. When A and B are each in thermal equilibrium with C, they are in thermal equilibrium with each other, which can be checked by placing them in contact with each other as in Part (*b*).

> If two objects are in thermal equilibrium with a third object, then all three of the objects are in thermal equilibrium with each other.
>
> ZEROTH LAW OF THERMODYNAMICS

Two objects are defined to have the same *temperature* if they are in thermal equilibrium with each other. The zeroth law, as we will see, enables us to define a temperature scale.

THE CENTIGRADE AND FAHRENHEIT TEMPERATURE SCALES

Any thermometric property can be used to establish a temperature scale. The common mercury thermometer consists of a glass bulb and tube containing a fixed amount of mercury.* When this thermometer is put in contact with a warmer object, the mercury expands, increasing the length of the mercury column (the glass expands too, but by a negligible amount). We can create a scale along the glass tube by using the following procedure. First, the thermometer is placed in ice and water in equilibrium† at a pressure of 1 atm. When the thermometer is in thermal equilibrium with the ice water, the top of the mercury column is marked on the glass tube. This mark represents the **ice-point** temperature (also called the **normal freezing point** of water). Next, the thermometer is placed in boiling water at a pressure

* Mercury is highly toxic. Today, alcohol is commonly used in thermometers.

† Water and ice in equilibrium provide a constant-temperature bath. When ice is placed in warm water, the water cools as some of the ice melts. Thermal equilibrium is eventually reached and no more ice melts. If the water/ice system is heated slightly, some more of the ice melts, but the temperature of the system does not change as long as some ice remains.

of 1 atm. When the thermometer is in thermal equilibrium with the boiling water, the top of the mercury column is marked. This mark represents the **steam-point temperature** (also called the **normal boiling point** of water).

The **centigrade temperature scale** defines the ice-point temperature as zero degrees centigrade (0°C) and the steam-point temperature as 100°C. The space between the 0-degree and 100-degree marks is divided into 100 equal intervals (degrees). Degree markings are also extended below and above these points. If L_t is the length of the mercury column, the centigrade temperature t_C is given by

$$t_C = \frac{L_t - L_0}{L_{100} - L_0} \times 100° \qquad 17\text{-}1$$

where L_0 is the length of the mercury column when the thermometer is in an ice bath and L_{100} is its length when the thermometer is in a steam bath. The normal temperature of the human body measured on the centigrade scale is about 37°C.

A shortcoming of the centigrade scale is that it depends on the thermometric property of some material, such as mercury. An improvement is the Celsius scale, discussed in Section 17-2, which is in close agreement with the centigrade scale. (So close is the agreement between these two scales that many refer to the Celsius scale as the centigrade scale.)

Historically, the **Fahrenheit temperature scale** (which is widely used in the United States) defines the ice-point temperature as 32°F and the steam-point temperature as 212°F.* To convert temperatures between Fahrenheit and centigrade scales, we note there are 100 centigrade degrees and 180 Fahrenheit degrees between the ice and steam points. A temperature change of one centigrade degree therefore equals a change of 1.8 = 9/5 Fahrenheit degrees. To convert a temperature from one scale to the other, we must also take into account the fact that the zero temperatures of the two scales are not the same. The general relation between a Fahrenheit temperature t_F and centigrade temperature t_C is

$$t_C = \tfrac{5}{9}(t_F - 32°) \qquad (\text{or } t_F = \tfrac{9}{5}t_C + 32°) \qquad 17\text{-}2$$

FAHRENHEIT–CENTIGRADE CONVERSION

Today, we define the Fahrenheit scale using Equation 17-2, with t_C the *Celsius* temperature.

Example 17-1 Converting Fahrenheit and Celsius Temperatures

Vivian measures her ill six-month old son's temperature with a Celsius thermometer and finds it to be 40.0°C. She then telephone's the doctor for advice. When she gives the doctor the baby's temperature, the doctor asks, "What is that in Fahrenheit?" She does the conversion using Equation 17-2 and says "102°F." Did she convert from Celsius to Fahrenheit correctly?

PICTURE Solve for t_F by using $t_C = \frac{5}{9}(t_F - 32°)$ (Equation 17-2), where $t_C = 40.0°$.

SOLVE

1. Solve $t_C = \frac{5}{9}(t_F - 32°)$ (Equation 17-2) for t_F in terms of t_C: $t_F = \frac{9}{5}t_C + 32°$
2. Substitute $t_C = 40.0°\text{C}$: $t_F = \frac{9}{5}(40.0°) + 32° = \boxed{104°\text{F}}$

   Vivian's estimate is off by 2°F.

CHECK The temperature of 40°C is 0.4 of the way between 0°C and 100°C, and the temperature of 72°F is 0.4 of the way between 0°F and 180°F. Thus, we expect the Fahrenheit temperature to be 72°F + 32°F = 104°F, which verifies our step-2 result.

PRACTICE PROBLEM 17-1 (*a*) Find the Celsius temperature equivalent to 68°F. (*b*) Find the Fahrenheit temperature equivalent to −40°C.

* When the German physicist Daniel Fahrenheit devised his temperature scale, he wanted all measurable temperatures to be positive. He originally chose 0°F for the coldest temperature he could obtain with a mixture of ice and salt water and 96°F (a convenient number with many factors for subdivision) for the temperature of the human body. He then modified his scale slightly to make the ice-point and steam-point temperatures whole numbers. This modification resulted in the average temperature of the human body being between 98° and 99°F.

Other thermometric properties can be used to set up thermometers and construct temperature scales. Figure 17-2 shows a bimetallic strip consisting of two different metals bonded together. When the strip is heated or cooled, it bends to accommodate the difference in the thermal expansion of the two metals. Figure 17-3 shows a thermometer consisting of a bimetallic coil with a pointer attached to indicate the temperature. When the thermometer is heated, the coil bends and the pointer moves. Like mercury thermometers, it is calibrated by dividing the interval between the ice point and the steam point into 100 centigrade degrees (or 180 Fahrenheit degrees).

FIGURE 17-2 A bimetallic strip. When heated or cooled, the two metals expand or contract by different amounts, causing the strip to bend.

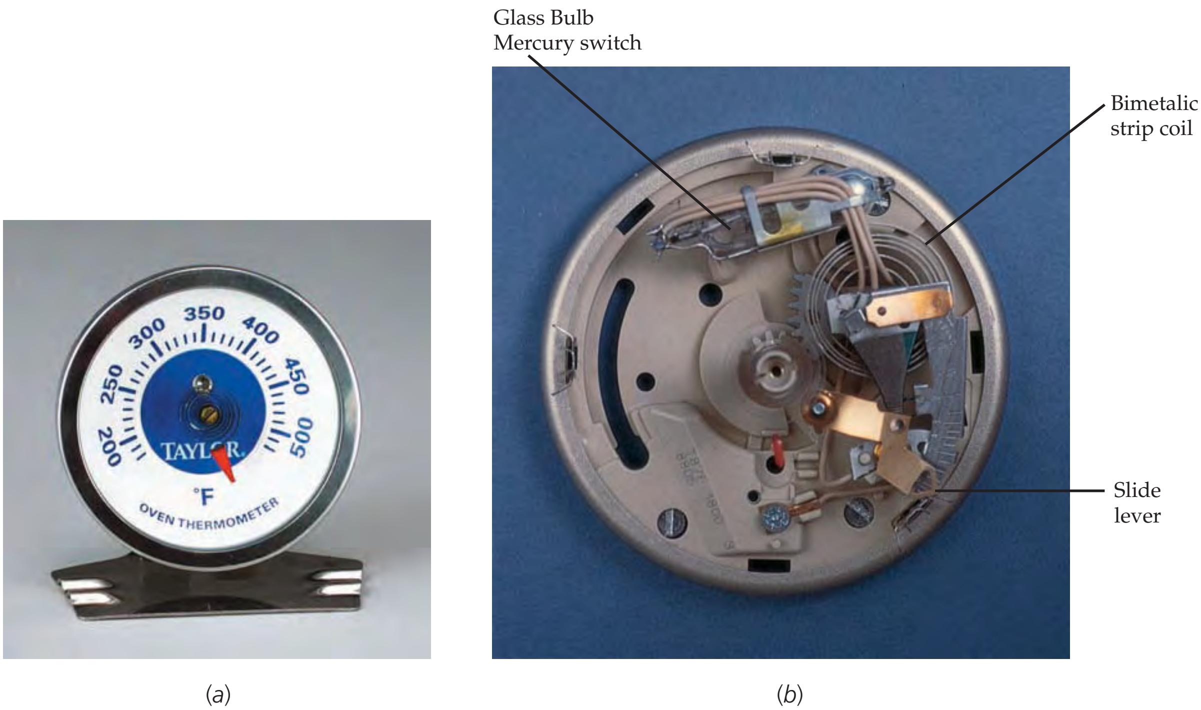

FIGURE 17-3 (*a*) A thermometer using a bimetallic strip in the form of a coil. (The red pointer is attached to one end of the coil.) When the temperature of the coil increases, the needle rotates clockwise because the outer metal expands more than the inner metal. (*b*) A home thermostat controls the central air conditioner. When the air gets warmer, the coil expands, the glass bulb mounted on it tilts, and mercury in the tube slides to close an electrical switch, turning on the air conditioning. A slide lever (at the lower right), used to rotate the coil mount, is used to set the desired temperature. The circuit will be broken when the cooler air causes the bimetallic coil to contract. *((a) Courtesy of Taylor Precision Products. (b) Richard Menga/Fundamental Photographs.)*

17-2 GAS THERMOMETERS AND THE ABSOLUTE TEMPERATURE SCALE

When different types of centigrade thermometers are calibrated in ice water and steam, they agree (by definition) at 0°C and 100°C, but they give slightly different readings at points in between. Discrepancies increase markedly above the steam point and below the ice point. However, in one group of thermometers, gas thermometers, measured temperatures agree closely with each other, even far from the calibration points. In a **constant-volume gas thermometer,** the gas volume is kept constant, and change in gas pressure is used to indicate a change in temperature (Figure 17-4). An ice-point pressure P_0 and steam-point pressure P_{100} are determined by placing the thermometer in ice–water and water–steam baths, and the interval between them is divided into 100 equal degrees (for the centigrade scale). If the pressure is P_t in a bath whose temperature is to be determined, that temperature in degrees centigrade is defined to be

$$t_C = \frac{P_t - P_0}{P_{100} - P_0} \times 100°C \qquad 17\text{-}3$$

CONSTANT-VOLUME CENTIGRADE GAS THERMOMETER

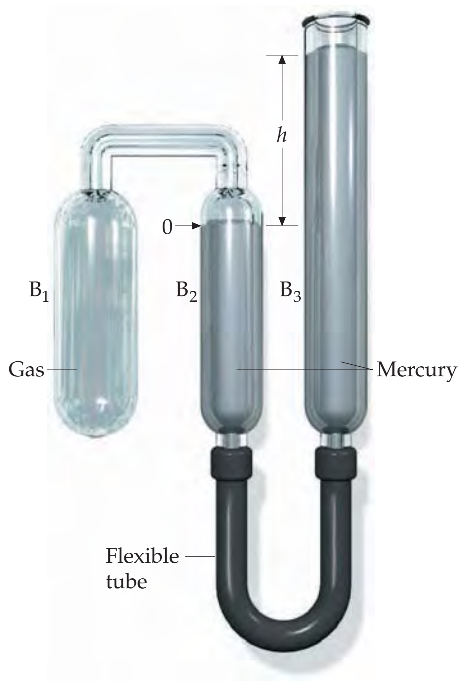

FIGURE 17-4 A constant-volume gas thermometer. The volume is kept constant by raising or lowering tube B_3 so that the mercury in tube B_2 remains at the zero mark. The temperature is chosen to be proportional to the pressure of the gas in tube B_1, which is indicated by the height h of the mercury column in tube B_3.

Suppose we measure a specific temperature, say the boiling point of sulfur at 1-atm pressure, using four constant-volume gas thermometers, each containing one of four gases: air, hydrogen, nitrogen, or oxygen. The thermometers are calibrated, meaning values for P_{100} and P_0 are determined for each. Each thermometer is then immersed in boiling sulfur, and when it is in thermal equilibrium with the sulfur, the pressure in the thermometer is measured. Next, the temperature is calculated using Equation 17-3. Will this process give the same result for each of the four thermometers? Surprisingly perhaps, the answer is yes. All four thermometers measure the same temperature as long as the density of the gas in each is sufficiently low.

One measure of the density of the gas in the thermometer is its pressure at the steam point, P_{100}. If we vary the amount of gas in a constant-volume gas thermometer, by either adding or removing gas, we change both P_{100} and P_0. As a result, each time the amount of gas is varied, the thermometer must be recalibrated. Figure 17-5 shows the results of measurements of the boiling point of sulfur using four constant-volume gas thermometers, each filled with air, hydrogen, nitrogen, or oxygen. For each thermometer the measured temperature is plotted as a function of the steam-point pressure P_{100} of the thermometer. As the amount of a gas is reduced, its density and the steam-point pressure both decrease. We see that when low densities of gas are used (small P_{100}), the thermometers are in close agreement. In the limit as gas density approaches zero, all gas thermometers give the same value for the temperature of boiling sulfur. This low-density temperature measurement is independent of the properties of any particular gas. Of course, there is nothing special about the boiling point of sulfur. Constant-volume gas thermometers that have low densities of gas are in agreement at any temperature. Thus, constant-volume gas thermometers that contain low densities of gas can be used to define temperature.

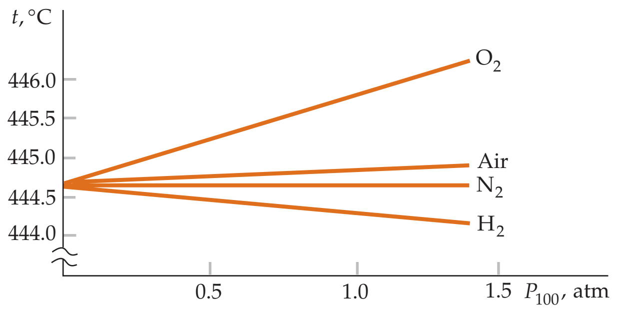

FIGURE 17-5 Temperature of the boiling point of sulfur measured with constant-volume gas thermometers filled with various gases. Increasing or decreasing the amount of gas in the thermometer varies the pressure P_{100} at the steam point of water. As the amount of gas is reduced, the temperature of the boiling point of sulfur measured by all the thermometers approaches the value 444.60°C. Note that the temperature axis shows a range of temperatures from 444°C to 446°C.

Now consider a series of temperature measurements using a constant-volume gas thermometer that has a very small but fixed amount of gas. According to Equation 17-3, the pressure in the thermometer P_t varies linearly with the measured temperature t_C. Figure 17-6 shows a plot of gas pressure versus measured

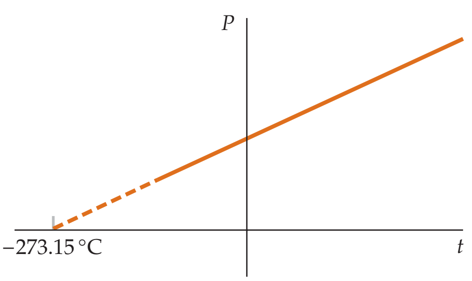

FIGURE 17-6 Plot of pressure versus temperature for a gas, as measured by a constant-volume gas thermometer. When extrapolated to zero pressure, the plot intersects the temperature axis at the value −273.15°C.

temperature in a constant-volume gas thermometer. When we extrapolate this straight line to zero gas pressure, the temperature approaches −273.15°C. This limit is the same no matter what kind of gas is used.

A reference state that is much more precisely reproducible than either the ice or steam points is the **triple point of water**—the unique temperature and pressure at which water, water vapor, and ice coexist in equilibrium (see Figure 17-7). This equilibrium state occurs at 4.58 mmHg and 0.01°C. The **ideal-gas temperature scale** is defined so that the temperature of the triple-point state is 273.16 kelvins (K). The temperature T of any other state is defined to be proportional to the pressure in a constant-volume gas thermometer:

FIGURE 17-7 Water at its triple point. The spherical flask contains liquid water, ice, and water vapor in thermal equilibrium. *(Richard Menga/Fundamental Photographs.)*

$$T = \frac{P}{P_3}T_3 \qquad \text{17-4}$$

CONSTANT-VOLUME IDEAL-GAS–TEMPERATURE THERMOMETER

where P is the observed pressure of the gas in the thermometer, P_3 is the pressure when the thermometer is immersed in a water–ice–vapor bath at its triple point, and T_3 = 273.16 K (the triple-point temperature). The value of P_3 depends on the amount of gas in the thermometer.

The Celsius degree is a degree unit that is the same size as the kelvin, but the zero point of the **Celsius scale** differs from the zero point of the ideal-gas temperature scale. By definition, zero on the Celsius scale corresponds to an ideal-gas temperature of exactly 273.15 K.

The lowest temperature that can be measured with a constant-volume gas thermometer is about 20 K, and requires helium for the gas. Below this temperature helium liquefies; all other gases liquefy at higher temperatures (Table 17-1). In Chapter 19, we see that the second law of thermodynamics can be used to define the **absolute temperature scale** independent of the properties of any substance, and with no limitations on the range of temperatures that can be measured. Temperatures as low as 10^{-10} kelvin have been measured. The absolute scale so defined is identical to that defined by Equation 17-4 for the range of temperatures for which gas thermometers can be used. The symbol T is used when referring to absolute temperature.

Because the Celsius degree and the kelvin are the same size, temperature *differences* are the same on both the Celsius scale and the absolute temperature scale (also called the **Kelvin scale**). That is, a temperature *change* of 1 K is identical to a temperature *change* of 1°C. The two scales differ only in the choice of zero temperature. To convert from degrees Celsius to kelvins, we merely add 273.15:*

$$T = t_C + 273.15\text{ K} \qquad \text{17-5}$$

CELSIUS–ABSOLUTE CONVERSION

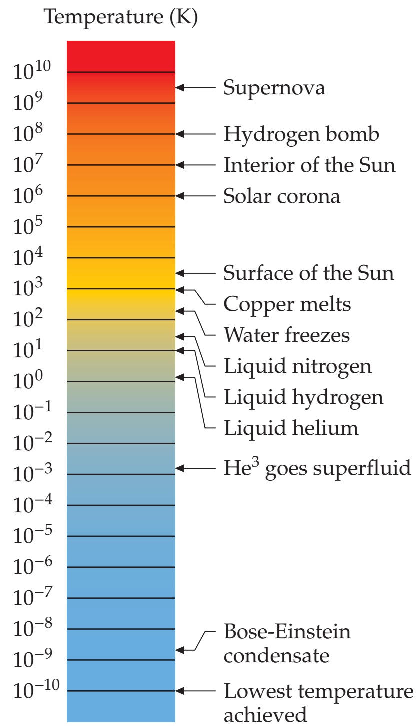
Although the Celsius and Fahrenheit scales are convenient for everyday use, the absolute scale is much more convenient for scientific purposes, partly because many formulas are more simply expressed using it, and partly because the absolute temperature can be given a fundamental interpretation.

* For most purposes, we can round off the temperature of absolute zero to −273°C.

! The ideal-gas temperature scale, defined by Equation 17-4, has the advantage that any measured temperature does not depend on the properties of the particular gas that is used, but depends only on the general properties of gases.

! Note that the SI temperature unit, the kelvin, is not a degree and is not accompanied by a degree symbol.

Table 17-1 The Temperatures of Various Places and Phenomena



Example 17-2 Converting from Kelvin to Fahrenheit

The "high-temperature" superconductor $YBa_2Cu_3O_7$ becomes superconducting when the temperature is decreased to 92 K. Find the superconducting threshold temperature in degrees Fahrenheit.

PICTURE First, convert to degrees Celsius, then to kelvins.

SOLVE

1. Convert from kelvins to degrees Celsius:

$$T = t_C + 273.15$$

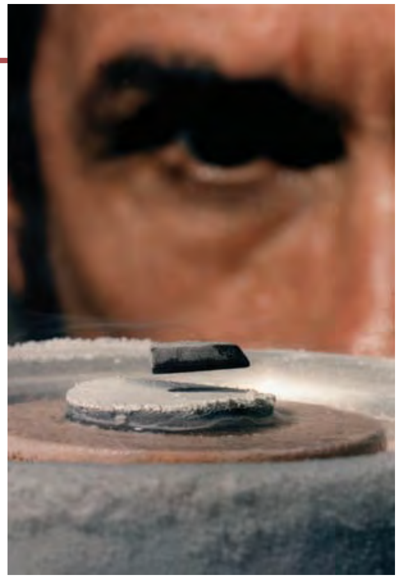
so $92 = t_C + 273.15 \Rightarrow t_C = -181.15°\text{C}$

2. To find the Fahrenheit temperature we use $t_C = \frac{5}{9}(t_F - 32°)$ (Equation 17-2):

$$t_C = \tfrac{5}{9}(t_F - 32°)$$

so $-181.15° = \frac{5}{9}(t_F - 32°) \Rightarrow t_F = \boxed{-294°\text{F}}$

CHECK A temperature of 92 K is closer to 0 K than it is to 273 K, so we should expect the Fahrenheit temperature to be considerably less than 32°F. Our result meets this expectation.



(U.S. Dept. of Energy.)

17-3 THE IDEAL-GAS LAW

The properties of gas samples that have low densities led to the definition of the ideal-gas temperature scale. If we compress such a gas while keeping its temperature constant, the pressure increases. Similarly, if a gas expands at constant temperature, its pressure decreases. To a good approximation, the product of the pressure and volume of a gas sample that has a low density is constant at a constant temperature. This result was discovered experimentally by Robert Boyle (1627–1691), and is known as **Boyle's law:**

$$PV = \text{constant} \qquad \text{(constant temperature)}$$

See Math Tutorial for more information on Direct and Inverse Proportions

A more general law exists that reproduces Boyle's law as a special case. According to Equation 17-4, the absolute temperature of a gas sample that has a low density is proportional to its pressure at constant volume. In addition, the absolute temperature of a gas sample that has a low density is proportional to its volume at constant pressure. This result was discovered experimentally by Jacques Charles (1746–1823) and Joseph Gay-Lussac (1778–1850). We can combine these two results by stating

$$PV = CT \tag{17-6}$$

where C is a constant that has positive value. We can see that this constant is proportional to the number of molecules of the gas sample by considering the following. Suppose that we have two containers that have identical volumes, each holding the same amount of the same kind of gas at the same temperature and pressure. If we consider the two containers as one system, we have twice the amount of gas at twice the volume, but at the same temperature and pressure. We have thus doubled the quantity $PV/T = C$ by doubling the amount of gas. We can therefore write C as a constant k times the number N of molecules in the gas:

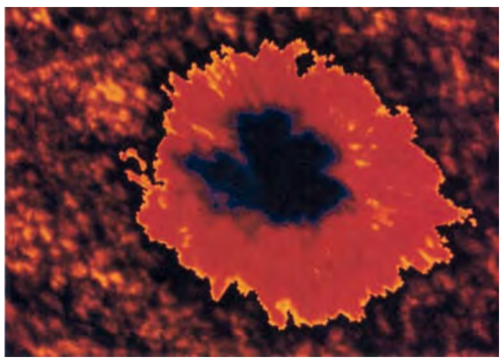
$$C = kN$$

Equation 17-6 then becomes

$$PV = NkT \tag{17-7}$$

The constant k is called **Boltzmann's constant.** It is found experimentally to have the same value for any kind of gas:

$$k = 1.381 \times 10^{-23}\ \text{J/K} = 8.617 \times 10^{-5}\ \text{eV/K} \tag{17-8}$$



Sunspots appear on the surface of the Sun when streams of gases slowly erupt from deep inside the star. The solar "flower" is 10,000 miles in diameter. The temperature variation, indicated by computer-enhanced color changes, is not fully understood. The central portion of the sunspot is cooler than the outer regions, as indicated by the dark area. The temperature at the Sun's core is of the order of 10^7 K, whereas at the surface the temperature is only about 6000 K. *(NASA.)*

An amount of gas is often expressed in moles. A **mole** (mol) of any substance is the amount of that substance that contains **Avogadro's number,** N_A, of particles (such as atoms or molecules). Avogadro's number is defined as the number of carbon atoms in exactly 12 g (1 mol) of ^{12}C:

$$N_A = 6.022 \times 10^{23}\ \text{mol}^{-1} \qquad 17\text{-}9$$

AVOGADRO'S NUMBER

If we have n moles of a substance, then the number of molecules is

$$N = nN_A \qquad 17\text{-}10$$

Equation 17-7 is then

$$PV = nN_AkT = nRT \qquad 17\text{-}11$$

where $R = N_Ak$ is called the **universal gas constant.** Its value, which is the same for all gases, is

$$R = N_Ak = 8.314\ \text{J/(mol}\cdot\text{K)} = 0.08206\ \text{L}\cdot\text{atm/(mol}\cdot\text{K)} \qquad 17\text{-}12$$

Figure 17-8 shows plots of $PV/(nT)$ versus the pressure P for several gases. For all gases, $PV/(nT)$ is nearly constant over a large range of pressures. Even oxygen, which varies the most in this graph, changes by only about 1 percent between 0 and 5 atm. An **ideal gas** is defined as a gas for which $PV/(nT)$ is constant for all pressures. The pressure, volume, and temperature of an ideal gas are related by

$$PV = nRT \qquad 17\text{-}13$$

IDEAL-GAS LAW

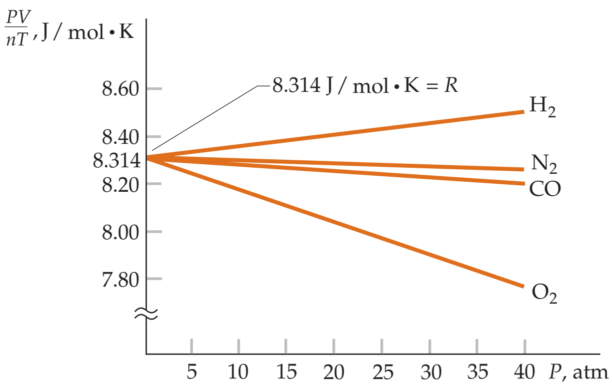


FIGURE 17-8 Plot of PV/nT versus P for real gases. In these plots, varying the amount of gas varies the pressure. The ratio PV/nT approaches the same value, 8.314 J/(mol · K), for all gases as we reduce their densities, and thereby their pressures, of the gases. This value is the universal gas constant R.

Equation 17-13, which relates the variables P, V, and T, is known as the ideal-gas law, and is an example of an **equation of state.** It can describe the properties of real gases that have low densities (and therefore low pressures). Corrections must be made to this equation if higher densities of gases are used. In Chapter 20, we discuss another equation of state, the van der Waals equation, which includes such corrections. For any density of gas, there is an equation of state relating P, V, and T for a given amount of gas. Thus, the state of a given amount of gas is completely specified by knowledge of any two of the three **state variables** P, V, and T.

PARTIAL PRESSURES

Dry air is about 21 percent oxygen and 79 percent nitrogen. Scuba divers often use oxygen-enriched air (called nitrox) because it extends the length of time for a dive. For very deep dives, a mixture of oxygen and helium (called heliox) is used because this mixture reduces the chance that a diver will suffer from nitrogen narcosis.

If we have a confined mixture of two or more gases, and if the mixture is sufficiently dilute (so each gas can be modeled as an ideal gas), then we can think of each gas as occupying the entire volume of the container. This is because the volume of the individual molecules of the gas is negligible compared to the volume of the empty space surrounding them. The total pressure exerted by the mixture is the sum of the individual pressures, called **partial pressures,** exerted by each of the individual gases in the mixture. Furthermore, the partial pressure of each gas in the mixture is the pressure it would exert if it alone occupied the container. This result—the total pressure is the sum of the partial pressures—is called the **law of partial pressures.**

PROBLEM-SOLVING STRATEGY

Dilute Gases

PICTURE A dilute gas is one for which the ideal-gas model gives sufficiently accurate results. The variables are pressure, volume, temperature, mass, and/or the amount of substance (number of moles).

SOLVE

1. Apply the ideal-gas law, $PV = nRT$, to each dilute gas. Be sure to use the absolute temperature and the absolute pressure.
2. For a mixture of dilute gases, the ideal-gas law applies to each gas in the mixture, the volume of each gas in the mixture is the volume of the container, and the pressure of each gas is the partial pressure of that gas. The pressure of the mixture is the sum of the partial pressures of the constituent gases.
3. Additional useful relations are $R = N_A k$, $N = nN_A$, and $m = nM$, where k is the Boltzmann constant, N is the number of molecules, m is the mass of the gas, and M is the molar mass.
4. Solve for the desired quantity.

CHECK The pressure, volume, and temperature can never be negative.

Example 17-3 Mixing the Gases

A 20-L tank of oxygen is at a pressure of $0.30P_{at}$, and a 30-L tank of nitrogen is at a pressure of $0.60P_{at}$. The temperature of each gas is 300 K. The oxygen is then transferred into the 30-L tank containing the nitrogen, where the two mix. What is the pressure of the mixture if its temperature is 300 K?

PICTURE The final volume of both gases is 30 L. The initial temperatures of both gases are equal. Thus, we can use Boyle's law ($P_iV_i = P_fV_f$) to find the partial pressure of each gas in the mixture. Then, we use the law of partial pressures to find the pressure of the mixture.

SOLVE

1. The pressure of the mixture is the sum of the partial pressures of the two gases:

$$P = P_{O_2} + P_{N_2}$$

2. The initial and final temperatures of the gases are the same. So, by using Boyle's law, we find the partial pressures of the gases:

$$P_iV_i = P_fV_f \Rightarrow P_f = \frac{V_i}{V_f}P_i$$

3. The final volume of the oxygen is 30 L (as is the final volume of the nitrogen):

$$P_{O_2} = \frac{V_i}{V_f}P_i = \frac{20\text{ L}}{30\text{ L}}0.30P_{at} = 0.20P_{at}$$

$$P_{N_2} = \frac{V_i}{V_f}P_i = \frac{30\text{ L}}{30\text{ L}}0.60P_{at} = 0.60P_{at}$$

4. The pressure is the sum of the partial pressures:

$$P = P_{O_2} + P_{N_2} = 0.20P_{at} + 0.60P_{at} = \boxed{0.80P_{at}}$$

CHECK We expect an increase in pressure in the 30-L tank when the oxygen is transferred into it. This expectation is met with our final result ($0.80P_{at}$ represents an increase in pressure of $0.20P_{at}$).

Example 17-4 Volume of an Ideal Gas

What volume is occupied by 1.00 mol of an ideal gas at a temperature of 0.00°C and a pressure of 1.00 atm?

PICTURE Use the ideal-gas law to determine the volume occupied by the ideal gas.

SOLVE

We can find the volume using the ideal-gas law, with $T = 273$ K:

$$V = \frac{nRT}{P} = \frac{(1.00\text{ mol})[0.0821\text{ L}\cdot\text{atm/(mol}\cdot\text{K)}](273.15\text{ K})}{1.00\text{ atm}} = \boxed{22.4\text{ L}}$$

CHECK Note that by writing R in L·atm/(mol·K), we can write P in atmospheres to get V in liters.

PRACTICE PROBLEM 17-2 Find (*a*) the number of moles n, and (*b*) the number of molecules N in 1.00 cm^3 of a gas at 0.00°C and 1.00 atm.

CONCEPT CHECK 17-1

Two identically sized dorm rooms in a suite, Toni's and Keisha's, are connected by an open door. Toni's room, which is air-conditioned, is 5.0°C cooler than Keisha's room. Whose room has more air in it?

The temperature of 0°C = 273.15 K and the pressure of 1 atm are often referred to as **standard temperature and pressure (STP),** or just **standard conditions.** We see from Example 17-4 that under standard conditions, 1 mol of an ideal gas occupies a volume of 22.4 L.

Figure 17-9 shows plots of P versus V at several constant temperatures T. These curves are called **isotherms.** The isotherms for an ideal gas are hyperbolas. For a fixed amount of gas, we can see from the ideal-gas law (Equation 17-13) that the quantity PV/T is constant. Using the subscripts 1 for the initial values and 2 for the final values, we have

$$\frac{P_2V_2}{T_2} = \frac{P_1V_1}{T_1} \qquad 17\text{-}14$$

IDEAL-GAS LAW FOR FIXED AMOUNT OF GAS

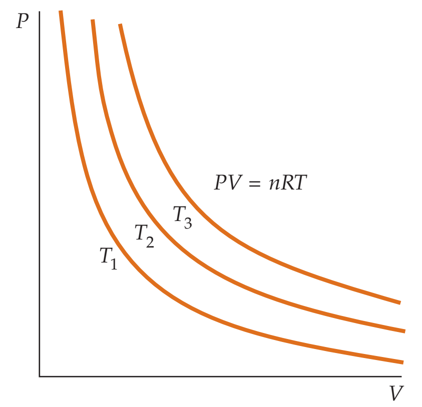

FIGURE 17-9 Isotherms on the PV diagram for a gas. For an ideal gas, these curves are hyperbolas given by $PV = nRT$. (The generic equation for a hyperbola that asymptotically approaches the coordinate axes is xy = constant.)

Example 17-5 Heating and Compressing a Gas

A gas has a volume of 2.00 L, a temperature of 30.0°C, and a pressure of 1.00 atm. When the gas is heated to 60.0°C and compressed to a volume of 1.50 L, what is its new pressure?

PICTURE Because the amount of gas is fixed, the pressure can be found using Equation 17-14. Let subscripts 1 and 2 refer to the initial and final states, respectively.

SOLVE

1. Express the pressure P_2 in terms of P_1 and the initial and final volumes and temperatures:

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2}$$
$$P_2 = \frac{T_2V_1}{T_1V_2}P_1$$

2. Calculate the initial and final absolute temperatures:

$$T_1 = 273.15 + 30.0 = 303.15\text{ K}$$
$$T_2 = 273.15 + 60.0 = 333.15\text{ K}$$

3. Substitute numerical values in step 1 to find P_2:

$$P_2 = \frac{(333.15\text{ K})(2.00\text{ L})}{(303.15\text{ K})(1.50\text{ L})}(1.00\text{ atm}) = \boxed{1.47\text{ atm}}$$

CHECK Heating a gas and compressing a gas each tend to increase the pressure. Thus, we expect the pressure to exceed the starting pressure of 1.00 atm. Our result of 1.47 atm meets this expectation.

PRACTICE PROBLEM 17-3 How many moles of gas are in the system described in this example?

The mass per mole of a substance is called its **molar mass,** M. (The terms *molecular weight or molecular mass* are also sometimes used.) The molar mass of ^{12}C is, by definition, 12 g/mol or 0.012 kg/mol. Molar masses of the elements are given in Appendix C. The molar mass of an element represents the average of the molar masses of the isotopes of that element—with the average weighted by the relative abundance of those isotopes on Earth. The molar mass of a compound such as CO_2 is the sum of the molar masses of the elements in the molecule. The molar mass of carbon is 12.011 g/mol and the molar mass of oxygen is 15.999 g/mol. Thus, the molar mass of CO_2 is 12.011 g/mol + 2 × 15.999 g/mol = 44.009 g/mol.

CONCEPT CHECK 17-2

If the temperature is decreased at constant pressure, what happens to the volume?

Example 17-6 The Mass of a Hydrogen Atom

The molar mass of hydrogen is 1.008 g/mol. What is the average mass of a hydrogen atom in a glass of H_2O (water)?

PICTURE Let m be the mass of a hydrogen atom. Because there are N_A hydrogen atoms in a mole of hydrogen, the molar mass M is given by $M = mN_A$. We can use this to solve for m.

SOLVE

The average mass of a hydrogen atom is the molar mass divided by Avogadro's number:

$$m = \frac{M}{N_A} = \frac{1.008\ \text{g/mol}}{6.022 \times 10^{23}\ \text{atoms/mol}} = \boxed{1.674 \times 10^{-24}\ \text{g/atom}}$$

CHECK The calculated mass of the hydrogen atom is, as expected, many many orders of magnitude less than the molar mass of about 1 g/atom.

TAKING IT FURTHER The three isotopes of hydrogen are protium ^1H, deuterium ^2H, and tritium ^3H. The relative abundance of ^1H in naturally occurring hydrogen is 99.985%.

Example 17-7 Floating a Hot-Air Balloon

A small hot-air balloon has a volume of 15.0 m^3 and is open at the bottom. The air inside the balloon is at an average temperature of 75°C, while the air next to the balloon has a temperature of 24°C, and a pressure, on average, of 1.00 atm. The balloon is tethered to prevent it from rising, and the tension in the tether is 10.0 N. Use 0.0290 kg/mol for the molar mass of air. (Neglect the gravitational force on the fabric of the balloon.) What is the pressure, on average, inside the balloon?

PICTURE Three forces act on the balloon and its contents, the buoyant force of the surrounding air, the tension force of the tether, and the gravitational force of Earth. The net force is the sum of these three forces. The buoyant force is equal to the weight of the displaced air (Archimedes' principle). The pressure, temperature, and volume of the gas are related by $PV = nRT$. The mass m of the air is equal to the number of moles n times the molar mass M of air.

SOLVE

(*a*) 1. The net force on the system (the balloon and air inside it) is zero. Sketch a free-body diagram (Figure 17-10) of the system:

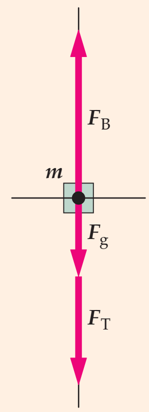

FIGURE 17-10

2. Apply Newton's second law to the system.

$$\Sigma\vec{F} = m\vec{a}$$
$$\vec{F}_T + \vec{F}_B + \vec{F}_g = 0 \Rightarrow F_B = F_T + F_g$$

3. The buoyant force is equal to the weight of a volume V of the air next to the balloon, where V is the volume of the air inside the balloon. Let ρ_1 be the average density of the air next to the balloon, and let ρ_2 be the average density of the air within the balloon:

$$F_B = \rho_1 V g$$
$$F_g = \rho_2 V g$$

4. Substitute from step 2 into the step-1 result:

$$F_T = F_B - F_g$$
$$F_T = \rho_1 V g - \rho_2 V g = (\rho_1 - \rho_2)Vg$$

5. The mass of a sample of air in the balloon is the number of moles n times the molar mass M of air:

$$\rho_1 = \frac{m_1}{V} = \frac{n_1 M}{V}$$

$$\rho_2 = \frac{m_2}{V} = \frac{n_2 M}{V}$$

6. Substitute from step 4 into the step-3 result:

$$F_T = \left(\frac{n_1 M}{V} - \frac{n_2 M}{V}\right)Vg \Rightarrow \frac{F_T}{Mg} = n_1 - n_2$$

7. Using the ideal-gas law ($PV = nRT$), substitute for n_1 and n_2:

$$\frac{F_T}{Mg} = \frac{P_1 V}{RT_1} - \frac{P_2 V}{RT_2}$$

8. Solve for P_2:

$$P_2 = \left(\frac{P_1}{T_1} - \frac{F_T R}{MgV}\right)T_2$$

9. Solve for the value of P_2. The temperature in kelvins equals 273 plus the temperature in degrees Celsius, 1 atm = 101.3 kPa and $R = 8.314\ \mathrm{J/(mol \cdot K)}$:

$$P_2 = \left(\frac{1.013 \times 10^5}{297} - \frac{10.0 \times 8.314}{0.0290 \times 9.81 \times 15.0}\right)348$$

$$= \boxed{1.12 \times 10^5\ \mathrm{Pa}} = \boxed{1.10\ \mathrm{atm}}$$

CHECK To produce a net upward force on the fabric of the balloon, the air inside the balloon must be at a higher pressure than the air outside the balloon. Thus, our result of 1.10 atm for the average pressure inside the balloon is plausible.

TAKING IT FURTHER The pressure at the opening at the bottom of the balloon is the same as the pressure in the surrounding air at that altitude. In a static fluid, the pressure decreases with increasing altitude, and the greater the density of the fluid, the greater the rate of decrease in pressure with altitude. The air inside the balloon is less dense than the outside air. Thus, inside the balloon the pressure decrease from the opening to the top of the balloon is less in the air inside the balloon than it is in the air adjacent to the balloon.

17-4 THE KINETIC THEORY OF GASES

The description of the behavior of a gas in terms of the macroscopic state variables P, V, and T can be related to simple averages of microscopic quantities, such as the mass and speed of the molecules in the gas. The resulting theory, called **the kinetic theory of gases,** provides a detailed model of dilute gases.

From the point of view of kinetic theory, a confined gas consists of a large number of rapidly moving particles. In a monatomic gas, like helium and neon, these particles are single atoms, but in polyatomic gases, like oxygen and carbon dioxide, the particles are molecules. In kinetic theory, it is common practice to refer to the constituent particles of a gas as molecules. (This is the practice, even though referring to a single atom as a molecule is something of a misnomer.) We shall follow this practice in the discussions that follow.

In a gas at room temperature, a very large number of molecules are moving at speeds of hundreds of meters per second. These molecules are making elastic collisions, both with each other and with the walls of a container. In the context of kinetic theory, we may neglect any effects due to gravity, so there are no preferred positions for the molecules in the container,* and no preferred directions for their velocity vectors either. The molecules are separated, on average, by distances that are large compared with their diameters. They also exert no forces on each other except when they collide. (This assumption is equivalent to assuming a very low gas density, which, as we saw in the last section, is the same as assuming that the gas is an ideal gas. Because momentum is conserved, the collisions that the molecules make with each other have no effect on the total momentum in any direction. Thus, such collisions can be neglected.)

* Because of gravity, the density of molecules at the bottom of the container is slightly greater than at the top. As discussed in Chapter 13, the density of air decreases by half at a height of about 5.5 km, so the variation over a normal sized container is negligible.

CALCULATING THE PRESSURE EXERTED BY A GAS

The pressure that a gas exerts on its container is due to collisions between gas molecules and the container walls. This pressure is a force per unit area and, by Newton's second law, this force is the rate of change of momentum of the gas molecules colliding with the wall.

Consider a rectangular container of volume V containing N gas molecules, each of mass m moving with a speed v. Let us calculate the force exerted by these molecules on the right-hand wall, which is perpendicular to the x axis and has area A. The molecules hitting this wall in a time interval Δt are those that are within distance $|v_x|\Delta t$ of the wall (Figure 17-11) and are moving to the right. Thus, the number of molecules hitting the wall during time Δt is the number per unit volume N/V multiplied by the volume $A|v_x|\Delta t$ multiplied by $\frac{1}{2}$ because, on average, only half the molecules are moving to the right. That is, during time Δt

$$\text{Number of molecules that hit the wall} = \frac{1}{2}\frac{N}{V}|v_x|\Delta t\ A$$

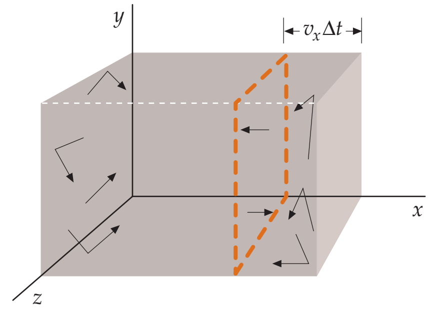

FIGURE 17-11 Gas molecules in a rectangular container. The molecules that both are moving to the right and are closer than $v_x\Delta t$ to the right wall will hit the right wall during time Δt.

The x component of momentum of a molecule is $+mv_x$ before it hits the wall, and $-mv_x$ after an elastic collision with the wall. The change in momentum has the magnitude $2mv_x$. The magnitude of the total change in momentum $|\Delta\vec{p}|$ of all molecules during a time interval Δt is $2m|v_x|$ multiplied by the number of molecules that hit the wall during this interval:

$$|\Delta\vec{p}| = (2m|v_x|) \times \left(\frac{1}{2}\frac{N}{V}|v_x|\Delta t\ A\right) = \frac{N}{V}mv_x^2 A\ \Delta t \qquad 17\text{-}15$$

The magnitude of the force exerted by the wall on the molecules, and the magnitude of the force exerted by the molecules on the wall, is the ratio $|\Delta\vec{p}|/\Delta t$. The pressure is the magnitude of this force divided by the area A:

$$P = \frac{F}{A} = \frac{1}{A}\frac{|\Delta\vec{p}|}{\Delta t} = \frac{N}{V}mv_x^2$$

or

$$PV = Nmv_x^2 \qquad 17\text{-}16$$

To allow for the fact that all the molecules in a container do not have the same speed, we merely replace v_x^2 with its average value $(v_x^2)_{av}$. Then, writing Equation 17-16 in terms of the kinetic energy $\frac{1}{2}mv_x^2$ associated with motion along the x axis, we have

$$PV = 2N\left(\tfrac{1}{2}mv_x^2\right)_{av} \qquad 17\text{-}17$$

THE MOLECULAR INTERPRETATION OF TEMPERATURE

Comparing Equation 17-17 with $PV = NkT$ (Equation 17-7), which was obtained experimentally for any gas that has a low density, we can see that

$$NkT = 2N\left(\tfrac{1}{2}mv_x^2\right)_{av} \quad \text{or} \quad \left(\tfrac{1}{2}mv_x^2\right)_{av} = \tfrac{1}{2}kT \qquad 17\text{-}18$$

Thus, the average kinetic energy associated with motion along the x axis is $\frac{1}{2}kT$. But there is nothing special about the x direction. Consequently,

$$(v_x^2)_{av} = (v_y^2)_{av} = (v_z^2)_{av} \quad \text{and} \quad (v^2)_{av} = (v_x^2)_{av} + (v_y^2)_{av} + (v_z^2)_{av} = 3(v_x^2)_{av}$$

Writing $(v_x^2)_{av} = \frac{1}{3}(v^2)_{av}$ and $K_{\text{trans av}}$ for the average translational kinetic energy of the molecules, Equation 17-18 becomes

$$K_{\text{trans av}} = \left(\tfrac{1}{2}mv^2\right)_{av} = \tfrac{3}{2}kT \qquad 17\text{-}19$$

AVERAGE TRANSLATIONAL KINETIC ENERGY OF A MOLECULE

In addition to translational kinetic energy, the molecules may also have rotational or vibrational kinetic energy. However, only the translational kinetic energy is relevant to the calculation of the pressure exerted by a gas on the walls of its container.

The absolute temperature is thus a measure of the average translational kinetic energy of the molecules. The total translational kinetic energy of n moles of a gas containing N molecules is

$$K_{\text{trans}} = N\left(\tfrac{1}{2}mv^2\right)_{\text{av}} = \tfrac{3}{2}NkT = \tfrac{3}{2}nRT \qquad \text{17-20}$$

where we have used $Nk = nN_{\text{A}}k = nR$. Thus, the translational kinetic energy is $\tfrac{3}{2}kT$ per molecule and $\tfrac{3}{2}RT$ per mole.

We can use these results to estimate the order of magnitude of the speeds of the molecules in a gas. The average value of v^2 is, by Equation 17-19,

$$(v^2)_{\text{av}} = \frac{3kT}{m} = \frac{3N_A kT}{N_A m} = \frac{3RT}{M}$$

where $M = N_{\text{A}}m$ is the molar mass. The square root of $(v^2)_{\text{av}}$ is referred to as the **root-mean-square** (rms) speed:

$$v_{\text{rms}} = \sqrt{(v^2)_{\text{av}}} = \sqrt{\frac{3kT}{m}} = \sqrt{\frac{3RT}{M}} \qquad \text{17-21}$$

ROOT-MEAN-SQUARE SPEED OF A MOLECULE

Note that Equation 17-21 is similar to Equation 15-5 for the speed of sound in a gas:

$$v_{\text{sound}} = \sqrt{\frac{\gamma RT}{M}} \qquad \text{17-22}$$

where $\gamma = 1.4$ for air. This is not surprising because a sound wave in air is a pressure disturbance propagated by collisions between air molecules.

Example 17-8 The rms Speed of Gas Molecules

Oxygen gas (O_2) has a molar mass of about 32.0 g/mol, and hydrogen gas (H_2) has a molar mass of about 2.00 g/mol. Calculate (*a*) the rms speed of an oxygen molecule when the temperature is 300 K, and (*b*) the rms speed of a hydrogen molecule at the same temperature.

PICTURE We find v_{rms} using Equation 17-21. For the units to work out right, we use $R = 8.314\ \text{J/(mol}\cdot\text{K)}$, and we express the molecular masses of O_2 and H_2 in kg/mol.

SOLVE

(*a*) 1. Substitute the given values into Equation 17-21:

$$v_{\text{rms}} = \sqrt{\frac{3\,RT}{M}} = \sqrt{\frac{3(8.314\ \text{J/mol}\cdot\text{K})(300\ \text{K})}{0.0320\ \text{kg/mol}}}$$
$$= 483.56\ \text{m/s} = \boxed{484\ \text{m/s}}$$

(*b*) 1. Repeat the calculation with $M = 0.00200$ kg/mol:

$$v_{\text{rms}} = \sqrt{\frac{3\,RT}{M}} = \sqrt{\frac{3(8.314\ \text{J/mol}\cdot\text{K})(300\ \text{K})}{0.00200\ \text{kg/mol}}}$$
$$= 1934\ \text{m/s} = \boxed{1.93 \times 10^3\ \text{m/s}}$$

CHECK Because v_{rms} is inversely proportional to $\sqrt{M}$ (Equation 17-21), and the molar mass of hydrogen is one-sixteenth that of oxygen, the rms speed of hydrogen is four times that of oxygen. Our calculations are consistent with the mass ratio because 1930/484 = 4.00.

TAKING IT FURTHER The rms speed of oxygen molecules is 484 m/s = 1080 mi/h, about 1.4 times the speed of sound in air, which at 300 K is about 343 m/s.

PRACTICE PROBLEM 17-4 Find the rms speed of nitrogen molecules (M = 28 g/mol) at 300 K.

THE EQUIPARTITION THEOREM

We have seen that the average kinetic energy associated with translational motion in any direction is $\frac{1}{2}kT$ per molecule (Equation 17-19) or, equivalently, $\frac{1}{2}RT$ per mole, where k is the Boltzmann constant and R is the universal gas constant. If the energy of a molecule associated with its motion in one direction is momentarily increased, say, by a collision between the molecule and a moving piston during a compression of the gas, collisions between that molecule and other molecules will quickly redistribute the added energy. When the gas is again in equilibrium, energy will be equally partitioned among the translational kinetic energies associated with motion in the x, y, and z directions. This sharing of the energy equally among the three terms in the translational kinetic energy is a special case of the **equipartition theorem,** a result that follows from classic statistical mechanics. Each component of position and momentum (including angular position and angular momentum) that appears as a squared term in the expression for the energy of the system is called a **degree of freedom.** Typical degrees of freedom are associated with the kinetic energy of translation, rotation, and vibration, and with the potential energy of vibration. The equipartition theorem states that:

> When a substance is in equilibrium, there is an average energy of $\frac{1}{2}kT$ per molecule or $\frac{1}{2}RT$ per mole associated with each degree of freedom.
>
> EQUIPARTITION THEOREM

In Chapter 18, we use the equipartition theorem to relate the measured heat capacities of gases to their molecular structure.

Example 17-9 Mixing the Gases *Conceptual*

A thermally insulated tank is divided into two 20-L sections by a partition. One 20-L section contains a mole of nitrogen at 300 K and the other 20-L section contains a mole of helium at 320 K. The partition is removed and the gases are allowed to mix. For the mixture, is the partial pressure of the nitrogen gas less than, equal to, or greater than the partial pressure of the helium gas? Is the final temperature of the mixture less than, equal to, or greater than 310 K?

PICTURE The tank is insulated, so the energy of its contents remains fixed. Any energy gained by the molecules of nitrogen is lost by the molecules of helium. After mixing, the temperature of each gas is equal to the temperature of the mixture, and the temperature of each gas is proportional to its translational kinetic energy. Helium is monatomic and nitrogen is diatomic. Thus, we should expect the energy gained by the nitrogen molecules to end up as rotational kinetic energy as well as translational kinetic energy.

SOLVE

1. After mixing, the volume, temperature, and number of moles are the same for both gases. The ideal-gas law relates the volume, temperature, partial pressure, and number of moles of each gas.

   The ideal-gas law implies that, for each gas, the partial pressure is completely specified by the volume, temperature, and number of moles. The volume, temperature, and number of moles are the same for both gases, so $\boxed{\text{the partial pressures are the same}}$ as well.

2. The tank is insulated, so the total energy of the two gases remains constant during the mixing.

   The tank is thermally insulated, so any energy gained by the nitrogen molecules is lost by the helium atoms. That is, the average increase in energy of a nitrogen molecule is equal to the average decrease in energy of a helium atom.

3. The final temperature of both gases is the same as the temperature of the mixture.

   After mixing, the temperature is the same for each gas, so the average translational kinetic energy is the same for the molecules of each gas.

4. Nitrogen is a diatomic gas and helium is a monatomic gas, so the nitrogen has more degrees of freedom than does helium. Some of the energy gained by the nitrogen will end up as an increase in rotational kinetic energy.

   The decrease in translational kinetic energy of the helium atoms is equal to the increase in translational kinetic energy PLUS the increase of rotational kinetic energy of the nitrogen molecules.

5. The change in temperature in each gas is proportional to the change in translational kinetic energy of each gas.

   The decrease in temperature of the helium gas is greater than the increase in temperature of the nitrogen gas. The final temperature is $\boxed{\text{less than 310 K}}$.

CHECK If the two gases had both been monatomic gases, the final temperature would have been equal to 310 K. This is so even if the atomic masses of the two substances were very different.

MEAN FREE PATH

The average speed of molecules in a gas at normal pressures is several hundred meters per second, yet if somebody across the room from you opens a perfume bottle, you do not detect the odor for several minutes. The reason for the time delay is that the perfume molecules do not travel directly toward you, but instead travel a zigzag path due to collisions with the air molecules. The average distance λ traveled by a molecule between collisions is called its **mean free path.** (The reason you smell the perfume at all is due to air currents (convection). The time for a perfume molecule to diffuse across a room is of the order of weeks.)

The mean free path of a gas molecule is related to its size, to the size of the surrounding gas molecules, and to the density of the gas. Consider one gas molecule of radius r_1 moving with speed v through a region of stationary molecules (Figure 17-12). The moving molecule will collide with another molecule of radius r_2 if the centers of the two molecules come within a distance $d = r_1 + r_2$ from each other. (If all the molecules are the same type, then d is the molecular diameter.) As the molecule moves, it will collide with any molecule whose center is in a circle of radius d (Figure 17-13). In some time t, the molecule moves a distance vt and collides with every molecule in the cylindrical volume $\pi d^2 vt$. The number of molecules in this volume is $n_V \pi d^2 vt$, where the number density $n_V = N/V$ is the number of molecules per unit volume. (After each collision, the direction of the molecule changes, so the path actually zigs and zags.) The total path length divided by the number of collisions is the mean free path:

$$\lambda = \frac{vt}{n_V \pi d^2 vt} = \frac{1}{n_V \pi d^2}$$

This calculation of the mean free path assumes that all but one of the gas molecules are stationary, which is not a realistic situation. When the motion of all the molecules is taken into account, the correct expression for the mean free path is given by

$$\lambda = \frac{1}{\sqrt{2}\, n_V \pi d^2} \qquad \text{17-23}$$

MEAN FREE PATH OF A MOLECULE

The average time between collisions is called the **collision time** τ. The reciprocal of the collision time, $1/\tau$, is equal to the average number of collisions per second, or the **collision frequency.** If v_{av} is the average speed, then the average distance traveled between collisions is

$$\lambda = v_{av}\tau \qquad \text{17-24}$$

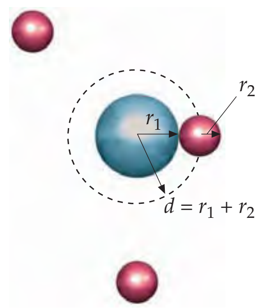

FIGURE 17-12 Model of a molecule (center sphere) moving in a gas. The molecule of radius r_1 will collide with any molecule of radius r_2 if their centers are a distance $d = r_1 + r_2$ apart, which is any molecule whose center is on a sphere of radius $d = r_1 + r_2$ centered about the molecule.

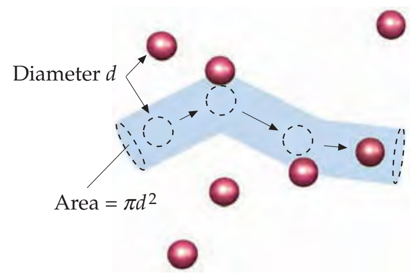

FIGURE 17-13 Model of a molecule moving with speed v in a gas of similar molecules. The motion is shown during time t. The molecule of diameter d will collide with any similar molecule whose center is in a cylinder of volume $\pi d^2 vt$. In this picture, all collisions are assumed to be elastic and all but one of the molecules are assumed to be at rest.

Example 17-10 Mean Free Path of a CO Molecule in Air *Context-Rich*

The local poison control center wants to know more about carbon monoxide and how it spreads through a room. You are asked (*a*) to calculate the mean free path of a carbon monoxide molecule, and (*b*) to estimate the mean time between collisions. The molar mass of carbon monoxide is 28.0 g/mol. Assume that the CO molecule is traveling in air at 300 K and 1.00 atm, and that the diameters of both CO molecules and air molecules are 3.75×10^{-10} m.

PICTURE (*a*) Because d is given, we can find λ from $\lambda = 1/\left(\sqrt{2}\, n_V \pi d^2\right)$ using the ideal-gas law ($PV = NkT$) to find $n_V = N/V$. (*b*) We can estimate the collision time by using v_{rms} for the average speed.

SOLVE

(*a*) 1. Write λ in terms of the number density n_V and the molecular diameter d:

$$\lambda = \frac{1}{\sqrt{2}\, n_V \pi d^2}$$

2. Use the ideal-gas law ($PV = NkT$) to calculate $n_V = N/V$:

$$n_V = \frac{N}{V} = \frac{P}{kT} = \frac{101.3 \times 10^3\ \text{Pa}}{(1.381 \times 10^{-23}\ \text{J/K})(300\ \text{K})} = 2.446 \times 10^{25}\ \text{molecules/m}^3$$

3. Substitute this value of n_V and the given value of d to calculate λ:

$$\lambda = \frac{1}{\sqrt{2}\, n_V \pi d^2} = \frac{1}{\sqrt{2}(2.451 \times 10^{25}/\text{m}^3)\pi(3.75 \times 10^{-10}\ \text{m}^2)^2}$$
$$= 6.5428 \times 10^{-8}\ \text{m} = \boxed{6.54 \times 10^{-8}\ \text{m}}$$

(*b*) 1. Write τ in terms of the mean free path λ:

$$\tau = \frac{\lambda}{v_{av}}$$

2. Estimate v_{av} by calculating v_{rms}:

$$v_{rms} = \sqrt{\frac{3RT}{M}} = \sqrt{\frac{3(8.3145\ \text{J/[mol}\cdot\text{K]})(300\ \text{K})}{0.0280\ \text{kg/mol}}} = 517.0\ \text{m/s}$$

3. Use $v_{av} \approx v_{rms}$ to estimate τ:

$$\tau = \frac{\lambda}{v_{av}} \approx \frac{\lambda}{v_{rms}} = \frac{6.530 \times 10^{-8}\ \text{m}}{517.0\ \text{m/s}} = \boxed{1.27 \times 10^{-10}\ \text{s}}$$

CHECK The mean free path [the Part-(*a*) step-3 result] is 174 times the molecular diameter $d = 3.75 \times 10^{-10}$ m. If the calculated value of the mean free path were less than the molecular diameter, then we would look for a mistake in our calculation.

TAKING IT FURTHER The collision frequency is about $1/\tau \approx 8 \times 10^9$ collisions per second. (That is a lot of collisions for one second.)

* THE DISTRIBUTION OF MOLECULAR SPEEDS

We would not expect all of the molecules in a gas to have the same speed. The calculation of the temperature of a gas allows us to calculate the mean square speed (the square of the rms speed), and therefore the average translational kinetic energy of molecules in a gas, but it does not yield any details about the *distribution* of molecular speeds. Before we consider this problem, we discuss the idea of distribution functions in general with some elementary examples from common experience.

Distribution functions Suppose that a teacher gave a 25-point quiz to a large number N of students. To describe the results, the teacher might give the average score, but this would not be a complete description. If all the students received a score of 12.5, for example, that would be quite different from half the students receiving 25 and the other half zero, but the average score would be the same in both cases. A complete description of the results would be to give the number of students n_i who received a score s_i for all the scores received. Alternatively, one could give the fraction of the students $f_i = n_i/N$ who received the score s_i. Both n_i and f_i, which are functions of the variable s, are called **distribution functions.** The fractional distribution is somewhat more convenient to use. The probability that one of the N students selected at random received the score s_i equals the total number of students who received that score n_i divided by N, that is, the probability equals f_i. Note that

$$\sum_i f_i = \sum_i \frac{n_i}{N} = \frac{1}{N}\sum_i n_i$$

and because $\Sigma n_i = N$,

$$\sum_i f_i = 1 \tag{17-25}$$

DEFINITION: NORMALIZATION CONDITION

Equation 17-25 is called the **normalization condition** for fractional distributions.

To find the average score, we add all the scores and divide by N. Because each score s_i was obtained by $n_i = Nf_i$ students, this is equivalent to

$$s_{\text{av}} = \frac{1}{N}\sum_i n_i s_i = \sum_i s_i f_i \tag{17-26}$$

Similarly, the average of any function $g(s)$ is defined by

$$g(s)_{\text{av}} = \frac{1}{N}\sum_i g(s_i) n_i = \sum_i g(s_i) f_i \tag{17-27}$$

AVERAGE OF $g(s)$

In particular, the average of the square of the scores is

$$(s^2)_{\text{av}} = \frac{1}{N}\sum_i s_i^2 n_i = \sum_i s_i^2 f_i \tag{17-28}$$

where $(s^2)_{\text{av}}$ is called the *mean square score* and the square root of $(s^2)_{\text{av}}$ is called the **root-mean-square score** s_{rms}:

$$s_{\text{rms}} = \sqrt{(s^2)_{\text{av}}} \tag{17-29}$$

DEFINITION: ROOT MEAN SQUARE OF s

A possible distribution function is shown in Figure 17-14. For this distribution, the most probable score (obtained by the most students) is 16, the average score is 14.2, and the rms score is 14.9.

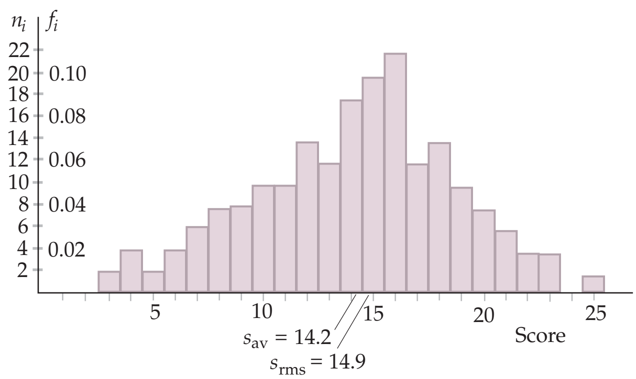

FIGURE 17-14 Grade distribution for a 25-point quiz given to 200 students. n_i is the number of students receiving grade s_i and $f_i = n_i/N$ is the fraction of students receiving grade s_i. The most probable score is 16.

Example 17-11 Making the Grade

Fifteen students took a 25-point quiz. Their scores are 25, 22, 22, 20, 20, 20, 18, 18, 18, 18, 18, 15, 15, 15, and 10. Find the average score and the rms score.

PICTURE The distribution function for this problem is $n_{25} = 1$, $n_{22} = 2$, $n_{20} = 3$, $n_{18} = 5$, $n_{15} = 3$, and $n_{10} = 1$. To find the average score, we use $s_{\text{av}} = N^{-1}\Sigma n_i s_i$ (Equation 17-26). To find the rms score, we use $(s^2)_{\text{av}} = N^{-1}\Sigma s_i^2 n_i$ (Equation 17-28) and then take the square root.

SOLVE

1. By definition, s_{av} is

$$s_{\text{av}} = \frac{1}{N}\sum_i n_i s_i = \frac{1}{15}[1(25) + 2(22) + 3(20) + 5(18) + 3(15) + 1(10)] = \frac{1}{15}(274) = 18.27 = \boxed{18.3}$$

2. To calculate s_{rms}, first find the average of s^2:

$$(s^2)_{\text{av}} = \frac{1}{N}\sum_1 n_i s_i^2 = \frac{1}{15}[1(25)^2 + 2(22)^2 + 3(20)^2 + 5(18)^2 + 3(15)^2 + 1(10)^2] = \frac{1}{15}(5188) = 345.9$$

3. Take the square root of $(s^2)_{\text{av}}$:

$$s_{\text{rms}} = \sqrt{(s^2)_{\text{av}}} = \boxed{18.6}$$

CHECK The average and rms scores differ by only 1 or 2 percent. In addition, the rms value is greater than the average value. The fact that the rms value is always greater than (or equal to) the mean is explained in the discussion following Equation 17-34*b*.

Now consider the case of a continuous distribution, for example, the distribution of heights in a population. For any finite number N, the number of people who are *exactly* 2-m tall is zero. If we assume that height can be determined to any desired accuracy, there are an infinite number of possible heights, so the probability is zero that anybody has any one particular (exact) height. Therefore, we divide the heights into intervals Δh (for example, Δh might be 1 cm or 0.5 cm) and ask what fraction of people has heights that fall in any particular interval. For very large N, this number is proportional to the size of the interval, provided the interval is sufficiently small. We define the distribution function $f(h)$ as the fraction of the number of people with heights in the interval between h and $h + \Delta h$. Then for N people, $Nf(h)\,\Delta h$ is the number of people whose height is between h and $h + \Delta h$. Figure 17-15 shows a possible height distribution.

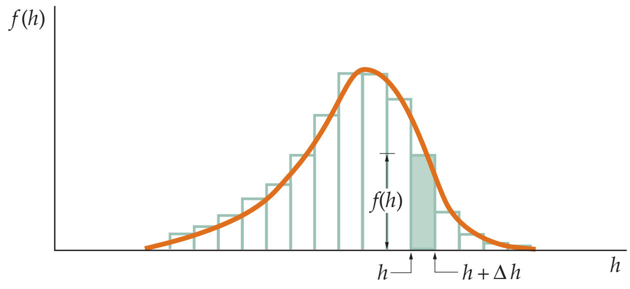

FIGURE 17-15 A possible height distribution function. The fraction of the number of heights between h and $h + \Delta h$ equals the shaded area $f(h)\,\Delta h$. The histogram can be approximated by a continuous curve as shown.

The fraction of people who have heights in a given interval Δh is the area $f(h)\,\Delta h$. If N is very large, we can choose Δh to be very small, and the histogram will approximate a continuous curve. We can therefore consider the distribution function $f(h)$ to be a continuous function, write the interval as dh, and replace the sums in Equations 17-25 through 17-28 by integrals:

$$\int f(h)\,dh = 1 \qquad \text{17-30}$$

NORMALIZATION CONDITION

$$h_{av} = \int hf(h)\,dh \qquad \text{17-31}$$

$$[g(h)]_{av} = \int g(h)f(h)\,dh \qquad \text{17-32}$$

AVERAGE VALUE OF $g(h)$

where $g(h)$ is an arbitrary function of h. Thus,

$$(h^2)_{av} = \int h^2 f(h)\,dh \qquad \text{17-33}$$

The probability of a person selected at random having a height between h and $h + dh$ is $f(h)\,dh$. A useful quantity characterizing a distribution is the **standard deviation** σ, defined by

$$\sigma^2 = [(x - x_{av})^2]_{av} \qquad \text{17-34}a$$

STANDARD DEVIATION σ

Expanding $(x - x_{av})^2$, we obtain

$$\sigma^2 = [x^2 - 2xx_{av} + x_{av}^2]_{av} = (x^2)_{av} - 2x_{av}x_{av} + x_{av}^2 = (x^2)_{av} - x_{av}^2$$

or

$$\sigma^2 = (x^2)_{av} - x_{av}^2 \qquad \text{17-34}b$$

The standard deviation is a measure of the spread of the values about the average value. For most distributions there will be few values that differ from x_{av} by more than a few multiples of σ. For the familiar bell-shaped distribution (called a normal distribution), 68.3 percent of the values are expected to fall within 1σ of x_{av} (i.e., between $x_{av} - \sigma$ and $x_{av} + \sigma$).

In Example 17-11, we found that the rms value was greater than the average value. This is a general feature for any distribution (unless all the values are identical, in which case $\sigma = 0$ and $x_{rms} = x_{av}$). From the definition of rms

People walking down a city street. Consider the various heights of the people you see. *(Getty Images/PhotoAlto.)*

(Equation 17-29), we have $x^2_{rms} = (x^2)_{av}$. By substituting x^2_{rms} for $(x^2)_{av}$ in Equation 17-34*b*, we obtain

$$\sigma^2 = x^2_{rms} - x^2_{av}$$

Because σ^2 and x_{rms} are always positive, x_{rms} must always be greater than $|x_{av}|$.

For the familiar bell-shaped distribution (called a normal distribution), 68.3 percent of the values fall within $x_{av} \pm \sigma$, 95.5 percent fall within $x_{av} \pm 2\sigma$, and 99.7 percent fall within $x_{av} \pm 3\sigma$. (This is known as the 68–95–99.7 rule.)

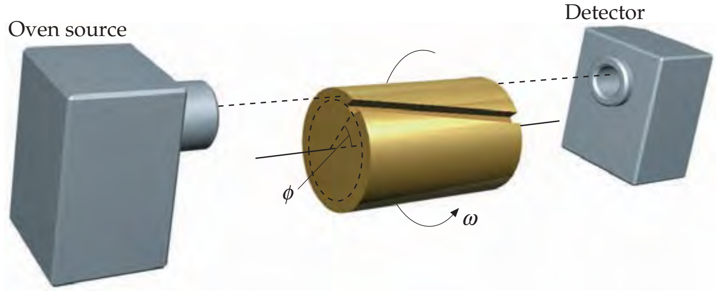

FIGURE 17-16 Schematic diagram of the apparatus for determining the speed distribution of the molecules of a gas. A substance is vaporized in an oven and the vapor molecules are allowed to escape through a hole in the oven wall into a vacuum chamber. The molecules are collimated into a narrow beam by a series of slits (not shown). The beam is aimed at a detector that counts the number of molecules that are incident on it in a given period of time. A rotating cylinder stops most of the beam. Small slits in the cylinder (only one of which is depicted here) allow the passage of molecules that have a narrow range of speeds that is determined by the angular speed of the rotating cylinder. Counting the number of molecules that reach the detector for each of a large number of angular speeds, gives a measure of the number of molecules in each range of speeds.

The Maxwell–Boltzmann distribution The distribution of the molecular speeds of a gas can be measured directly using the apparatus illustrated in Figure 17-16. In Figure 17-17, these speeds are shown for two different temperatures. The quantity $f(v)$ in Figure 17-17 is called the **Maxwell–Boltzmann speed distribution function.** In a gas of N molecules, the number with speeds in the range between v and $v + dv$ is dN, given by

$$dN = Nf(v)\,dv \tag{17-35}$$

The fraction $dN/N = f(v)\,dv$ in a particular range dv is illustrated by the shaded region in the figure. The Maxwell–Boltzmann speed distribution function can be derived using statistical mechanics. The result is

$$f(v) = \frac{4}{\sqrt{\pi}}\left(\frac{m}{2kT}\right)^{3/2} v^2 e^{-mv^2/(2kT)} \tag{17-36}$$

MAXWELL–BOLTZMANN SPEED DISTRIBUTION FUNCTION

The most probable speed v_{max}, that speed for which $f(v)$ is maximum, is given by

$$v_{max} = \sqrt{\frac{2\,kT}{m}} = \sqrt{\frac{2\,RT}{M}} \tag{17-37}$$

MOST PROBABLE SPEED

The rms speed is given by $v_{rms} = \sqrt{3RT/M}$ (Equation 17–21). Comparing Equation 17-37 with Equation 17-21, we see that the most probable speed is slightly less than the rms speed.

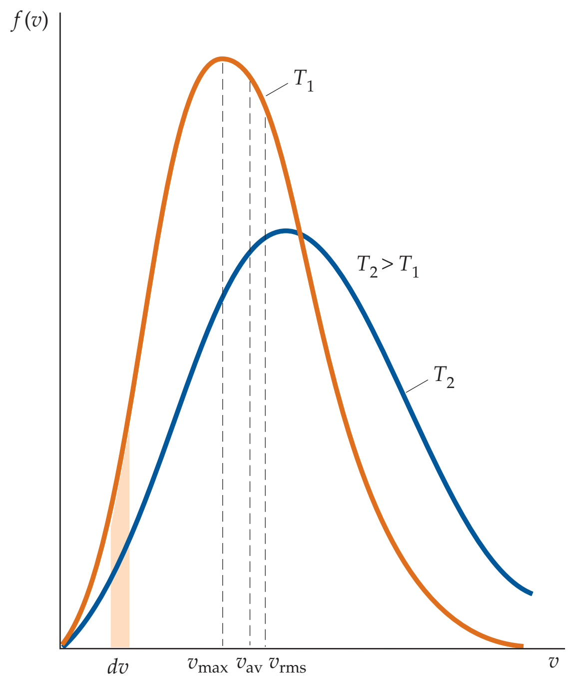

FIGURE 17-17 Distributions of molecular speeds in a gas at two temperatures, T_1 and $T_2 > T_1$. The shaded area $f(v)\,dv$ equals the fraction of the number of molecules having a particular speed in a narrow range of speeds dv. The mean speed v_{av} and the rms speed v_{rms} are both slightly greater than the most probable speed v_{max}.

Example 17-12 Using the Maxwell–Boltzmann Distribution

Calculate the mean square speed (the average value of v^2) for the molecules in a gas using the Maxwell–Boltzmann distribution function.

PICTURE The average value of v^2 is calculated from $(h^2)_{av} = \int h^2 f(h)\,dh$ (Equation 17-33), with v replacing h and $f(v)$ given by Equation 17-36.

SOLVE

1. By definition, $(v^2)_{av}$ is
$$(v^2)_{av} = \int_0^\infty v^2 f(v)\, dv$$

2. Use Equation 17-36 for $f(v)$:
$$(v^2)_{av} = \int_0^\infty v^2 \frac{4}{\sqrt{\pi}}\left(\frac{m}{2kT}\right)^{3/2} v^2 e^{-mv^2/(2kT)}\, dv = \frac{4}{\sqrt{\pi}}\left(\frac{m}{2kT}\right)^{3/2} \int_0^\infty v^4 e^{-mv^2/(2kT)}\, dv$$

3. The integral in step 2 can be found in standard integral tables:
$$\int_0^\infty v^4 e^{-mv^2/(2kT)}\, dv = \frac{3}{8}\sqrt{\pi}\left(\frac{2kT}{m}\right)^{5/2}$$

4. Use this result to calculate $(v^2)_{av}$:
$$(v^2)_{av} = \frac{4}{\sqrt{\pi}}\left(\frac{m}{2kT}\right)^{3/2} \frac{3}{8}\sqrt{\pi}\left(\frac{2kT}{m}\right)^{5/2} = \boxed{\frac{3kT}{m}}$$

CHECK Our result agrees with $v_{rms} = \sqrt{3kT/m}$ from Equation 17-21.

In Example 17-8 we found that the rms speed of hydrogen molecules is about 1.93 km/s. This is about 17 percent of the escape speed at the surface of Earth, which we found to be 11.2 km/s in Section 11-3. So why is there no free hydrogen in Earth's atmosphere? As we can see from Figure 17-17, a considerable fraction of the molecules of a gas in equilibrium have speeds greater than the rms speed. When the rms speed of the molecules of a particular gas is as great as 15 to 20 percent of the escape speed for a planet, enough of the molecules have speeds greater than the escape speed so that most of the gas does not remain in the atmosphere of that planet very long before escaping. Thus, there is virtually no hydrogen gas in Earth's atmosphere. The rms speed of oxygen molecules, on the other hand, is about one-fourth that of hydrogen molecules, which makes it only about 4 percent of the escape speed at the surface of Earth. Therefore, only a negligible fraction of the oxygen molecules have speeds greater than the escape speed, and oxygen remains in Earth's atmosphere.

CONCEPT CHECK 17-3

As any low-temperature physicist knows, liquid nitrogen is much cheaper than liquid helium. One reason for this is that while nitrogen is the most common constituent of the atmosphere, only minute amounts of helium are found in the atmosphere. (Helium is found in natural gas deposits.) Why are only minute amounts of helium found in the atmosphere?

The energy distribution The Maxwell–Boltzmann speed distribution as given by Equation 17-36 can also be written as a translational-kinetic-energy distribution. We write the number of molecules with translation kinetic energy E in the range between E and $E + dE$ as

$$dN = NF(E)\, dE$$

where $F(E)$ is the energy distribution function. This will be the same number as given by Equation 17-36, with the energy E related to the speed v by $E = \frac{1}{2}mv^2$. Then

$$dE = mv\, dv$$

and

$$Nf(v)\, dv = NF(E)\, dE$$

We can write

$$f(v)\, dv = Cv^2 e^{-mv^2/(2kT)}\, dv = Cve^{-E/(kT)} v\, dv = C\left(\frac{2E}{m}\right)^{1/2} e^{-E/(kT)} \frac{dE}{m}$$

where $C = (4/\sqrt{\pi})[m/(2kT)]^{3/2}$ (from Equation 17-36). The translational-kinetic-energy distribution function $F(E)$ is thus given by

$$F(E) = \frac{4}{\sqrt{\pi}}\left(\frac{m}{2kT}\right)^{3/2}\left(\frac{2}{m}\right)^{1/2} \frac{1}{m} E^{1/2} e^{-E/(kT)}$$

Simplifying, we obtain the **Maxwell–Boltzmann energy distribution function:**

$$F(E) = \frac{2}{\sqrt{\pi}}\left(\frac{1}{kT}\right)^{3/2} E^{1/2} e^{-E/(kT)} \qquad 17\text{-}38$$

MAXWELL–BOLTZMANN ENERGY DISTRIBUTION FUNCTION

In the language of statistical mechanics, the energy distribution is considered to be the product of two factors: one factor is called the **density of states** and is proportional to $\sqrt{E}$, the other factor is the probability of a state being occupied, which is $e^{-E/(kT)}$, and is called the **Boltzmann factor.**

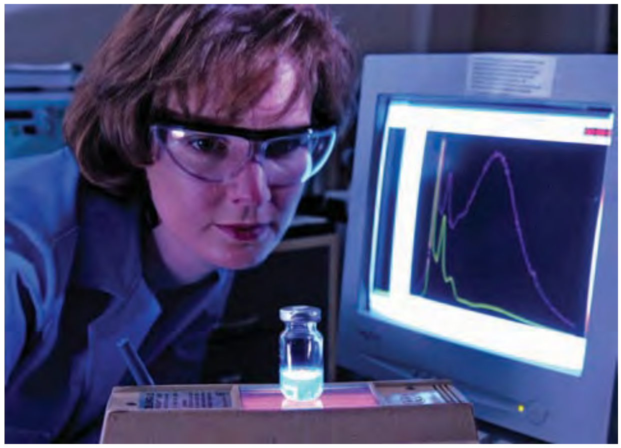
Physics Spotlight

Molecular Thermometers



A scientist views a sample that is fluorescing in two wavelengths. It is fluorescing because it is being illuminated from below by ultraviolet light. The ratio of the two wavelengths is a sensitive thermometric property of the material. *(LeRoy N. Sanchez/Los Alamos National Laboratory.)*

Molecular thermometers show changes in temperature by changes in the molecules themselves. Molecular thermometers can be simple and inexpensive and are targets of recent intensive research.

Mood rings feature liquid crystals[*] that show changes in the wearer's finger temperature by changing color. Many liquid crystals have *thermochromic* properties—they change color with temperature. These liquid crystals are made up of twisted molecules. As the temperature changes, the twist of each molecule tightens or loosens, which changes how the liquid crystal absorbs and reflects light. Some liquid crystals are sensitive to changes as small as 0.1°C.[†] Any particular liquid crystal will show color changes over a small temperature range, usually less than 7°C. However, different liquid crystals can be encased in different compartments within strips to allow sensing of a range of temperatures from −30°C to 120°C. These strip thermometers are used as aquarium thermometers, as well as fever thermometers.[‡] Liquid crystal thermometers provide real-time monitoring,[#] and are an inexpensive option when cost is a concern.[°]

Fluorescent thermometers can be useful in monitoring temperature changes of very small computer chips during manufacturing processes as well as monitoring temperature changes in automobiles during manufacturing and aerodynamic testing.[§] When these thermometers are bathed in ultraviolet light, most respond by fluorescing (emitting light) in two wavelengths. The ratio of these two wavelengths is related to the temperature. A recently developed fluorescent thermometer is accurate to 0.05°C, and indicates temperatures ranging from 25°C to 140°C[¶] by changes in the ratio of wavelengths of emitted light. As the ratio changes, the visible color changes with the temperature.

But there are times that molecular thermometers must measure temperatures that are higher than 150°C. In that case, objects that need to be measured can be coated with a powder that phosphoresces, or briefly shines, when excited with light. The length of time the phosphors shine depends upon the temperature of the coated object. Phosphorescence time duration has been used by the steel industry to determine whether steel is at the right temperature for the formation of desired alloys. Phosphor thermometry allows measurement of 700°C steel within 3°C.[**] Conventional thermometry had errors of as much as 40°C. The accuracy could save the steel industry up to $70 million per year.

Real-time thermometers cannot tell what has happened in the past. The highest, or endpoint, cooking temperature that meat reaches is an important measurement for food safety. The endpoint cooking temperature (EPT) determines whether food-related illness is likely to occur. Unfortunately, it is not possible to measure the EPT once the meat has cooled. But the ratio of three large molecules in beef allows determination of the EPT within 2°C,[††] even if the beef has been frozen and thawed since cooking. It may soon be possible to tell whether precooked meats delivered to nursing homes and schools have reached a safe temperature before cooling.

Because of the wide number of applications, from inexpensive temperature monitoring to detection of past temperatures and real-time industrial monitoring, molecular thermometry has a glowing future.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Centigrade and Fahrenheit Scale	On the centigrade scale, the ice point is defined to be 0°C and the steam point is 100°C. On the Fahrenheit scale, the ice point is 32°F and the steam point is 212°F. Temperatures on the Fahrenheit and centigrade scales are related by $t_C = \frac{5}{9}(t_F - 32°)$	17-2
2. Gas Thermometers	Gas thermometers have the property that they all agree with each other in the measurement of any temperature as long as the density of the gas is very low. The ideal-gas temperature T (in kelvins) is defined by $T = \frac{P}{P_3}T_3$	17-4
	where P is the observed pressure of the gas in the thermometer, P_3 is the pressure when the thermometer is immersed in a water–ice–vapor bath at its triple point, and $T_3 = 273.16$ K (the triple-point temperature).	
3. Celsius Scale	The Celsius temperature t_C is related to the ideal-gas temperature T in kelvins by $t_C = T + 273.15\ \text{K}$	17-5
4. Ideal Gas	At low densities, all gases obey the ideal-gas law.	
Equation of state	$PV = nRT$	17-13
Universal gas constant	$R = N_A k = 8.314\ \text{J/(mol}\cdot\text{K)} = 0.08206\ \text{L}\cdot\text{atm/(mol}\cdot\text{K)}$	17-12
Boltzmann's constant	$k = 1.381 \times 10^{-23}\ \text{J/K} = 8.617 \times 10^{-5}\ \text{eV/K}$	17-8
Avogadro's number	$N_A = 6.022 \times 10^{23}\ \text{mol}^{-1}$	17-9
Equation for a fixed amount of gas	A form of the ideal-gas law that is useful for solving problems involving a fixed amount of gas is $\frac{P_2V_2}{T_2} = \frac{P_1V_1}{T_1}$	17-14
5. Kinetic Theory of Gases		
Molecular interpretation of temperature	The absolute temperature T is a measure of the average molecular translational kinetic energy.	
Equipartition theorem	When a system is in equilibrium, there is an average energy of $\frac{1}{2}kT$ per molecule ($\frac{1}{2}RT$ per mole) associated with each degree of freedom.	
Average kinetic energy	For an ideal gas, the average translational kinetic energy of the molecules is $K_{\text{trans av}} = \left(\frac{1}{2}mv^2\right)_{\text{av}} = \frac{3}{2}kT$	17-19
Total translational kinetic energy	The total translational kinetic energy of n moles of a gas containing N molecules is given by $K_{\text{trans}} = N\left(\frac{1}{2}mv^2\right)_{\text{av}} = \frac{3}{2}NkT = \frac{3}{2}nRT$	17-20
rms speed of molecules	The rms speed of a molecule of a gas is related to the absolute temperature by $v_{\text{rms}} = \sqrt{(v^2)_{\text{av}}} = \sqrt{\frac{3kT}{m}} = \sqrt{\frac{3RT}{M}}$	17-21
	where m is the mass of the molecule and M is the molar mass.	
Mean free path	The mean free path λ of a molecule is related to its diameter d and the number of molecules per unit volume n_V by $\lambda = \frac{1}{\sqrt{2}\, n_V \pi d^2}$	17-23

TOPIC	RELEVANT EQUATIONS AND REMARKS	
*6. **Maxwell–Boltzmann Speed Distribution**	$f(v) = \frac{4}{\sqrt{\pi}}\left(\frac{m}{2kT}\right)^{3/2} v^2 e^{-mv^2/(2kT)}$	17-36
Maxwell–Boltzmann Energy Distribution	$F(E) = \frac{2}{\sqrt{\pi}}\left(\frac{1}{kT}\right)^{3/2} E^{1/2} e^{-E/(kT)}$	17-38

Answers to Concept Checks

17-1 Toni's room has more air in it.

17-2 It decreases.

17-3 The rms speed of helium is about 12 percent of the escape speed from Earth's surface. Thus there are enough helium molecules with speeds above escape speed for the helium to slowly escape Earth.

Answers to Practice Problems

17-1 (*a*) 20°C, (*b*) −40°F

17-2 (*a*) $n = 4.47 \times 10^{-5}$ mol, (*b*) $N = 2.69 \times 10^{19}$ molecules

17-3 $n = 0.0804$ mol

17-4 5.2×10^2 m/s

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • True or false:

(*a*) The zeroth law of thermodynamics states that two objects in thermal equilibrium with each other must be in thermal equilibrium with a third object.
(*b*) The Fahrenheit and Celsius temperature scales differ only in the choice of the **ice-point** temperature.
(*c*) The Celsius degree and the kelvin are the same size.

2 • How can you determine if two objects are in thermal equilibrium with each other when putting them into physical contact with each other would have undesirable effects? (For example, if you put a piece of sodium in contact with water there would be a violent chemical reaction.)

3 • "Yesterday I woke up and it was 20°F in my bedroom," said Mert to his old friend Mort. "That's nothing," replied Mort. "My room was −5.0°C." Who had the colder room, Mert or Mort? SSM

4 • Two identical vessels contain different ideal gases at the same pressure and temperature. It follows that (*a*) the number of gas molecules is the same in both vessels, (*b*) the total mass of gas is the same in both vessels, (*c*) the average speed of the gas molecules is the same in both vessels, (*d*) None of the above.

5 • Figure 17-18 shows a plot of volume V versus absolute temperature T for a process that takes a fixed amount of an ideal gas from point A to point B. What happens to the pressure of the gas during this process? SSM

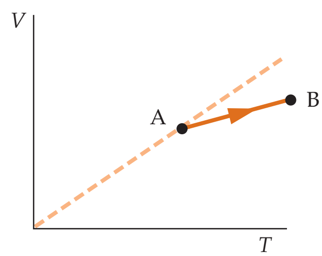

FIGURE 17-18 Problem 5

6 • Figure 17-19 shows a plot of pressure P versus absolute temperature T for a process that takes a sample of an ideal gas from point A to point B. What happens to the volume of the gas during this process?

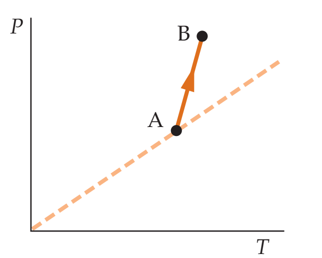

FIGURE 17-19 Problem 6

7 • If a vessel contains equal amounts, by mass, of helium and argon, which of the following are true?
(*a*) The partial pressure exerted by each of the two gases on the walls of the container is the same.
(*b*) The average speed of a helium atom is the same as that of an argon atom.
(*c*) The number of helium atoms and argon atoms in the vessel are equal.
(*d*) None of the above.

8 • By what factor must the absolute temperature of a gas be increased to double the rms speed of its molecules?

9 • Two different gases are at the same temperature. What can be said about the average translational kinetic energies of the molecules? What can be said about the rms speeds of the gas molecules?

10 • A vessel holds a mixture of helium (He) and methane (CH_4). The ratio of the rms speed of the He atoms to that of the CH_4 molecules is (*a*) 1, (*b*) 2, (*c*) 4, (*d*) 16.

11 • True or false: If the pressure of a fixed amount of gas increases, the temperature of the gas must increase.

12 • Why might the Celsius and Fahrenheit scales be more convenient than the absolute scale for ordinary, nonscientific purposes?

13 • An astronomer claims that the temperature at the center of the Sun is about 10^7 degrees. Do you think that this temperature is in kelvins, degrees Celsius, or does it not matter?

14 • Imagine that you have a fixed amount of ideal gas in a container that expands to maintain constant pressure. If you double the absolute temperature of the gas, the average speed of the molecules (*a*) remains constant, (*b*) doubles, (*c*) quadruples, (*d*) increases by a factor of $\sqrt{2}$.

15 • Suppose that you compress an ideal gas to half its original volume, while also halving its absolute temperature. During this process, the pressure of the gas (*a*) halves, (*b*) remains constant, (*c*) doubles, (*d*) quadruples. SSM

16 • The average translational kinetic energy of the molecules of a gas depends on (*a*) the number of moles and the temperature, (*b*) the pressure and the temperature, (*c*) the pressure only, (*d*) the temperature only.

17 •• Which speed is greater, the speed of sound in a gas or the rms speed of the molecules of the gas? Justify your answer, using the appropriate formulas, and explain why your answer is intuitively plausible. SSM

18 •• Imagine that you increase the temperature of a gas while holding its volume fixed. Explain in terms of molecular motion why the pressure of the gas on the walls of its container increases.

19 •• Imagine that you compress a gas while holding it at a fixed temperature (perhaps by immersing the container in cool water). Explain in terms of molecular motion why the pressure of the gas on the walls of its container increases.

20 •• Oxygen has a molar mass of 32 g/mol, and nitrogen has a molar mass of 28 g/mol. The oxygen and nitrogen molecules in a room have:
(*a*) equal average translational kinetic energies, but the oxygen molecules have a larger average speed than the nitrogen molecules have.
(*b*) equal average translational kinetic energies, but the oxygen molecules have a smaller average speed than the nitrogen molecules have.
(*c*) equal average translational kinetic energies and equal average speeds.
(*d*) equal average speeds, but the oxygen molecules have a larger average translational kinetic energy than the nitrogen molecules have.
(*e*) equal average speeds, but the oxygen molecules have a smaller average translational kinetic energy than the nitrogen molecules have.
(*f*) None of the above.

21 •• Liquid nitrogen is relatively cheap, while liquid helium is relatively expensive. One reason for the difference in price is that while nitrogen is the most common constituent of the atmosphere, only small traces of helium can be found in the atmosphere. Use ideas from this chapter to explain why it is that only small traces of helium can be found in the atmosphere. SSM

ESTIMATION AND APPROXIMATION

22 • Estimate the total number of air molecules in your classroom.

23 •• Estimate the density of dry air at sea level on a warm summer day.

24 •• A stoppered test tube that has a volume of 10.0 mL has 1.00 mL of water at its bottom. The water has a temperature of 100°C and is initially at a pressure of 1.00 atm. The test tube is held over a flame until the water has completely boiled away. Estimate the final pressure inside the test tube.

25 •• In Chapter 11, we found that the escape speed at the surface of a planet of radius R is $v_e = \sqrt{2gR}$, where g is the acceleration due to gravity at the surface of the planet. If the rms speed of a gas is greater than about 15 to 20 percent of the escape speed of a planet, virtually all of the molecules of that gas will escape the atmosphere of the planet.
(*a*) At what temperature is v_{rms} for O_2 equal to 15 percent of the escape speed for Earth?
(*b*) At what temperature is v_{rms} for H_2 equal to 15 percent of the escape speed for Earth?
(*c*) Temperatures in the upper atmosphere reach 1000 K. How does this help account for the low abundance of hydrogen in Earth's atmosphere?
(*d*) Compute the temperatures for which the rms speeds of O_2 and H_2 are equal to 15 percent of the escape speed at the surface of the moon, where g is about one-sixth of its value on Earth and R = 1738 km. How does this account for the absence of an atmosphere on the moon? SSM

26 •• The escape speed for gas molecules in the atmosphere of Mars is 5.0 km/s and the surface temperature of Mars is typically 0°C. Calculate the rms speeds for (*a*) H_2, (*b*) O_2, and (*c*) CO_2 at this temperature. (*d*) Are H_2, O_2, and CO_2 likely to be found in the atmosphere of Mars?

27 •• The escape speed for gas molecules in the atmosphere of Jupiter is 60 km/s and the surface temperature of Jupiter is typically −150°C. Calculate the rms speeds for (*a*) H_2, (*b*) O_2, and (*c*) CO_2 at this temperature. (*d*) Are H_2, O_2, and CO_2 likely to be found in the atmosphere of Jupiter? SSM

Jupiter as seen from about twelve million miles. Because the escape speed at the surface of Jupiter is about 600 km/s, Jupiter easily retains hydrogen in its atmosphere. *(Jet Propulsion Laboratory/NASA.)*

28 •• Estimate the average pressure on the front wall of a racquetball court, due to the collisions of the ball with the wall during a game. Use any reasonable numbers for the mass of the ball, its typical speed, and the dimensions of the court. Is the average pressure from the ball significant compared to that from the air?

29 •• To a first approximation, the Sun consists of a gas of equal numbers of protons and electrons. (The masses of these particles can be found in Appendix B.) The temperature at the center of the Sun is about 1×10^7 K, and the density of the Sun is about 1×10^5 kg/m^3. Because the temperature is so high, the protons and electrons are separate particles (rather than being joined together to form hydrogen atoms). (*a*) Estimate the pressure at the center of the Sun. (*b*) Estimate the rms speeds of the protons and the electrons at the center of the Sun.

30 •• **CONTEXT-RICH, ENGINEERING APPLICATION** You are designing a vacuum chamber for fabricating reflective coatings. Inside this chamber, a small sample of metal will be vaporized so that its atoms travel in straight lines (the effects of gravity are negligible during the brief time of flight) to a surface where they land to form a very thin film. The sample of metal is 30 cm from the surface to which the metal atoms will adhere. How low must the pressure in the chamber be so that the metal atoms only rarely collide with air molecules before they land on the surface?

31 ••• **BIOLOGICAL APPLICATION** In normal breathing conditions, approximately 5 percent of each exhaled breath is carbon dioxide. Given this information, and neglecting any difference in water-vapor content, estimate the typical difference in mass between an inhaled breath and an exhaled breath. SSM

TEMPERATURE SCALES

32 • A certain ski wax is rated for use between −12 and −7.0°C. What is this temperature range on the Fahrenheit scale?

33 • The melting point of gold is 1945.4°F. Express this temperature in degrees Celsius. SSM

34 • A weather report indicates that the temperature is expected to drop by 15.0°C over the next four hours. By how many degrees on the Fahrenheit scale will the temperature drop?

35 • The length of the column of mercury in a thermometer is 4.00 cm when the thermometer is immersed in ice water at 1 atm of pressure, and 24.0 cm when the thermometer is immersed in boiling water at 1 atm of pressure. Assume that the length of the mercury column varies linearly with temperature. (*a*) Sketch a graph of the length of the mercury column versus temperature (in degrees Celsius). (*b*) What is the length of the column at room temperature (22.0°C)? (*c*) If the mercury column is 25.4 cm long when the thermometer is immersed in a chemical solution, what is the temperature of the solution?

36 • The temperature of the interior of the Sun is about 1.0×10^7 K. What is this temperature in (*a*) Celsius degrees, (*b*) Fahrenheit degrees?

37 • The boiling point of nitrogen, N_2, is 77.35 K. Express this temperature in degrees Fahrenheit.

38 • The pressure of a constant-volume gas thermometer is 0.400 atm at the ice point and 0.546 atm at the steam point. (*a*) Sketch a graph of pressure versus Celsius temperature for this thermometer. (*b*) When the pressure is 0.100 atm, what is the temperature? (*c*) What is the pressure at 444.6°C (the boiling point of sulfur)?

39 • A constant-volume gas thermometer reads 50.0 torr at the triple point of water. (*a*) Sketch a graph of pressure versus absolute temperature for this thermometer. (*b*) What will be the pressure when the thermometer measures a temperature of 300 K? (*c*) What ideal-gas temperature corresponds to a pressure of 678 torr? SSM

40 • A constant-volume gas thermometer has a pressure of 30.0 torr when it reads a temperature of 373 K. (*a*) Sketch a graph of pressure versus absolute temperature for this thermometer. (*b*) What is its triple-point pressure P_3? (*c*) What temperature corresponds to a pressure of 0.175 torr?

41 • At what temperature do the Fahrenheit and Celsius temperature scales give the same reading?

42 • Sodium melts at 371 K. What is the melting point of sodium on the Celsius and Fahrenheit temperature scales?

43 • The boiling point of oxygen at 1.00 atm is 90.2 K. What is the boiling point of oxygen at 1.00 atm on the Celsius and Fahrenheit scales?

44 •• On the Réaumur temperature scale, the melting point of ice is 0°R and the boiling point of water is 80°R. Derive expressions for converting temperatures on the Réaumur scale to the Celsius and Fahrenheit scales.

45 ••• **ENGINEERING APPLICATION** A thermistor is a solid-state device widely used in a variety of engineering applications. Its primary characteristic is that its electrical resistance varies greatly with temperature. Its temperature dependence is given approximately by $R = R_0 e^{B/T}$, where R is in ohms (Ω), T is in kelvins, and R_0 and B are constants that can be determined by measuring R at calibration points such as the ice point and the steam point. (*a*) If $R = 7360\,\Omega$ at the ice point and $153\,\Omega$ at the steam point, find R_0 and B. (*b*) What is the resistance of the thermistor at $t = 98.6$°F? (*c*) What is the rate of change of the resistance with temperature (dR/dT) at the ice point and the steam point? (*d*) At which temperature is the thermistor most sensitive? SSM

THE IDEAL-GAS LAW

46 • An ideal gas in a cylinder fitted with a piston (Figure 17-20) is held at fixed pressure. If the temperature of the gas increases from 50° to 100°C, by what factor does the volume change?

FIGURE 17-20 Problems 46, 71

47 • A 10.0-L vessel contains gas at a temperature of 0.00°C and a pressure of 4.00 atm. How many moles of gas are in the vessel? How many molecules? SSM

48 •• A pressure as low as 1.00×10^{-8} torr can be achieved using an oil diffusion pump. How many molecules are there in 1.00 cm^3 of a gas at this pressure if its temperature is 300 K?

49 •• You copy the following paragraph from a Martian physics textbook: "1 *snorf* of an ideal gas occupies a volume of 1.35 *zaks*. At a temperature of 22 *glips*, the gas has a pressure of 12.5 *klads*. At a temperature of −10 *glips*, the same gas now has a pressure of 8.7 *klads*." Determine the temperature of absolute zero in *glips*.

50 •• A motorist inflates the tires of her car to a gauge pressure of 180 kPa on a day when the temperature is –8.0°C. When she arrives at her destination, the tire pressure has increased to 245 kPa. What is the temperature of the tires if we assume that (*a*) the tires do not expand, or (*b*) that the tires expand so the volume of the enclosed air increases by 7 percent?

51 •• A room is 6.0 m by 5.0 m by 3.0 m. (*a*) If the air pressure in the room is 1.0 atm and the temperature is 300 K, find the number of moles of air in the room. (*b*) If the temperature increases by 5.0 K and the pressure remains constant, how many moles of air leave the room?

52 •• Imagine that 10.0 g of liquid helium, initially at 4.20 K, evaporate into an empty balloon that is kept at 1.00-atm pressure. What is the volume of the balloon at (*a*) 25.0 K, and (*b*) 293 K?

53 •• A closed container with a volume of 6.00 L holds 10.0 g of liquid helium at 25.0 K and enough air to fill the rest of its volume at a pressure of 1.00 atm. The helium then evaporates and the container warms to room temperature (293 K). What is the final pressure inside the container?

54 •• An automobile tire is filled to a gauge pressure of 200 kPa when its temperature is 20°C. (Gauge pressure is the difference between the actual pressure and atmospheric pressure.) After the car has been driven at high speeds, the tire temperature increases to 50°C. (*a*) Assuming that the volume of the tire does not change and that air behaves as an ideal gas, find the gauge pressure of the air in the tire. (*b*) Calculate the gauge pressure if the tire expands so the volume of the enclosed air increases by 10 percent.

55 •• After nitrogen (N_2) and oxygen (O_2), the most abundant molecule in Earth's atmosphere is water, H_2O. However, the fraction of H_2O molecules in a given volume of air varies dramatically, from practically zero percent under the driest conditions to a high of 4 percent where it is very humid. (*a*) At a given temperature and pressure, would air be denser when its water vapor content is large or small? (*b*) What is the difference in mass, at room temperature and atmospheric pressure, between a cubic meter of air with no water vapor molecules and a cubic meter of air in which 4 percent of the molecules are water vapor molecules? SSM

56 •• A scuba diver is 40 m below the surface of a lake, where the temperature is 5.0°C. He releases an air bubble that has a volume of 15 cm^3. The bubble rises to the surface, where the temperature is 25°C. Assume that the air in the bubble is always in thermal equilibrium with the surrounding water, and assume that there is no exchange of molecules between the bubble and the surrounding water. What is the volume of the bubble right before it breaks the surface? *Hint: Remember that the pressure also changes.*

57 •• **Engineering Application** A hot-air balloon is open at the bottom. The balloon, which has a volume of 446 m^3, is filled with air that has an average temperature of 100°C. The air outside the balloon has a temperature of 20.0°C and a pressure of 1.00 atm. How large a payload (including the envelope of the balloon itself) can the balloon lift? Use 29.0 g/mol for the molar mass of air. (Neglect the volume of both the payload and the envelope of the balloon.) SSM

58 ••• A helium balloon is used to lift a load of 110 N. The weight of the envelope of the balloon is 50.0 N and the volume of the helium when the balloon is fully inflated is 32.0 m^3. The temperature of the air is 0°C and the atmospheric pressure is 1.00 atm. The balloon is inflated with a sufficient amount of helium gas that the net upward force on the balloon and its load is 30.0 N. Neglect any effects due to the changes of temperature as the altitude changes. (*a*) How many moles of helium gas are contained in the balloon? (*b*) At what altitude will the balloon be fully inflated? (*c*) Does the balloon ever reach the altitude at which it is fully inflated? (*d*) If the answer to Part (*c*) is "Yes," what is the maximum altitude attained by the balloon?

KINETIC THEORY OF GASES

59 • (*a*) One mole of argon gas is confined to a 1.0-liter container at a pressure of 10 atm. What is the rms speed of the argon atoms? (*b*) Compare your answer to the rms speed for helium atoms under the same conditions. SSM

60 • Find the total translational kinetic energy of the molecules of 1.0 L of oxygen gas at a temperature of 0.0°C and a pressure of 1.0 atm.

61 • Estimate the rms speed and the average kinetic energy of a hydrogen atom in a gas at a temperature of 1.0×10^7 K. (At this temperature, which is approximately the temperature in the interior of a star, hydrogen atoms are ionized and become protons.)

62 • Liquid helium has a temperature of only 4.20 K and is in equilibrium with its vapor at atmospheric pressure. Calculate the rms speed of a helium atom in the vapor at this temperature, and comment on the result.

63 • Show that the mean free path for a molecule in an ideal gas at temperature T and pressure P is given by $\lambda = kT/(\sqrt{2}\,P\pi d^2)$.

64 •• **Engineering Application** State-of-the-art vacuum equipment can attain pressures as low as 7.0×10^{-11} Pa. Suppose that a chamber contains helium at this pressure and at room temperature (300 K). Estimate the mean free path and the collision time for helium in the chamber. Assume the diameter of a helium atom is 1.0×10^{-10} m.

65 •• Oxygen (O_2) is confined to a cube-shaped container 15 cm on an edge at a temperature of 300 K. Compare the average kinetic energy of a molecule of the gas to the change in its gravitational potential energy if it falls 15 cm (the height of the container). SSM

* THE DISTRIBUTION OF MOLECULAR SPEEDS

66 •• Use calculus to show that $f(v)$, given by Equation 17-36, has its maximum value at a speed $v = \sqrt{2kT/m}$.

67 •• The fractional distribution function $f(v)$ is defined in Equation 17-36. Because $f(v)\,dv$ gives the fraction of molecules that have speeds in the range between v and $v + dv$, the integral of $f(v)\,dv$ over all the possible ranges of speeds must equal 1. Given that the integral $\int_0^\infty v^2 e^{-av^2}\,dv = \sqrt{(\pi/4)}a^{-3/2}$, show that $\int_0^\infty f(v)\,dv = 1$, where $f(v)$ is given by Equation 17-36. SSM

68 •• Given that the integral $\int_0^\infty v^3 e^{-av^2}\,dv = (1/2a^2)$, calculate the average speed v_{av} of molecules in a gas using the Maxwell–Boltzmann distribution function.

69 •• **Multistep** The translational kinetic energies of the molecules of a gas are distributed according to the Maxwell–Boltzmann energy distribution, Equation 17-38. (*a*) Determine the most probable value of the translational kinetic energy (in terms of the temperature T) and compare this value to the average value. (*b*) Sketch a graph of the translational kinetic energy distribution [$f(E)$ versus E] and label the most probable energy and the average energy. (Do not worry about calibrating the vertical scale of the graph.) (*c*) Your teacher says, "Just looking at the graph $f(E)$ versus E allows you to see that the average translational kinetic energy is considerably greater than the most probable translational kinetic energy." What feature(s) of the graph support her claim?

GENERAL PROBLEMS

70 • Find the temperature at which the rms speed of a molecule of hydrogen gas equals 343 m/s.

71 •• (*a*) If 1.0 mol of a gas in a cylindrical container occupies a volume of 10 L at a pressure of 1.0 atm, what is the temperature of the gas in kelvins? (*b*) The cylinder is fitted with a piston so that the volume of the gas (Figure 17-20) can vary. When the gas is heated at constant pressure, it expands to a volume of 20 L. What is the temperature of the gas in kelvins? (*c*) Next, the volume is fixed at 20 L, and the gas's temperature is increased to 350 K. What is the pressure of the gas now?

72 •• **MULTISTEP** (*a*) The volume per molecule of a gas is the reciprocal of the number density (the number of molecules per unit volume). Find the average volume per molecule for dry air at room temperature and atmospheric pressure. (*b*) Take the cube root of your answer to Part (*a*) to obtain a rough estimate of the average distance *d* between air molecules. (*c*) Find or estimate the average diameter *D* of an air molecule, and compare it to your answer to Part (*b*). (*d*) Sketch the molecules in a cube-shaped volume of air, with the edge length of the cube equal to 3*d*. Make your figure to scale and place the molecules in what you think is a typical configuration. (*e*) Use your picture to explain why the mean free path of an air molecule is much greater than the average distance between molecules.

73 •• **CONCEPTUAL** The Maxwell–Boltzmann distribution applies not just to gases, but also to the molecular motions within liquids. The fact that not all molecules have the same speed helps us understand the process of evaporation. (*a*) Explain in terms of molecular motion why a drop of water becomes cooler as molecules evaporate from the drop's surface. (Evaporative cooling is an important mechanism for regulating our body temperatures, and is also used to cool buildings in hot, dry locations.) (*b*) Use the Maxwell–Boltzmann distribution to explain why even a slight increase in temperature can greatly increase the rate at which a drop of water evaporates. SSM

74 •• A cubic metal box that has 20-cm-long edges contains air at a pressure of 1.0 atm and a temperature of 300 K. The box is sealed so that the enclosed volume remains constant, and it is heated to a temperature of 400 K. Find the force due to the internal air pressure on each wall of the box.

75 •• **ENGINEERING APPLICATION** In attempting to create liquid hydrogen for fuel, one of the proposals is to convert plain old water (H_2O) into H_2 and O_2 gases by *electrolysis*. How many moles of each of these gases result from the electrolysis of 2.0 L of water? SSM

76 •• A 40-cm-long hollow cylinder of negligible mass rests on its side on a horizontal frictionless table. The cylinder is divided into two equal sections by a vertical nonporous membrane. One section contains nitrogen and the other contains oxygen. The pressure of the nitrogen is twice that of the oxygen. How far will the cylinder move if the membrane breaks?

77 •• A cylinder of fixed volume contains a mixture of helium gas (He) and hydrogen gas (H_2) at a temperature T_1 and pressure P_1. If the temperature is doubled to $T_2 = 2T_1$, the pressure would also double, except for the fact that at this temperature the H_2 is essentially 100 percent dissociated into H_1. In reality, at pressure $P_2 = 2P_1$ the temperature is $T_2 = 3T_1$. If the mass of the hydrogen in the cylinder is *m*, what is the mass of the helium in the cylinder?

78 •• The mean free path for O_2 molecules at a temperature of 300 K and at 1.00-atm pressure is 7.10×10^{-8} m. Use these data to estimate the size of an O_2 molecule.

79 •• **ENGINEERING APPLICATION** Current experiments in atomic trapping and cooling can create low-density gases of rubidium and other atoms with temperatures in the nanokelvin (10^{-9} K) range. These atoms are trapped and cooled using magnetic fields and lasers in ultrahigh vacuum chambers. One method that is used to measure the temperature of a trapped gas is to turn the trap off and measure the time it takes for molecules of the gas to fall a given distance. Consider a gas of rubidium atoms at a temperature of 120 nK. Calculate how long it would take an atom traveling at the rms speed of the gas to fall a distance of 10.0 cm if (*a*) it were initially moving directly downward, and (*b*) if it were initially moving directly upward. Assume that the atom does not collide with any other atoms along its trajectory. SSM

80 ••• A cylinder is filled with 0.10 mol of an ideal gas at standard temperature and pressure, and a 1.4-kg piston seals the gas in the cylinder (Figure 17-21) with a frictionless seal. The trapped column of gas is 2.4 m high. The piston and cylinder are surrounded by air, also at standard temperature and pressure. The piston is released from rest and starts to fall. The motion of the piston ceases after the oscillations stop with the piston and the trapped air in thermal equilibrium with the surrounding air. (*a*) Find the height of the gas column. (*b*) Suppose that the piston is pushed down below its equilibrium position by a small amount and then released. Assuming that the temperature of the gas remains constant, find the frequency of vibration of the piston.

FIGURE 17-21 Problem 80

81 ••• **SPREADSHEET, MULTISTEP** To solve this problem, you will use a **spreadsheet** to study the distribution of molecular speeds in a gas. Figure 17-22 should help you get started. (*a*) Enter the values for constants *R*, *M*, and *T*, as shown. Then in column A, enter values of speeds ranging from 0 to 1200 m/s, in increments of 1 m/s. (This spreadsheet will be long.) In cell B7, enter the formula for the Maxwell–Boltzmann fractional speed distribution. This formula contains parameters *v*, *R*, *M* and *T*. Substitute A7 for *v*, B$1 for *R*, B$2 for *M* and B$3 for *T*. Then use the FILL DOWN command to enter the formula in the cells below B7. Create a graph of $f(v)$ versus *v* using the data in columns A and B. (*b*) Explore how the graph changes as you increase and decrease the temperature, and describe the results. (*c*) Add a third column in which each cell contains the cumulative sum of all $f(v)$ values, multiplied by the interval size *dv* (which equals 1), in the rows above and including the row in question. What is the physical interpretation of the numbers in this column? (*d*) For nitrogen gas at 300 K, what percentage of the molecules has speeds less than 200 m/s? (*e*) For nitrogen gas at 300 K, what percentage of the molecules has speeds greater than 700 m/s?

CHAPTER 18

THE MEN'S LITTLE 500 BICYCLE RACE HAS BEEN HELD AT INDIANA UNIVERSITY SINCE 1951. (THE CLIMATIC SCENE OF THE 1979 MOVIE BREAKING AWAY FEATURED THIS RACE WHEN A TEAM OF LOCALS, THE CUTTERS, COMPETED.) ONLY IU STUDENTS ARE PERMITTED TO COMPETE IN THIS 200-LAP 50-MILE EVENT. THIS PICTURE IS THE 2006 RACE. (THE RACE WAS WON BY ALPHA TAU OMEGA). *(AJ Mast/Icon SMI/Corbis.)*

Heat and the First Law of Thermodynamics

? Pumping up a bicycle tire requires how much work on the air in order to compress it? (See Example 18-13.)

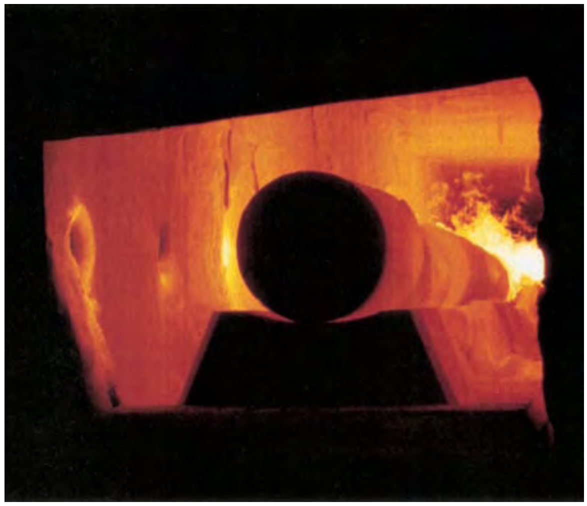
The relation between heating a system, doing work on the system, and the change in the internal energy of the system is the basis of the first law of thermodynamics. In Part I of this book, we discussed motion; now, we consider the role that heat plays in the generation of motion—whether it is the movement of people hurrying to catch a bus, the cyclic motion of pistons in a car engine, or even the drips of water sliding down a glass of cold lemonade on a hot day.

For years, the power generated by heating has been harnessed. From early steam engines to internal combustion automobile engines to jet engines, engineers have been finding ways to improve the performance of their machines to get the most energy out of them. Even athletes today train and eat to optimize their performance on the field, essentially treating their bodies like other mechanical engines.

In this chapter, we define heat capacity, and examine how heating a sample can cause either an increase in its temperature or a change in its phase (from solid to liquid, for example). We then examine the relationship between changes in the internal energy of a system, the energy transferred to the system via heat and work, and express the law of conservation of energy for systems as the first law of thermodynamics. Finally, we shall see how the heat capacity of a system is related to its molecular structure.

18-1 HEAT CAPACITY AND SPECIFIC HEAT

Heat is the transfer of energy due to a difference in temperature. During the seventeenth century, Galileo, Newton, and other scientists generally supported the theory of the ancient Greek atomists who considered thermal energy to be a manifestation of molecular motion. During the next century, methods were developed for making quantitative measurements of the amount of energy transferred because of differences in temperature, and it was found that if objects are in thermal contact, the amount of energy that is released by one object equals the amount that is absorbed by the other object. This discovery led to a theory of in which heat was modeled as a conserved material substance. In this theory, an invisible fluid called "caloric" flowed out of one object and into another, and this caloric could be neither created nor destroyed.



Steel ingots in a twin-tube tunnel furnace. The three 53-cm-diameter carbon-steel ingots seen here have been heated for about 7 hours to approximately 1340°C. Each 3200-kg ingot sits on a furnace car that transports it through the 81-m-long furnace, which is divided into 12 separate heating zones so that the temperature of the ingot is increased gradually to prevent cracking. The ingots, glowing a yellow-whitish color, exit the furnace to be milled into large, heavy-walled pipes. *(Phoenix Pipe & Tube/Lana Berkovich.)*

The caloric theory reigned until the nineteenth century, when it was observed that kinetic friction between objects could produce an unlimited transfer of energy between objects, deposing of the idea that caloric was a substance present in a fixed amount. The modern theory of heat did not emerge until the 1840s, when James Joule (1818–1889) demonstrated that when a viscous liquid is stirred with a paddle, the increase or decrease of a given amount of thermal energy was always accompanied by the decrease or increase of an equivalent quantity of mechanical energy. Thermal energy, therefore, is not itself conserved. Instead, thermal energy is a form of internal energy, and it is energy that is conserved.

When a warmer object is in thermal contact with a cooler object, the energy being transferred from the warmer object to the cooler object due to the difference in the temperatures of the two objects is called **heat.** The energy is no longer identified as heat once it has been transferred to the cooler object. Instead, it is identified as part of the internal energy of the cooler object. The **internal energy** of an object is its total energy in the center-of-mass reference frame of the object. In this book Q is the symbol for heat and E_{int} is the symbol for internal energy.

When energy is transferred to a substance by heating it, the temperature of the substance usually increases.* The amount of heat Q needed to increase the temperature of a sample of the substance is proportional to both the temperature change and the mass of the sample:

$$Q = \Delta E_{\text{int}} = C\,\Delta T = mc\,\Delta T \qquad 18\text{-}1$$

DEFINITION: HEAT CAPACITY

* An exception occurs during a change in phase, as when water freezes or evaporates. Changes of phase are discussed in Section 18-2.

where C is the **heat capacity,** which is defined as the change in internal energy required to increase the temperature of a sample by one degree. The **specific heat** capacity c is the heat capacity per unit mass:

> ! The term *heat capacity* does not mean that a body contains a certain amount of heat.

$$c = \frac{C}{m} \qquad 18\text{-}2$$

DEFINITION: SPECIFIC HEAT

The term *specific heat* is short for specific heat capacity. The historical unit of heat, the **calorie,** was originally defined to be the amount of heat needed to increase the temperature of one gram of water one Celsius degree.* Because we now recognize that heat is a measure of energy transfer, we can define the calorie in terms of the SI unit of energy, the joule:

$$1 \text{ cal} = 4.184 \text{ J} \qquad 18\text{-}3$$

The U.S. customary unit of heat is the **Btu** (for British thermal unit), which was originally defined to be the amount of energy needed to increase the temperature of 1 pound of water by 1°F. The Btu is related to the calorie and to the joule by

$$1 \text{ Btu} = 252 \text{ cal} = 1.054 \text{ kJ} \qquad 18\text{-}4$$

The original definition of the calorie implies that the specific heat of water (in the liquid state) is†

$$c_{\text{water}} = 1 \text{ cal/(g} \cdot \text{K)} = 1 \text{ kcal/(kg} \cdot \text{K)} = 4.184 \text{ kJ/(kg} \cdot \text{K)} \qquad 18\text{-}5a$$

Similarly, from the definition of the Btu, the specific heat of water in U.S. customary units is

$$c_{\text{water}} = 1 \text{ Btu/(lb} \cdot {}^\circ\text{F)} \qquad 18\text{-}5b$$

The heat capacity per mole is called the **molar specific heat** c',

$$c' = \frac{C}{n}$$

where n is the number of moles. Because $C = mc$, the molar specific heat c' and specific heat c are related by

$$c' = \frac{C}{n} = \frac{mc}{n} = Mc \qquad 18\text{-}6$$

MOLAR SPECIFIC HEAT

where $M = m/n$ is the molar mass. Table 18-1 lists the specific heats and molar specific heats of some solids and liquids. Note that the molar heats of all the metals are about the same. We discuss the significance of the similar specific-heat values of metals in Section 18-7.

Table 18-1 Specific Heats and Molar Specific Heats of Some Solids and Liquids

Substance	c, kJ/kg·K	c, kcal/kg·K or Btu/lb·F°	c', J/mol·K
Aluminium	0.900	0.215	24.3
Bismuth	0.123	0.0294	25.7
Copper	0.386	0.0923	24.5
Glass	0.840	0.20	—
Gold	0.126	0.0301	25.6
Ice (−10°C)	2.05	0.49	36.9
Lead	0.128	0.0305	26.4
Silver	0.233	0.0558	24.9
Tungsten	0.134	0.0321	24.8
Zinc	0.387	0.0925	25.2
Alcohol (ethyl)	2.4	0.58	111
Mercury	0.140	0.033	28.3
Water	4.18	1.00	75.2
Steam (at 1 atm)	2.02	0.48	36.4

Liquids are in red typeface and gases are in blue typeface.

* The kilocalorie is then the amount of heat needed to increase the temperature of 1 kg of water by 1°C. The "calorie" used in measuring the energy equivalent of foods is actually the kilocalorie.

† Careful measurement shows that the specific heat of water varies by about 1 percent over the temperature range from 0° to 100°C. We will usually neglect this small variation.

1 line short

Example 18-1 Increasing the Temperature

A jewelry designer is creating gold charms. To make the charms, he must melt gold to fill molds. How much heat is needed to increase the temperature of 3.00 kg of gold from 22°C (room temperature) to 1063°C, the melting point of gold?

PICTURE The amount of heat Q needed to increase the temperature of the substance (gold) is proportional to the temperature change and to the mass of the substance.

SOLVE

1. The required heat is given by Equation 18-1, with $c = 0.126\ \mathrm{kJ/(kg \cdot K)}$ from Table 18-1:

$$Q = mc\,\Delta T = (3.00\ \mathrm{kg})(0.126\ \mathrm{kJ/(kg \cdot K)})(1041\ \mathrm{K}) = \boxed{393\ \mathrm{kJ}}$$

CHECK The problem asks for an amount of energy and the answer came out in joules, which are energy units.

TAKING IT FURTHER Note that we use $\Delta T = 1063°\mathrm{C} - 22°\mathrm{C} = 1041°\mathrm{C} = 1041\ \mathrm{K}$.

PRACTICE PROBLEM 18-1 A 2.0-kg aluminum block is originally at 10°C. If 36 kJ of energy are added to the block, what is its final temperature?

We see from Table 18-1 that the specific heat of liquid water is considerably larger than that of other common substances. Thus, water is an excellent material for storing thermal energy, as in a solar heating system. It is also an excellent coolant, as in a car engine. (The coolant in automotive engines is a mixture of water and ethylene glycol.)

Large bodies of water, such as lakes or oceans, tend to moderate fluctuations of the air temperature nearby because the bodies of water can absorb or release large quantities of heat while undergoing only very small changes in temperature. *(From Frank Press and Raymond Siever,* Understanding Earth, *3rd ed., W. H. Freeman and Company, 2001.)*

CALORIMETRY

To measure the specific heat of an object, we can first heat it to some known temperature, say the boiling point of water. Then, we transfer the object to a water bath of known mass and initial temperature. Finally, we measure the final equilibrium temperature of the system (the object, the water in the bath, and the water-bath container). If the system is thermally isolated from its surroundings (by insulating the container, for example), then the heat released by the object will equal the heat absorbed by the water and the container. This procedure is called **calorimetry,** and the insulated water container is called a **calorimeter.**

Let m be the mass of the object, let c be its specific heat, and let T_{io} be the initial temperature of the object. If T_{f} is the final temperature of both the object, the water and container, the heat released by the object is

$$Q_{\mathrm{out}} = mc(T_{\mathrm{io}} - T_{\mathrm{f}})$$

Similarly, if T_{iw} is the initial temperature of the water and container, then the heat absorbed by the water and container is

$$Q_{\mathrm{in}} = m_{\mathrm{w}}c_{\mathrm{w}}(T_{\mathrm{f}} - T_{\mathrm{iw}}) - m_{\mathrm{c}}c_{\mathrm{c}}(T_{\mathrm{f}} - T_{\mathrm{iw}})$$

where m_{w} and $c_{\mathrm{w}} = 4.18\ \mathrm{kJ/(kg \cdot K)}$ are the mass and specific heat of the water, and m_{c} and c_{c} are the mass and specific heat of the container. (Note that we have expressed the temperature differences so that they are both positive quantities. As a consequence, our expressions for Q_{in} and Q_{out} are both positive.) Setting these amounts of heat equal yields an equation that can be solved for the specific heat c of the object:

$$Q_{out} = Q_{in} \Rightarrow mc(T_{io} - T_f) = m_w c_w (T_f - T_{iw}) + m_c c_c (T_f - T_{iw}) \qquad 18\text{-}7$$

Because only temperature differences occur in Equation 18-7, and because the kelvin and the Celsius degree are the same size, it does not matter whether we use kelvins or Celsius degrees.

Example 18-2 Measuring Specific Heat

To measure the specific heat of lead, you heat 600 g of lead shot to 100.0°C and place it in an aluminum calorimeter of mass 200 g that contains 500 g of water initially at 17.3°C. If the final temperature of the mixture is 20.0°C, what is the specific heat of lead? (The specific heat of the aluminum container is 0.900 kJ/(kg·K).)

PICTURE We set the heat released by the lead equal to the heat absorbed by the water and container and solve for the specific heat of lead c_{Pb}.

SOLVE

1. Write the heat released by the lead in terms of its specific heat: $Q_{Pb} = m_{Pb} c_{Pb} |\Delta T_{Pb}|$
2. Write the heat absorbed by the water: $Q_w = m_w c_w \, \Delta T_w$
3. Write the heat absorbed by the container: $Q_c = m_c c_c \, \Delta T_c$
4. Set the heat released equal to the heats absorbed by the water and the container: $Q_{out} = Q_{in} \Rightarrow Q_{Pb} = Q_w + Q_c$

   $m_{Pb} c_{Pb} |\Delta T_{Pb}| = m_w c_w \, \Delta T_w + m_c c_c \, \Delta T_c$

   where $\Delta T_c = \Delta T_w = 2.7$ K and $|\Delta T_{Pb}| = 80.0$ K
5. Solve for c_{Pb}:

$$c_{Pb} = \frac{(m_w c_w + m_c c_c)\,\Delta T_w}{m_{Pb}|\Delta T_{Pb}|}$$

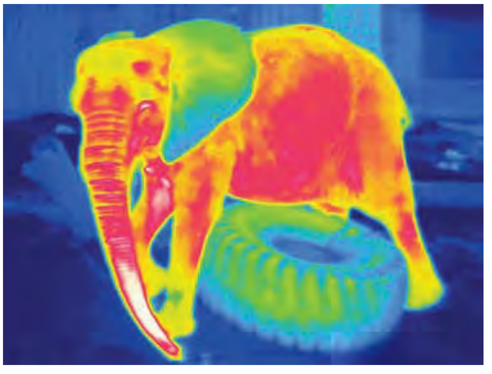
$$= \frac{[(0.50\text{ kg})(4.18\text{ kJ/(kg}\cdot\text{K)}) + (0.20\text{ kg})(0.90\text{ kJ/(kg}\cdot\text{K)})](2.7\text{ K})}{(0.600\text{ kg})(80.0\text{ K})}$$

$$= 0.128\text{ kJ/(kg}\cdot\text{K)} = \boxed{0.13\text{ kJ/(kg}\cdot\text{K)}}$$

CHECK As expected, the specific heat of lead is considerably less than that of water. (The specific heat of liquid water is 4.18 kJ/(kg·K).)

TAKING IT FURTHER The step-5 result is expressed to two figures because the temperature change of the water is known to only two figures.

PRACTICE PROBLEM 18-2 A solar home contains 1.00×10^5 kg of concrete (specific heat = 1.00 kJ/kg·K). How much heat is released by the concrete when it cools from 25°C to 20°C?



(Edward Kinsman/ Photo Researchers, Inc.)

18-2 CHANGE OF PHASE AND LATENT HEAT

If heat is absorbed by ice at 0°C, the temperature of the ice does not change. Instead, the ice melts. Melting is an example of a **phase change** or **change of state.** Common types of phase changes include fusion (liquid to solid), melting (solid to liquid), vaporization (liquid to vapor or gas), condensation (gas or vapor to liquid), and sublimation (solid directly to gas or vapor, such as solid carbon dioxide, or dry ice, changing to vapor). Other types of phase changes exist as well, such as the change of a solid from one crystalline form to another. For example, carbon graphite under intense pressure becomes a diamond.

Molecular theory can help us to understand why temperature remains constant during a phase change. The molecules in a liquid are close together and exert attractive forces on each other, whereas molecules in a gas are far apart. Because of this intermolecular attraction, it takes energy to remove molecules from a liquid to form a gas. Consider a pot of water sitting over a flame on the stove. At first, as the water is heated, the motions of its molecules increase and the temperature increases. When the temperature reaches the boiling point, the molecules can no longer increase their kinetic energy and remain in the liquid. As the liquid water vaporizes, the added energy goes into breaking the intermolecular attractions. That is, it goes into increasing the potential energy of the molecules rather than their kinetic energy. Because temperature is a measure of the average translational *kinetic* energy of molecules, the temperature does not change.

For a pure substance, a change in phase at a given pressure occurs only at a particular temperature. For example, pure water at a pressure of 1 atm changes from solid to liquid at 0°C (the normal melting point of water) and from liquid to gas at 100°C (the normal boiling point of water).

The energy required to melt a sample of a substance of mass m with no change in its temperature is proportional to the mass of the sample:

$$Q_f = mL_f \qquad 18\text{-}8$$

where L_f is called the **latent heat of fusion** of the substance. At a pressure of 1 atm, the latent heat of fusion for water is 333.5 kJ/kg = 79.7 kcal/kg. If the phase change is from liquid to gas, the heat required is

$$Q_v = mL_v \qquad 18\text{-}9$$

where L_v is the **latent heat of vaporization.** For water at a pressure of 1 atm, the latent heat of vaporization is 2.26 MJ/kg = 540 kcal/kg. Table 18-2 gives the melting and boiling points and the latent heats of fusion and vaporization, all at 1 atm, for various substances.

Although melting indicates that the ice has experienced a change in phase, the temperature of the ice does not change. *(From Donald Wink, Sharon Gislason, and Sheila McNicholas,* The Practice of Chemistry, *W. H. Freeman and Company, 2002.)*

Table 18-2 Melting Point (MP), Latent Heat of Fusion (L_f), Boiling Point (BP), and Latent Heat of Vaporization (L_v), all at 1 atm, for Various Substances

Substance	MP, K	L_f, kJ/kg	BP, K	L_v, kJ/kg
Alcohol, ethyl	159	109	351	879
Bromine	266	67.4	332	369
Carbon dioxide	—	—	194.6*	573*
Copper	1356	205	2839	4726
Gold	1336	62.8	3081	1701
Helium	—	—	4.2	21
Lead	600	24.7	2023	858
Mercury	234	11.3	630	296
Nitrogen	63	25.7	77.35	199
Oxygen	54.4	13.8	90.2	213
Silver	1234	105	2436	2323
Sulfur	388	38.5	717.75	287
Water (liquid)	273.15	333.5	373.15	2257
Zinc	692	102	1184	1768

* These values are for sublimation. Carbon dioxide does not have a liquid state at 1 atm.

Example 18-3 Changing Ice into Steam

How much heat is needed to change 1.5 kg of ice at −20°C and 1.0 atm into steam?

PICTURE The heat required to change the ice into steam consists of four parts: Q_1, the heat needed to increase the temperature of the ice from −20°C to 0°C; Q_2, the heat needed to melt the ice; Q_3, the heat needed to increase the temperature of the water from 0°C to 100°C; and Q_4, the heat needed to vaporize the water. In calculating Q_1 and Q_3, we assume that the specific heats are constant, with the values 2.05 kJ/kg·K for ice and 4.18 kJ/kg·K for water.

SOLVE

1. Use $Q_1 = mc\,\Delta T$ to find the heat needed to increase the temperature of the ice to 0°C:
   $Q_1 = mc\,\Delta T = (1.5\text{ kg})(2.05\text{ kJ/kg}\cdot\text{K})(20\text{ K})$
   $= 61.5\text{ kJ} = 0.0615\text{ MJ}$
2. Use L_f from Table 18-2 to find the heat Q_2 needed to melt the ice:
   $Q_2 = mL_f = (1.5\text{ kg})(333.5\text{ kJ/kg}) = 500\text{ kJ} = 0.500\text{ MJ}$
3. Find the heat Q_3 needed to increase the temperature of the water from 0°C to 100°C:
   $Q_3 = mc\,\Delta T = (1.5\text{ kg})(4.18\text{ kJ/kg}\cdot\text{K})(100\text{ K}) = 627\text{ kJ} = 0.627\text{ MJ}$
   $Q_3 = 627\text{ kJ} = 0.627\text{ MJ}$
4. Use L_v from Table 18-2 to find the heat Q_4 needed to vaporize the water:
   $Q_4 = mL_V = (1.5\text{ kg})(2.26\text{ MJ/kg}) = 3.39\text{ MJ}$
5. Sum your results to find the total heat Q:
   $Q = Q_1 + Q_2 + Q_3 + Q_4 = \boxed{4.6\text{ MJ}}$

CHECK You may have observed that much less time is needed to bring a kettle full of water to a boil than the time needed to boil the kettle dry. This observation is consistent with the fact that our step-3 result is less than 20 percent of our step-4 result.

TAKING IT FURTHER Notice that most of the heat was needed to vaporize the water, and that the amount needed to melt the ice was a significant fraction of the heat needed to increase the temperature of the liquid water by 100°C. A graph of temperature versus time for the case in which the heat is absorbed at a constant rate of 1.0 kJ/s is shown in Figure 18-1. Note that it takes considerably longer to vaporize the water than it does to melt the ice or to increase the temperature of the water. When all of the water has vaporized, the temperature again increases as heat is absorbed.

PRACTICE PROBLEM 18-3 An 830-g piece of lead is heated to its melting point of 600 K. How much additional energy must be absorbed by the lead at 600 K to completely melt all 830 g?

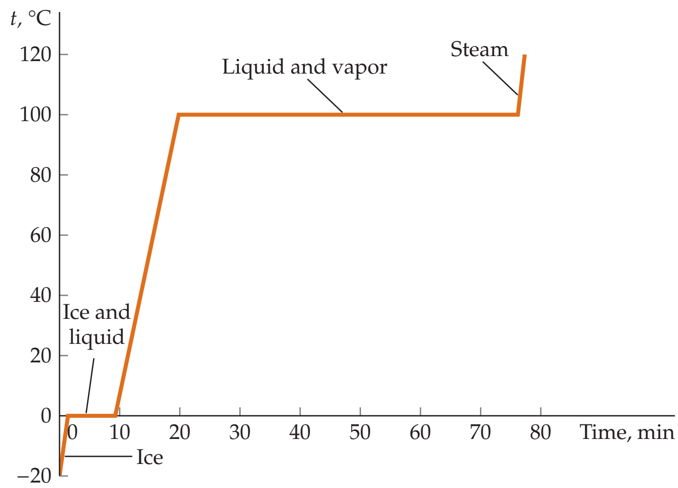


FIGURE 18-1 A 1.5-kg sample of water is heated from −20°C to 120°C at a constant rate of 60 kJ/min.

Example 18-4 A Cool Drink *Context-Rich*

A 2.0-liter pitcher of lemonade has been sitting on the picnic table in the sunlight all day at 33°C. You pour 0.24 kg into a Styrofoam cup and add 2 ice cubes (each 0.025 kg at 0.0°C). (*a*) Assuming no heat is released to the surroundings, what is the final temperature of the lemonade? (*b*) What is the final temperature if you add six, instead of the two, ice cubes?

PICTURE We set the heat released by the lemonade equal to the heat absorbed by the ice cubes. Let T_f be the final temperature of the lemonade and water. We assume that lemonade has the same specific heat as water.

SOLVE

(*a*) 1. Write the heat absorbed by the lemonade in terms of the final temperature T_f:

$$Q_{out} = m_L c|\Delta T| = m_L c(T_{Li} - T_f)$$

2. Write the heat absorbed by the ice cubes and resulting water in terms of the final temperature:

$$Q_{in} = m_{ice}L_f + m_{ice}c\,\Delta T_w = m_{ice}L_f + m_{ice}c(T_f - T_{wi})$$

3. Set the heat released equal to the heat absorbed and solve for T_f:

$$Q_{out} = Q_{in}$$

$$m_L c(T_{Li} - T_f) = m_{ice}L_f + m_{ice}c(T_f - T_{wi})$$

so
$$T_f = \frac{(m_{ice}T_{wi} + m_L T_{Li})c - m_{ice}L_f}{(m_L + m_{ice})c}$$

$$= \frac{(0.050 \times 273.15 + 0.24 \times 306.15)4.18 - 0.050 \times 333.5}{0.29 \times 4.18}$$

$$= 286.7\text{ K} = \boxed{14°\text{C}}$$

(*b*) 1. For 6 ice cubes, $m_{ice} = 0.15$ kg. Find the final temperature as in step 3 of Part (*a*):

$$T_f = \frac{(m_{ice}T_{wi} + m_L T_{Li})c - m_{ice}L_f}{(m_L + m_{ice})c}$$

$$= \frac{(0.150 \times 273.15 + 0.24 \times 306.15)4.18 - 0.150 \times 333.5}{0.39 \times 4.18}$$

$$= 262.8\text{ K} = -10.4\text{ °C}$$

2. A final temperature below 0°C cannot be correct! No amount of ice at 0°C can decrease the temperature of warm lemonade to below 0°C. Our calculation is wrong because our assumption that all of the ice melts was wrong. Instead, the heat released by the lemonade as it cools from 32°C to 0°C is not enough to melt all of the ice. The final temperature is thus:

$$= \boxed{0°\text{C}}$$

CHECK Let us calculate how much ice is melted. For the lemonade to cool from 33°C to 0°C, it must release heat in the amount $Q = (0.24\text{ kg})(4.18\text{ kJ/kg}\cdot\text{K})(33\text{ K}) = 33.1$ kJ. The mass of ice that this amount of heat will melt is $m_{ice} = Q/L_f = 33.1\text{ kJ}/(333.5\text{ kJ/kg}) = 0.10$ kg. This is the mass of only 4 ice cubes. Adding more than 4 ice cubes does not decrease the temperature below 0°C. It merely increases the amount of ice in the ice–lemonade mixture at 0°C. In problems like this one, we should first find out how much ice must be melted to reduce the temperature of the liquid to 0°C. If less than that amount is added, we can proceed as in Part (*a*). If more ice is added, the final temperature is 0°C.

18-3 JOULE'S EXPERIMENT AND THE FIRST LAW OF THERMODYNAMICS

We can increase the temperature of a system by adding energy but we can also increase its temperature by doing work on it. Figure 18-2 is a diagram of the apparatus Joule used in a famous experiment in which he determined the amount of work needed to increase the temperature of one pound of water by one Fahrenheit degree. Here, the system is a thermally insulated container of water. Joule's apparatus converts the potential energy of falling weights into work done on the water by an attached paddle, as shown in the figure. Joule found that he could increase the temperature of 1.00 lb of water by 1.00°F by dropping 772 lbs of attached weights a distance of one foot. Converting to modern units and using current values, Joule found that it takes about 4.184 J (the energy units adopted by the scientific community in 1948) to increase the temperature of 1 g of water by 1°C. The result that 4.184 J of mechanical energy is exactly equivalent to 1 cal of heat is known as the **mechanical equivalence of heat.**

FIGURE 18-2 Schematic diagram for Joule's experiment. Insulating walls surround water. As the weights fall at constant speed, they turn a paddle wheel, which does work on the water. If friction is negligible, the work done by the paddle wheel on the water equals the loss of mechanical energy of the weights, which is determined by calculating the loss in the potential energy of the weights.

There are other ways of doing work on this system. For example, we could let gravity do the work by dropping the insulated container of water from some

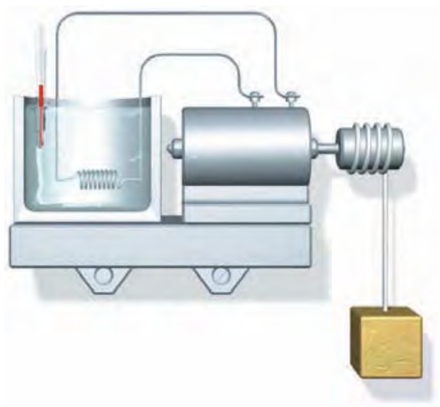

FIGURE 18-3 Another method of doing work on a thermally insulated container of water. Electrical work is done on the system by the generator, which is driven by the falling weight.

CONCEPT CHECK 18-1

Joule's experiment establishing the mechanical equivalence of heat involved the conversion of mechanical energy into internal energy. Give some examples of the internal energy of a system being converted into mechanical energy.

height h, letting the system make an inelastic collision with the ground, or we could do mechanical work to generate electricity and then use the electricity to heat the water (Figure 18-3). During all such experiments, the same amount of work is required to produce a given temperature change. By the conservation of energy, the work done equals the increase in the internal energy of the system.

Example 18-5 Warming Water by Dropping It

(*a*) At Niagara Falls, the water drops 50 m. If the decrease in the gravitational potential energy of the water is equal to the increase in the internal energy of the water, compute the increase in its temperature. (*b*) At Yosemite Falls, the water drops 740 m. If the decrease in the gravitational potential energy of the water is equal to the increase in the internal energy of the water, compute the increase in its temperature. (These temperature increases are not easily observed because as the water falls its temperature is affected by several other effects. For example it cools by evaporation and it is warmed as the air does work on it via the viscosity interaction.)

PICTURE The kinetic energy of the water just before it hits the bottom equals its original potential energy mgh. During the collision, this energy is converted into internal energy, which in turn causes an increase in temperature given by $mc\,\Delta T$.

SOLVE

(*a*) 1. Set the decrease in the potential energy equal to the increase in the internal energy:

$$mgh = mc\,\Delta T$$

2. Solve for the temperature change:

$$\Delta T = \frac{gh}{c} = \frac{(9.81\ \text{N/kg})(50\ \text{m})}{4.184\ \text{kJ/kg}\cdot\text{K}} = 0.117\ \text{K} = \boxed{0.12\ \text{K}}$$

(*b*) Repeat the calculation with $h = 740$ m:

$$\Delta T = \frac{gh}{c} = \frac{(9.81\ \text{N/kg})(740\ \text{m})}{4.184\ \text{kJ/kg}\cdot\text{K}} = 1.74\ \text{K} = \boxed{1.7\ \text{K}}$$

CHECK Yosemite Falls is 14.8 times higher than Niagara Falls, so the potential energy change of the Yosemite Falls water is 14.8 times larger than the potential energy change of Niagara Falls water. Thus, the change in temperature should be 14.8 times greater for Yosemite Falls water than for Niagara Falls water. Multiplying 0.117 K by 14.8 gives 1.73 K, which is very close to our Part-(*b*) result.

TAKING IT FURTHER These calculations illustrate one of the difficulties with Joule's experiment—a large amount of mechanical energy must be dissipated to produce a measurable change in the temperature of the water.

Suppose that we perform Joule's experiment, but replace the insulating walls of the container with conducting walls. We find that the work needed to produce a given change in the temperature of the system depends on how much heat is absorbed or released by the system by conduction through the walls. However, if we sum the work done on the system and the net heat absorbed by the system, the result is always the same for a given temperature change. That is, the sum of the heat transfer *into* the system and the work done *on* the system equals the change in the internal energy of the system. This result is the **first law of thermodynamics,** which is simply a statement of the conservation of energy.

Let W_{on} stand for the work done by the surroundings *on* the system. For example, suppose our system is a gas confined to a cylinder by a piston. If the piston compresses the gas, the surroundings do work on the gas and W_{on} is positive. (However, if the gas expands against the piston, the gas does work on the surroundings and W_{on} is negative.) Also, let Q_{in} stand for the heat transfer into the system. If heat is transferred into the system, then Q_{in} is positive; if heat is transferred out of the system, then Q_{in} is negative (Figure 18-4). Using these conventions, and denoting the internal energy by E_{int},* the first law of thermodynamics is written

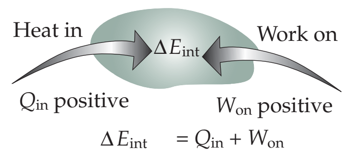

FIGURE 18-4 Sign convention for the first law of thermodynamics.

$$\Delta E_{int} = Q_{in} + W_{on} \qquad 18\text{-}10$$

The change in the internal energy of the system equals the heat transfer into the system plus the work done on the system.

FIRST LAW OF THERMODYNAMICS

Equation 18-10 is the same as the work–energy theorem $W_{ext} = \Delta E_{sys}$ of Chapter 7 (Equation 7-9), except we have added the heat term Q_{in} and called the energy of the system E_{int}.

Example 18-6 Stirring the Water

You do 25 kJ of work on a system consisting of 3.0 kg of water by stirring it with a paddle wheel. During this time, 15 kcal of heat is released by the system due to poor thermal insulation. What is the change in the internal energy of the system?

PICTURE We express all energies in joules and apply the first law of thermodynamics.

SOLVE

1. ΔE_{int} is found by using the first law of thermodynamics: $\Delta E_{int} = Q_{in} + W_{on}$
2. Heat is *released* by the system, thus the Q_{in} term is negative: $Q_{in} = -15\text{ kcal} = -(15\text{ kcal})\left(\dfrac{4.18\text{ kJ}}{1\text{ kcal}}\right) = -62.7\text{ kJ}$
3. The work is done *on* the system, thus W_{on} term is positive: $W_{on} = +25\text{ kJ}$
4. Substitute these quantities and solve for ΔE_{int}: $\Delta E_{int} = Q_{in} + W_{on} = (-62.7\text{ kJ}) + (+25\text{ kJ})$ $= -37.7\text{ kJ} = \boxed{-38\text{ kJ}}$

CHECK The heat loss exceeds the work gain, so the change in internal energy is negative.

It is important to understand that the internal energy E_{int} is a function of the state of the system, just as P, V, and T are functions of the state of the system. Consider a gas in some initial state (P_i, V_i). The temperature T_i can be determined by the equation of state. For example, if the gas is ideal, the $T_i = P_iV_i/(nR)$. The internal energy $E_{int\,i}$ also depends only on the state of the gas, which is determined

* Another commonly used symbol for internal energy is *U*.

by any two state variables such as P and V, P and T, or V and T. If we slowly heat the gas or cool the gas, do work on the gas, or let the gas do work, the gas will move through a sequence of states; that is, it will have different values of the state functions P, V, T, and E_{int}.

On the other hand, the heat Q and the work W are not functions of the state of the system. That is, there are no functions Q or W associated with any particular state of the gas. We could take the gas through a sequence of states beginning and ending at state (P_i, V_i) during which the gas did work that has a positive value and absorbed an equal amount of heat. Or we could take it through a different sequence of states such that work was done on the gas and heat was released from the gas. Heat is not something that is contained in a system. Rather, heat is a measure of the energy that is transferred from one system to another because of a difference in temperature. Work is a measure of the energy that is transferred from one system to another because the point of contact of a force exerted by one system on the other undergoes a displacement with a component that is parallel to the force.

> ! If the gas is then returned to its original state (P_i, V_i), the temperature T and the internal energy E_{int} must equal their original values.

> ! It is correct to say that the internal energy of a system has increased, but it is not correct to say either that the work of a system has increased or that the heat of a system has increased.

For very small amounts of heat absorbed, work done, or changes in internal energy, it is customary to write Equation 18-10 as

$$dE_{\text{int}} = dQ_{\text{in}} + dW_{\text{on}} \tag{18-11}$$

In this equation, dE_{int} is the differential of the internal-energy function. However, neither dQ_{in} nor dW_{on} is a differential of any function. Instead, dQ_{in} merely represents a small amount of energy transferred to or from the system by heating or cooling, and dW_{on} represents a small amount energy transferred to or from the system by work being done on or by the system.

18-4 THE INTERNAL ENERGY OF AN IDEAL GAS

The translational kinetic energy K of the molecules in an *ideal* gas is related to the absolute temperature T by Equation 17-20:

$$K = \tfrac{3}{2}nRT$$

where n is the number of moles of gas and R is the universal gas constant. If the internal energy of a gas is just this translational kinetic energy, then $E_{\text{int}} = K$, and

$$E_{\text{int}} = \tfrac{3}{2}nRT \tag{18-12}$$

Then, the internal energy will depend only on the temperature of the gas, and not on its volume or pressure. If the molecules have other types of energy in addition to translational kinetic energy, such as rotational energy, the internal energy will be greater than that given by Equation 18-12. But according to the equipartition theorem (Chapter 17, Section 4), the average energy associated with any degree of freedom will be $\frac{1}{2}RT$ per mole ($\frac{1}{2}kT$ per molecule), so again, the internal energy will depend only on the temperature and not on the volume or pressure.

We can imagine that the internal energy of a *real* gas might include other kinds of energy, which depend on the pressure and volume of the gas. Suppose, for example, that nearby gas molecules exert attractive forces on each other. Work is then required to increase the separation of the molecules. Then, if the average distance between the molecules is increased, the potential energy associated with the molecular attraction will increase. The internal energy of the gas will then depend on the volume of the gas as well as on its temperature.

Joule, using an apparatus like the one shown in Figure 18-5, performed a simple but interesting experiment to determine whether or not the internal energy of a gas depends on its volume. The compartment on the left in Figure 18-5 initially contains a gas and the compartment on the right has been evacuated. A stopcock that is

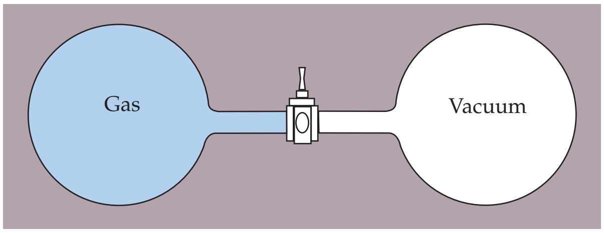

FIGURE 18-5 Free expansion of a gas. When the stopcock on the gas is opened, the gas expands rapidly into the evacuated chamber. Because no work is done on the gas and the whole system is thermally insulated, the initial and final internal energies of the gas are equal.

initially closed connects the two compartments. The whole system is thermally insulated from its surroundings by rigid walls so that no energy can be transferred into or out of the system by heating or cooling *and* no energy can be transferred by work being done on or by the gas. When the stopcock is opened, the gas rushes into the evacuated chamber. This process is called a **free expansion.** The gas eventually reaches thermal equilibrium with itself. Because no work has been done on the gas and no heat has been transferred to it, the final internal energy of the gas must equal its initial internal energy. If the gas molecules exert attractive forces on one another, the potential energy associated with these forces will increase as the volume increases. Because energy is conserved, the kinetic energy of translation will therefore decrease, which will result in a decrease in the temperature of the gas.

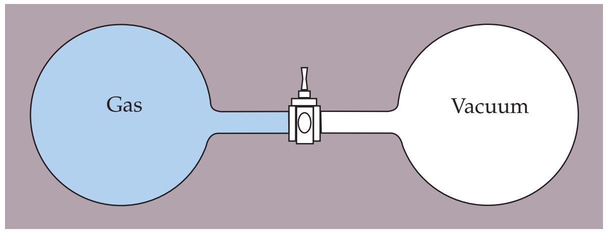

FIGURE 18-5 *(repeated)*
Free expansion of a gas. When the stopcock on the gas is opened, the gas expands rapidly into the evacuated chamber. Because no work is done on the gas and the whole system is thermally insulated, the initial and final internal energies of the as are equal.

When Joule performed this experiment, he found the final temperature to be equal to the initial temperature. Subsequent experiments verified this result for gases at low densities. This result implies that for a gas at low density—that is, for an ideal gas—the temperature depends only on the internal energy, or as we usually think of it, the internal energy depends only on the temperature. However, if the experiment is done with a large amount of gas initially in the left compartment so that the initial density is high, then the temperature after expansion is slightly cooler than the temperature before the expansion. This result indicates that a small attraction exists between the gas molecules of a gas.

18-5 WORK AND THE DIAGRAM FOR A GAS

In many types of engines, a gas does work expanding against a moving piston. For example, in a steam engine, water is heated in a boiler to produce steam. The steam then does work as it expands and drives a piston. In an automobile engine, a mixture of gasoline vapor and air is ignited, causing it to combust. The resulting high temperatures and pressures cause the gas to expand rapidly, driving a piston and doing work. In this section, we see how we can mathematically describe the work done by an expanding gas.

QUASI-STATIC PROCESSES

Figure 18-6 shows an ideal gas confined in a container that has a tightly fitting piston that we assume to be frictionless. If the piston moves, the volume of the gas changes. The temperature or pressure or both must also change because these three variables are related by the equation of state $PV = nRT$. If we suddenly push in the piston to compress the gas, the pressure will initially be greater near the piston than far from it. The gas eventually will settle down to a new equilibrium pressure and temperature. We cannot determine such macroscopic variables as T, P, or E_{int} for the entire gas system until equilibrium is restored in the gas. However, if we

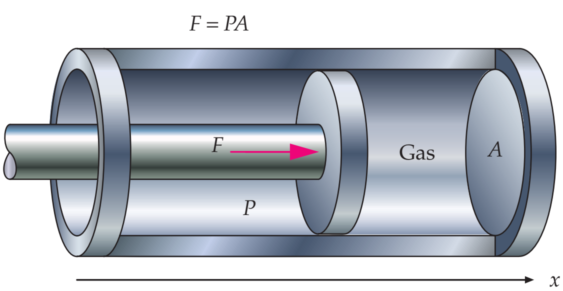

FIGURE 18-6 Gas confined in a thermally insulated cylinder with a movable piston. If the piston moves a distance dx, the volume of the gas changes by $dV = A\,dx$. The work done by the gas is $PA\,dx = P\,dV$, where P is the pressure.

move the piston slowly in small steps and allow equilibrium to be reestablished after each step, we can compress or expand the gas in such a way that the gas is never far from an equilibrium state. During this kind of process, called a **quasi-static process,** the gas moves through a series of equilibrium states. In practice, it is possible to approximate quasi-static processes fairly well.

Let us begin with a gas at a high pressure, and let it expand quasi-statically. The magnitude of the force F exerted by the gas on the piston is PA, where A is the area of the piston and P is the gas pressure. As the piston moves a small distance dx, the work done *by* the gas *on* the piston is

$$dW_{\text{by gas}} = F_x\,dx = PA\,dx = P\,dV \qquad \text{18-13}$$

where $dV = A\,dx$ is the increase in the volume of the gas. During the expansion the piston exerts a force of magnitude PA on the gas, but opposite in direction to the force of the gas on the piston. Thus, work done *by* the piston *on* the gas is just the negative of the work done *by* the gas

$$dW_{\text{on gas}} = -dW_{\text{by gas}} = -P\,dV \qquad \text{18-14}$$

Note that for an expansion, dV is positive, the gas does work on the piston, so $dW_{\text{on gas}}$ is negative, and for a compression, dV is negative, work is done on the gas, so $dW_{\text{on gas}}$ is positive.

The work done on the gas during an expansion or a compression from a volume of V_i to a volume of V_f is

$$W_{\text{on gas}} = -\int_{V_i}^{V_f} P\,dV \qquad \text{18-15}$$

WORK DONE ON A GAS

To calculate this work, we need to know how the pressure varies during the expansion or compression. The various possibilities can be illustrated most easily using a PV diagram.

PV DIAGRAMS

We can represent the states of a gas on a diagram of P versus V. Because by specifying both P and V we specify the state of the gas, each point on the PV diagram indicates a particular state of the gas. Figure 18-7 shows a PV diagram with a directed horizontal line representing a series of states that all have the same value of P. This line represents a *compression* at constant pressure. Such a process is called an **isobaric compression.** For a volume change of ΔV (ΔV is negative for a compression), we have

$$W_{\text{on}} = -\int_{V_i}^{V_f} P\,dV = -P\int_{V_i}^{V_f} dV = -P\,\Delta V = |P\,\Delta V|$$

which is equal to the shaded area under the curve (directed line) in the figure. For a compression, the work done on the gas is equal to the area under the P-versus-V curve. (For an expansion the work done on the gas is equal to the negative of the area under the P-versus-V curve.) Because pressures are often given in atmospheres and volumes are often given in liters, it is convenient to have a conversion factor between liter-atmospheres and joules:

$$1\ \text{L}\cdot\text{atm} = (10^{-3}\ \text{m}^3)(101.325 \times 10^3\ \text{N/m}^2) \approx 101.3\ \text{J} \qquad \text{18-16}$$

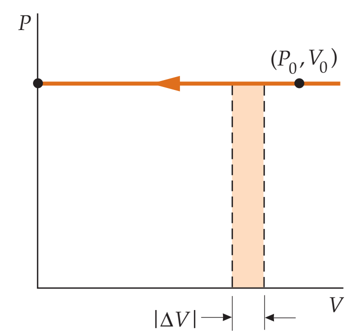

FIGURE 18-7 Each point on a PV diagram, such as (P_0, V_0), represents a particular state of the gas. The horizontal line represents states with a constant pressure P_0. The shaded area, $P_0|\Delta V|$, represents the work done on the gas as it is compressed an amount $|\Delta V|$.

PRACTICE PROBLEM 18-4

If 5.00 L of an ideal gas at a pressure of 2.00 atm is cooled so that it contracts at constant pressure until its volume is 3.00 L, what is the work done on the gas?

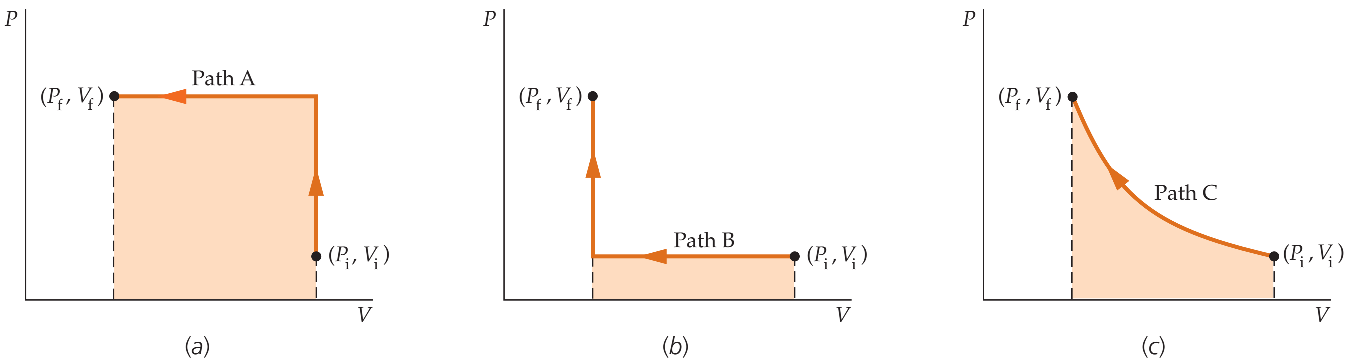

FIGURE 18-8 Three paths on *PV* diagrams connecting an initial state (P_i, V_i) and a final state (P_f, V_f). The corresponding shaded area indicates the work done on the gas along each path.

Figure 18-8 shows three different possible paths on a *PV* diagram for a gas that is initially in state (P_i, V_i) and is finally in state (P_f, V_f). We assume that the gas is ideal and have chosen the original and final states to have the same temperature so that $P_iV_i = P_fV_f = nRT$. Because the internal energy depends only on the temperature, the initial and final internal energies are the same also.

In Figure 18-8*a*, the gas is heated **isometrically** (at constant volume)* until its pressure is P_f, after which it is cooled isobarically (at constant pressure) until its volume is V_f. The work done on the gas along the constant-volume (vertical) part of path A is zero; along the constant pressure (horizontal) part of the path A, it is

$$P_f|V_f - V_i| = -P_f(V_f - V_i).$$

In Figure 18-8*b*, the gas is first cooled at constant pressure until its volume is V_f, after which it is heated at constant volume until its pressure is P_f. The work done on the gas along this path is $P_i|V_f - V_i| = -P_i(V_f - V_i)$, which is much less than that done along the path shown in Figure 18-8*a*, as can be seen by comparing the shaded regions in Figure 18-8*a* and Figure 18-8*b*.

In Figure 18-8*c*, path *C* represents an **isothermal** compression, meaning that the temperature remains constant. (Keeping the temperature constant during the compression requires that energy be transferred out of the gas via heat during the compression.) We can calculate the work done on the gas along path *C* by using $P = nRT/V$. Hence, the work done on the gas as it is compressed from V_i to V_f along path *C* is

$$W_{\text{on}} = -\int_{V_i}^{V_f} P\,dV = -\int_{V_i}^{V_f} \frac{nRT}{V}\,dV$$

Because *T* is constant for an isothermal process, we can factor it from the integral. We then have

$$W_{\text{isothermal}} = -nRT\int_{V_i}^{V_f} \frac{dV}{V} = -nRT\ln\frac{V_f}{V_i} = nRT\ln\frac{V_i}{V_f} \qquad \text{18-17}$$

WORK DONE ON GAS DURING ISOTHERMAL COMPRESSION

See **Math Tutorial** *for more information on* **Logarithms**

We see that the amount of work done on the gas is different for each process illustrated. The change in internal energy of the gas depends on the initial and final states of the gas, but does not depend on the path taken. The change in internal energy equals the work done on the gas plus the heat transfer into the gas. Thus, we can see that because the work done is different for each process illustrated, the amount of heat transfer also must be different for each process. This discussion illustrates the fact that both the work done and the amount of heat transfer depend only on how a system transitions from one state to another, but the change in the internal energy of the system does not.

* Constant-volume processes are also called *isochoric processes or isovolumetric processes.*

PROBLEM-SOLVING STRATEGY

Calculating Work Done by an Ideal Gas During a Constrained Quasi-Static Process

PICTURE The increment of work done by a gas is equal to the pressure times the increment of volume. That is, $dW_{\text{by}} = P\,dV$. It follows that $W_{\text{by}} = \int_{V_i}^{V_f} P\,dV$. The constraint dictates how to evaluate this integral.

SOLVE

1. If the volume V is constant, then dV equals zero and $W_{\text{by}} = 0$.
2. If the pressure P is constant, then $W_{\text{by}} = P\int_{V_i}^{V_f} dV = P(V_f - V_i)$.
3. If the temperature T is constant, then $P = nRT/V$ and
$$W_{\text{by}} = \int_{V_i}^{V_f} \frac{nRT}{V}dV = nRT\int_{V_i}^{V_f}\frac{dV}{V} = nRT\ln\frac{V_f}{V_i}$$
4. If no energy is transferred to or from the gas via heat, then see Section 18-9.

CHECK If the volume increases then the W_{by} must be positive, and vice versa.

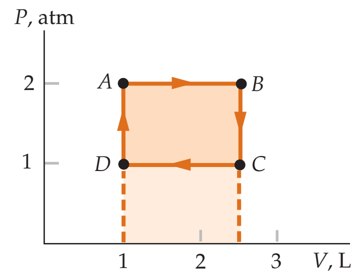

FIGURE 18-9

Example 18-7 Work Done on an Ideal Gas

An ideal gas undergoes a cyclic process from point A to point B to point C to point D and back to point A, as shown in Figure 18-9. The gas begins at a volume of 1.00 L and a pressure of 2.00 atm and expands at constant pressure until the volume is 2.50 L, after which it is cooled at constant volume until its pressure is 1.00 atm. It is then compressed at constant pressure until its volume is again 1.00 L, after which it is heated at constant volume until it is back in its original state. Find the total work done on the gas and the total amount of heat transfer into it during the cycle.

PICTURE We calculate the work done during each step. Because $\Delta E_{\text{int}} = 0$ for any complete cycle, the first law of thermodynamics implies that the total amount of heat transfer into the gas plus the total work done on the gas equals zero.

SOLVE

1. From point A to point B the process is a constant pressure expansion, so the work done on the gas has a negative value. The work done on the gas equals the negative of the shaded area under the AB curve, shown in Figure 18-10*a*:

$$W_{AB} = -P\,\Delta V = -P(V_B - V_A)$$
$$= -(2.00\text{ atm})(2.50\text{ L} - 1.00\text{ L})$$
$$= -3.00\text{ L}\cdot\text{atm}$$

2. Convert the units to joules:

$$W_{AB} = -3.00\text{ L}\cdot\text{atm} \times \frac{101.3\text{ J}}{1\text{ L}\cdot\text{atm}} = -304\text{ J}$$

3. From point B to point C (Figure 18-10) the gas cools at constant volume, so the work done is zero:

$$W_{BC} = 0$$

4. As the gas undergoes a constant pressure compression from point C to point D, the work done on it has a positive value. This work equals the area under the CD curve, shown in Figure 18-10*b*:

$$W_{CD} = -P\,\Delta V = -P(V_D - V_C)$$
$$= -(1.00\text{ atm})(1.00\text{ L} - 2.50\text{ L})$$
$$= 1.50\text{ L}\cdot\text{atm} = 152\text{ J}$$

5. As the gas is heated back to its original state A, the volume is again constant (Figure 18-10), so no work is done:

$$W_{DA} = 0$$

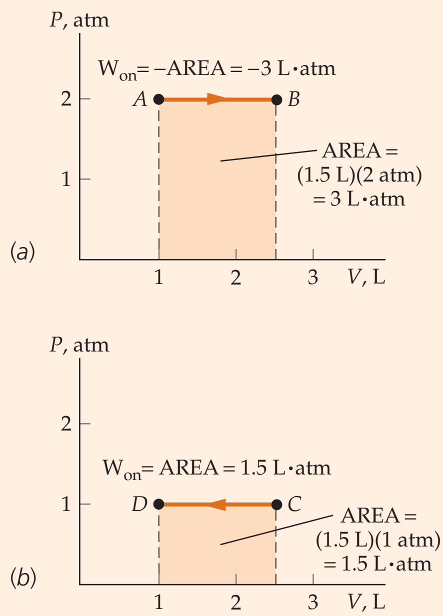

FIGURE 18-10 (*a*) The work done on the gas during the expansion from A to B is equal to the negative of the area under the curve. (*b*) The work done on the gas during the compression from C to D is equal to the area under the curve.

6. The total work done by the gas is the sum of the work done along each step:

$$W_{\text{total}} = W_{AB} + W_{BC} + W_{CD} + W_{DA}$$
$$= (-304\text{ J}) + 0 + 152\text{ J} + 0 = \boxed{-152\text{ J}}$$

7. Because the gas is back in its original state, the total change in internal energy is zero:

$$\Delta E_{\text{int}} = 0$$

8. The amount of heat transfer into the gas is found from the first law of thermodynamics:

$$\Delta E_{\text{int}} = Q_{\text{in}} + W_{\text{on}}$$
$$\text{so}\quad Q_{\text{in}} = \Delta E_{\text{int}} - W_{\text{on}} = 0 - (-152\text{ J}) = \boxed{152\text{ J}}$$

CHECK We expect the net energy transferred to the gas to be zero for a cyclic process, which is the case in this Example because the work done on the gas is −152 J and the amount of heat transfer into the gas is +152 J.

TAKING IT FURTHER The work done by the gas equals the negative of the work done on the gas, so the total work done by the gas during the cycle is +152 J. During the cycle, the gas absorbs 152 J of heat from its surroundings and does 152 J of work on its surroundings. This process leaves the gas in its initial state. The total work done by the gas equals the area enclosed by the cycle in Figure 18-9. Such cyclic processes have important applications for heat engines, as we will see in Chapter 19.

18-6 HEAT CAPACITIES OF GASES

The determination of the heat capacity of a substance provides information about its internal energy, which is related to its molecular structure. For all substances that expand when heated, the heat capacity at constant pressure C_P is greater than the heat capacity at constant volume C_V. If heat is absorbed by a substance at constant pressure, the substance expands and does positive work on its surroundings (Figure 18-11). Therefore, it takes more heat to obtain a given temperature change at constant pressure than to obtain the same temperature change when heated at constant volume. The expansion is usually negligible for solids and liquids, so for them $C_P \approx C_V$. But a gas heated at constant pressure readily expands and does a significant amount of work, so $C_P - C_V$ is not negligible.

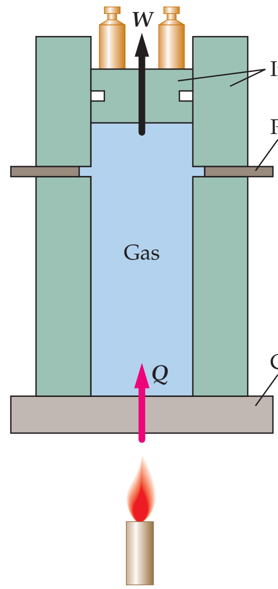

FIGURE 18-11 Heat is absorbed and the pressure remains constant. The gas expands, thus doing work on the piston.

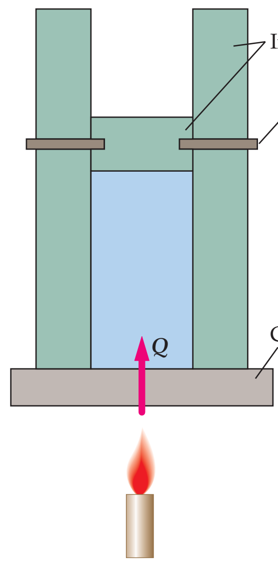

FIGURE 18-12 The piston is held in place by pins. Heat is absorbed at constant volume, so no work is done and all the heat is transferred into the internal energy of the gas.

If heat is absorbed by a gas at constant volume, no work is done (Figure 18-12), so the amount of heat transfer into the gas equals the increase in the internal energy of the gas. Writing Q_V for the amount of heat transfer into the gas at constant volume, we have

$$Q_V = C_V\,\Delta T$$

Because $W = 0$, we have from the first law of thermodynamics,

$$\Delta E_{\text{int}} = Q_V + W = Q_V$$

Thus,

$$\Delta E_{\text{int}} = C_V\,\Delta T$$

Taking the limit as ΔT approaches zero, we obtain

$$dE_{\text{int}} = C_V\,dT \qquad \text{18-18}a$$

and

$$C_V = \frac{dE_{\text{int}}}{dT} \qquad \text{18-18}b$$

The heat capacity at constant volume is the rate of change of the internal energy with temperature. Because E_{int} and T are both state functions, Equations 18-18*a* and 18-18*b* hold for any process.

Now let us calculate the difference $C_P - C_V$ for an ideal gas. From the definition of C_P, the amount of heat transfer into the gas at constant pressure is

$$Q_P = C_P\,\Delta T$$

From the first law of thermodynamics,

$$\Delta E_{\text{int}} = Q_P + W_{\text{on}} = Q_P - P\,\Delta V$$

Then

$$\Delta E_{\text{int}} = C_{\text{P}}\,\Delta T - P\,\Delta V \qquad \text{or} \qquad C_{\text{P}}\,\Delta T = \Delta E_{\text{int}} + P\,\Delta V$$

For infinitesimal changes, this becomes

$$C_{\text{P}}\,dT = dE_{\text{int}} + P\,dV$$

Using Equation 18-18*a* for dE_{int}, we obtain

$$C_{\text{P}}\,dT = C_{\text{V}}\,dT + P\,dV \qquad \text{18-19}$$

The pressure, volume, and temperature for an ideal gas are related by

$$PV = nRT$$

Taking the differentials of both sides of the ideal-gas law, we obtain

$$P\,dV + V\,dP = nR\,dT$$

For a constant-pressure process $dP = 0$, so

$$P\,dV = nR\,dT$$

Substituting $nR\,dT$ for $P\,dV$ in Equation 18-19 gives

$$C_{\text{P}}\,dT = C_{\text{V}}\,dT + nR\,dT = (C_{\text{V}} + nR)\,dT$$

Therefore,

$$C_{\text{P}} = C_{\text{V}} + nR \qquad \text{18-20}$$

which shows that, for an ideal gas, the heat capacity at constant pressure is greater than the heat capacity at constant volume by the amount nR.

Table 18-3 lists measured molar heat capacities c'_{P} and c'_{V} for several gases. Note from this table that the ideal-gas prediction, $c'_{\text{P}} - c'_{\text{V}} = R$, holds quite well for all gases. The table also shows that c'_{V} is approximately $1.5R$ for all monatomic gases, $2.5R$ for all diatomic gases, and greater than $2.5R$ for gases consisting of more complex molecules. We can understand these results by considering the molecular model of a gas (Chapter 17). The total translational kinetic energy of n moles of a gas is $K_{\text{trans}} = \frac{3}{2}nRT$ (Equation 17-20). Thus, if the internal energy of a gas consists of translational kinetic energy only, we have

$$E_{\text{int}} = \tfrac{3}{2}nRT \qquad \text{18-21}$$

Table 18-3 Molar Heat Capacities in of Various Gases at

Gas	c'_{P}	c'_{V}	c'_{V}/R	$c'_{\text{P}} - c'_{\text{V}}$	$(c'_{\text{P}} - c'_{\text{V}})/R$
Monatomic					
He	20.79	12.52	1.51	8.27	0.99
Ne	20.79	12.68	1.52	8.11	0.98
Ar	20.79	12.45	1.50	8.34	1.00
Kr	20.79	12.45	1.50	8.34	1.00
Xe	20.79	12.52	1.51	8.27	0.99
Diatomic					
N_2	29.12	20.80	2.50	8.32	1.00
H_2	28.82	20.44	2.46	8.38	1.01
O_2	29.37	20.98	2.52	8.39	1.01
CO	29.04	20.74	2.49	8.30	1.00
Polyatomic					
CO_2	36.62	28.17	3.39	8.45	1.02
N_2O	36.90	28.39	3.41	8.51	1.02
H_2S	36.12	27.36	3.29	8.76	1.05

The heat capacities are then

$$C_V = \frac{dE_{\text{int}}}{dT} = \tfrac{3}{2}nR \qquad \text{18-22}$$

C_V FOR AN IDEAL MONATOMIC GAS

and

$$C_P = C_V + nR = \tfrac{5}{2}nR \qquad \text{18-23}$$

C_P FOR AN IDEAL MONATOMIC GAS

The results in Table 18-3 agree well with these predictions for monatomic gases, but for other gases, the heat capacities are greater than those predicted by Equations 18-22 and 18-23. The internal energy for a gas consisting of diatomic or more complicated molecules is evidently greater than $\frac{3}{2}nRT$. The reason is that such molecules can have other types of energy, such as rotational or vibrational energy, in addition to translational kinetic energy.

Example 18-8 Heating, Cooling, and Compressing an Ideal Gas

A system consisting of 0.32 mol of a monatomic ideal gas, with $c'_V = \frac{3}{2}RT$, occupies a volume of 2.2 L at a pressure of 2.4 atm, as represented by point A in Figure 18-13. The system is carried through a cycle consisting of three processes:

1. The gas is heated at constant pressure until its volume is 4.4 L at point B.
2. The gas is cooled at constant volume until the pressure decreases to 1.2 atm (point C).
3. The gas undergoes an isothermal compression back to point A.

(*a*) What is the temperature at points A, B, and C? (*b*) Find W, Q, and ΔE_{int} for each process and for the entire cycle.

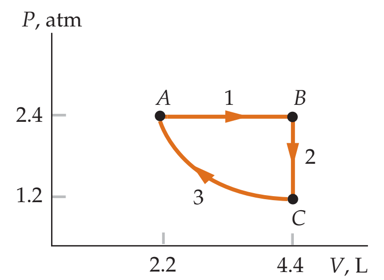

FIGURE 18-13 The total work done *on* the gas during one cycle is the negative of the area enclosed by the curves. The total work done *by* the gas during one cycle is the area enclosed by the curves.

PICTURE You can find the temperatures at all points from the ideal-gas law. You can find the work for each process by finding the area under the curve, and the heat transferred by using the given heat capacity and the initial and final temperatures for each process. In process 3, T is constant, so $\Delta E_{\text{int}} = 0$ and the heat absorbed by the gas plus the work done on the gas equals zero.

SOLVE

(*a*) Find the temperatures at points A, B, and C using the ideal-gas law:

$$T_C = T_A = \frac{P_A V_A}{nR} = \frac{(2.4\text{ atm})(2.2\text{ L})}{(0.32\text{ mol})(0.08206\text{ L}\cdot\text{atm}/(\text{mol}\cdot\text{K}))}$$
$$= 201\text{ K} = \boxed{2.0 \times 10^2\text{ K}}$$

$$T_B = \frac{P_B V_B}{nR} = \frac{P_A 2V_A}{nR} = 2\frac{P_A V_A}{nR} = 2T_A = 402\text{ K} = \boxed{4.0 \times 10^2\text{ K}}$$

(*b*) 1. For process 1, use $W_1 = -P_c\,\Delta V$ to calculate the work, and $C_P = \frac{5}{2}nR$ to calculate the heat Q_1. Then use W_1 and Q_1 to calculate $\Delta E_{\text{int 1}}$:

$$W_1 = -P_A\,\Delta V = -P_A(V_B - V_A) = -(2.4\text{ atm})(2.2\text{ L})$$
$$= -5.28\text{ L}\cdot\text{atm}\left(\frac{101.3\text{ J}}{1\text{ L}\cdot\text{atm}}\right) = -534.9\text{ J} = \boxed{-0.53\text{ kJ}}$$

$$Q_1 = C_P\,\Delta T = \tfrac{5}{2}nR\,\Delta T = \tfrac{5}{2}(0.32\text{ mol})(8.314\text{ J}/(\text{mol}\cdot\text{K}))(201\text{ K})$$
$$= 1337\text{ J} = \boxed{1.3\text{ kJ}}$$

$$\Delta E_{\text{int 1}} = Q_1 + W_1 = 1337\text{ J} - 534.9\text{ J} = 802\text{ J} = \boxed{0.80\text{ kJ}}$$

2. For process 2, use $C_V = \frac{3}{2}nR$ and $T_C - T_B$ from step 1 to find Q_2:

$$W_2 = \boxed{0}$$

Then, because $W_2 = 0$, $\Delta E_{\text{int 2}} = Q_2$:

$$Q_2 = C_V\,\Delta T = \tfrac{3}{2}nR\,\Delta T = \tfrac{3}{2}(0.32\text{ mol})[8.314\text{ J}/(\text{mol}\cdot\text{K})](-201\text{ K})$$
$$= -802\text{ J} = \boxed{-0.80\text{ kJ}}$$

$$\Delta E_{\text{int 2}} = W_2 + Q_2 = 0 + (-802\text{ J}) = \boxed{-0.80\text{ kJ}}$$

3. Calculate W_3 from $W = -nRT \ln(V_A/V_C)$ (Equation 18-17) in the isothermal compression. Then, because $\Delta E_{\text{int}\,3} = 0$, $Q_3 = -W_3$:

$$W_3 = nRT_A \ln\frac{V_A}{V_C} = (0.32\text{ mol})[8.314\text{ J/(mol}\cdot\text{K)}](-201\text{ K})\ln 2.0$$
$$= 371\text{ J} = \boxed{0.37\text{ kJ}}$$
$$\Delta E_{\text{int}\,3} = \boxed{0}$$
$$Q_3 = \Delta E_{\text{int}\,3} - W_3 = -371\text{ J} = \boxed{-0.37\text{ kJ}}$$

4. Find the total work W, the total heat Q, and the total change ΔE_{int} by summing the quantities found in steps 2, 3, and 4:

$$W_{\text{total}} = W_1 + W_2 + W_3 = (-535\text{ J}) + 0 + 371\text{ J} = \boxed{-0.16\text{ kJ}}$$
$$Q_{\text{total}} = Q_1 + Q_2 + Q_3 = 1337\text{ J} + (-802\text{ J}) + (-371\text{ J})$$
$$= \boxed{0.16\text{ kJ}}$$
$$\Delta E_{\text{int total}} = \Delta E_{\text{int}\,1} + \Delta E_{\text{int}\,2} + \Delta E_{\text{int}\,3}$$
$$= 802\text{ J} + (-802\text{ J}) + 0 = \boxed{0.00\text{ kJ}}$$

CHECK The total change in internal energy is zero, as it must be for a cyclic process. The total work done on the gas plus the total heat absorbed by the gas equals zero.

TAKING IT FURTHER The total work done on the gas equals the area under the *CA* curve minus the area under the *AB* curve, which equals the negative of the area enclosed by the three curves in Figure 18-13.

HEAT CAPACITIES AND THE EQUIPARTITION THEOREM

According to the equipartition theorem stated in Section 4 of Chapter 17, the internal energy of n moles of a gas should equal $\frac{1}{2}nRT$ for each degree of freedom of the gas molecules. The heat capacity at constant volume of a gas should then be $\frac{1}{2}nR$ times the number of degrees of freedom of the molecules. From Table 18-2, nitrogen, oxygen, hydrogen, and carbon monoxide all have molar heat capacities at constant volume of about $\frac{5}{2}R$. Thus, the molecules in each of these gases have five degrees of freedom. About 1880, Rudolf Clausius speculated that these gases must consist of diatomic molecules that can rotate about two axes, giving them two additional degrees of freedom (Figure 18-14). The two degrees of freedom besides the three for translation are now known to be associated with their rotation about each of the two axes, x' and y', perpendicular to the line joining the atoms. The kinetic energy of a diatomic molecule is therefore

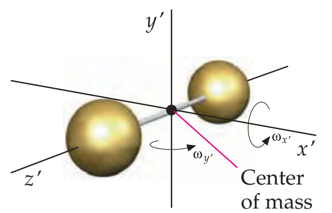

FIGURE 18-14 Rigid-dumbbell model of a diatomic molecule.

$$K = \tfrac{1}{2}mv_x^2 + \tfrac{1}{2}mv_y^2 + \tfrac{1}{2}mv_z^2 + \tfrac{1}{2}I_{x'}\omega_{x'}^2 + \tfrac{1}{2}I_{y'}\omega_{y'}^2$$

The total internal energy of n moles of such a gas is then

$$E_{\text{int}} = 5 \times \tfrac{1}{2}nRT = \tfrac{5}{2}nRT \qquad \text{18-24}$$

and the heat capacity at constant volume is

$$C_V = \tfrac{5}{2}nR \qquad \text{18-25}$$

Apparently, diatomic gases do not rotate about the line joining the two atoms—if they did, there would be six degrees of freedom and C_V would be $\frac{6}{2}nR = 3nR$, which is contrary to experimental results. Furthermore, monatomic gases do not rotate at all. We will see in Section 18-8 that these puzzling facts are easily explained when we take the quantization of angular momentum into account.

Example 18-9 Heating a Diatomic Ideal Gas

A sample consisting of 2.00 mol of oxygen gas at an initial pressure of 1.00 atm is heated from a temperature of 20.0°C to a temperature of 100.0°C. Assume that the sample can be modeled as an ideal gas. (*a*) What amount of heat transfer into the sample is required if the volume is kept constant during the heating? (*b*) What amount of heat transfer into the sample is required if the pressure is kept constant? (*c*) How much work does the gas do in Part (*b*)?

PICTURE The amount of heat transfer needed for constant-volume heating is $Q_V = C_V\,\Delta T$, where $C_V = \frac{5}{2}nR$ (because oxygen is a diatomic gas). For constant-pressure heating, $Q_P = C_P\,\Delta T$, where $C_P = C_V + nR$. Finally, the amount of work done by the gas equals the negative of the work done on the gas, which can be found from $\Delta E_{int} = Q_{in} + W_{on}$. (Alternatively, $W_{by} = P\,\Delta V$.)

SOLVE

(*a*) 1. Write the amount of heat transfer needed for constant volume in terms of C_V and ΔT:

$$Q_V = C_V\,\Delta T$$

2. Calculate the amount of heat transfer needed for $\Delta T = 80°C = 80$ K:

$$Q_V = C_V\,\Delta T = \tfrac{5}{2}nR\,\Delta T = \tfrac{5}{2}(2.00\text{ mol})[8.314\text{ J/(mol}\cdot\text{K)}](80.0\text{ K}) = \boxed{3.33\text{ kJ}}$$

(*b*) 1. Write the amount of heat transfer needed for constant pressure in terms of C_P and ΔT:

$$Q_P = C_P\,\Delta T$$

2. Calculate the heat capacity at constant pressure:

$$C_P = C_V + nR = \tfrac{5}{2}nR + nR = \tfrac{7}{2}nR$$

3. Calculate the amount of heat transfer needed at constant pressure for $\Delta T = 80$ K:

$$Q_P = C_P\,\Delta T = \tfrac{7}{2}(2.00\text{ mol})[8.314\text{ J/(mol}\cdot\text{K)}](80.0\text{ K}) = \boxed{4.66\text{ kJ}}$$

(*c*) 1. The work W_{on} can be found from the first law of thermodynamics:

$$\Delta E_{int} = Q_{in} + W_{on} \quad\text{so}\quad W_{on} = \Delta E_{int} - Q_{in}$$

2. The internal energy change equals the heat transferred at constant volume, which was calculated in Part (*a*):

$$\Delta E_{int} = Q_V = C_V\,\Delta T = \tfrac{5}{2}nR\,\Delta T$$

and $Q_P = C_P\,\Delta T = \tfrac{7}{2}nR\,\Delta T$

so $W_{on} = \Delta E_{int} - Q_P = \tfrac{5}{2}nR\,\Delta T - \tfrac{7}{2}nR\,\Delta T = -nR\,\Delta T$

$$= -(2.00\text{ mol})[8.314\text{ J/(mol}\cdot\text{K)}](80.0\text{ K}) = -1.33\text{ kJ}$$

3. The work done by the gas at constant pressure is then:

$$W_{by} = -W_{on} = \boxed{1.33\text{ kJ}}$$

CHECK Note that the work done by the gas in part (c) has a positive value. This is as expected because the gas expands when heated at constant pressure.

PRACTICE PROBLEM 18-5 Find the initial and final volumes of this gas from the ideal-gas law, and use them to calculate the work done by the gas if the heat is added at constant pressure using $W_{by} = P\,\Delta V$.

Example 18-10 Vibrational Modes of Carbon Dioxide *Conceptual*

The carbon dioxide molecule consists of a carbon atom directly between two oxygen atoms. This molecule has three distinct modes of vibration. Sketch these modes in a reference frame where the center of mass of the molecule is at rest.

PICTURE If the molecule were not vibrating, the centers of the atoms would lie in a straight line. When vibrating the atoms can move both parallel and perpendicular to the line through their centers. There are two stretching modes in which the atoms move parallel to the line through their centers, and one bending mode where they move perpendicular to the line through their centers.

SOLVE

1. In the symmetric stretch mode (Figure 18-15a) the carbon atom remains stationary and the oxygen atoms oscillate 180° out of phase with each other. Can you see why this mode is sometimes referred to as the breathing mode?
2. In the asymmetric stretch mode (Figure 18-15*b*) the two oxygen atoms vibrate in phase with each other, but 180° out of phase with the motion of the carbon atom:
3. In the bending mode (Figure 18-15*c*) the two oxygen atoms vibrate in phase with each other, but 180° out of phase with the motion of the carbon atom:

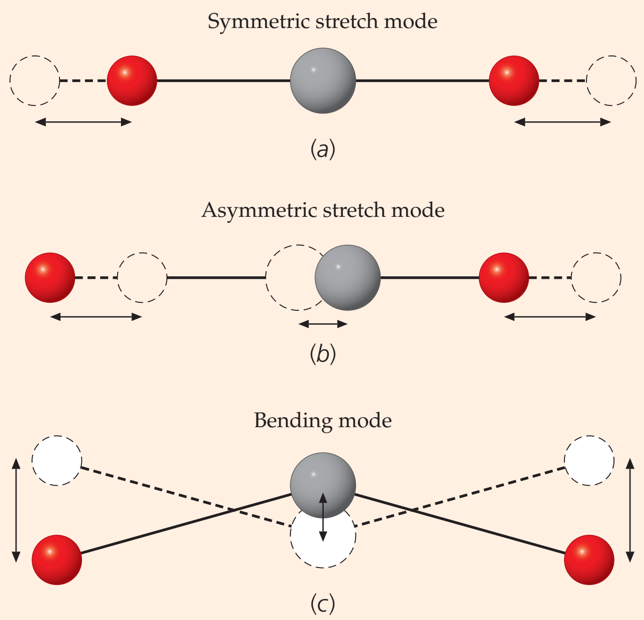

FIGURE 18-15

18-7 HEAT CAPACITIES OF SOLIDS

In Section 18-1, we noted that all of the metals listed in Table 18-1 have approximately equal molar specific heats. Most solids have molar heat capacities approximately equal to $3R$:

$$c' = 3R = 24.9 \text{ J/mol}\cdot\text{K} \qquad 18\text{-}26$$

This result is known as the **Dulong–Petit law.** We can understand this law by applying the equipartition theorem to the simple model for a solid shown in Figure 18-16. According to this model, a solid consists of a regular array of atoms in which each of the atoms has a fixed equilibrium position and is connected by springs to its neighbors. Each atom can vibrate in the x, y, and z directions. The total energy of an atom in a solid is

$$E = \tfrac{1}{2}mv_x^2 + \tfrac{1}{2}mv_y^2 + \tfrac{1}{2}mv_z^2 + \tfrac{1}{2}k_{\text{eff}}x^2 + \tfrac{1}{2}k_{\text{eff}}y^2 + \tfrac{1}{2}k_{\text{eff}}z^2$$

where k_{eff} is the effective force constant of the hypothetical springs. Each atom thus has six degrees of freedom. The equipartition theorem states that a substance in equilibrium has an average energy of $\frac{1}{2}RT$ per mole for each degree of freedom. Thus, the internal energy of a mole of a solid is

$$E_{\text{int m}} = 6 \times \tfrac{1}{2}RT = 3RT \qquad 18\text{-}27$$

which means that c' is equal to $3R$.

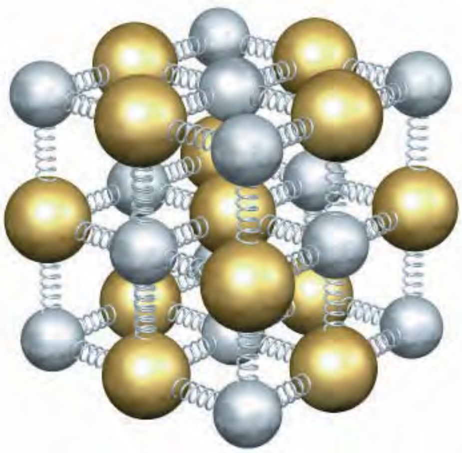

FIGURE 18-16 Model of a solid in which the atoms are connected to each other by springs. The internal energy of the molecule consists of the kinetic and potential energies of vibration.

Example 18-11 Using the Dulong–Petit Law

The molar mass of copper is 63.5 g/mol. Use the Dulong–Petit law to calculate the specific heat of copper.

PICTURE The Dulong–Petit law gives the molar specific heat of a solid, c'. The specific heat is then $c = c'/M$ (Equation 18-6), where M is the molar mass.

SOLVE

1. The Dulong–Petit law gives c' in terms of R: $c' = 3R$

2. Using $M = 63.5$ g/mol for copper, the specific heat is: $c = \dfrac{c'}{M} = \dfrac{3R}{M} = \dfrac{3(8.314 \text{ J/(mol}\cdot\text{K))}}{63.5 \text{ g/mol}}$

$= 0.392 \text{ J/(g}\cdot\text{K)} = \boxed{0.392 \text{ kJ/(kg}\cdot\text{K)}}$

CHECK This result differs from the measured value of 0.386 kJ/kg·K, given in Table 18-1, by less than 2 percent.

PRACTICE PROBLEM 18-6 The specific heat of a certain metal is measured to be 1.02 kJ/kg·K. (*a*) Calculate the molar mass of this metal, assuming that the metal obeys the Dulong–Petit law. (*b*) What is the metal?

18-8 FAILURE OF THE EQUIPARTITION THEOREM

Although the equipartition theorem had spectacular successes in explaining the heat capacities of gases and solids, it had equally spectacular failures. For example, if a diatomic gas molecule like the one in Figure 18-14 rotates about the line joining the atoms, there should be an additional degree of freedom. Similarly, if a diatomic molecule is not rigid, the two atoms should vibrate along the line joining them. We would then have two more degrees of freedom corresponding to kinetic and potential energies of vibration. But according to the measured values of the molar

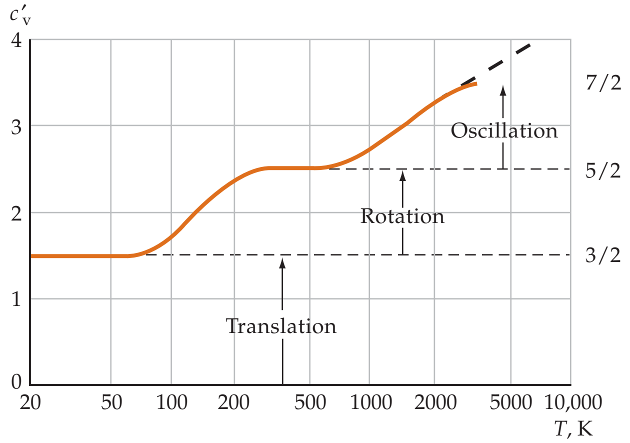

FIGURE 18-17 Temperature dependence of the molar heat capacity of H_2. (The curve is qualitative in those regions where c'_v is changing.) Ninety-five percent of H_2 molecules are dissociated into atomic hydrogen at 5000 K.

heat capacities in Table 18-3, diatomic gases apparently do not rotate about the line joining them, nor do they vibrate. The equipartition theorem does not give explanations for this consequence, or for the fact that monatomic atoms do not rotate about any of the three possible perpendicular axes in space. Furthermore, heat capacities are found to depend on temperature, contrary to the predictions of the equipartition theorem. The most spectacular case of the temperature dependence of heat capacity is that of H_2, as shown in Figure 18-17. At temperatures below 70 K, c'_v for H_2 is $\frac{3}{2}R$, which is the same as that for a gas of molecules that translate, but do not rotate or vibrate. At temperatures between 250 K and 700 K, $c'_v = \frac{5}{2}R$, which is that for molecules that translate and rotate but do not vibrate. And at temperatures above 700 K, the H_2 molecules begin to vibrate. However, the molecules dissociate before c'_v reaches $\frac{7}{2}R$. Finally, the equipartition theorem predicts a constant value of $3R$ for the heat capacity of solids. While this result holds for many, although not all, solids at high temperatures, it does not hold at very low temperatures.

The equipartition theorem fails because the energy is **quantized.** That is, a molecule can have only certain values of internal energy, as illustrated schematically by the energy-level diagram in Figure 18-18. The molecule can gain or lose energy only if the gain or loss takes it to another allowed level. For example, the energy that can be transferred between colliding gas molecules is of the order of kT, the typical thermal energy of a molecule. The validity of the equipartition theorem depends on the relative size of kT and the spacing of the allowed energy levels.

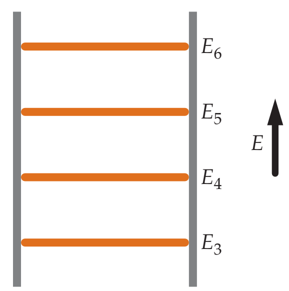

FIGURE 18-18 Energy-level diagram. A bound system can have only certain discrete energies.

> If the spacing of the allowed energy levels is large compared with kT, energy cannot be transferred by collisions and the classic equipartition theorem is not valid. If the spacing of the levels is much smaller than kT, energy quantization will not be noticed and the equipartition theorem will hold.
>
> CONDITIONS FOR THE VALIDITY OF THE EQUIPARTITION THEOREM

Consider the rotation of a molecule. The energy of rotation is

$$E = \frac{1}{2}I\omega^2 = \frac{(I\omega)^2}{2I} = \frac{L^2}{2I} \qquad 18\text{-}28$$

where I is the moment of inertia of the molecule, ω is its angular velocity, and $L = I\omega$ is its angular momentum. In Section 10-5, we mentioned that angular momentum is quantized, and its magnitude is restricted to

$$L = \sqrt{\ell(\ell + 1)}\hbar \qquad \ell = 0, 1, 2, \ldots \qquad 18\text{-}29$$

where $\hbar = h/(2\pi)$, and h is Planck's constant. The energy of a rotating molecule is therefore quantized to the values

$$E = \frac{L^2}{2I} = \frac{\ell(\ell+1)\hbar^2}{2I} = \ell(\ell+1)\,E_{0r} \qquad \text{18-30}$$

where

$$E_{0r} = \frac{\hbar^2}{2I} \qquad \text{18-31}$$

is characteristic of the energy gap between levels. If this energy is much less than kT, we expect classical physics and the equipartition theorem to hold. Let us define a critical temperature T_c by

$$kT_c = E_{0r} = \frac{\hbar^2}{2I} \qquad \text{18-32}$$

If T is much greater than this critical temperature, then kT will be much greater than the spacing of the energy levels, which is of the order of kT_c, and we expect classical physics and the equipartition theorem to be valid. If T is less than or of the order of T_c, then kT will not be much greater than the energy-level spacing, and we expect classical physics and the equipartition theorem to break down. Let us estimate T_c for some cases of interest.

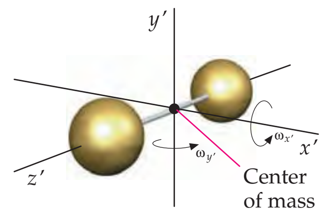

FIGURE 18-19 Rigid-dumbbell model of a diatomic molecule.

1. *Rotation of* H_2 *about an axis perpendicular to the line joining the H atoms and through the center of mass* (Figure 18-19): The moment of inertia of H_2 about the axis is

$$I_H = 2M_H\left(\frac{r_s}{2}\right)^2 = \frac{1}{2}M_H r_s^2$$

where M_H is the mass of an H atom and r_s is the separation distance. For hydrogen, $M_H = 1.67 \times 10^{-27}$ kg, and $r_s \approx 8 \times 10^{-11}$ m. The critical temperature is then

$$T_c = \frac{\hbar^2}{2kI} = \frac{\hbar^2}{kM_H r_s^2}$$
$$= \frac{(1.05 \times 10^{-34}\ \mathrm{J \cdot s})^2}{(1.38 \times 10^{-23}\ \mathrm{J/K})(1.67 \times 10^{-27}\ \mathrm{kg})(8 \times 10^{-11}\ \mathrm{m})^2} \approx 75\ \mathrm{K}$$

As we see from Figure 18-17, this is approximately the temperature below which the rotational energy does not contribute to the heat capacity.

2. O_2: Because the mass of O_2 is about 16 times that of H_2, and the separation is about the same, the critical temperature for O_2 should be about $(75/16) \approx 4.6$ K. For all temperatures for which O_2 exists as a gas, $T \gg T_c$, so kT is much greater than the energy level spacing. Consequently, we expect the equipartition theorem of classical physics to apply.

3. *Rotation of a monatomic gas*: Consider the He atom that has a nucleus that is composed of two protons and two neutrons and has two electrons. The mass of an electron is about 8000 times smaller than the mass of the He nucleus, but the radius of the nucleus is about 100,000 times smaller than the distance from the nucleus to an electron. Therefore, the moment of inertia of the He atom is almost entirely due to its two electrons. The distance from the He nucleus to one of its electrons is about half the separation distance of the H atoms in H_2, and the electron mass is about 2000 times smaller than that of the H nucleus. Thus, using $m_e = M_H/2000$ and $r = r_s/2$, we find the moment of inertia of the two electrons in He to be roughly

$$I_{He} = 2m_e r^2 \approx 2\frac{M_H}{2000}\left(\frac{r_s}{2}\right)^2 = \frac{I_H}{2000}$$

The critical temperature for He is thus about 2000 times that of H_2 or about 150,000 K. This is much higher than the dissociation temperature (the temperature at which electrons are stripped from their nuclei) for helium. So, the gap between allowed energy levels is always much greater than kT, and the He molecules cannot be induced to rotate by collisions occurring in the gas. Other monatomic gases have slightly greater moments of inertia because they have more electrons, but their critical temperatures are still tens of thousands of kelvins. Therefore, their molecules also cannot be induced to rotate by collisions occurring in the gas.

4. *Rotation of a diatomic gas about the axis joining the atoms*: We see from our discussion of monatomic gases that the moment of inertia for a diatomic gas molecule about this axis will also be due mainly to the electrons and will be of the same order of magnitude as for a monatomic gas. Again, the critical temperature, T_c, calculated in order for this rotation to occur due to collisions between molecules in the gas, exceeds the gas's dissociation temperature, making rotation under those circumstances impossible.

It is interesting to note that the successes of the equipartition theorem in explaining the measured heat capacities of gases and solids led to the first real understanding of molecular structure in the nineteenth century, whereas its failures played an important role in the development of quantum mechanics in the twentieth century.

Example 18-12 Rotational Energy of the Hydrogen Atom

At room temperature (300 K) hydrogen gas is diatomic. However, at higher temperatures, the hydrogen molecules dissociate. At a temperature of 8000 K, hydrogen gas is 99.99 percent monatomic. (*a*) Estimate the lowest (nonzero) rotational energy for the hydrogen atom and compare it to kT at room temperature. (*b*) Calculate the critical temperature T_c for a gas of atomic hydrogen.

PICTURE From Equation 18-30, the lowest rotational energy is for $\ell = 1$. We use Equation 18-30 to determine the energy in terms of the moment of inertia. We can neglect the moment of inertia of the nucleus because its radius is 100,000 times smaller than the radius of the atom. Therefore, the moment of inertia for the atom is essentially the moment of inertia of the electron about the nucleus. Then $I = m_e r^2$, where $r = 5.29 \times 10^{-11}$ m is the distance from the nucleus to the electron.

SOLVE

(*a*) 1. The lowest energy greater than zero occurs for $\ell = 1$:

$$E_\ell = \frac{\ell(\ell + 1)\hbar^2}{2I} \qquad \ell = 0, 1, 2, \ldots$$

so $$E_1 = \frac{1(1 + 1)\hbar^2}{2m_e r^2} = \frac{\hbar^2}{m_e r^2}$$

2. The numerical values are:

$\hbar = 1.05 \times 10^{-34}\ \mathrm{J \cdot s}$
$m_e = 9.11 \times 10^{-31}$ kg
$r = 5.29 \times 10^{-11}$ m

3. Substitute the numerical values:

$$E_1 = \frac{\hbar^2}{m_e r^2} = \boxed{4.32 \times 10^{-18}\ \mathrm{J}}$$

4. The value of kT at $T = 300$ K is

$$kT = (1.38 \times 10^{-23}\ \mathrm{J/K})(300\ \mathrm{K}) = 4.14 \times 10^{-21}\ \mathrm{J}$$

5. Compare E_1 and kT:

$$\frac{E_1}{kT} = \frac{4.32 \times 10^{-18}\ \mathrm{J}}{4.14 \times 10^{-21}\ \mathrm{J}} \approx 10^3$$

$\boxed{E_1 \text{ is about three orders of magnitude larger than } kT.}$

(*b*) Set $kT_c = E_1$ and solve for T_c:

$$kT_c = E_1$$

$$T_c = \frac{E_1}{k} = \frac{4.32 \times 10^{-18}\ \mathrm{J}}{1.38 \times 10^{-23}\ \mathrm{J/K}} = \boxed{3.13 \times 10^5\ \mathrm{K}}$$

CHECK The critical temperature of a hydrogen atom (~3×10^5 K) is so high that the atom would be ionized well before the critical temperature could be reached. This "explains" why no rotational degrees of freedom contribute to the heat capacity of hydrogen atoms.

18-9 THE QUASI-STATIC ADIABATIC COMPRESSION OF A GAS

A process in which no heat transfers into or out of a system is called an **adiabatic process.** Such a process occurs either when the system is extremely well insulated or when the process happens very quickly. Consider the quasi-static adiabatic compression of a gas in which the gas in a thermally insulated container is slowly compressed by a piston, which is thereby doing work on the gas. Because no heat is transferred to or from the gas, the work done on the gas equals the increase in the internal energy of the gas, and the temperature of the gas increases. The curve representing this process on a PV diagram is shown in Figure 18-20.

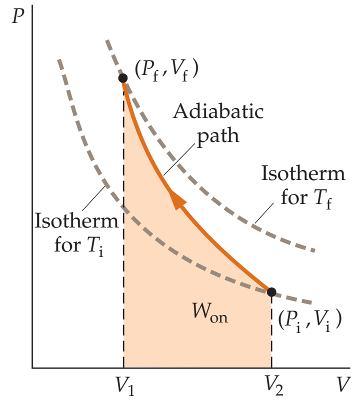

FIGURE 18-20 Quasi-static adiabatic compression of an ideal gas. The dashed lines are the isotherms for the initial and final temperatures. The curve connecting the initial and final states of the adiabatic compression is steeper than the isotherms because the temperature increases during the compression.

We can find the equation for the adiabatic curve for an ideal gas by using the equation of state ($PV = nRT$) and the first law of thermodynamics ($dE_{int} = dQ_m + dW_{on}$). The first law of thermodynamics gives

$$C_V\,dT = 0 + (-P\,dV) \qquad 18\text{-}33$$

where we have used $dE_{int} = C_V\,dT$ (Equation 18-18*a*), $dQ_m = 0$ (the process is adiabatic), and $dW_{on} = -P\,dV$ (Equation 18-15). Then, substituting for P using $P = nRT/V$, we obtain

$$C_V\,dT = -nRT\frac{dV}{V}$$

Separating variables by dividing both sides by TC_V, we obtain

$$\frac{dT}{T} + \frac{nR}{C_V}\frac{dV}{V} = 0$$

Integration gives

$$\ln T + \frac{nR}{C_V}\ln V = \text{constant}$$

Simplifying,

$$\ln T + \frac{nR}{C_V}\ln V = \ln T + \ln V^{nR/C_V} = \ln(TV^{nR/C_V}) = \text{constant}$$

Thus,

$$TV^{nR/C_V} = \text{constant} \qquad 18\text{-}34$$

where the constants in the two preceding equations are not the same constant. Equation 18-34 can be rewritten by noting that $C_P - C_V = nR$, so

$$\frac{nR}{C_V} = \frac{C_P - C_V}{C_V} = \frac{C_P}{C_V} - 1 = \gamma - 1 \qquad 18\text{-}35$$

Clouds form if rising moist air cools due to adiabatic expansion of the air. Cooling causes water vapor to condense into liquid droplets. *(Will and Deni McIntyre/Photo Researchers.)*

where γ is the ratio of the heat capacities:

$$\gamma = \frac{C_P}{C_V} \qquad 18\text{-}36$$

Therefore,

$$TV^{\gamma-1} = \text{constant} \qquad 18\text{-}37$$

We can eliminate T from Equation 18-37 using $PV = nRT$. We then have

$$\frac{PV}{nR}V^{\gamma-1} = \text{constant}$$

or

$$PV^{\gamma} = \text{constant} \qquad 18\text{-}38$$

QUASI-STATIC ADIABATIC PROCESS

Equation 18-38 relates P and V for adiabatic expansions and compressions. Solving $PV = nRT$ (the ideal gas equation) for V, then substituting the resulting expression for V into Equation 18-38, and then simplifying, gives

$$\frac{T^{\gamma}}{P^{\gamma-1}} = \text{constant} \qquad 18\text{-}39$$

PRACTICE PROBLEM 18-7

Show that for quasi-static adiabatic process $T^{\gamma}/P^{\gamma-1} = \text{constant}$.

The work done on the gas in an adiabatic compression can be calculated from the first law of thermodynamics:

$$dE_{int} = dQ_{in} + dW_{on} \qquad \text{or} \qquad dW_{on} = dE_{int} - dQ_{in}$$

Because $dE_{int} = C_V\,dT$ and $dQ_{in} = 0$, we have

$$dW_{on} = C_V\,dT$$

Then

$$W_{adiabatic} = \int dW_{on} = \int C_V\,dT = C_V\,\Delta T \qquad 18\text{-}40$$

ADIABATIC WORK ON IDEAL GAS

where we have assumed that C_v is constant.* We note that the work done on the gas depends only on the change in the temperature of the gas. During an adiabatic compression, work is done on the gas, and its internal energy and temperature increase. During a quasi-static adiabatic *expansion*, work is done *by* the gas, and the internal energy and temperature decrease.

We can use the ideal-gas law to write Equation 18-40 in terms of the initial and final values of the pressure and volume. If T_i is the initial temperature and T_f is the final temperature, we have for the work done

$$W_{adiabatic} = C_V\,\Delta T = C_V(T_f - T_i)$$

Using $PV = nRT$, we obtain

$$W_{adiabatic} = C_V\left(\frac{P_fV_f}{nR} - \frac{P_iV_i}{nR}\right) = \frac{C_V}{nR}(P_fV_f - P_iV_i)$$

Using Equation 18-35 to simplify this expression, we have

$$W_{adiabatic} = \frac{P_fV_f - P_iV_i}{\gamma - 1} \qquad 18\text{-}41$$

* For an ideal gas, E_{int} is proportional to the absolute temperature, and therefore $C_v = dE_{int}/dT$ is a constant.

Example 18-13 Quasi-Static Adiabatic Compression of Air

A hand pump is used to inflate a bicycle tire to a gauge pressure of 482 kPa (about 70.0 lb/in.^{2}). (*a*) How much work must be done if each stroke of the pump is a quasi-static adiabatic process? Atmospheric pressure is 1.00 atm, the outdoor air temperature is 20°C, and the volume of the air in the tire remains constant at 1.00 L. (*b*) What is the pressure in the inflated tire after the pump is removed and the temperature of the air in the tire returns to 20°C?

PICTURE The work done is found from $\Delta E_{int} = Q_{in} + W_{on}$, with $Q_{in} = 0$. For an ideal gas, $\Delta E_{int} = C_V \Delta T$ (Equation 18-40). Because the process is both quasi-static and adiabatic, we know that $T^\gamma/P^{\gamma-1}$ = constant (Equation 18-39). (This relation yields the final temperature.) Find γ using $\gamma = C_P/C_V$, $C_P = C_V + nR$, and $C_V = \frac{5}{2}nR$ (Equations 18-36, 18-20, and 18-25). Let subscript 1 refer to initial values, and subscript 2 to final values. Then $P_1 = 1.00$ atm, $V_2 = 1.00$ L, and $T_1 = 20°\text{C} = 293$ K.

SOLVE

(*a*) 1. To find the work done, we apply the first law of thermodynamics. Because the compression is adiabatic, $Q_{in} = 0$:

$$\Delta E_{int} = Q_{in} + W_{on} = 0 + W_{on}$$

2. For an ideal gas, the change in internal energy is $C_V \Delta T$:

$$W = \Delta E_{int} = C_V \Delta T$$

3. For a diatomic gas, $C_V = \frac{5}{2}nR$:

$$W = C_V \Delta T = \tfrac{5}{2}nR\,\Delta T$$

4. The final temperature can be determined using $T^\gamma/P^{\gamma-1}$ = constant (Equation 18-39):

$$\frac{T_1^\gamma}{P_1^{\gamma-1}} = \frac{T_2^\gamma}{P_2^{\gamma-1}} \Rightarrow T_2 = \left(\frac{P_2}{P_1}\right)^{(\gamma-1)/\gamma} T_1$$

5. Find γ for a diatomic gas using Equations 18-36, 18-20 and 18-25:

$$\gamma = \frac{C_P}{C_V} = \frac{C_V + nR}{C_V} = 1 + \frac{nR}{C_V} = 1 + \frac{nR}{\frac{5}{2}nR} = \frac{7}{5} = 1.4$$

6. Solve for T_2. The given pressure is a gauge pressure, so add 1.00 atm = 101.3 kPa to the given pressure of 482 kPa:

$$T_2 = \left(\frac{P_2}{P_1}\right)^{(\gamma-1)/\gamma} T_1 = \left(\frac{583\text{ kPa}}{101.3\text{ kPa}}\right)^{0.4/1.4} 293\text{ K} = 483\text{ K}$$

$$P_2 = P_1\left(\frac{V_1}{V_2}\right)^\gamma = (1.00\text{ atm})\left(\frac{4.00\text{ L}}{2.00\text{ L}}\right)^{1.4} = \boxed{2.64\text{ atm}}$$

7. Calculate the work using the step-3 result. Use $PV = nRT$ (the ideal-gas law) to express nR in terms of P_2, V_2, and T_2:

$$W = \frac{5}{2}nR\,\Delta T = \frac{5}{2}\frac{P_2V_2}{T_2}(T_2 - T_1)$$

$$= \frac{5}{2}\frac{(583\text{ kPa})(1.00 \times 10^{-3}\text{ m}^3)}{483\text{ K}}(483\text{ K} - 293\text{ K}) = \boxed{634\text{ J}}$$

(*b*) The air in the tire cools at constant volume. Thus, $P_3/T_3 = P_2/T_3$, where P_3 and T_3 are the final pressure and temperature:

$$\frac{P_3}{T_3} = \frac{P_2}{T_2}, \quad \text{where} \quad T_3 = T_0 = 293\text{ K}$$

$$P_3 = \frac{T_3}{T_2}P_2 = \frac{293\text{ K}}{634\text{ K}}2.64\text{ atm} = \boxed{1.22\text{ atm}}$$

CHECK For the adiabatic compression the final temperature is higher than the initial temperature, as expected, and the work done on the gas is positive, as expected.

TAKING IT FURTHER (1) The work can also be calculated using $W_{adiabatic} = (P_fV_f - P_iV_i)/(\gamma - 1)$ (Equation 18-41), but using $W_{adiabatic} = C_V\Delta T$ is preferable because it is more directly connected to a principle (the first law of thermodynamics) and thus is easier to recall. (2) A real bicycle pump and tire are not insulated, so the process of pumping up the tire would not be even approximately adiabatic.

SPEED OF SOUND WAVES

We can use Equation 18-38 to calculate the adiabatic bulk modulus of an ideal gas, which is related to the speed of sound waves in air. We first compute the differential of both sides of PV^{γ} = constant (Equation 18-38):

$$P\,d(V^{\gamma}) + V^{\gamma}\,dP = 0$$

or

$$\gamma PV^{\gamma-1}\,dV + V^{\gamma}\,dP = 0$$

Then

$$dP = -\frac{\gamma P\,dV}{V}$$

Referring to Equation 13-6, the adiabatic bulk modulus* is then:

$$B_{\text{adiabatic}} = -\frac{dP}{dV/V} = \gamma P \qquad \text{18-42}$$

The speed of sound (Equation 15-4) is given by

$$v = \sqrt{\frac{B_{\text{adiabatic}}}{\rho}}$$

where the mass density ρ is related to the number of moles n and the molecular mass M by $\rho = m/V = nM/V$. Using the ideal-gas law, $PV = nRT$, we can eliminate V from the density

$$\rho = \frac{nM}{V} = \frac{nM}{nRT/P} = \frac{MP}{RT}$$

Using this result and γP for $B_{\text{adiabatic}}$, we obtain

$$v = \sqrt{\frac{B_{\text{adiabatic}}}{\rho}} = \sqrt{\frac{\gamma P}{MP/(RT)}} = \sqrt{\frac{\gamma RT}{M}}$$

which is Equation 15-5, the speed of sound in a gas.

* The bulk modulus, discussed in Chapter 13, is the negative ratio of the pressure change to the fractional change in volume, $B = -\Delta P/(\Delta V/V)$. The isothermal bulk modulus, which describes changes that occur at constant temperature, differs from the adiabatic bulk modulus, which describes changes with no heat transfer. For sound waves at audible frequencies, the pressure changes occur too rapidly for appreciable heat transfer, so the appropriate bulk modulus is the adiabatic bulk modulus.

Physics Spotlight

Respirometry: Breathing the Heat

Calorimetry, the study and measurement of heat transfer, helps to determine the full energy budget of systems. Wilber O. Atwater, the first director of experimental stations for the U.S. Department of Agriculture,* ambitiously decided to measure the energy budgets of people. This effort involved measuring and analyzing the food and water given to participants, measuring, analyzing, and burning the waste of the participants, and analyzing the temperature, chemistry, and moisture of a tiny room in which the participants lived.† This room was thermally insulated, and the interior was a copper box, which was lined with copper water tubes for careful measurement of heat released, and electric coils for temperature maintenance. Any change in temperature of the air in the room was due to energy coming from the people in the room. This energy was measured by the changes in temperature registered by the sensitive hanging thermometer within the box, and by changes in the temperature of the water pumped through the tubes lining the walls.‡

About 5 kcal of energy is expended for every 1 L of oxygen consumed. The oxygen consumption of this man is being monitored while he walks on a treadmill. *(Philippe Psaila/Photo Researchers, Inc.)*

But although this copper room excelled at measuring the energy budgets of people at rest and in action, it was expensive and difficult to use. This led to indirect calorimetry by measuring respiration —*respirometry*. Further research showed that better than 95 percent# of human energy expenditure could reliably be calculated just by measuring the amounts of inhaled oxygen and exhaled carbon dioxide.° One figure that is frequently used today is 5 kcal/L of oxygen consumption.§ Depending on the measuring equipment, the volume of oxygen may be calculated from partial pressure of oxygen in the inhaled air, or it may be based on medically administered oxygen inhaled by the subject.

Respirometry is extremely useful, because it is the fastest measure of energy use by organisms. With appropriate modifications, respirometry is used for cattle,¶ poultry,** exotic animals,†† and even sewage sludge.‡‡ Recently, respirometry has been used to determine whether compost is mature enough to be added to soil. If the gas exchange rate of the compost is high, then bacterial activity is still high, and the compost is not fully mature.##

In medical care, respirometry is used to tailor nutritional therapy, especially for badly injured or very ill patients.°°, §§ In sports and fitness centers, handheld respirometers give rapid, accurate measurements of energy requirements for athletes and dieters¶¶ and are used to help patients, dieters, and athletes reach and maintain a healthy weight.

Finally, respirometry is used as a tool to help evaluate public policy and set nutrition standards. A study compared the calculations from two different nutrition standards to actual respirometry measurements of sedentary and active adults. One standard called for more energy than the participants actually used.*** As indirect calorimetry becomes less expensive, it is being used to help study the energy needs of people around the world.

Summary

1. The first law of thermodynamics, which is a statement of the conservation of energy, is a fundamental law of physics.
2. The equipartition theorem is a fundamental law of classical physics. It breaks down if the typical thermal energy kT is small compared to the spacing of quantized energy levels.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Heat	If energy is transferred from one system to another due to a temperature difference, the energy transferred is called heat.	
Calorie	The calorie, originally defined as the heat necessary to increase the temperature of 1 g of water by 1°C, is now defined to be exactly 4.184 joules.	
2. Heat Capacity	Heat capacity is the amount of heat needed to increase the temperature of a substance by one degree. $C = \frac{Q}{\Delta T}$	18-1
At constant volume	$C_V = \frac{Q_V}{\Delta T}$	
At constant pressure	$C_P = \frac{Q_P}{\Delta T}$	
Specific heat (heat capacity per unit mass)	$c = \frac{C}{m}$	18-2
Molar specific heat (heat capacity per mole)	$c' = \frac{C}{n}$	18-6
Heat capacity–internal energy relation	$C_V = \frac{dE_{int}}{dT}$	18-18*a*
Ideal gas	$C_P - C_V = nR$	18-20
Monatomic ideal gas	$C_V = \frac{3}{2}nR$	18-22
Diatomic ideal gas	$C_V = \frac{5}{2}nR$	18-25
3. Fusion and Vaporization	Both melting and vaporization occur at a constant temperature.	
Latent heat of fusion	The heat needed to melt a substance is the product of the mass of the substance and its latent heat of fusion L_f: $Q_f = mL_f$	18-8
L_f of water	$L_f = 333.5$ kJ/kg	
Latent heat of vaporization	The heat needed to vaporize a liquid is the product of the mass of the liquid and its latent heat of vaporization, L_v: $Q_v = mL_v$	18-9
L_v of water	$L_v = 2257$ kJ/kg	
4. First Law of Thermodynamics	The change in the internal energy of a system equals the energy transferred into the system via heat plus the energy transferred into the system via work: $\Delta E_{int} = Q_{in} + W_{on}$	18-10
5. Internal Energy E_{int}	The internal energy of a system is a property of the state of the system, as are the pressure, volume, and temperature. Heat and work are not properties of state.	
Ideal gas	E_{int} depends only on the temperature T.	

TOPIC	RELEVANT EQUATIONS AND REMARKS	
Monatomic ideal gas	$E_{\text{int}} = \frac{3}{2}nRT$	18-12
Internal energy related to heat capacity	$dE_{\text{int}} = C_V\,dT$	18-18*b*
6. Quasi-Static Process	A quasi-static process is one that occurs slowly so that the system moves through a series of equilibrium states.	
Isometric (isochoric)	$V = \text{constant}$	
Isobaric	$P = \text{constant}$	
Isothermal	$T = \text{constant}$	
Adiabatic	$Q = 0$	
Adiabatic, ideal gas	$TV^{\gamma-1} = \text{constant}$	18-37
	$PV^{\gamma} = \text{constant}$	18-38
	$T^{\gamma}/P^{\gamma-1} = \text{constant}$	18-39
	where	
	$\gamma = C_P/C_V$	18-36
7. Work Done on a Gas	$W_{\text{on}} = -\int_{V_i}^{V_f} P\,dV = C_V\,\Delta T - Q_{\text{in}}$	18-10, 18-15, and 18-18
Isometric	$W_{\text{on}} = -\int_{V_i}^{V_f} P\,dV = 0 \qquad V_f = V_i$	
Isobaric	$W_{\text{on}} = -\int_{V_i}^{V_f} P\,dV = -P\int_{V_i}^{V_f} dV = -P\,\Delta V$	
Isothermal	$W_{\text{isothermal}} = -\int_{V_i}^{V_f} P\,dV = -nRT\int_{V_i}^{V_f}\frac{dV}{V} = nRT\ln\frac{V_i}{V_f}$	18-17
Adiabatic	$W_{\text{adiabatic}} = C_V\,\Delta T$	18-40
8. Equipartition Theorem	The equipartition theorem states that if a system is in equilibrium, there is an average energy of $\frac{1}{2}kT$ per molecule or $\frac{1}{2}RT$ per mole associated with each degree of freedom.	
Failure of the equipartition theorem	The equipartition theorem fails if the thermal energy ($\sim kT$) that can be transferred in collisions is smaller than the energy gap ΔE between quantized energy levels. For example, monatomic gas molecules cannot rotate, because the first nonzero energy permitted is much greater than kT.	
9. Dulong–Petit Law	The molar specific heat of most solids is $3R$. This is predicted by the equipartition theorem, assuming a solid atom has six degrees of freedom.	

Answer to Concept Check

18-1 A compressed spring in a dart gun is released, and its internal energy goes into the dart kinetic energy acquired by the dart. The compressed air in a tank is released, and the air is used to raise a car on a lift in a service station.

Answers to Practice Problems

18-1 30°C

18-2 500 kJ

18-3 20.5 kJ

18-4 405 J

18-5 $V_i = 48.0$ L, $V_f = 61.1$ L, $W = 13.1$ L·atm $= 1.33$ kJ

18-6 (*a*) $M = 24.4$ g/mol. (*b*) The metal must be magnesium, which has a molar mass of 24.3 g/mol

18-7 For a quasi-static process, $PV^{\gamma} = \text{constant}$. Solving the ideal-gas law for V gives $V = nRT/P$. Substituting nRT/P into the equation PV^{γ} gives $P(nRT/P)^{\gamma} = \text{constant}$. Rearranging gives $T^{\gamma}/P^{\gamma-1} = \text{constant}/(nR)$.

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

Use 343 m/s as the speed of sound unless otherwise indicated.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*

Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • Object A has a mass that is twice the mass of object B, and object A has a specific heat that is twice the specific heat of object B. If equal amounts of heat are transferred to these objects, how do the subsequent changes in their temperatures compare? (*a*) $\Delta T_A = 4\Delta T_B$, (*b*) $\Delta T_A = 2\Delta T_B$, (*c*) $\Delta T_A = \Delta T_B$, (*d*) $\Delta T_A = \frac{1}{2}\Delta T_B$, (*e*) $\Delta T_A = \frac{1}{4}\Delta T_B$.

2 • Object A has a mass that is twice the mass of object B. The temperature change of object A is equal to the temperature change of object B when the objects absorb equal amounts of heat. It follows that their specific heats are related by (*a*) $c_A = 2c_B$, (*b*) $2c_A = c_B$, (*c*) $c_A = c_B$, (*d*) None of the above.

3 • The specific heat of aluminum is more than twice the specific heat of copper. A block of copper and a block of aluminum have the same mass and temperature (20°C). The blocks are simultaneously dropped into a single calorimeter containing water at 40°C. Which statement is true when thermal equilibrium is reached? (*a*) The aluminum block is at a higher temperature than the copper block. (*b*) The aluminum block has absorbed less energy than the copper block. (*c*) The aluminum block has absorbed more energy than the copper block. (*d*) Both (*a*) and (*c*) are correct statements. SSM

4 • A block of copper is in a pot of boiling water and has a temperature of 100°C. The block is removed from the boiling water and immediately placed in an insulated container filled with a quantity of water that has a temperature of 20°C and the same mass as the block of copper. (The heat capacity of the insulated container is negligible.) The final temperature will be closest to (*a*) 40°C, (*b*) 60°C, (*c*) 80°C.

5 • You pour both a certain amount of water at 100°C and an equal amount of water at 20°C into an insulated container. The final temperature of the mixture will be (*a*) 60°C, (*b*) less than 60°C, (*c*) greater than 60°C.

6 • You pour some water at 100°C and some ice cubes at 0°C into an insulated container. The final temperature of the mixture will be (*a*) 50°C, (*b*) less than 50°C, but larger than 0°C, (*c*) 0°C, (*d*) You cannot tell the final temperature from the data given.

7 • You pour some water at 100°C and some ice cubes at 0°C into an insulated container. When thermal equilibrium is reached, you notice some ice remains and floats in liquid water. The final temperature of the mixture is (*a*) above 0°C, (*b*) less than 0°C, (*c*) 0°C, (*d*) You cannot tell the final temperature from the data given.

8 • Joule's experiment establishing the mechanical equivalence of heat involved the conversion of mechanical energy into internal energy. Give some everyday examples in which some of the internal energy of a system is converted into mechanical energy.

9 • Can a gas absorb heat while its internal energy does not change? If so, give an example. If not, explain why not.

10 • The equation $\Delta E_{\text{int}} = Q + W$ is the formal statement of the first law of thermodynamics. In this equation, the quantities Q and W, respectively, represent (*a*) the heat absorbed by the system and the work done by the system, (*b*) the heat absorbed by the system and the work done on the system, (*c*) the heat released by the system and the work done by the system, (*d*) the heat released by the system and the work done on the system.

11 • A real gas cools during a free expansion, while an ideal gas does not cool during a free expansion. Explain the reason for this difference. SSM

12 • An ideal gas that has a pressure of 1.0 atm and a temperature of 300 K is confined to half of an insulated container by a thin partition. The other half of the container is a vacuum. The partition is punctured and equilibrium is quickly reestablished. Which of the following is correct? (*a*) The gas pressure is 0.50 atm and the temperature of the gas is 150 K. (*b*) The gas pressure is 1.0 atm and the temperature of the gas is 150 K. (*c*) The gas pressure is 0.50 atm and the temperature of the gas is 300 K. (*d*) None of the above

13 • A gas consists of ions that repel each other. The gas undergoes a free expansion in which no heat is absorbed or released and no work is done. Does the temperature of the gas increase, decrease, or remain the same? Explain your answer.

14 • Two gas-filled rubber balloons that have equal volumes are located at the bottom of a dark, cold lake. The temperature of the water decreases with increasing depth. One balloon rises rapidly and expands adiabatically as it rises. The other balloon rises more slowly and expands isothermally. The pressure in each balloon remains equal to the pressure in the water just next to the balloon. Which balloon has the larger volume when it reaches the surface of the lake? Explain your answer.

15 • A gas changes its state quasi-statically from A to C along the paths shown in Figure 18-21. The work done by the gas is (*a*) greatest for path A → B → C, (*b*) least for path A → C, (*c*) greatest for path A → D → C, (*d*) The same for all three paths.

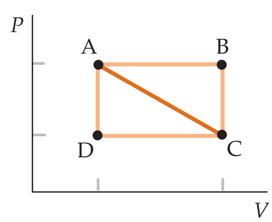

FIGURE 18-21 Problem 15

16 • When an ideal gas undergoes an adiabatic process, (*a*) no work is done by the system, (*b*) no heat is transferred to the system, (*c*) the internal energy of the system remains constant, (*d*) the amount of heat transfer into the system equals the amount of work done by the system.

17 • True or false:
(*a*) When a system can go from state 1 to state 2 by several different processes, the amount of heat absorbed by the system will be the same for all processes.
(*b*) When a system can go from state 1 to state 2 by several different processes, the amount of work done on the system will be the same for all processes.
(*c*) When a system goes from state 1 to state 2 by several different processes, the change in the internal energy of the system will be the same for all processes.
(*d*) The internal energy of a given amount of an ideal gas depends only on its absolute temperature.
(*e*) A quasi-static process is one in which the system is never far from being in equilibrium.
(*f*) For any substance that expands when heated, its C_P is greater than its C_V.

18 • The volume of a sample of gas remains constant while its pressure increases. (*a*) The internal energy of the system is unchanged. (*b*) The system does work. (*c*) The system absorbs no heat. (*d*) The change in internal energy must equal the heat absorbed by the system. (*e*) None of the above

19 •• When an ideal gas undergoes an isothermal process, (*a*) no work is done by the system, (*b*) no heat is absorbed by the system, (*c*) the heat absorbed by the system equals the change in the system's internal energy, (*d*) the heat absorbed by the system equals the work done by the system.

20 •• Consider the following series of sequential quasi-static processes that a system undergoes: (*1*) an adiabatic expansion, (*2*) an isothermal expansion, (*3*) an adiabatic compression, and (*4*) an isothermal compression that brings the system back to its original state. Sketch the series of processes on a *PV* diagram, and then sketch the series of processes on a *VT* diagram (in which volume is plotted as a function of temperature).

21 • An ideal gas in a cylinder is at pressure P and volume V. During a quasi-static adiabatic process, the gas is compressed until its volume has decreased to $V/2$. Then, in a quasi-static isothermal process, the gas is allowed to expand until its volume again has a value of V. What kind of process will return the system to its original state? Sketch the cycle on a graph. SSM

22 •• Metal A is denser than metal B. Which would you expect to have a higher heat capacity per unit mass—metal A or metal B? Why?

23 •• An ideal gas undergoes a process during which $P\sqrt{V}$ = constant and the volume of the gas decreases. Does its temperature increase, decrease, or remain the same during this process? Explain.

ESTIMATION AND APPROXIMATION

24 • **Engineering Application, Context-Rich** During the early stages of designing a modern electric generating plant, you are in charge of the team of environmental engineers. The new plant is to be located on the ocean and will use ocean water for cooling. The plant will produce electrical power at the rate of 1.00 GW. Because the plant will have an efficiency of one-third (typical of most modern plants), heat will be released to the cooling water at the rate of 2.00 GW. If environmental codes require that only water with a temperature increase of 15°F or less can be returned to the ocean, estimate the flow rate (in kg/s) of cooling water through the plant.

25 •• A typical microwave oven has a power consumption of about 1200 W. Estimate how long it should take to boil a cup of water in the microwave, assuming that 50 percent of the electrical power consumption goes into heating the water. How does this estimate correspond to everyday experience? SSM

26 •• A demonstration of the heating of a gas under adiabatic compression involves putting a small strip of paper into a large glass test tube, which is then sealed with a piston. If the piston compresses the trapped air very rapidly, the paper will catch fire. Assuming that the burning point of paper is 451°F, estimate the factor by which the volume of the air trapped by the piston must be reduced for this demonstration to work.

27 •• A small change in the volume of a liquid occurs when heating the liquid at constant pressure. Use the following data to estimate the fractional contribution this change makes to the heat capacity of water between 4.00°C and 100°C. The density of water at 4.00°C and 1.00 atm pressure is 1.000 g/cm^3. The density of liquid water at 100°C and 1.00 atm pressure is 0.9584 g/cm^3.

HEAT CAPACITY, SPECIFIC HEAT, LATENT HEAT

28 • **Engineering Application, Context-Rich** You designed a solar home that contains 1.00×10^5 kg of concrete (specific heat = 1.00 kJ/kg·K). How much heat is released by the concrete at night when it cools from 25.0°C to 20.0°C?

29 • How much heat must be absorbed by 60.0 g of ice at −10.0°C to transform it into 60.0 g of liquid water at 40.0°C? SSM

30 •• How much heat must be released by 0.100 kg of steam at 150°C to transform it into 0.100 kg of ice at 0.00°C?

31 •• A 50.0-g piece of aluminum at 20°C is cooled to −196°C by placing it in a large container of liquid nitrogen at that temperature. How much nitrogen is vaporized? (Assume that the specific heat of aluminum is constant over this temperature range.)

32 •• **Engineering Application, Context-Rich** You are supervising the creation of some lead castings for use in the construction industry. Each casting involves one of your workers pouring 0.500 kg of molten lead that has a temperature of 327°C into a cavity in a large block of ice at 0°C. How much liquid water should you plan on draining per hour if there are 100 workers who are able to each average one casting every 10.0 min?

CALORIMETRY

33 • **Engineering Application, Context-Rich** While spending the summer on your uncle's horse farm, you spend a week apprenticing with his farrier (a person who makes and fits horseshoes). You observe the way he cools a shoe after pounding the hot, pliable shoe into the correct size and shape. Suppose a 750-g iron horseshoe is taken from the farrier's fire, shaped, and at a temperature of 650°C, dropped into a 25.0-L bucket of water at 10.0°C. What is the final temperature of the water after the horseshoe and water arrive at equilibrium? Neglect any heating of the bucket and assume the specific heat of iron is 460 J/(kg·K). SSM

34 • The specific heat of a certain metal can be determined by measuring the temperature change that occurs when a piece of the metal is heated and then placed in an insulated container that is made of the same material and contains water. Suppose the piece of metal has a mass of 100 g and is initially at 100°C. The container has a mass of 200 g and contains 500 g of water at an initial temperature of 20.0°C. The final temperature is 21.4°C. What is the specific heat of the metal?

35 •• **BIOLOGICAL APPLICATION** During his many appearances at the Tour de France, champion bicyclist Lance Armstrong typically expended an average power of 400 W, 5.0 hours a day for 20 days. What quantity of water, initially at 24°C, could be brought to a boil if you could harness all of that energy?

36 •• A 25.0-g glass tumbler contains 200 mL of water at 24.0°C. If two 15.0-g ice cubes, each at a temperature of −3.00°C, are dropped into the tumbler, what is the final temperature of the drink? Neglect any heat transfer between the tumbler and the room.

37 •• A 200-g piece of ice at 0°C is placed in 500 g of water at 20°C. This system is in a container of negligible heat capacity and is insulated from its surroundings. (*a*) What is the final equilibrium temperature of the system? (*b*) How much of the ice melts? SSM

38 •• A 3.5-kg block of copper at a temperature of 80°C is dropped into a bucket containing a mixture of ice and water whose total mass is 1.2 kg. When thermal equilibrium is reached, the temperature of the water is 8.0°C. How much ice was in the bucket before the copper block was placed in it? (Assume that the heat capacity of the bucket is negligible.)

39 •• A well-insulated bucket of negligible heat capacity contains 150 g of ice at 0°C. (*a*) If 20 g of steam at 100°C is injected into the bucket, what is the final equilibrium temperature of the system? (*b*) Is any ice left after the system reaches equilibrium?

40 •• A calorimeter of negligible heat capacity contains 1.00 kg of water at 303 K and 50.0 g of ice at 273 K. (*a*) Find the final temperature T. (*b*) Find the final temperature T if the mass of ice is 500 g.

41 •• A 200-g aluminum calorimeter contains 600 g of water at 20.0°C. A 100-g piece of ice cooled to −20.0°C is placed in the calorimeter. (*a*) Find the final temperature of the system, assuming no heat is transferred to or from the system. (*b*) A 200-g piece of ice at −20.0°C is added. How much ice remains in the system after the system reaches equilibrium? (*c*) Would the answer for Part (*b*) change if both pieces of ice were added at the same time?

42 •• The specific heat of a 100-g block of a substance is to be determined. The block is placed in a 25-g copper calorimeter holding 60 g of water at 20°C. Then, 120 mL of water at 80°C are added to the calorimeter. When thermal equilibrium is reached, the temperature of the system is 54°C. Determine the specific heat of the block.

43 •• A 100-g piece of copper is heated in a furnace to a temperature t_C. The copper is then inserted into a 150-g copper calorimeter containing 200 g of water. The initial temperature of the water and calorimeter is 16.0°C, and the temperature after equilibrium is established is 38.0°C. When the calorimeter and its contents are weighed, 1.20 g of water are found to have evaporated. What was the temperature t_C? SSM

44 ••• A 200-g aluminum calorimeter contains 500 g of water at 20.0°C. Aluminum shot with a mass equal to 300 g is heated to 100.0°C and is then placed in the calorimeter. Find the final temperature of the system, assuming that there is no heat transfer to the surroundings.

FIRST LAW OF THERMODYNAMICS

45 • A diatomic gas does 300 J of work and also absorbs 2.50 kJ of heat. What is the change in internal energy of the gas?

46 • If a gas absorbs 1.67 MJ of heat while doing 800 kJ of work, what is the change in the internal energy of the gas?

47 • If a gas absorbs 84 J of heat while doing 30 J of work, what is the change in the internal energy of the gas?

48 •• A lead bullet initially at 30°C just melts upon striking a target. Assuming that all of the initial kinetic energy of the bullet goes into the internal energy of the bullet, calculate the impact speed of the bullet.

49 •• During a cold day, you can warm your hands by rubbing them together. Assume the coefficient of kinetic friction between your hands is 0.500, the normal force between your hands is 35.0 N, and that you rub them together at an average relative speed of 35.0 cm/s. (*a*) What is the rate at which mechanical energy is dissipated? (*b*) Assume further that the mass of each of your hands is 350 g, the specific heat of your hands is 4.00 kJ/kg·K, and that all the dissipated mechanical energy goes into increasing the temperature of your hands. How long must you rub your hands together to produce a 5.00°C increase in their temperature?

WORK AND THE *PV* DIAGRAM FOR A GAS

In Problems 50 through 53, the initial state of 1.00 mol of a dilute gas is $P_1 = 3.00$ atm, $V_1 = 1.00$ L, and $E_{\text{int }1} = 456$ J, and its final state is $P_2 = 2.00$ atm, $V_2 = 3.00$ L, and $E_{\text{int }2} = 912$ J.

50 • The gas is allowed to expand at constant pressure until it reaches its final volume. It is then cooled at constant volume until it reaches its final pressure. (*a*) Illustrate this process on a *PV* diagram and calculate the work done by the gas. (*b*) Find the heat absorbed by the gas during this process.

51 • The gas is first cooled at constant volume until it reaches its final pressure. It is then allowed to expand at constant pressure until it reaches its final volume. (*a*) Illustrate this process on a *PV* diagram and calculate the work done by the gas. (*b*) Find the heat absorbed by the gas during this process. SSM

52 •• The gas is allowed to expand isothermally until it reaches its final volume and its pressure is 1.00 atm. It is then heated at constant volume until it reaches its final pressure. (*a*) Illustrate this process on a *PV* diagram and calculate the work done by the gas. (*b*) Find the heat absorbed by the gas during this process.

53 •• The gas is heated and is allowed to expand such that it follows a single straight-line path on a PV diagram from its initial state to its final state. (*a*) Illustrate this process on a PV diagram and calculate the work done by the gas. (*b*) Find the heat absorbed by the gas during this process.

54 •• In this problem, 1.00 mol of a dilute gas initially has a pressure equal to 1.00 atm, a volume equal to 25.0 L and an internal energy equal to 456 J. As the gas is slowly heated, the plot of its state on a PV diagram moves in a straight line to the final state. The gas now has a pressure equal to 3.00 atm, a volume equal to 75.0 L and an internal energy equal to 912 J. Find the work done and the heat absorbed by the gas.

55 •• In this problem, 1.00 mol of the ideal gas is heated while its volume changes, so that $T = AP^2$, where A is a constant. The temperature changes from T_0 to $4T_0$. Find the work done by the gas.

56 •• **ENGINEERING APPLICATION, CONTEXT-RICH** A sealed, almost-empty spray paint can still contains a residual amount of the propellant: 0.020 mol of nitrogen gas. The can's warning label clearly states: "Do Not Dispose by Incineration." (*a*) Explain this warning and draw the PV diagram for the gas if, in fact, the can is subject to a high temperature. (*b*) You are in charge of testing the can. The manufacturer claims it can withstand an internal gas pressure of 6.00 atm before it breaks. The can is initially at room-temperature and standard pressure in your testing laboratory. You begin to heat it uniformly using a heating element that has a power output of 200 W. The can and element are in an insulating oven, and you can assume 1.0% of the heat released by the heating element is absorbed by the gas in the can. How long should you expect the heating element to remain on before the can bursts?

57 •• An ideal gas initially at 20°C and 200 kPa has a volume of 4.00 L. It undergoes a quasi-static, isothermal expansion until its pressure is reduced to 100 kPa. Find (*a*) the work done by the gas, and (*b*) the heat absorbed by the gas during the expansion. SSM

HEAT CAPACITIES OF GASES AND THE EQUIPARTITION THEOREM

58 • The heat capacity at constant volume of a certain amount of a monatomic gas is 49.8 J/K. (*a*) Find the number of moles of the gas. (*b*) What is the internal energy of the gas at $T = 300$ K? (*c*) What is the heat capacity at constant pressure of the gas?

59 •• The heat capacity at constant pressure of a certain amount of a diatomic gas is 14.4 J/K. (*a*) Find the number of moles of the gas. (*b*) What is the internal energy of the gas at $T = 300$ K? (*c*) What is the molar heat capacity of this gas at constant volume? (*d*) What is the heat capacity of this gas at constant volume? SSM

60 •• (*a*) Calculate the heat capacity per unit mass of air at constant volume and the heat capacity per unit mass of air at constant pressure. Assume that air has a temperature of 300 K and a pressure of 1.00×10^5 N/m^2. Also, assume that air is composed of 74.0 percent N_2 molecules (molecular weight 28.0 g/mol) and 26.0 percent O_2 molecules (molar mass of 32.0 g/mol) and that both components are ideal gases. (*b*) Compare your answer for the specific heat at constant pressure to the value listed in the *Handbook of Chemistry and Physics* of 1.032 kJ/kg·K.

61 •• In this problem, 1.00 mol of an ideal diatomic gas is heated at constant volume from 300 K to 600 K. (*a*) Find the increase in the internal energy of the gas, the work done by the gas, and the heat absorbed by the gas. (*b*) Find the same quantities if this gas is heated from 300 K to 600 K at constant pressure. Use the first law of thermodynamics and your results for Part (*a*) to calculate the work done by the gas. (*c*) Again calculate the work done in Part (*b*). This time calculate it by integrating the equation $dW = P\,dV$.

62 •• A diatomic gas is confined to a closed container of constant volume V_0 and at a pressure P_0. The gas is heated until its pressure triples. What amount of heat had to be absorbed by the gas in order to triple the pressure?

63 •• In this problem, 1.00 mol of air is confined in a cylinder with a piston. The confined air is maintained at a constant pressure of 1.00 atm. The air is initially at 0°C and has volume V_0. Find the volume after 13,200 J of heat are absorbed by the trapped air.

64 •• The heat capacity at constant pressure of a sample of a gas is greater than the heat capacity at constant volume by 29.1 J/K. (*a*) How many moles of the gas are present? (*b*) If the gas is monatomic, what are C_V and C_P? (*c*) What are the values of C_V and C_P at normal room temperatures?

65 •• Carbon dioxide (CO_2) at a pressure of 1.00 atm and a temperature of −78.5°C sublimates directly from a solid to a gaseous state without going through a liquid phase. What is the change in the heat capacity at constant pressure per mole of CO_2 when it undergoes sublimation? (Assume that the gas molecules can rotate but do not vibrate.) Is the change in the heat capacity positive or negative during sublimation? The CO_2 molecule is pictured in Figure 18-22. SSM

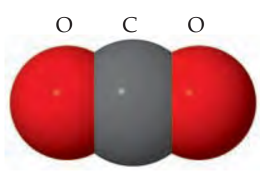

FIGURE 18-22 Problem 65

66 •• In this problem, 1.00 mol of a monatomic ideal gas is initially at 273 K and 1.00 atm. (*a*) What is the initial internal energy of the gas? (*b*) Find the work done by the gas when 500 J of heat are absorbed by the gas at constant pressure. What is the final internal energy of the gas? (*c*) Find the work done by the gas when 500 J of heat are absorbed by the gas at constant volume. What is the final internal energy of the gas?

67 •• List all of the degrees of freedom possible for a water molecule and estimate the heat capacity of water at a temperature very far above its boiling point. (Ignore the fact the molecule might dissociate at high temperatures.) Think carefully about all of the different ways in which a water molecule can vibrate.

HEAT CAPACITIES OF SOLIDS AND THE DULONG–PETIT LAW

68 • The Dulong–Petit law was originally used to determine the molar mass of a substance from its measured heat capacity. The specific heat of a certain solid substance is measured to be 0.447 kJ/kg·K. (*a*) Find the molar mass of the substance. (*b*) What element has this specific-heat value?

QUASI-STATIC ADIABATIC EXPANSION OF A GAS

69 •• A 0.500-mol sample of an ideal monatomic gas at 400 kPa and 300 K, expands quasi-statically until the pressure decreases to 160 kPa. Find the final temperature and volume of the gas, the work done by the gas, and the heat absorbed by the gas if the expansion is (*a*) isothermal, and (*b*) adiabatic. SSM

70 •• A 0.500-mol sample of an ideal diatomic gas at 400 kPa and 300 K expands quasi-statically until the pressure decreases to 160 kPa. Find the final temperature and volume of the gas, the work done by the gas, and the heat absorbed by the gas if the expansion is (*a*) isothermal, and (*b*) adiabatic.

71 •• A 0.500-mol sample of helium gas expands adiabatically and quasi-statically from an initial pressure of 5.00 atm and temperature of 500 K to a final pressure of 1.00 atm. Find (*a*) the final temperature of the gas, (*b*) the final volume of the gas, (*c*) the work done by the gas, and (*d*) the change in the internal energy of the gas.

CYCLIC PROCESSES

72 •• A 1.00-mol sample of N_2 gas at 20.0°C and 5.00 atm is allowed to expand adiabatically and quasi-statically until its pressure equals 1.00 atm. It is then heated at constant pressure until its temperature is again 20.0°C. After it reaches a temperature of 20.0°C, it is heated at constant volume until its pressure is again 5.00 atm. It is then compressed at constant pressure until it is back to its original state. (*a*) Construct a *PV* diagram showing each process in the cycle. (*b*) From your graph, determine the work done by the gas during the complete cycle. (*c*) How much heat is absorbed (or released) by the gas during the complete cycle?

73 •• A 1.00-mol sample of an ideal diatomic gas is allowed to expand. This expansion is represented by the straight line from 1 to 2 in the *PV* diagram (Figure 18-23). The gas is then compressed isothermally. This compression is represented by the curved line from 2 to 1 in the *PV* diagram. Calculate the work per cycle done by the gas. SSM

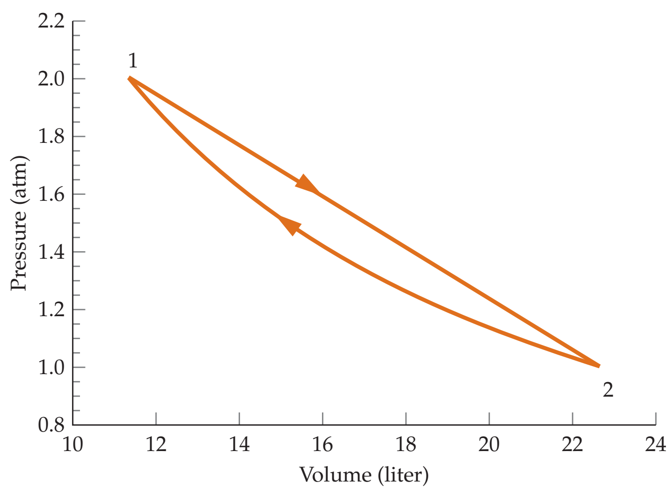

FIGURE 18-23 Problem 73

74 •• A 2.00-mol sample of an ideal monatomic gas has an initial pressure of 2.00 atm and an initial volume of 2.00 L. The gas is taken through the following quasi-static cycle: It is expanded isothermally until it has a volume of 4.00 L. Next, it is heated at constant volume until it has a pressure of 2.00 atm. It is then cooled at constant pressure until it is back to its initial state. (*a*) Show this cycle on a *PV* diagram. (*b*) Find the temperature at the end of each part of the cycle. (*c*) Calculate the heat absorbed and the work done by the gas during each part of the cycle.

75 ••• At point D in Figure 18-24, the pressure and temperature of 2.00 mol of an ideal monatomic gas are 2.00 atm and 360 K, respectively. The volume of the gas at point B on the *PV* diagram is three times that at point D and its pressure is twice that at point C. Paths AB and CD represent isothermal processes. The gas is carried through a complete cycle along the path DABCD. Determine the total amount of work done by the gas and the heat absorbed by the gas along each portion of the cycle. SSM

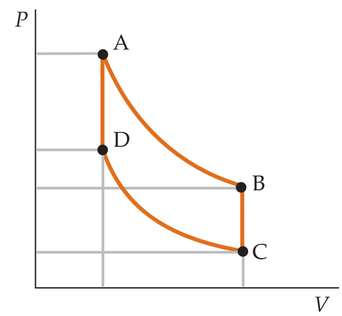

FIGURE 18-24 Problems 75, 76

76 ••• At point D in Figure 18-24, the pressure and temperature of 2.00 mol of an ideal diatomic gas are 2.00 atm and 360 K, respectively. The volume of the gas at point B on the *PV* diagram is three times that at point D and its pressure is twice that at point C. Paths AB and CD represent isothermal processes. The gas is carried through a complete cycle along the path DABCD. Determine the total amount of work done by the gas and the heat absorbed by the gas along each portion of the cycle.

77 ••• A sample consisting of n moles of an ideal gas is initially at pressure P_1, volume V_1, and temperature T_h. It expands isothermally until its pressure and volume are P_2 and V_2. It then expands adiabatically until its temperature is T_c and its pressure and volume are P_3 and V_3. It is then compressed isothermally until it is at a pressure P_4 and a volume V_4, which is related to its initial volume V_1 by $T_c V_4^{\gamma-1} = T_h V_1^{\gamma-1}$. The gas is then compressed adiabatically until it is back in its original state. (*a*) Assuming that each process is quasi-static, plot this cycle on a *PV* diagram. (This cycle is known as the Carnot cycle for an ideal gas.) (*b*) Show that the heat Q_h absorbed during the isothermal expansion at T_h is $Q_h = nRT_h \ln(V_2/V_1)$. (*c*) Show that the heat Q_c released by the gas during the isothermal compression at T_c is $Q_c = nRT_c \ln(V_3/V_4)$. (*d*) Using the result that $TV^{\gamma-1}$ is constant for a quasi-static adiabatic expansion, show that $V_2/V_1 = V_3/V_4$. (*e*) The efficiency of a Carnot cycle is defined as the net work done by the gas, divided by the heat absorbed Q_h by the gas. Using the first law of thermodynamics, show that the efficiency is $1 - Q_c/Q_h$. (*f*) Using your results from the previous parts of this problem, show that $Q_c/Q_h = T_c/T_h$.

GENERAL PROBLEMS

78 • During the process of quasi-statically compressing an ideal diatomic gas to one-fifth of its initial volume, 180 kJ of work are done on the gas. (*a*) If this compression is accomplished isothermally at room temperature (293 K), how much heat is released by the gas? (*b*) How many moles of gas are in this sample?

79 • The *PV* diagram in Figure 18-25 represents 3.00 mol of an ideal monatomic gas. The gas is initially at point A. The paths AD and BC represent isothermal changes. If the system is brought to point C along the path AEC, find (*a*) the initial and final temperatures of the gas, (*b*) the work done by the gas, and (*c*) the heat absorbed by the gas. SSM

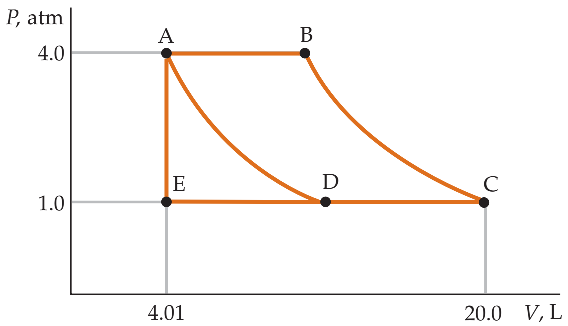

FIGURE 18-25 Problems 79, 80, 81, 82

80 •• The *PV* diagram in Figure 18-25 represents 3.00 mol of an ideal monatomic gas. The gas is initially at point A. The paths AD and BC represent isothermal changes. If the system is brought to point C along the path ABC, find (*a*) the initial and final temperatures of the gas, (*b*) the work done by the gas, and (*c*) the heat absorbed by the gas.

81 •• The *PV* diagram in Figure 18-25 represents 3.00 mol of an ideal monatomic gas. The gas is initially at point A. The paths AD and BC represent isothermal changes. If the system is brought to point C along the path ADC, find (*a*) the initial and final temperatures of the gas, (*b*) the work done by the gas, and (*c*) the heat absorbed by the gas.

82 •• Suppose that the paths AD and BC in Figure 18-25 represent adiabatic processes. What are the work done by the gas and the heat absorbed by the gas in following the path ABC?

83 •• **BIOLOGICAL APPLICATION, CONTEXT-RICH** As part of a laboratory experiment, you test the calorie content of various foods. Assume that when you eat these foods, 100% of the energy released by the foods is absorbed by your body. Suppose you burn a 2.50-g potato chip, and the resulting flame warms a small aluminum can of water. After burning the potato chip, you measure its mass to be 2.20 g. The mass of the can is 25.0 g, and the volume of water contained in the can is 15.0 mL. If the temperature increase in the water is 12.5°C, how many kilocalories (1 kcal = 1 dietary calorie) per 150-g serving of these potato chips would you estimate there are? Assume the can of water captures 50.0 percent of the heat released during the burning of the potato chip. *Note: Although the joule is the SI unit of choice in most thermodynamic situations, the food industry in the United States currently expresses the energy released during metabolism in terms of the "dietary calorie," which is our kilocalorie.* SSM

84 •• **ENGINEERING APPLICATION** Diesel engines operate without spark plugs, unlike gasoline engines. The cycle that diesel engines undergo involves adiabatically compressing the air in a cylinder, and then fuel is injected. When the fuel is injected, if the air temperature inside the cylinder is above the fuel's flashpoint, the fuel-air mixture will ignite. Most diesel engines have compression ratios in the range from 14:1 to 25:1. For this range of compression ratios (which are the ratio of maximum to minimum volume), what is the range of maximum temperatures of the air in the cylinder, assuming the air is taken into the cylinder at 35°C? Most modern gasoline engines typically have compression ratios on the order of 8:1. Explain why you expect the diesel engine to require a better (more efficient) cooling system than its gasoline counterpart.

85 •• At very low temperatures, the specific heat of a metal is given by $c = aT + bT^3$. For copper, $a = 0.0108\ \mathrm{J/kg \cdot K^2}$ and $b = 7.62 \times 10^{-4}\ \mathrm{J/kg \cdot K^4}$. (*a*) What is the specific heat of copper at 4.00 K? (*b*) How much heat is required to heat copper from 1.00 to 3.00 K?

86 •• How much work must be done on 30.0 g of carbon monoxide (CO) at standard temperature and pressure to compress it to one-fifth of its initial volume if the process is (*a*) isothermal, (*b*) adiabatic?

87 •• How much work must be done on 30.0 g of carbon dioxide (CO_2) at standard temperature and pressure to compress it to one-fifth of its initial volume if the process is (*a*) isothermal, (*b*) adiabatic?

88 •• How much work must be done on 30.0 g of argon (Ar) at standard temperature and pressure to compress it to one-fifth of its initial volume if the process is (*a*) isothermal, (*b*) adiabatic?

89 •• A thermally insulated system consists of 1.00 mol of a diatomic gas at 100 K and 2.00 mol of a solid at 200 K that are separated by a rigid insulating wall. Find the equilibrium temperature of the system after the insulating wall is removed, assuming that the gas obeys the ideal-gas law and that the solid obeys the Dulong–Petit law. SSM

90 •• When an ideal gas undergoes a temperature change at constant volume, its internal energy change is given by the formula $\Delta E_{\mathrm{int}} = C_{\mathrm{V}}\,\Delta T$. However, this formula correctly gives the change in internal energy whether the volume remains constant or not. (*a*) Explain why this formula gives correct results for an ideal gas even when the volume changes. (*b*) Using this formula, along with the first law of thermodynamics, show that for an ideal gas $C_{\mathrm{P}} = C_{\mathrm{V}} + nR$.

91 •• An insulated cylinder is fitted with an insulated movable piston to maintain constant pressure. The cylinder initially contains 100 g of ice at −10°C. Heat is transferred to the ice at a constant rate by a 100-W heater. Make a graph showing the temperature of the ice/water/steam as a function of time starting at t_{i} when the temperature is −10°C and ending at t_{f} when the temperature is 110°C.

92 •• (*a*) In this problem, 2.00 mol of a diatomic ideal gas expands adiabatically and quasi-statically. The initial temperature of the gas is 300 K. The work done by the gas during the expansion is 3.50 kJ. What is the final temperature of the gas? (*b*) Compare your result to the result you would get if the gas were monatomic.

93 •• A vertical insulated cylinder is divided into two parts by a movable piston of mass *m*. The piston is initially held at rest. The top part of the cylinder is evacuated and the bottom part is filled with 1.00 mol of diatomic ideal gas at temperature 300 K. After the piston is released and the system comes to equilibrium, the volume occupied by gas is halved. Find the final temperature of the gas.

94 ••• According to the Einstein model of a crystalline solid, the internal energy per mole is given by $U = (3N_AkT_E)/(e^{T_E/T} - 1)$ where T_E is a characteristic temperature called the *Einstein temperature*, and T is the temperature of the solid in kelvins. Use this expression to show that a crystalline solid's molar heat capacity at constant volume is given by

$$c'_V = 3R\left(\frac{T_E}{T}\right)^2 \frac{e^{T_E/T}}{(e^{T_E/T} - 1)^2}$$

95 ••• (*a*) Use the results of Problem 94 to show that in the limit that $T \gg T_E$, the Einstein model gives the same expression for specific heat that the Dulong-Petit law does. (*b*) For diamond, T_E is approximately 1060 K. Integrate numerically $dE_{int} = c'_v\, dT$ to find the increase in the internal energy if 1.00 mol of diamond is heated from 300 K to 600 K. SSM

96 ••• Use the results of the Einstein model in Problem 94 to determine the molar internal energy of diamond (T_E = 1060 K) at 300 K and 600 K, and thereby the increase in internal energy as diamond is heated from 300 K to 600 K. Compare your result to that of Problem 95.

97 ••• During an isothermal expansion, an ideal gas at an initial pressure P_0 expands until its volume is twice its initial volume V_0. (*a*) Find its pressure after the expansion. (*b*) The gas is then compressed adiabatically and quasi-statically until its volume is V_0 and its pressure is $1.32P_0$. Is the gas monatomic, diatomic, or polyatomic? (*c*) How does the translational kinetic energy of the gas change in each stage of this process?

98 ••• If a hole is punctured in a tire, the gas inside will gradually leak out. Assume the following: The area of the hole is A; the tire volume is V; and the time, τ, it takes for most of the air to leak out of the tire can be expressed in terms of the ratio A/V, the temperature T, the Boltzmann constant k, and the initial mass m of the gas inside the tire. (*a*) Based on these assumptions, use dimensional analysis to find an estimate for τ. (*b*) Use the result of Part (*a*) to estimate the time it takes for a car tire with a nail hole punched in it to go flat.

CHAPTER 19

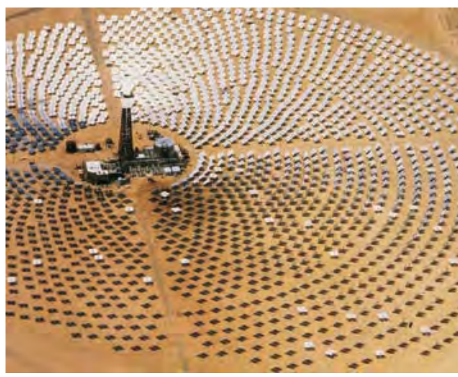
DIVERS CARRY TANKS OF AIR TO ALLOW THEM TO STAY UNDERWATER FOR LONG PERIODS OF TIME. *(Paul Springett/ Alamy.)*

The Second Law of Thermodynamics

? The probability that at a given instant the molecules of air in one of the tanks are all in the half of the tank opposite the hose connection is very very small. Just how small is it? (See Example 19-13.)

We are often asked to conserve energy. But according to the first law of thermodynamics, energy is always conserved. What then does it mean to conserve energy if the total amount of energy in the universe does not change regardless of what we do? The first law of thermodynamics does not tell the whole story. Energy is always conserved, but some forms of energy are more useful than others. The possibility or impossibility of putting energy to *use* is the subject of the second law of thermodynamics. Scientists and engineers are constantly trying to improve the efficiency of heat engines (devices that transform heat into work). In the power industry engineers strive to achieve higher efficiencies in transforming the thermal energy liberated by the burning of fossil fuels and the fission of uranium and plutonium into useful work.

In this chapter, we examine the second law of thermodynamics as it relates directly to heat engines as well as refrigerators. We also discuss an ideal heat engine—the Carnot engine. Irreversibility and entropy are also covered as they relate to the availability of energy, disorder, and probability.



Solar energy is directed toward the solar oven at the center by this circular array of reflectors at Barstow, California. *(Sandia National Laboratory.)*

19-1 HEAT ENGINES AND THE SECOND LAW OF THERMODYNAMICS

> No system can absorb heat from a single reservoir and convert it entirely into work without additional net changes in the system or its surroundings.
>
> SECOND LAW OF THERMODYNAMICS: KELVIN STATEMENT

A common example of the conversion of work into heat is movement with friction. For example, suppose you spend two minutes pushing a block this way and that way along a tabletop in a closed path, leaving the block in its initial position. Also, suppose that the block–table system is initially in thermal equilibrium with its surroundings. The work you do on the system is converted into internal energy of the system, and as a result the block–table system becomes warmer. Consequently, the system is no longer in thermal equilibrium with its surroundings. However, the system will transfer energy as heat to its surroundings until it returns to thermal equilibrium with those surroundings. Because the final and initial states of the system are the same, the first law of thermodynamics dictates that the energy transferred to the environment as heat equals the work done by you on the system. The reverse process never occurs—a block and table that are warm will never spontaneously cool by converting their internal energy into work that causes the block to push your hand around the table! Yet such an amazing occurrence would not violate the first law of thermodynamics or any other physical laws we have encountered so far. It does, however, violate the second law of thermodynamics. Thus, there is a lack of symmetry in the roles played by heat and work that is not evident from the first law. This lack of symmetry is related to the fact that some processes are *irreversible*.

Many other irreversible processes exist, seemingly quite different from one another, but all related to the second law. For example, heat transfer is an irreversible process. If we place a hot body in contact with a cold body, heat will transfer from the hot body to the cold body until they are at the same temperature. However, the reverse does not occur. Two bodies in contact at the same temperature remain at the same temperature; heat is not transferred from one to the other leaving one colder and the other warmer. This experimental fact gives us an equivalent statement of the second law of thermodynamics.

> A process whose only net result is to absorb heat from a cold reservoir and release the same amount of heat to a hot reservoir is impossible.
>
> SECOND LAW OF THERMODYNAMICS: CLAUSIUS STATEMENT

We will show in this chapter that the Kelvin and Clausius statements of the second law are equivalent.

The study of the efficiency of heat engines gave rise to the first clear statements of the second law. A **heat engine** is a cyclic device whose purpose is to convert as much heat into work as possible. Heat engines contain a **working substance** (water in a steam engine) that absorbs a quantity of heat Q_h from a high temperature reservoir, does work W on its surroundings, and releases heat Q_c as it returns to its initial state, where Q_h, W, and Q_c represent magnitudes and are never negative.

> ! Q_h, W, and Q_c represent magnitudes and are never negative.

The earliest heat engines were steam engines, invented in the eighteenth century for pumping water from coal mines. Today steam engines are used to generate electricity. In a typical steam engine, liquid water under several hundred atmospheres of pressure absorbs heat from a high temperature reservoir until it vaporizes at about 500°C (Figure 19-1). This steam expands against a piston (or turbine blades), doing work, and then exits at a much lower temperature. The steam is cooled further in the condenser where it condenses by releasing heat to a low temperature reservoir. The water is then pumped back into the boiler and heated again.

Figure 19-2 is a schematic diagram of the heat engine used in many automobiles—the internal-combustion engine. With the exhaust valve closed, a mixture of gasoline vapor and air enters the combustion chamber as the piston moves down during the intake stroke. The mixture is then compressed, after which it is ignited by a spark from the spark plug. The hot gases then expand, driving the piston down and doing work on it during the *power stroke*. The gases are then exhausted through the exhaust valve, and the cycle repeats.

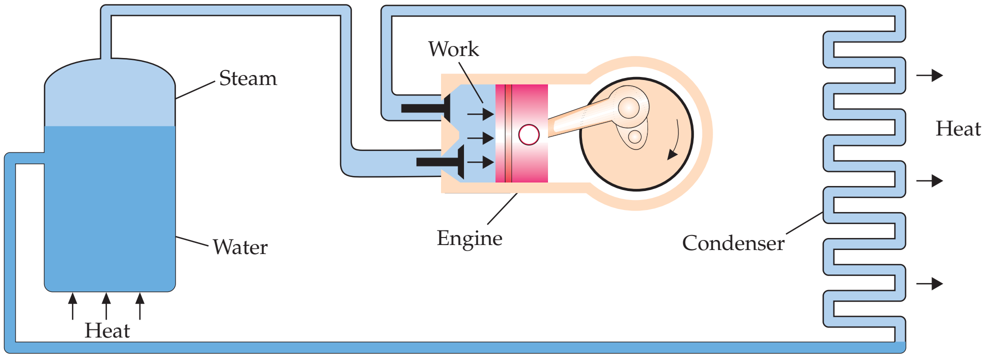


FIGURE 19-1 Schematic drawing of a steam engine. High-pressure steam does work on the piston.

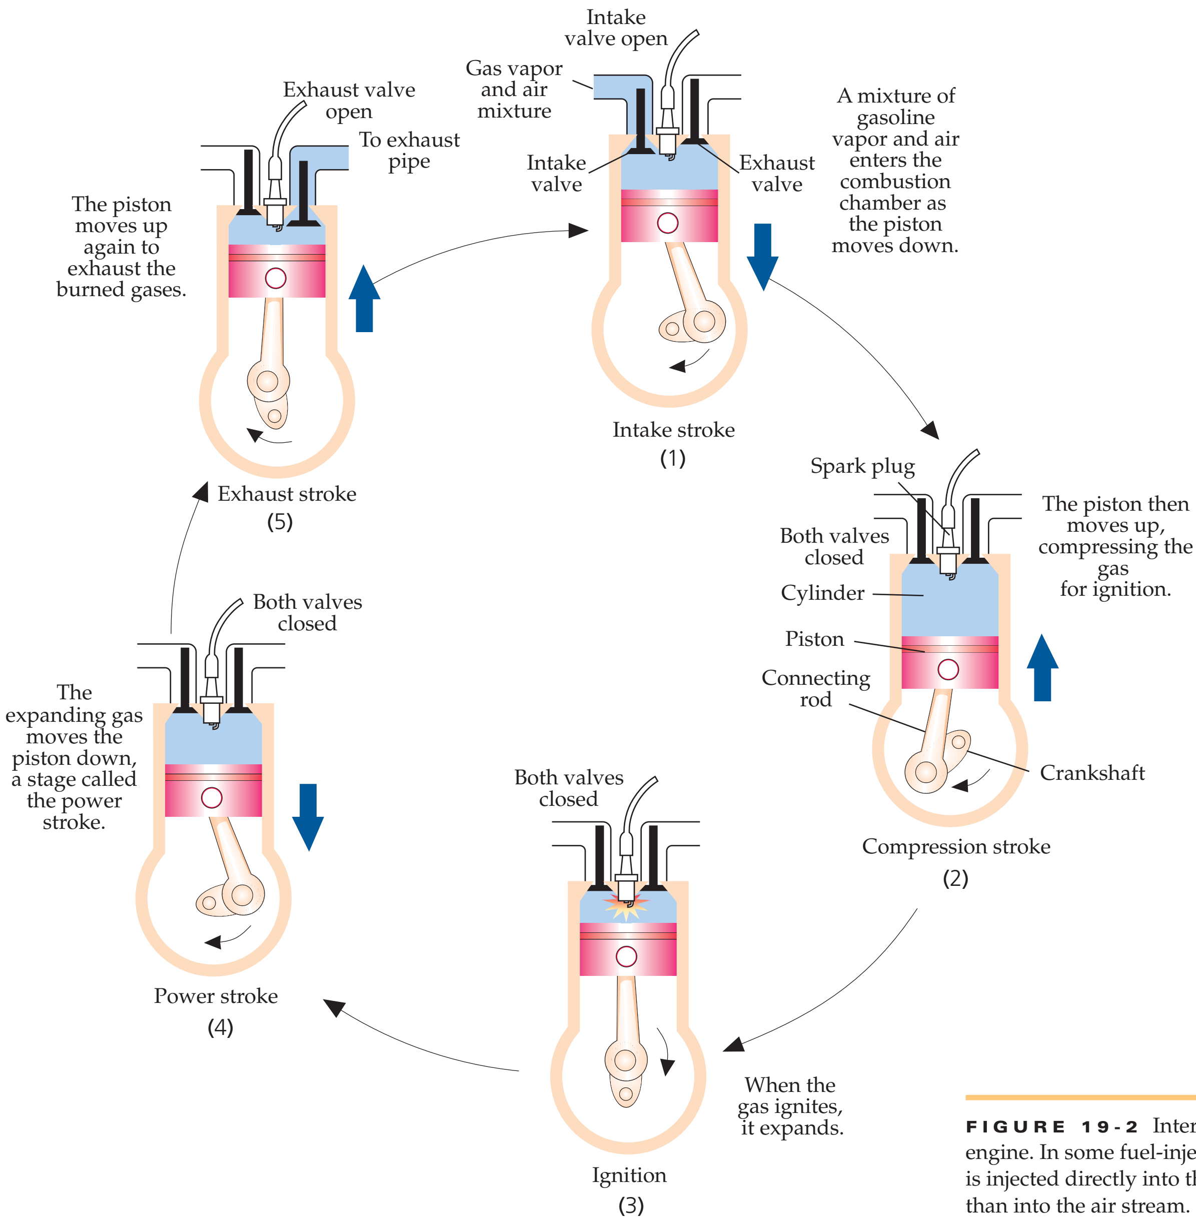

FIGURE 19-2 Internal-combustion engine. In some fuel-injected engines, the fuel is injected directly into the cylinder rather than into the air stream.

An idealized model of the processes in the internal combustion engine is called the **Otto cycle** and is shown in Figure 19-3.

Figure 19-4 shows a schematic representation of a basic heat engine. The heat absorbed is transferred from a hot **heat reservoir** at temperature T_h, and the heat released is transferred into a cold heat reservoir at a lower temperature T_c. A hot or cold heat reservoir is an idealized body or system that has a very large heat capacity so that it can absorb or release heat with no noticeable change in its temperature. In practice, burning fossil fuel often acts as the high-temperature reservoir, and the surrounding atmosphere or a lake often acts as the low-temperature reservoir. Applying the first law of thermodynamics ($\Delta E_{int} = Q_{in} + W_{on}$) to the heat engine gives

$$W = Q_h - Q_c \qquad 19\text{-}1$$

where W is the work done *by* the engine during one complete cycle, $Q_h - Q_c$ is the total heat transferred to the engine during one cycle, and ΔE_{int} is the change in internal energy of the engine (including the working substance) during one cycle. Because the initial and final states of the engine for a complete cycle are the same, the initial and final internal energies of the engine are equal. Thus, $\Delta E_{int} = 0$.

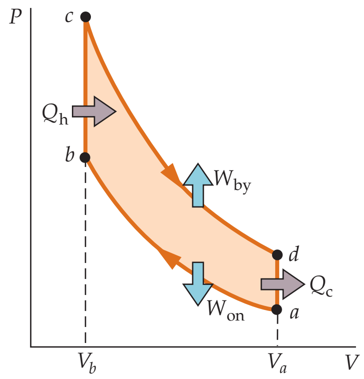

FIGURE 19-3 Otto cycle, representing the internal-combustion engine. The fuel–air mixture is adiabatically compressed from a to b. It is then heated (by combustion) at constant volume to c. The power stroke is represented by the adiabatic expansion from c to d. The cooling at constant volume from d to a represents the release of heat. The combustion products are exchanged for a fresh fuel–air mixture at constant pressure at step a (not shown). Work is done on the system during the adiabatic compression, and work is done by the system during the adiabatic expansion.

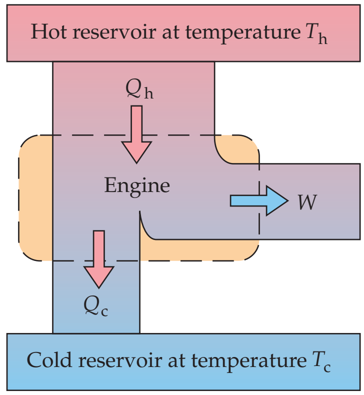

FIGURE 19-4 Schematic representation of a heat engine. The engine absorbs heat Q_h from a hot reservoir at a temperature T_h, does work W, and releases heat Q_c to a cold reservoir at a temperature T_c.

The efficiency ε of a heat engine is defined as the ratio of the work done by the engine to the heat absorbed from the high temperature reservoir:

$$\varepsilon = \frac{W}{Q_h} = \frac{Q_h - Q_c}{Q_h} = 1 - \frac{Q_c}{Q_h} \qquad 19\text{-}2$$

DEFINITION: EFFICIENCY OF A HEAT ENGINE

! The word *cycle* in this statement is important because *it* is possible to convert heat completely into work in a noncyclic process.

The heat Q_h is usually produced by burning some fuel that must be paid for, such as coal or oil, so it is desirable to get the most efficient use of the fuel as possible. The best steam engines operate near 40 percent efficiency; the best internal-combustion engines operate near 50 percent efficiency. At 100 percent efficiency ($\varepsilon = 1$), all the heat absorbed from the hot reservoir would be converted into work and no heat would be released to the cold reservoir. However, *it is impossible to make a heat engine with an efficiency of 100 percent.* This assertion is the **heat-engine statement of the second law of thermodynamics.** It is another way of expressing the Kelvin statement given earlier:

> It is impossible for a heat engine working in a cycle to produce *only the effect* of absorbing heat from a single reservoir and performing an equivalent amount of work.
>
> SECOND LAW OF THERMODYNAMICS: HEAT-ENGINE STATEMENT

An exhaust manifold feeds the header pipes seen on this top-fuel dragster in order for the engine to release heat and reduce its temperature. *(© 2002 Robert Briggs.)*

An ideal gas undergoing an isothermal expansion does just this. But after the expansion, the gas is not in its original state. To bring the gas back to its original state, work must be done on the gas, and some heat will be released.

The second law tells us that to do work with energy absorbed from a heat reservoir, we must have a colder reservoir available to absorb the energy that is not used by the engine to do work. If this were not true, we could design a ship that has a heat engine that is powered by simply extracting energy as heat from the ocean. Unfortunately, the lack of a colder reservoir, which would absorb heat from the engine, makes this enormous reservoir of energy unavailable for such use. (It is theoretically possible to run a heat engine between the warmer surface water of the ocean and the colder water at greater depths, but no practical scheme for using this temperature difference has yet emerged.) In order to convert heat at a single temperature into the energy that does work (with no other changes in the source or object), a separate cold reservoir must be used.

PROBLEM-SOLVING STRATEGY

Calculating the Work Done by a Heat Engine Operating in a Cycle

PICTURE A heat engine absorbs heat from a high-temperature heat reservoir, does work and releases heat to a low-temperature heat reservoir. Conservation of energy informs us that the heat absorbed by the engine per cycle equals the heat released by the engine per cycle plus the work done by the engine per cycle. The efficiency of a heat engine is defined as the ratio of the work done by the engine per cycle to the heat absorbed by the engine per cycle. The working substance for the engine is an ideal gas for virtually all calculations in this text.

SOLVE

1. For an integral number of cycles, the change in internal energy $\Delta E_{\text{int}} = 0$, so $Q_h = W + Q_c$.
2. The efficiency is given by $\varepsilon = W/Q_h$.
3. The work during a step in a cycle is given by $W_{\text{step}} = \int_{V_i}^{V_f} P\,dV$, where $P = nRT/V$.
4. The heat absorbed by the gas during a step is given by $C\,\Delta T$, where C is the heat capacity.

CHECK The work done, W, must be equal to $Q_h - Q_c$ if the engine completes an integral number of cycles.

Example 19-1 Efficiency of a Heat Engine

During each cycle, a heat engine absorbs 200 J of heat from a hot reservoir, does work, and releases 160 J to a cold reservoir. What is the efficiency of the engine?

PICTURE We use the definition of the efficiency of a heat engine $\varepsilon = W/Q_h$ (Equation 19-2).

SOLVE

1. The efficiency is the work done divided by the heat absorbed: $\varepsilon = \dfrac{W}{Q_h}$
2. The heat absorbed and the heat released are given: $Q_h = 200\text{ J}$ and $Q_c = 160\text{ J}$
3. The work is found from the first law: $W = Q_h - Q_c = 200\text{ J} - 160\text{ J} = 40\text{ J}$
4. Substitute the values of Q_h and W to calculate the efficiency: $\varepsilon = \dfrac{W}{Q_h} = \dfrac{40\text{ J}}{200\text{ J}} = 0.20 = \boxed{20\%}$

CHECK The efficiency is dimensionless. In this example, both W and Q_h are both expressed in joules, so the ratio is dimensionless, as expected.

PRACTICE PROBLEM 19-1 A heat engine has an efficiency of 35 percent. (*a*) How much work does it perform in a cycle if it absorbs 150 J of heat per cycle from the high-temperature reservoir? (*b*) How much heat is transferred to the low-temperature reservoir per cycle?

Example 19-2 The Otto Cycle

Try It Yourself

(*a*) Find the efficiency of the Otto cycle shown in Figure 19-3. (*b*) Express your answer in terms of the ratio of the volumes $r = V_a/V_b$.

PICTURE (*a*) To find ε, you need to find Q_h and Q_c. Heat transfer occurs only during the two constant-volume processes, b to c and d to a. You can thus find Q_h and Q_c, and therefore ε in terms of the temperatures T_a, T_b, T_c, and T_d. (*b*) The temperatures can be related to the volumes using $TV^{\gamma-1}$ = constant for adiabatic processes.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
(*a*) 1. Write the efficiency in terms of Q_h and Q_c:	$\varepsilon = 1 - \frac{Q_{cold}}{Q_{hot}} = 1 - \frac{Q_c}{Q_h}$
2. The release of heat occurs at constant volume from d to a. Write Q_c in terms of C_v and the temperatures T_a and T_d:	$Q_c = \lvert Q_{d\to a}\rvert = C_v\lvert T_a - T_d\rvert = C_v(T_d - T_a)$
3. The absorption of heat occurs at constant volume from b to c. Write Q_h in terms of C_v and the temperatures T_c and T_b:	$Q_h = Q_{b\to c} = C_v(T_c - T_b)$
4. Substitute these expressions Q_c and Q_h to find the efficiency in terms of the temperatures T_a, T_b, T_c, and T_d:	$\varepsilon = \boxed{1 - \frac{T_d - T_a}{T_c - T_b}}$
(*b*) 1. Relate T_c to T_d using $TV^{\gamma-1}$ = constant, and $V_a/V_c = r$:	$T_cV_c^{\gamma-1} = T_dV_d^{\gamma-1}$ $T_c = T_d\frac{V_d^{\gamma-1}}{V_c^{\gamma-1}} = T_dr^{\gamma-1}$
2. Relate T_b to T_a as in step 1:	$T_b = T_ar^{\gamma-1}$
3. Use these relations to eliminate T_c and T_b from ε in Part (*a*) so that ε is expressed in terms of r:	$\varepsilon = 1 - \frac{T_d - T_a}{T_dr^{\gamma-1} - T_ar^{\gamma-1}} = \boxed{1 - \frac{1}{r^{\gamma-1}}}$

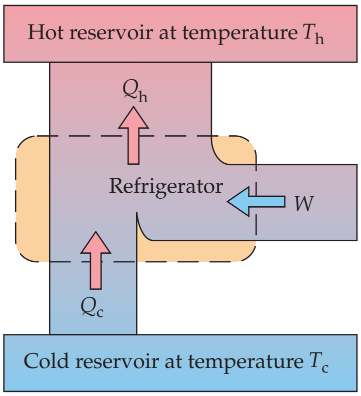
CHECK The Part-(*b*) result is a dimensionless number, as expected. In addition, the expression for ε is between 0 and 1, and approaches 0 as r approaches 1, as expected.

TAKING IT FURTHER The ratio r (volume before compression/volume after compression) is called the compression ratio.

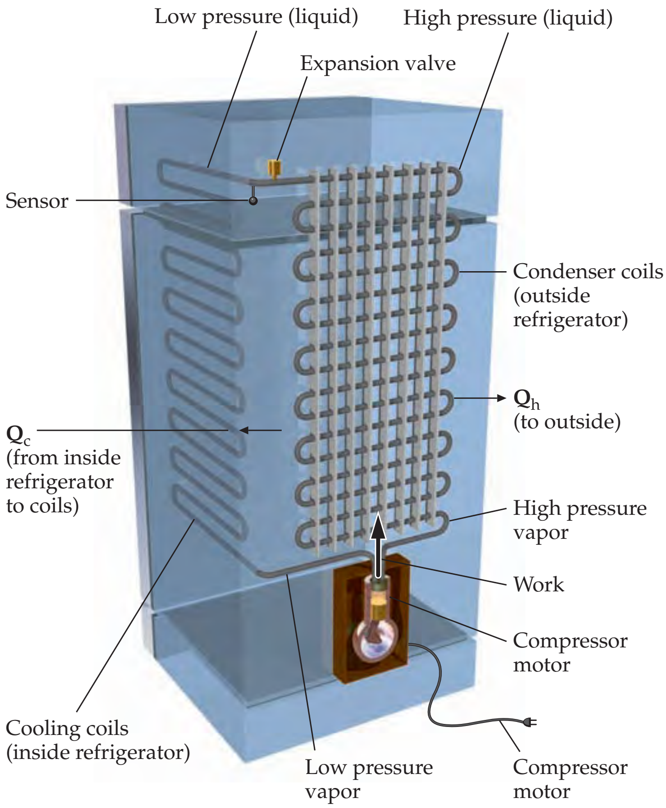
19-2 REFRIGERATORS AND THE SECOND LAW OF THERMODYNAMICS

A **refrigerator** is essentially a heat engine run backward (Figure 19-5*a*). The refrigerator's engine absorbs heat from the interior of the refrigerator (cold reservoir) and releases heat to the surroundings (hot reservoir) (Figure 19-5*b*). Experience shows that such a transfer always requires that work be done on the refrigerator—a result known as the **refrigerator statement of the second law of thermodynamics,** which is another way of expressing the Clausius statement:

FIGURE 19-5 (*a*) Schematic representation of a refrigerator. Work W is done on the refrigerator and it absorbs heat Q_c from a cold reservoir and releases heat Q_h. (*b*) An actual refrigerator.



(*a*)



(*b*)

It is impossible for a refrigerator working in a cycle to produce *only the effect* of absorbing heat from a cold object and releasing the same amount of heat to a hot object.

SECOND LAW OF THERMODYNAMICS: REFRIGERATOR STATEMENT

Were the preceding statement not true, we could cool our homes in the summer with refrigerators that released heat to the outdoors without using electricity or any other energy source.

A measure of a refrigerator's performance is the ratio Q_c/W of the heat absorbed from the low-temperature reservoir to the work done on the refrigerator. (This work equals the electrical energy that comes from the wall outlet.) The ratio Q_c/W is called the **coefficient of performance** (COP):

$$\mathrm{COP} = \frac{Q_c}{W} \tag{19-3}$$

DEFINITION: COEFFICIENT OF PERFORMANCE (REFRIGERATOR)

The greater the COP, the better the refrigerator. Typical refrigerators have coefficients of performance of about 5 or 6. [In the United States, the coefficient of performance of air conditioners is called the seasonal energy efficiency ratio (SEER).]* In terms of this ratio, the refrigerator statement of the second law states that the COP of a refrigerator cannot be infinite.

(*Anderson Ross/PhotoDisk/Getty.*)

* The SEER of an air conditioner is equal to the seasonal average of Q_c/W, with Q_c in BTUs and W in watt-hours.

Example 19-3 Making Ice Cubes *Context-Rich*

You have half an hour before guests start arriving for your party when you suddenly realize that you forgot to buy ice for drinks. You quickly put 1.00 L of water at 10.0°C into your ice cube trays and pop them into the freezer. Will you have ice in time for your guests? The label on your refrigerator states that the appliance has a coefficient of performance of 5.5 and a power rating of 550 W. You estimate that only 10 percent of the electrical power contributes to the cooling and freezing of the water.

PICTURE Work equals power times time. We are given the power, so we need to find the work to determine the time. The work W is related to Q_c by COP $= W/Q_c$ (Equation 19-3). To find Q_c we calculate how much heat must be released by the water.

SOLVE

1. The time needed is related to the power available and the work required:

$$P = W/\Delta t \Rightarrow \Delta t = W/P$$

2. The work is related to the coefficient of performance and the heat absorbed:

$$\text{COP} = \frac{Q_c}{W}$$

3. The heat Q_c absorbed from the inside of the refrigerator equals the heat Q_{cool} to be absorbed from the water to cool the water plus the heat Q_{freeze} to be absorbed from the water to freeze the water:

$$Q_c = Q_{cool} + Q_{freeze}$$

4. The release of heat needed to cool 1.00 L of water (mass 1 kg) by 10°C is:

$$Q_{cool} = mc\,\Delta T = (1.00\text{ kg})[4.18\text{ kJ}/(\text{kg}\cdot\text{K})](10.0\text{ K}) = 41.8\text{ kJ}$$

5. The release of heat needed to freeze 1 L of water into ice cubes is:

$$Q_{freeze} = mL_f = (1.00\text{ kg})(333.5\text{ kJ/kg}) = 333.5\text{ kJ}$$

6. Add these heats to obtain Q_c:

$$Q_c = 41.8\text{ kJ} + 333.5\text{ kJ} = 375\text{ kJ}$$

7. Substitute Q_c into step 2 to find the work W:

$$W = \frac{Q_c}{\text{COP}} = \frac{375\text{ kJ}}{5.5} = 68.2\text{ kJ}$$

8. Use this value of W and 55 W for the available power to find the time t:

$$\Delta t = \frac{W}{P} = \frac{68.2\text{ kJ}}{55\text{ J/s}} = 1.24\text{ ks} \times \frac{1\text{ min}}{60\text{ s}} = 20.7\text{ min}$$

$\boxed{\text{Your guests will have ice.}}$

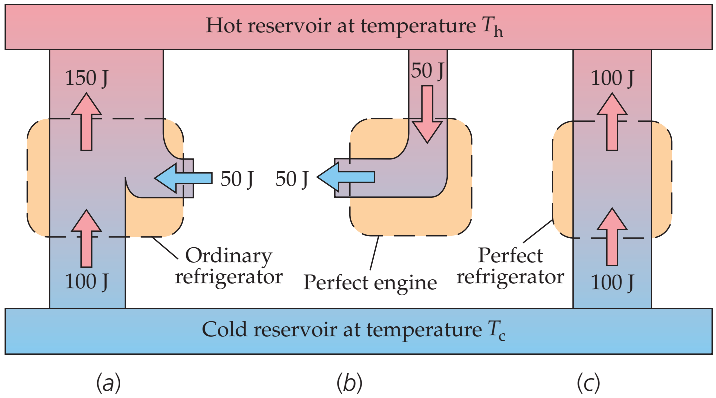
CHECK Twenty minutes is a short, but feasible, time to freeze one liter of water.

PRACTICE PROBLEM 19-2 A refrigerator has a coefficient of performance of 4.0. How much heat per cycle is absorbed by the hot reservoir if 200 kJ of heat per cycle are released by the cold reservoir?

EQUIVALENCE OF THE HEAT-ENGINE AND REFRIGERATOR STATEMENTS

The heat-engine and refrigerator statements (that is, the Kelvin and Clausius statements, respectively) of the second law of thermodynamics seem quite different, but they are actually equivalent. The heat-engine statement is, "It is impossible for a heat engine working in a cycle to produce *only the effect* of absorbing heat from a single reservoir and performing an equivalent amount of work," whereas the refrigerator statement is, "It is impossible for a refrigerator working in a cycle to produce *only the effect* of absorbing heat from a cold object and releasing the same amount of heat to a hot object." We can prove the equivalence of these statements by showing that if either statement is assumed to be false, then the other must also be false. We will use a numerical example to show that if the heat-engine statement is false, then the refrigerator statement is false.

Figure 19-6*a* shows an ordinary refrigerator that uses 50 J of work to absorb 100 J of heat from a cold reservoir and release 150 J of heat to a hot reservoir. Suppose the heat-engine statement of the second law were not true. Then, a "perfect" heat engine could absorb 50 J of heat from the hot reservoir and do 50 J of work with 100 percent efficiency. We could use this perfect heat engine to absorb 50 J of heat from the hot reservoir and do 50 J of work (Figure 19-6*b*) on the ordinary refrigerator. Then, the combination of the perfect heat engine and the ordinary refrigerator would be a perfect refrigerator, transferring 100 J of energy as heat from the cold reservoir to the hot reservoir without requiring any work, as illustrated in Figure 19-6*c*. This violates the refrigerator statement of the second law. Thus, if the heat-engine statement is false, the refrigerator statement is also false. Similarly, if a perfect refrigerator existed, it could be used in conjunction with an ordinary heat engine to construct a perfect heat engine. Thus, if the refrigerator statement is false, the heat-engine statement is also false. It then follows that if one statement is true, the other is also true. Therefore, the heat-engine statement and the refrigerator statement are equivalent.



(*a*) An ordinary refrigerator absorbs 100 J from a cold reservoir, requiring the input of 50 J of work.

(*b*) A perfect heat engine violates the heat engine statement of the second law by absorbing 50 J from the hot reservoir and converting it completely into work.

(*c*) Putting the two together makes a perfect refrigerator that violates the refrigerator statement of the second law by absorbing 100 J from the cold reservoir and releasing the same amount of heat to the hot reservoir with no other effect.

FIGURE 19-6 Demonstration of the equivalence of the heat-engine and refrigerator statements of the second law of thermodynamics.

19-3 THE CARNOT ENGINE

According to the second law of thermodynamics, it is impossible for a heat engine working between two heat reservoirs to be 100 percent efficient. What, then, is the maximum possible efficiency for such an engine? A young French engineer, Sadi Carnot answered this question in 1824, before either the first or the second law of thermodynamics had been established. Carnot found that a *reversible engine* is the most efficient engine that can operate between any two given reservoirs. This result is known as the Carnot theorem:

> No engine working between two given heat reservoirs can be more efficient than a reversible engine working between these two reservoirs.
>
> CARNOT THEOREM

A reversible engine working in a cycle between two heat reservoirs is called a **Carnot engine,** and its cycle is called a **Carnot cycle.** Figure 19-7 illustrates the Carnot theorem with a numerical example worked out in the figure caption.

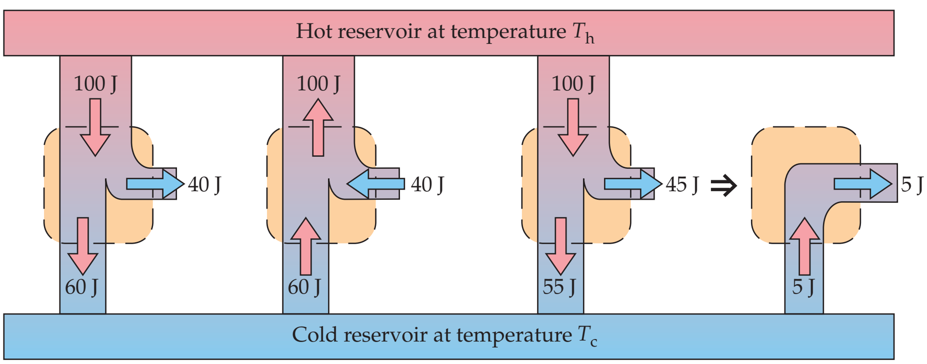


FIGURE 19-7 Illustration of the Carnot theorem. (*a*) A reversible heat engine with 40 percent efficiency absorbs 100 J from a hot reservoir, does 40 J work, and releases 60 J to the cold reservoir. (*b*) If the same engine runs backwards as a refrigerator, 40 J of work are done to absorb 60 J from the cold reservoir and release 100 J to the hot reservoir. (*c*) An assumed heat engine working between the same two reservoirs with an efficiency of 45 percent, which is greater than that of the reversible engine in Part (*a*). (*d*) The net effect of running the engine in Part (*c*) in conjunction with the refrigerator in Part (*b*) is the same as that of a perfect heat engine that absorbs 5 J from the cold reservoir and converts it completely into work with no other effect, violating the second law of thermodynamics. Thus, the reversible engine in Part (*a*) is the most efficient engine that can operate between these two reservoirs.

If no engine can have a greater efficiency than a Carnot engine, it follows that all Carnot engines working between the same two reservoirs have the same efficiency. This efficiency, called the **Carnot efficiency,** must be independent of the working substance of the engine, and thus can depend only on the temperatures of the reservoirs.

Let us look at what makes a process reversible or irreversible. According to the second law, heat is transferred from hot objects to cold objects and never the other way around. Thus, the transfer of heat from a hot object to a cold one is *not* reversible. Also, friction can transform work into internal thermal energy, but friction can never transform internal thermal energy into work. The conversion of work into thermal energy by friction is *not* reversible. Friction and other dissipative forces irreversibly transform mechanical energy into thermal energy. A third type of irreversibility occurs when a system passes through nonequilibrium states, such as when there is turbulence in a gas or when a gas explodes. For a system to undergo a reversible process, the system must be able to go through the same equilibrium states in the reverse order.

From these considerations and our statements of the second law of thermodynamics, we can list some conditions that are necessary for a process to be reversible:

1. No mechanical energy is transformed into internal thermal energy by friction, viscous forces, or other dissipative forces.
2. Energy transfer as heat only occurs between objects with an infinitesimal difference in temperature.
3. The process must be quasi-static so that the system is always at or infinitesimally near an equilibrium state.

CONDITIONS FOR REVERSIBILITY

Any process that violates any of the preceding conditions is irreversible. Most processes we observe in nature are irreversible. To have a reversible process, great care must be taken to eliminate frictional and other dissipative forces and to make the process quasi-static. Because this can never be completely accomplished, a reversible process is an idealization similar to the idealization of motion without friction in mechanics problems. Reversibility can, nevertheless, be closely approximated in practice.

We can now understand the features of a Carnot cycle, which is a reversible cycle between two heat reservoirs. Because all heat transfer must be done isothermally in order for the process to be reversible, the heat absorbed from the hot reservoir must be absorbed isothermally. The next step is a quasi-static, adiabatic expansion to the lower temperature of the cold reservoir. Next, heat is released isothermally to the cold reservoir. Finally, there is a quasi-static, adiabatic compression to the higher temperature of the hot reservoir. The Carnot cycle thus consists of four reversible steps:

1. A quasi-static, isothermal absorption of heat from a hot reservoir
2. A quasi-static, adiabatic expansion to a lower temperature
3. A quasi-static, isothermal release of heat to a cold reservoir
4. A quasi-static, adiabatic compression back to the original state

STEPS IN A CARNOT CYCLE

One way to calculate the efficiency of a Carnot engine is to choose as the working substance a material of which we have some knowledge—an ideal gas—and then explicitly calculate the work done on it over a Carnot cycle (Figure 19-8*a* and Figure 19-8*b*). Because all Carnot cycles have the same efficiency independent of the working substance, our result will be valid in general.

The efficiency of the Carnot cycle (Equation 19-2) is

$$\varepsilon = 1 - \frac{Q_c}{Q_h}$$

The heat Q_h is absorbed during the isothermal expansion from state 1 to state 2. The first law of thermodynamics is $\Delta E_{int} = Q_{in} + W_{on}$. For an isothermal expansion of an ideal gas $\Delta E_{int} = 0$. Applying the first law to the isothermal expansion from state 1 to state 2, we have $Q_h = Q_{in}$, so Q_h equals the work done by the gas:

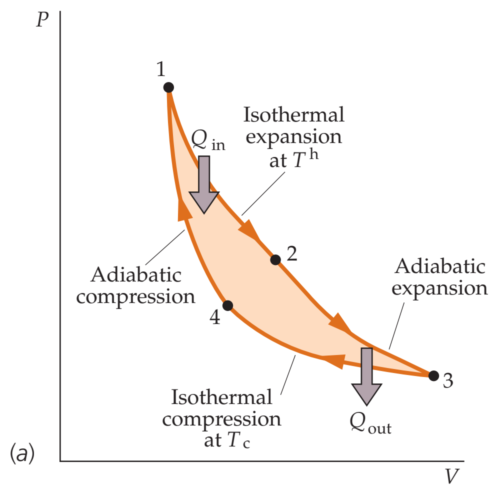
$$Q_h = W_{by\ gas} = \int_{V_1}^{V_2} P\,dV = \int_{V_1}^{V_2} \frac{nRT_h}{V}\,dV = nRT_h \int_{V_1}^{V_2} \frac{dV}{V} = nRT_h \ln\frac{V_2}{V_1}$$

Similarly, the heat released to the cold reservoir equals the work done on the gas during the isothermal compression at temperature T_c from state 3 to state 4. This work has the same magnitude as that done by the gas if it expands from state 4 to state 3. The heat rejected is thus

$$Q_c = W_{on\ gas} = nRT_c \ln\frac{V_3}{V_4}$$

The ratio of these heats is

$$\frac{Q_c}{Q_h} = \frac{T_c \ln\dfrac{V_3}{V_4}}{T_h \ln\dfrac{V_2}{V_1}} \qquad \text{19-4}$$



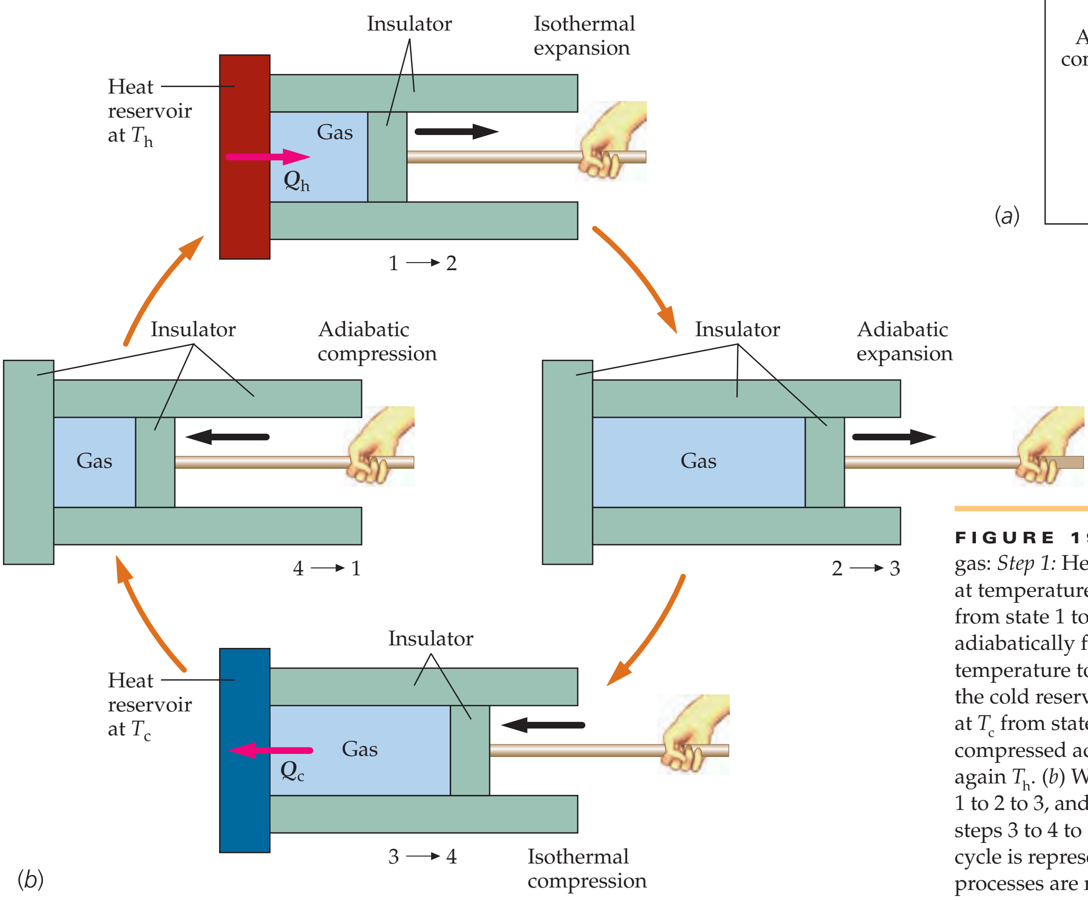


FIGURE 19-8 (*a*) Carnot cycle for an ideal gas: *Step 1:* Heat is absorbed from a hot reservoir at temperature T_h during an isothermal expansion from state 1 to state 2. *Step 2:* The gas expands adiabatically from state 2 to state 3, reducing its temperature to T_c. *Step 3:* The gas releases heat to the cold reservoir as it is compressed isothermally at T_c from state 3 to state 4. *Step 4:* The gas is compressed adiabatically until its temperature is again T_h. (*b*) Work is done by the gas during steps 1 to 2 to 3, and work is done on the gas during steps 3 to 4 to 1. The net work done during the cycle is represented by the shaded area. All processes are reversible. All steps are quasi-static.

Power plant at Wairakei, New Zealand, that converts geothermal energy into electricity. *(Jean-Pierre Horlin/The Image Bank.)*

We can relate the ratios V_2/V_1 and V_3/V_4 using Equation 18-37 for a quasi-static adiabatic expansion. For the expansion from state 2 to state 3, we have

$$T_h V_2^{\gamma-1} = T_c V_3^{\gamma-1}$$

Similarly, for the adiabatic compression from state 4 to state 1, we have

$$T_h V_1^{\gamma-1} = T_c V_4^{\gamma-1}$$

Dividing the first of these two equations by the second, we obtain

$$\left(\frac{V_2}{V_1}\right)^{\gamma-1} = \left(\frac{V_3}{V_4}\right)^{\gamma-1} \quad \Rightarrow \quad \frac{V_2}{V_1} = \frac{V_3}{V_4}$$

Thus, Equation 19-4 gives

$$\frac{Q_c}{Q_h} = \frac{T_c \ln \frac{V_2}{V_1}}{T_h \ln \frac{V_2}{V_1}} = \frac{T_c}{T_h} \qquad 19\text{-}5$$

The Carnot efficiency ε_C is thus

$$\varepsilon_C = 1 - \frac{T_c}{T_h} \qquad 19\text{-}6$$

CARNOT EFFICIENCY

Equation 19-6 demonstrates that because the Carnot efficiency must be independent of the working substance of any particular engine, it depends only on the temperatures of the two reservoirs.

Example 19-4 Efficiency of a Steam Engine

A steam engine works between a hot reservoir at 100°C (373 K) and a cold reservoir at 0.0°C (273 K). (*a*) What is the maximum possible efficiency of this engine? (*b*) If the engine is run backwards as a refrigerator, what is its maximum coefficient of performance?

PICTURE The maximum efficiency is the Carnot efficiency given by Equation 19-6. To find the maximum COP, we use the definition of efficiency ($\varepsilon = W/Q_h$), the definition of COP ($\text{COP} = Q_c/W$), and, because it is a reversible cycle, $Q_c/Q_h = T_c/T_h$ (Equation 19-5).

SOLVE

(a) The maximum efficiency is the Carnot efficiency:

$$\varepsilon_{max} = \varepsilon_C = 1 - \frac{T_c}{T_h} = 1 - \frac{273\text{ K}}{373\text{ K}} = 0.268 = \boxed{26.8\%}$$

(*b*) 1. Write the expression for the COP if the engine is run in reverse for a single cycle:

$$\text{COP} = \frac{Q_c}{W}$$

2. The work is equal to $Q_h - Q_c$ (the heat absorbed from the high-temperature reservoir minus the heat released to the low-temperature reservoir):

$$\text{COP} = \frac{Q_c}{Q_h - Q_c} = \frac{1}{\dfrac{Q_h}{Q_c} - 1}$$

3. Substitute for Q_h/Q_c using $Q_c/Q_h = T_c/T_h$ (Equation 19-5) and solve for the COP:

$$\text{COP}_{max} = \frac{1}{\dfrac{T_h}{T_c} - 1} = \frac{1}{\dfrac{373\text{ K}}{273\text{ K}} - 1} = \boxed{2.73}$$

CHECK Solving the Part (*a*) result for the ratio of temperatures, substituting into the Part-(*b*) step-3 result, and rearranging gives $\text{COP}_{max} = \varepsilon_C^{-1} - 1$. Substituting 0.268 (the Part-(*a*) result) for ε_C gives $\text{COP}_{max} = 2.73$ (the Part-(*b*) result).

TAKING IT FURTHER Even though an efficiency of 26.8 percent seems to be quite low, it is the greatest efficiency possible for any engine working between these two temperatures. Real engines operating between these temperatures will have lower efficiencies because of friction, heat leaks, and other irreversible processes. Real refrigerators will have lower coefficients of performance than 2.73. It can be shown that the coefficient of performance of a Carnot refrigerator is $T_c/\Delta T$, where $\Delta T = T_h - T_c$.

The Carnot efficiency gives us an upper limit on possible efficiencies, and is therefore useful to know. For example, we calculated in Example 19-4 that the Carnot efficiency is 26.8 percent. This means that, no matter how much we reduce friction and other irreversible losses, the best efficiency obtained between reservoirs at 373 K and 273 K is 26.8 percent. We would know, then, that an engine working between those two temperatures with an efficiency of 25 percent is a very good engine!

For an actual engine, the **work lost** is the work done by a reversible engine operating between the same two temperatures minus the work done by the actual engine, assuming both engines complete an integral number of cycles and both absorb the same amount of heat from the high-temperature reservoir. The ratio of the work done by the actual engine and the work done by a reversible engine operating between the same two temperatures is called the ***second law efficiency.***

Example 19-5 Work Lost by an Engine

An engine absorbs 200 J from a hot reservoir at 373 K, does 48.0 J of work, and releases 152 J to a cold reservoir at 273 K. What is the work lost due to irreversible processes in this engine?

PICTURE The work lost is the work done by a reversible engine operating between the same two temperatures minus the 18 J of work done by the engine, assuming both engines absorb the same amount of heat from the high-temperature reservoir.

SOLVE

1. The work lost is the maximum amount of work that could be done minus the work actually done: $W_{\text{lost}} = W_{\text{max}} - W$
2. The maximum amount of work that could be done is the work done using a Carnot engine: $W_{\text{max}} = \varepsilon_{\text{C}} Q_{\text{h}}$
3. The work lost is then: $W_{\text{lost}} = \varepsilon_{\text{C}} Q_{\text{h}} - W$
4. The Carnot efficiency can be expressed in terms of the temperatures: $\varepsilon_{\text{C}} = 1 - \dfrac{T_{\text{c}}}{T_{\text{h}}}$
5. Substituting for ε_{C} gives:

$$W_{\text{lost}} = \left(1 - \frac{T_{\text{c}}}{T_{\text{h}}}\right)Q_{\text{h}} - W = \left(1 - \frac{273\text{ K}}{373\text{ K}}\right)(200\text{ J}) - 48\text{ J}$$
$$= 53.6\text{ J} - 48.0\text{ J} = \boxed{5.6\text{ J}}$$

CHECK The Carnot efficiency for these two temperatures is 26.8%. The work done by the engine in this example is given as 48.0 J, and 48.0 J is 24% of 200 J. In addition, the 5.6 J of work lost is 2.4% of 200 J. Because 24% plus 2.4% equals 26.8%, our answer is plausible.

TAKING IT FURTHER The 5.6 J of energy in the answer is not "lost" to the universe—total energy is conserved. That 5.6 J of energy transferred to the cold reservoir by the nonideal engine of the problem is only lost in that it would have been converted into useful work if an ideal (reversible) engine had been used.

Example 19-6 Work Lost Between Heat Reservoirs

If 200 J of heat are released by a reservoir at 373 K and absorbed by a second reservoir at 273 K, how much work capability is "lost" in this process?

PICTURE No work is done during the transfer of the 200 J. Thus, the work lost is 100 percent of the work that would be done by a reversible engine operating between the same two reservoirs that absorbs 200 J from the high-temperature reservoir.

SOLVE

1. The work lost is the work done by a reversible engine minus the work done by the process described here. This process is the transfer of 200 J of heat from the high-temperature reservoir to the low-temperature reservoir, so the work done is zero:

$$W_{\text{lost}} = W_{\text{rev}} - W = W_{\text{rev}} - 0$$

2. The work done by a reversible engine operating between the same two reservoirs and the absorption of 200 J from the high-temperature reservoir is:

$$W_{\text{rev}} = \varepsilon Q_h = \left(1 - \frac{T_c}{T_h}\right)Q_h = \left(1 - \frac{273\text{ K}}{373\text{ K}}\right)(200\text{ J}) = 53.6\text{ J}$$

3. Calculate the work lost:

$$W_{\text{lost}} = W_{\text{rev}} = \boxed{53.6\text{ J}}$$

CHECK In Example 19-4, we calculated the efficiency of a reversible engine operating between 273 K and 373 K to be 26.8%. Our step-3 result is plausible because 53.6 J is 26.8% of the 200 J absorbed from the reservoir.

PRACTICE PROBLEM 19-3 A reversible engine works between heat reservoirs at 500 K and 300 K. (*a*) What is its efficiency? (*b*) If during each cycle the engine absorbs 200 kJ of heat from the hot reservoir, how much work does it do during each cycle?

PRACTICE PROBLEM 19-4 A real engine works between heat reservoirs at 500 K and 300 K. It absorbs 500 kJ of heat from the hot reservoir and does 150 kJ of work during each cycle. What is its efficiency?

THE THERMODYNAMIC OR ABSOLUTE TEMPERATURE SCALE

In Chapter 17, the ideal-gas temperature scale was defined in terms of the properties of gases that have low densities. Because the Carnot efficiency depends only on the temperatures of the two heat reservoirs, it can be used to define the ratio of the temperatures of the reservoirs independent of the properties of any substance. We *define* the ratio of the thermodynamic temperatures of the hot and cold reservoirs to be

$$\frac{T_c}{T_h} = \frac{Q_c}{Q_h} \qquad 19\text{-}7$$

DEFINITION OF THERMODYNAMIC TEMPERATURE

where Q_h is the energy absorbed from the hot reservoir and Q_c is the energy released to the cold reservoir by a Carnot engine operating in a cycle and working between the two reservoirs. Thus, to find the ratio of two reservoir temperatures, we set up a reversible engine operating between them and measure the energy transferred as heat to or from each reservoir during one cycle. The **thermodynamic temperature** is completely specified by Equation 19-7 *and* the choice of one fixed point. If the fixed point is defined to be 273.16 K for the triple point of water, then the thermodynamic temperature scale matches the ideal-gas temperature scale for the range of temperatures over which a gas thermometer can be used. Any temperature that reads zero at absolute zero is called an *absolute-temperature scale*.

* 19-4 HEAT PUMPS

A **heat pump** is a refrigerator with a different objective. Typically, the objective of a refrigerator is to cool an object or region of interest. The objective of a heat pump, however, is to heat an object or region of interest. For example, if you use a heat pump to heat your house, you transfer heat from the cold air outside the house to the warmer air inside it. Your objective is to heat the region inside your house. If work W is done on a heat pump to absorb heat Q_c from the cold reservoir and release heat Q_h to the hot reservoir, the coefficient of performance for a heat pump is defined as

$$\mathrm{COP_{HP}} = \frac{Q_h}{W} \tag{19-8}$$

DEFINITION: COEFFICIENT OF PERFORMANCE (HEAT PUMP)

This coefficient of performance differs from that for the refrigerator, which is Q_c/W (Equation 19-3). Using $W = Q_h - Q_c$, this can be written

$$\mathrm{COP_{HP}} = \frac{Q_h}{Q_h - Q_c} = \frac{1}{1 - \dfrac{Q_c}{Q_h}} \tag{19-9}$$

The maximum coefficient of performance is obtained using a Carnot heat pump. Then Q_c and Q_h are related by Equation 19-5. Substituting $Q_c/Q_h = T_c/T_h$ into Equation 19-9, we obtain for the maximum coefficient of performance

$$\mathrm{COP_{HP\,max}} = \frac{1}{1 - \dfrac{T_c}{T_h}} = \frac{T_h}{T_h - T_c} = \frac{T_h}{\Delta T} \tag{19-10}$$

where ΔT is the difference in temperature between the hot and cold reservoirs. Real heat pumps have coefficients of performance less than the $\mathrm{COP_{HP\,max}}$ because of friction, heat leaks, and other irreversible processes.

The two COPs are related. Using $Q_h = Q_c + W$, we can relate Equations 19-3 and 19-10:

$$\mathrm{COP_{HP}} = \frac{Q_h}{W} = \frac{Q_c + W}{W} = 1 + \frac{Q_c}{W} = 1 + \mathrm{COP} \tag{19-11}$$

where COP is the coefficient of performance of a refrigerator.

Example 19-7 An Ideal Heat Pump

An ideal heat pump is used to pump heat from the outside air at −5°C to the hot-air supply for the heating fan in a house, which is at 40°C. How much work is required to pump 1.0 kJ of heat into the house?

PICTURE Use Equation 19-11 with $\mathrm{COP_{HP\,max}}$ calculated from Equation 19-10 for $T_c = 25°\mathrm{C} = 268\ \mathrm{K}$ and $\Delta T = 45\ \mathrm{K}$.

SOLVE

1. Using the definition of $\mathrm{COP_{HP}}$ ($\mathrm{COP_{HP}} = Q_h/W$), relate the work done to the heat released:
$$\mathrm{COP_{HP}} = \frac{Q_h}{W}$$
2. Relate the ideal or maximum $\mathrm{COP_{HP}}$ to the temperatures (Equation 19-10):
$$\mathrm{COP_{HP}} = \mathrm{COP_{HP\,max}} = \frac{T_h}{\Delta T}$$
3. Solve for the work:
$$W = \frac{Q_h}{\mathrm{COP_{HP}}} = Q_h \frac{\Delta T}{T_h} = (1.0\ \mathrm{kJ})\frac{45\ \mathrm{K}}{313\ \mathrm{K}}$$
$$W = \boxed{0.14\ \mathrm{kJ}}$$

CHECK Our step-3 expression for the work ensures the work has the same dimensions as heat. (The ratio $\Delta T/T_h$ is dimensionless.)

TAKING IT FURTHER The $\mathrm{COP_{HP\,max}} = T_h/\Delta T = 7.0$. That is, the amount of heat released inside the house by the heat pump is 7 times larger than the amount of work done on the heat pump. (Only 0.14 kJ of work is needed to pump 1.0 kJ of heat into the hot-air supply in the house.)

19-5 IRREVERSIBILITY, DISORDER, AND ENTROPY

Many irreversible processes exist that cannot be described by the heat-engine or refrigerator statements of the second law, such as a glass falling to the floor and breaking or a balloon popping. However, all irreversible processes have one thing in common—the system plus its surroundings move toward a less ordered state.

Suppose a box of negligible mass that contains a gas of mass M at a temperature T is moving along a frictionless table with a velocity v_{cm} (Figure 19-9*a*). The total kinetic energy of the gas has two components: that associated with the movement of its center of mass $\frac{1}{2}Mv_{cm}^2$, and the kinetic energy of the motion of its molecules relative to its center of mass. The center-of-mass energy $\frac{1}{2}Mv_{cm}^2$ is ordered mechanical energy that could be converted entirely into work. (For example, if a weight were attached to the moving box by a string passing over a pulley, this energy could be used to lift the weight.) The relative energy is the internal thermal energy of the gas, which is related to its temperature T. It is random, nonordered energy that cannot be converted entirely into work.

Now, suppose that the box hits a fixed wall and stops (Figure 19-9*b*). This inelastic collision is clearly an irreversible process. The ordered mechanical energy of the gas $\frac{1}{2}Mv_{cm}^2$ is transformed into random internal energy, and the temperature of the gas increases. The gas still has the same total energy, but now all of that energy is associated with the random motion of the gas molecules relative to the center of mass, which is now at rest. Thus, the gas has become less ordered (more disordered), and has lost some of its ability to do work.

There is a thermodynamic function called **entropy** S that is a measure of the disorder of a system. Entropy S, like pressure P, volume V, temperature T, and internal energy E_{int}, is a function of the state of a system. As with potential energy and internal energy, it is the *change* in entropy that is important. The change in entropy dS of a system as it goes from one state to another is defined as

$$dS = \frac{dQ_{rev}}{T} \qquad 19\text{-}12$$

DEFINITION: ENTROPY CHANGE

where dQ_{rev} is the heat absorbed by the system in a *reversible* process. If dQ_{rev} is negative, then the entropy change of the system has a negative value and the entropy of the system has decreased.

The term dQ_{rev} does not mean that a reversible heat transfer must take place in order for the entropy of a system to change. Indeed, there are many situations in which the entropy of a system changes when there is no transfer of heat whatsoever, for example, the box of gas colliding with the wall in Figure 19-9. Equation 19-12 simply gives us a method for *calculating* the entropy difference between two states of a system. Because entropy is a state function, the change in entropy when the

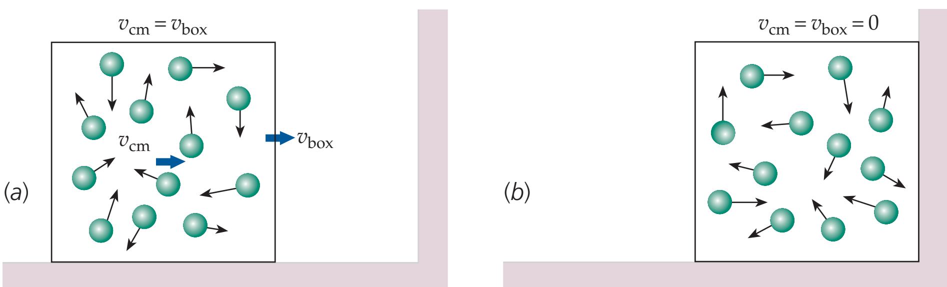

FIGURE 19-9 (*a*) A box of negligible mass contains a gas. The box and the center of mass of the gas move toward the wall at the same speed. (*b*) A short time after the box undergoes a perfectly inelastic collision with the wall, both the box and the center of mass of the gas are at rest, and the gas has a higher temperature.

system moves from an initial state to a final state depends only on the system's initial and final states, and not on the process by which the change occurs. That is, if S_1 is the entropy of the system when it is in state 1, and if S_2 is the entropy of the system when it is in state 2, then we calculate the difference in the entropy $S_2 - S_1$ by evaluating the integral $\int_1^2 dQ/T$ for *any* reversible path (process) that takes the system from state 1 to state 2.

ENTROPY OF AN IDEAL GAS

We can illustrate that dQ_{rev}/T is in fact the differential of a state function for an ideal gas (even though dQ_{rev} is not). Consider an arbitrary reversible quasi-static process in which a system consisting of an ideal gas absorbs an amount of heat dQ_{rev}. According to the first law, dQ_{rev} is related to the change in the internal energy dE_{int} of the gas and the work done on the gas ($dW_{\mathrm{on}} = -P\,dV$) by

$$dE_{\mathrm{int}} = dQ_{\mathrm{rev}} + dW_{\mathrm{on}} = dQ_{\mathrm{rev}} - P\,dV$$

See Math Tutorial *for more information on* Integrals

For an ideal gas, we can write dE_{int} in terms of the heat capacity, $dE_{\mathrm{int}} = C_{\mathrm{v}}\,dT$, and we can substitute nRT/V for P from the equation of state. Then

$$C_{\mathrm{v}}\,dT = dQ_{\mathrm{rev}} - nRT\frac{dV}{V} \qquad \text{19-13}$$

Equation 19-13 cannot be integrated directly unless we know how T depends on V and how C_{v} depends on T. This is just another way of saying that dQ_{rev} is not a differential of a state function Q_{rev}. But if we divide each term by T, we obtain

$$C_{\mathrm{v}}\frac{dT}{T} = \frac{dQ_{\mathrm{rev}}}{T} - nR\frac{dV}{V} \qquad \text{19-14}$$

Because C_{v} depends only on T, the term on the left can be integrated, as can the term on the right.* Thus, dQ_{rev}/T is the differential of a function, the entropy function S:

$$dS = \frac{dQ_{\mathrm{rev}}}{T} = C_{\mathrm{v}}\frac{dT}{T} + nR\frac{dV}{V} \qquad \text{19-15}$$

For simplicity, we will assume that C_{v} is constant. Integrating Equation 19-15 from state 1 to state 2, we obtain

$$\Delta S = \int \frac{dQ_{\mathrm{rev}}}{T} = C_{\mathrm{v}}\ln\frac{T_2}{T_1} + nR\ln\frac{V_2}{V_1} \qquad \text{19-16}$$

ENTROPY CHANGE FOR AN IDEAL GAS

Equation 19-16 gives the entropy change of an ideal gas that goes from an initial state of volume V_1 and temperature T_1 to a final state of volume V_2 and temperature T_2.

ENTROPY CHANGES FOR VARIOUS PROCESSES

ΔS for an isothermal expansion of an ideal gas If an ideal gas undergoes an isothermal expansion, then $T_2 = T_1$ and its entropy change is

$$\Delta S = \int \frac{dQ_{\mathrm{rev}}}{T} = 0 + nR\ln\frac{V_2}{V_1} \qquad \text{19-17}$$

The entropy change of the gas is positive because V_2 is greater than V_1. During this process, an amount of heat Q_{rev} is released by the reservoir and is absorbed by the gas. This heat equals the work done by the gas:

$$Q_{\mathrm{rev}} = W_{\mathrm{by}} = \int_{V_1}^{V_2} P\,dV = nRT\int_{V_1}^{V_2}\frac{dV}{V} = nRT\ln\frac{V_2}{V_1} \qquad \text{19-18}$$

* Mathematically, the factor $1/T$ is called an integrating factor for Equation 19-13.

The entropy change of the gas is $+Q_{\text{rev}}/T$. Because the same amount of heat is released by the reservoir at temperature T, the entropy change of the reservoir is $-Q_{\text{rev}}/T$. The net entropy change of the gas plus the reservoir is zero. We will refer to the system under consideration plus its surroundings as the "universe." This example illustrates a general result:

> During a reversible process, the entropy change of the universe is zero.

ΔS for a free expansion of an ideal gas During the free expansion of a gas discussed in Section 18-4, the gas is initially confined in one compartment of a container, which is connected by a stopcock to another compartment that is evacuated. The whole system has rigid walls and is thermally insulated from its surroundings so that no heat can be absorbed by, or released from, the system, and no work can be done on (or by) the system (Figure 19-10). When the stopcock is opened, the gas rushes into the evacuated chamber. The gas eventually reaches thermal equilibrium. Because no work is done on the gas and no heat is either absorbed or released by the gas, the final internal energy of the gas must equal its initial internal energy. If we assume that the gas is ideal, then its internal energy depends only on the temperature T, so its final temperature equals its initial temperature.

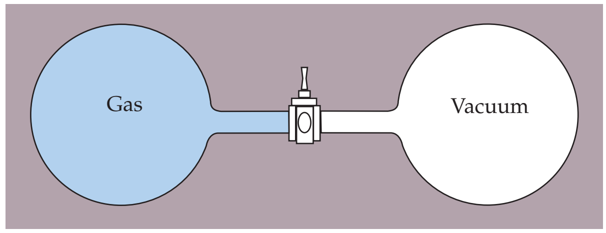

FIGURE 19-10 Adiabatic free expansion of a gas. When the stopcock is opened, the gas expands rapidly into the evacuated chamber. The initial and final internal energies of the gas are equal because no work is done on the gas during the expansion, because the entire system is insulated from its surroundings, and because the heat capacities of the chambers and valve are negligible.

We might think that there is no entropy change of the gas because there is no heat transfer. But this process is not reversible, so $\int dQ/T$ cannot be used to find the change in entropy of the gas. However, the initial and final states of the gas in the free expansion are the same as those of the gas in the isothermal expansion just discussed. *Because the change in the entropy of a system for any process depends only on the initial and final states of the system, the entropy change of the gas for the free expansion is the same as that for the isothermal expansion.* If V_1 is the initial volume of the gas and V_2 is its final volume, the entropy change of the gas is given by Equation 19-17, or

$$\Delta S_{\text{gas}} = nR \ln \frac{V_2}{V_1}$$

In this case, there is no change in the surroundings, so the entropy change of the gas is also the entropy change of the universe:

$$\Delta S_{\text{u}} = nR \ln \frac{V_2}{V_1} \qquad \text{19-19}$$

Note that because V_2 is greater than V_1, the change in entropy of the universe for this irreversible process is positive; that is, the entropy of the universe increases. This is also a general result:

> During an irreversible process, the entropy of the universe increases.

If the final volume during the free expansion were less than the initial volume, then the entropy of the universe would decrease—but this does not happen during free expansions. That is, a gas does not freely contract by itself into a smaller volume.* This leads us to yet another statement of the second law of thermodynamics:

> For any process, the entropy of the universe never decreases.

* What is actually the case, is that the probability of a gas freely contracting into a smaller volume is minuscule (except when the gas contains only an extremely small number of molecules).

Example 19-8 Free Expansion of an Ideal Gas

Find the entropy change for the free expansion of 0.75 mol of an ideal gas from $V_1 = 1.5\text{ L}$ to $V_2 = 3.0\text{ L}$.

PICTURE For a free expansion of an ideal gas the initial and final temperatures are the same. Thus, the entropy change ΔS for a free expansion from V_1 to V_2 is the same as ΔS for an isothermal process from V_1 to V_2. For the isothermal process $\Delta E_{\text{int}} = 0$, so $Q = W_{\text{by}}$. First, we calculate Q, then we set $\Delta S = Q/T$.

SOLVE

1. The entropy change is the same as for a reversible isothermal expansion from V_1 to V_2:

$$\Delta S = \Delta S_{\text{isothermal}} = \int_1^2 \frac{dQ_{\text{rev}}}{T} = \frac{1}{T}\int_1^2 dQ_{\text{rev}} = \frac{Q}{T}$$

2. The heat Q that would be absorbed by the gas during an isothermal expansion at temperature T equals the work done by the gas during the expansion:

$$Q = W_{\text{by}} = nRT\ln\frac{V_2}{V_1}$$

3. Substitute this value of Q to calculate ΔS:

$$\Delta S = \frac{Q}{T} = nR\ln\frac{V_2}{V_1} = (0.75\text{ mol})(8.31\text{ J/(mol}\cdot\text{K)})\ln 2$$

$$= \boxed{4.3\text{ J/K}}$$

CHECK The units in step 3 are such that moles cancel leaving joules per kelvin. Joules per kelvin are the correct units for entropy changes because, by definition, $\Delta S = \int dQ/T$.

CONCEPT CHECK 19-1

A living organism consists of highly organized matter. Does the growth of a living organism constitute a violation of the second law of thermodynamics? That is, during this process does the entropy of the universe increase or decrease?

ΔS for constant-pressure processes If a substance is heated from temperature T_1 to temperature T_2 at constant pressure, the heat absorbed dQ is related to its temperature change dT by

$$dQ = C_\text{p}\,dT$$

We can approximate reversible heat transfer if we have a large number of heat reservoirs with temperatures ranging from just slightly greater than T_1 to T_2 in very small steps. We could place the substance, with initial temperature T_1, in contact with the first reservoir at a temperature just slightly greater than T_1 and let the substance absorb a small amount of heat. Because the heat transfer from each reservoir is approximately isothermal, the process will be approximately reversible. We then place the substance in contact with the next reservoir at a slightly higher temperature, and so on, until the final temperature T_2 is reached. If heat dQ is absorbed reversibly, the entropy change of the substance is

$$dS = \frac{dQ}{T} = C_\text{p}\frac{dT}{T}$$

Integrating from T_1 to T_2, we obtain the total entropy change of the substance:

$$\Delta S = C_\text{p}\int_{T_1}^{T_2}\frac{dT}{T} = C_\text{p}\ln\frac{T_2}{T_1} \qquad \text{19-20}$$

This result gives the entropy change of a substance that is heated from T_1 to T_2 by any process, reversible or irreversible, as long as the final pressure equals the initial pressure and C_p is constant. It also gives the entropy change of a substance that is cooled. In the case of cooling, T_2 is less than T_1, and $\ln(T_2/T_1)$ is negative, giving a negative entropy change.

PRACTICE PROBLEM 19-5

Find the change in entropy of 1.00 kg of water that is heated at constant pressure from 0°C to 100°C.

PRACTICE PROBLEM 19-6

Derive Equation 19-20 directly from Equation 19-16.

Example 19-9 Entropy Changes During Heat Transfer

Suppose a 1.00-kg sample of water at temperature $T_1 = 30.0°C$ is added to a 2.00-kg sample of water at $T_2 = 90.0°C$ in an insulated calorimeter of negligible heat capacity at a constant pressure of 1.00 atm. (*a*) Find the change in entropy of the system. (*b*) Find the change in entropy of the universe.

PICTURE When the two samples of water are combined, they eventually come to a final equilibrium temperature, T_f, that can be found by setting the heat released equal to the heat absorbed. To calculate the entropy change of each sample of water, we consider a reversible isobaric (constant pressure) heating of the 1.00-kg sample of water from 30°C to T_f, and a reversible isobaric cooling of the 2.00-kg sample from 90°C to T_f using Equation 19-20. The entropy change of the system is the sum of the entropy changes of each part. The entropy change of the universe is the entropy change of the system plus the entropy change of its surroundings. To find the entropy change of the surroundings, assume a negligible amount of heat is absorbed or released by the calorimeter during the time it takes the water to reach its final temperature.

SOLVE

(*a*) 1. Calculate T_f by setting the heat released equal to the heat absorbed:

$$T_f = 70°C = 343\text{ K}$$

2. Use your result for T_f and Equation 19-20 to calculate ΔS_1 and ΔS_2:

$$\Delta S_1 = \int_1^f \frac{dQ_{rev}}{T} = \int_{T_1}^{T_f} \frac{C_p\,dT}{T} = C_p \int_{T_1}^{T_f} \frac{dT}{T} = C_p \ln\frac{T_f}{T_1} = m_1 c_p \ln\frac{T_f}{T_1}$$

$$= (1.00\text{ kg})(4.184\text{ kJ/kg}\cdot\text{K}) \ln\frac{343\text{ K}}{303\text{ K}} = 0.519\text{ kJ/K}$$

$$\Delta S_2 = (2.00\text{ kg})(4.184\text{ kJ/kg}\cdot\text{K}) \ln\frac{343\text{ K}}{363\text{ K}} = -0.474\text{ kJ/K}$$

3. Add ΔS_1 and ΔS_2 to find the total entropy change of the system:

$$\Delta S_{system} = \boxed{+0.045\text{ kJ/K}}$$

(*b*) 1. The calorimeter is insulated, so the surroundings are unchanged:

$$\Delta S_{surroundings} = 0$$

2. Add ΔS_{system} and $\Delta S_{surroundings}$ to find the entropy change of the universe:

$$\Delta S_u = \boxed{+0.045\text{ kJ/K}}$$

CHECK The Part-(*b*) result is a positive number, as expected. (The process is irreversible and the entropy change of the universe is never negative.)

ΔS for a perfectly inelastic collision Because mechanical energy is converted into internal thermal energy during an inelastic collision, such a process is clearly irreversible. The entropy of the universe must therefore increase. Consider a block of mass m falling from a height h and making a perfectly inelastic collision with the ground. Let the block, ground, and atmosphere all be at the same temperature T, which is not significantly changed by the process. If we consider the block, ground, and atmosphere as our thermally isolated system, there is no heat absorbed or released by the system. The state of the system has been changed because its internal energy has been increased by an amount mgh. This change is the same as if we added heat $Q = mgh$ to the system at constant temperature T. To calculate the change in entropy of the system, we thus consider a reversible process in which heat $Q_{rev} = mgh$ is absorbed at a constant temperature T. According to Equation 19-12, the change in entropy of the system is then

$$\Delta S = \frac{Q_{rev}}{T} = \frac{mgh}{T}$$

This positive entropy change is also the entropy change of the universe.

ΔS for heat transfer from one reservoir to another Heat transfer is also an irreversible process, and so we expect the entropy of the universe to increase when this occurs. Consider the simple case of heat Q transferred from a hot reservoir at a temperature T_h to a cold reservoir at a temperature T_c. The state of a heat reservoir is determined by its temperature and its internal energy only. The change in entropy of a heat reservoir due to a heat transfer is the same whether the heat transfer is reversible or not. If heat Q is absorbed by a reservoir at temperature T, then the entropy of the reservoir increases by Q/T, and if the heat Q is released by a reservoir at temperature T, then the entropy of the reservoir changes by $-Q/T$. In the case of heat transfer, the hot reservoir releases heat, so its entropy change is

$$\Delta S_h = -\frac{Q}{T_h}$$

The cold reservoir absorbs heat, so its entropy change is

$$\Delta S_c = +\frac{Q}{T_c}$$

The net entropy change of the universe is

$$\Delta S_u = \Delta S_c + \Delta S_h = \frac{Q}{T_c} - \frac{Q}{T_h} \qquad 19\text{-}21$$

Note that, because heat transfers from a hot reservoir to a cold reservoir, the change in entropy of the universe is positive.

ΔS for a Carnot cycle Because a Carnot cycle is by definition reversible, the entropy change of the universe after a cycle must be zero. We demonstrate this by showing that the entropy change of the reservoirs in a Carnot engine is zero. (Because a Carnot engine works in a cycle, the entropy change of the engine itself is zero, so the entropy change of the universe is just the sum of the entropy changes of the reservoirs.) The entropy change of the hot reservoir is $\Delta S_h = -(Q_h/T_h)$, and the entropy change of the cold reservoir is $\Delta S_c = +(Q_c/T_c)$. The heats Q_h and Q_c are related to the temperatures T_h and T_c by the definition of thermodynamic temperature (Equation 19-7)

$$\frac{T_c}{T_h} = \frac{Q_c}{Q_h} \qquad \left(\text{or} \quad \frac{Q_h}{T_h} = \frac{Q_c}{T_c}\right)$$

The entropy change of the universe is thus

$$\Delta S_u = \Delta S_{\text{engine}} + \Delta S_h + \Delta S_c = 0 - \frac{Q_h}{T_h} + \frac{Q_c}{T_c} = 0$$

The entropy change of the universe is zero as expected.

Notice that we have ignored any entropy change associated with the energy transferred by work from the Carnot engine to its surroundings. If this work is used to raise a weight, or some other ordered process, then there is no entropy change. However, if this work is used to push a block across a tabletop or other surface where friction is involved, then there is an additional entropy increase associated with this work.

Example 19-10 Entropy Changes in a Carnot Cycle

During each cycle, a Carnot engine absorbs 100 J from a reservoir at 400 K, does work, and releases heat to a reservoir at 300 K. Compute the entropy change of each reservoir for each cycle, and show explicitly that the entropy change of the universe is zero for this reversible process.

PICTURE Because the engine works during a cycle, its entropy change is zero. We therefore compute the entropy change of each reservoir and add them to obtain the entropy change of the universe.

SOLVE

1. The entropy change of the universe equals the sum of the entropy changes of the reservoirs:

$$\Delta S_u = \Delta S_{400} + \Delta S_{300}$$

2. Calculate the entropy change of the hot reservoir:

$$\Delta S_{400} = -\frac{Q_h}{T_h} = -\frac{100\text{ J}}{400\text{ K}} = \boxed{-0.250\text{ J/K}}$$

3. The entropy change of the cold reservoir is Q_c divided by T_c, where $Q_c = Q_h - W$:

$$\Delta S_{300} = \frac{Q_c}{T_c} = \frac{Q_h - W}{T_c}$$

4. We use $W = \varepsilon_C Q_h$ (Equation 19-2) to relate W to Q_h. The efficiency is the Carnot efficiency (Equation 19-6):

$$W = \varepsilon Q_h, \quad \text{where} \quad \varepsilon = \varepsilon_C = 1 - (T_c/T_h),$$

$$\text{so} \quad W = \left(1 - \frac{T_c}{T_h}\right)Q_h$$

5. Calculate the entropy change of the cold reservoir:

$$\Delta S_{300} = \frac{Q_h - W}{T_c} = \frac{Q_h - Q_h\left(1 - \frac{T_c}{T_h}\right)}{T_c} = \frac{Q_h}{T_h}$$

$$= \frac{100\text{ J}}{400\text{ K}} = \boxed{0.250\text{ J/K}}$$

6. Substitute these results into step 1 to find the entropy change of the universe:

$$\Delta S_u = \Delta S_{400} + \Delta S_{300}$$

$$\Delta S_u = -0.250\text{ J/K} + 0.250\text{ J/K} = \boxed{0.000\text{ J/K}}$$

CHECK The entropy change of the universe is positive, as the second law of thermodynamics requires.

TAKING IT FURTHER Suppose that an ordinary, nonreversible engine removed 100 J from the hot reservoir. Because its efficiency must be less than that of a Carnot engine, it would do less work and release more heat to the cold reservoir. Then, the entropy increase of the cold reservoir would be greater than the entropy decrease of the hot reservoir, and the entropy change of the universe would be positive.

Example 19-11 The *ST* Plot — Conceptual

Because entropy is a state function, thermodynamic processes can be represented as *ST*, *SV*, or *SP* diagrams in addition to the *PV* diagrams we have used so far. Make a sketch of the Carnot cycle on an *ST* plot.

PICTURE The Carnot cycle consists of first a reversible isothermal expansion, then a reversible adiabatic expansion, followed by a reversible isothermal compression and then a reversible adiabatic compression. During the isothermal processes, heat is absorbed or released reversibly, so S increases or decreases , but T remains constant. During the adiabatic processes, the temperature changes, but because $\Delta Q_{rev} = 0$, S is constant.

SOLVE

1. During the reversible isothermal expansion (1 to 2 in Figure 19-11*a*), heat is absorbed reversibly, so S increases and T remains constant:
2. During the reversible adiabatic expansion (2 to 3 in Figure 19-11*b*), the temperature decreases while S remains constant as T decreases:
3. During the isothermal compression (3 to 4 in Figure 19-11*c*), heat is released reversibly, so S decreases and T remains constat:
4. During the reversible adiabatic compression (4 to 1 in Figure 19-11*d*), the temperature increases while S is constant as T increases:

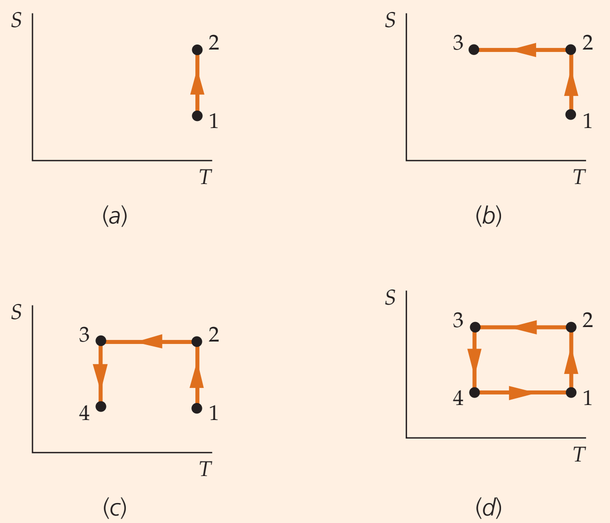

FIGURE 19-11 An S-versus-T plot of a Carnot cycle using an ideal gas.

CHECK The plot of S versus T is a closed curve, as expected. This is as expected for a complete cycle, because both S and T are state functions.

TAKING IT FURTHER The Carnot cycle is a rectangle if plotted on an S-versus-T diagram.

19-6 ENTROPY AND THE AVAILABILITY OF ENERGY

If an irreversible process occurs, energy is conserved, but some of the energy becomes unavailable to do work and is "wasted." Consider a block falling to the ground. The entropy change of the universe for this process is mgh/T. When the block was at a height h, its potential energy mgh could have been used to do useful work. But after the inelastic collision of the block with the ground, this energy is no longer fully available for doing useful work because it has become the disordered internal energy of the block and its surroundings.

The energy that has become unavailable (wasted) is equal to $mgh = T\,\Delta S_u$. This is a general result:

> During an irreversible process, energy equal to $T\,\Delta S_u$ becomes unavailable to do work, where T is the temperature of the coldest available reservoir.

For simplicity, we will call the energy that becomes unavailable to do work the "lost work":

$$W_{\text{lost}} = T\,\Delta S_u \qquad \text{19-22}$$

Example 19-12 A Sliding Box Revisited

Suppose that the box shown in Figure 19-9*a* and Figure 19-9*b* has a mass of 2.4 kg and slides with a speed of $v = 3.0$ m/s before crashing into a fixed wall and stopping. The temperature T of the box, table, and surroundings is 293 K and does not change appreciably as the box comes to rest. Find the entropy change of the universe.

PICTURE The initial mechanical energy of the box $\frac{1}{2}Mv^2$ is converted to the internal energy of the box–wall–surroundings system. The entropy change is equivalent to what would occur if the heat $Q = \frac{1}{2}Mv^2$ were absorbed by the box-wall system reversibly.

SOLVE

1. The entropy change of the universe is Q/T:

$$\Delta S_u = \frac{Q}{T} = \frac{\frac{1}{2}Mv^2}{T} = \frac{\frac{1}{2}(2.4\text{ kg})(3.0\text{ m/s})^2}{293\text{ K}}$$

$$\Delta S_u = \boxed{37\text{ mJ/K}}$$

CHECK The result is greater than zero, as is always the case for an irreversible process.

TAKING IT FURTHER Energy is conserved, but the energy $T\,\Delta S_u = \frac{1}{2}Mv^2$ is no longer available to do work.

During the free expansion discussed earlier, the ability to do work was also lost. In that case, the entropy change of the universe was $nR\ln(V_2/V_1)$, so the work lost was $nRT\ln(V_2/V_1)$. This is the amount of work that could have been done if the gas had expanded quasi-statically and isothermally from V_1 to V_2, as given by Equation 19-17.

If all the heat Q released by a hot reservoir is absorbed by a cold reservoir, the change in entropy of the universe is given by Equation 19-21, and the work lost is

$$W_{\text{lost}} = T_c\,\Delta S_u = T_c\left(\frac{Q}{T_c} - \frac{Q}{T_h}\right) = Q\left(1 - \frac{T_c}{T_h}\right)$$

We can see that this is just the work that could have been done by a Carnot engine running between these reservoirs, transferring heat Q from the hot reservoir and doing work $W = \varepsilon_C Q$, where $\varepsilon_C = 1 - T_c/T_h$.

19-7 ENTROPY AND PROBABILITY

Entropy, which is a measure of the disorder of a system, is related to probability. Essentially, a state of high order has a relatively low probability, whereas a state of low order has a relatively high probability. Thus, during an irreversible process, the universe moves from a state of relatively low probability to one of relatively high probability.

Let us consider a free expansion in which a gas expands from an initial volume V_1 to a final volume $V_2 = 2V_1$. The entropy change of the universe for this process is given by Equation 19-19:

$$\Delta S = nR \ln \frac{V_2}{V_1} = nR \ln 2$$

Why is this process irreversible? Why can the gas not spontaneously contract back into its original volume? Such a contraction would not violate the first law of thermodynamics, as there is no energy change involved. The reason that the gas does not compress to its original volume is merely that such a contraction is extremely *improbable*.

Example 19-13 The Probability of a Free Contraction

Suppose a gas consisting of only 10 molecules occupies a cube. What is the probability that all 10 molecules will be in the left half of the cube at a given instant?

PICTURE The chance that any one particular molecule will be in the left half of the container at any given instant is $\frac{1}{2}$. Using this information, we can calculate the probability that all 10 molecules will be in the left half at a given instant?

SOLVE

1. The chance that any one molecule is in the left half is the same as the chance that the same molecule is in the right half:

   The probability that any one particular molecule will be in the left half of the container at any given instant is $\frac{1}{2}$.

2. The chance that molecules 1 and 2 are both in the left half (at any given time) is the chance that molecule 1 is in the left half times the chance that molecule 2 is in the left half:

   The chance that any particular two molecules are both in the left half (at any given time) is $\frac{1}{2} \times \frac{1}{2} = \frac{1}{4}$.

   The chances are equal that molecules 1 and 2 are both in the left half, both in the right half, that molecule 1 is in the left half and molecule 2 is in the right half, or that molecule 2 is in the left half and molecule 1 is in the right half. The chance for any one of these options is $\frac{1}{4}$:

3. The chance that molecules 1, 2, and 3 are all in the left half at any given time is equal to the chance that molecules 1 and 2 are both in the left half times the chance that molecule 3 is in the left half:

   The chance that any particular three molecules are all in the left half (at any given instant) is $\frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} = \left(\frac{1}{2}\right)^3 = \frac{1}{8}$.

4. Continuing this line of reasoning to determine the chance that all 10 molecules are in the left half gives:

   The chance that all 10 molecules are in the left half (at any given instant) is $\boxed{\left(\frac{1}{2}\right)^{10} = \frac{1}{1024}}$

CHECK We intuitively know the chance that all 10 molecules are on the left side at a given instant is pretty small. It is the same as the chance that a tossed coin comes up heads 10 times in a row.

Although the probability of all 10 molecules in Example 19-13 being on one side of the container is small, we would not be completely surprised to see it occur. If we look at the gas once each second, we could expect to see it happen once in every 1024 seconds, or about once every 17 minutes. If we started with the 10 molecules randomly distributed and then found them all in the left half of the original volume, the entropy of the universe would have *decreased* by $nR \ln 2$. However, this decrease is extremely small, because the number of moles n corresponding to 10 molecules is only about 10^{-23}. Still, it would violate the entropy statement of the second law of thermodynamics, which says that for any process, the entropy of the universe never decreases. Therefore, if we wish to apply the second law of thermodynamics to microscopic systems such as a small number of molecules, we should consider the second law to be a statement of *probability*.

We can relate the probability of a gas spontaneously contracting into a smaller volume to the change in its entropy. If the original volume is V_1, the probability p of finding N molecules in a smaller volume V_2 is

$$p = \left(\frac{V_2}{V_1}\right)^N$$

Taking the natural logarithm of both sides of this equation, we obtain

$$\ln p = N \ln \frac{V_2}{V_1} = nN_\mathrm{A} \ln \frac{V_2}{V_1} \qquad \text{19-23}$$

where n is the number of moles and N_A is Avogadro's number. The entropy change of the gas is

$$\Delta S = nR \ln \frac{V_2}{V_1} \qquad \text{19-24}$$

Substituting for $n \ln(V_1/V_2)$ in Equation 19-24, we see that

$$\Delta S = \frac{R}{N_\mathrm{A}} \ln p = k \ln p \qquad \text{19-25}$$

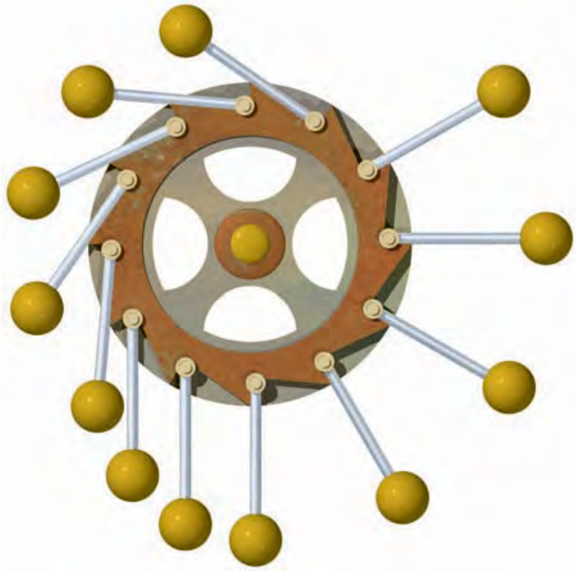
where $k = R/N_\mathrm{a}$ is Boltzmann's constant.

It may be disturbing to learn that irreversible processes, such as the spontaneous contraction of a gas or the spontaneous transfer of heat from a cold body to a hot body, are not impossible—they are just improbable. As we have just seen, there is a reasonable chance that an irreversible process will occur in a system consisting of a very small number of molecules; however, *thermodynamics itself is applicable only to macroscopic systems*, that is, to systems that have a very large number of molecules. Consider trying to measure the pressure of a gas consisting of only 10 molecules. The pressure would vary wildly depending on whether no molecule, 2 molecules, or 10 molecules were colliding with the wall of the container at the time of measurement. The macroscopic variables of pressure and temperature are not applicable to a microscopic system with only 10 molecules.

As we increase the number of molecules in a system, the chance of a process occurring in which the entropy of the universe decreases diminishes dramatically. For example, if we have 50 molecules in a container, the chance that they will all be in the left half of the container is $(\frac{1}{2})^{50} \approx 10^{-15}$. Thus, if we look at the gas once each second, we could expect to see all 50 molecules in the left half of the volume about once in every 10^{15} seconds or once in every 36 million years! For 1 mole (6×10^{23} molecules), the chance that all will end up in half of the volume is vanishingly small, essentially zero. For macroscopic systems, then, the probability of a process resulting in a decrease in the entropy of the universe is so extremely small that the distinction between improbable and impossible becomes blurred.

Physics Spotlight

The Perpetual Battle over Perpetual Motion



The wheel only appears to be unbalanced. However, note that there are more balls to the left of the axis than to the right of it. A calculation of the center of mass will show it is located directly below the axis. (Reducing the number of balls to four makes this calculation relatively simple.)

People dream of getting work done for free. Perpetual motion machines that do effective work with no energy, or are completely efficient, are a focus of those dreams. Perpetual motion cannot work. Physicists classify perpetual motion machines into two categories, depending on which law of thermodynamics they violate.

Category one machines violate the first law of thermodynamics—they claim to create energy out of nothing, or to create more energy than they use. The earliest known attempts at perpetual motion involved rotary motion and gravity. An overbalanced wheel had hinged rods that would supposedly cause the wheel to perpetually rotate toward one side. Another design, favored by Leonardo da Vinci, involved a water wheel that powered both a mill and a pump that pumped the water high enough that it would power the water wheel.* None of these attempts accounted for the energy needed to move the hinged rods relative to the larger wheel, or for the energy lost in turning the water wheel itself.

Later, buoyancy and rotary motion were part of popular attempts at perpetual motion.† Designs for buoyancy wheels and belts have included air pockets, chains, and connected hoses.‡ None of these designs has taken into account the work needed to fill the air pockets, nor the work needed to move the inner weights.

Category two machines violate the second law of thermodynamics. These machines do not claim to create energy. Instead, they are heat- or vapor-driven machines with impossible efficiency. One of the most famous machines was the Zeromotor, proposed by John Gamgee in 1880 to power ships' propellers.# The Zeromotor was a specially designed ammonia motor. Because ammonia boils at a temperature close to 0°C, liquid ammonia would be injected into a cylinder with a piston. The ammonia would expand and push the piston. The act of pushing the piston would cool the ammonia enough that it would condense, expand again, and go through the entire cycle without heat absorbed or released. This directly contradicts Carnot's work. Gamgee's Zeromotor, of course, did not work. Neither have any other engines based on the violation of the second law of thermodynamics. The vapor never condenses, and the heat engine never completes a single full cycle.

The French Academy of Science claimed that the pursuit of perpetual motion was a waste of time when it voted in 1775 to not consider patents for perpetual motion machines.° By 1856, submitting patents for perpetual motion machines to either the U.S. or the British Patent Office was not recommended.§ In the end, though, people still want free work. It is possible to find recent claims of engines that create more energy than they use.¶ It is also possible to find scientists upset by the latest unworkable patent** that slipped by the U.S. Patent and Trademark Office.†† The perpetual battle about perpetual motion rages on, but physicists are now able to explain why it is not possible.

Summary

The second law of thermodynamics is a fundamental law of nature.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Efficiency of a Heat Engine	If the engine absorbs Q_h from a hot reservoir, does work W, and releases heat Q_c to a cold reservoir, its efficiency is $$\varepsilon = \frac{W}{Q_h} = \frac{Q_h - Q_c}{Q_h} = 1 - \frac{Q_c}{Q_h}$$	19-2
2. Coefficient of Performance of a Refrigerator	$$\text{COP} = \frac{Q_c}{W}$$	19-3
3. Coefficient of Performance of a Heat Pump	$$\text{COP}_{\text{HP}} = \frac{Q_h}{W}$$	19-8
4. Equivalent Statements of the Second Law of Thermodynamics		
The Kelvin statement	No system can absorb heat from a single reservoir and convert it entirely into work without additional net changes in the system or its surroundings.	
The heat-engine statement	It is impossible for a heat engine working in a cycle to produce *only the effect* of absorbing heat from a single reservoir and performing an equivalent amount of work.	
The Clausius statement	A process whose only net result is to absorb heat from a cold reservoir and release the same amount of heat to a hot reservoir is impossible.	
The refrigerator statement	It is impossible for a refrigerator working in a cycle to produce *only the effect* of absorbing heat from a cold object and releasing the same amount of heat to a hot object.	
The entropy statement	The entropy of the universe (system plus surroundings) can never decrease.	
5. Conditions for a Reversible Process	1. No mechanical energy is transformed into internal thermal energy by friction, viscous forces, or other dissipative forces. 2. Energy transfer as heat can only occur between objects whose temperatures differ by an infinitesimal amount. 3. The process must be quasi-static so that the system is always in an equilibrium state (or infinitesimally near an equilibrium state).	
6. Carnot Engine	A Carnot engine is a reversible engine that works between two heat reservoirs. It operates in a Carnot cycle, which consists of:	
Carnot cycle	1. A quasi-static isothermal absorption of heat from a hot reservoir 2. A quasi-static adiabatic expansion to a lower temperature 3. A quasi-static isothermal release of heat to a cold reservoir at temperature T_c 4. A quasi-static adiabatic compression back to the original state	
Carnot efficiency	$$\varepsilon_C = 1 - \frac{Q_c}{Q_h} = 1 - \frac{T_c}{T_h}$$	19-6
7. Thermodynamic Temperature	The ratio of the thermodynamic temperatures of two reservoirs is defined to be the ratio of the heat released to the heat absorbed by Carnot engine running between the reservoirs: $$\frac{T_c}{T_h} = \frac{Q_c}{Q_h}$$ In addition, the triple point of water has a thermodynamic temperature of 273.16 K.	19-7

TOPIC	RELEVANT EQUATIONS AND REMARKS
8. **Entropy**	Entropy is a measure of the disorder of a system. The difference in entropy between two nearby states is given by $$dS = \frac{dQ_{rev}}{T} \qquad \text{19-12}$$ where dQ_{rev} is the heat absorbed during a reversible process taking the system from one state to the other. The entropy change of a system can be positive or negative.
Entropy and loss of work capability	During an irreversible process, the entropy of the universe S_u increases and an amount of energy $$W_{lost} = T\,\Delta S_u \qquad \text{19-22}$$ becomes unavailable for doing work.
Entropy and probability	Entropy is related to probability. A highly ordered system is one of low probability and low entropy. An isolated system moves toward a state of high probability, low order, and high entropy.

Answer to Concept Check

19-1 No. The development of a living organism comes at the expense of a great increase in disorder elsewhere. Much of this disorder can be traced back to the Sun, where nuclear reactions generate an increase in disorder, and thus an increase in entropy.

Answers to Practice Problems

19-1 (*a*) 52.5 J, (*b*) 97.5 J

19-2 250 kJ

19-3 (*a*) 40%, (*b*) 80 kJ

19-4 30%

19-5 $\Delta S = 1.31$ kJ/K

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • ENGINEERING APPLICATION Modern automobile gasoline engines have efficiencies of about 25 percent. About what percentage of the heat of combustion is not used for work but released as heat? (*a*) 25%, (*b*) 50%, (*c*) 75%, (*d*) 100%, (*e*) You cannot tell from the data given.

2 • If a heat engine does 100 kJ of work per cycle while releasing 400 kJ of heat, what is its efficiency? (*a*) 20%, (*b*) 25%, (*c*) 80%, (*d*) 400%, (*e*) You cannot tell from the data given.

3 • If the heat absorbed by a heat engine is 600 kJ per cycle, and it releases 480 kJ of heat each cycle, what is its efficiency? (*a*) 20%, (*b*) 80%, (*c*) 100%, (*d*) You cannot tell from the data given.

4 • Explain what distinguishes a refrigerator from a "heat pump."

5 • An air conditioner's COP is mathematically identical to that of a refrigerator, that is, $COP_{AC} = COP_{ref} = Q_c/W$. However a heat pump's COP is defined differently, as $COP_{hp} = Q_h/W$. Explain clearly *why* the two COPs are defined differently. *Hint: Think of the end use of the three different devices.* SSM

6 • Explain why you cannot cool your kitchen by leaving your refrigerator door open on a hot day. (Why does turning on a room air conditioner cool down the room, but opening a refrigerator door does not?)

7 • ENGINEERING APPLICATION Why do steam-power-plant designers try to increase the temperature of the steam as much as possible?

8 • To increase the efficiency of a Carnot engine, you should (*a*) decrease the temperature of the hot reservoir, (*b*) increase the temperature of the cold reservoir, (*c*) increase the temperature of the hot reservoir, (*d*) change the ratio of maximum volume to minimum volume.

9 •• Explain why the following statement is true: To increase the efficiency of a Carnot engine, you should make the difference between the two operating temperatures as large as possible; but to increase the efficiency of a Carnot cycle *refrigerator*, you should make the difference between the two operating temperatures as small as possible. SSM

10 •• A Carnot engine operates between a cold temperature reservoir of 27°C and a high temperature reservoir of 127°C. Its efficiency is (*a*) 21%, (*b*) 25%, (*c*) 75%, (*d*) 79%.

11 •• The Carnot engine in Problem 10 is run in reverse as a refrigerator. Its COP is (*a*) 0.33, (*b*) 1.3, (*c*) 3.0, (*d*) 4.7.

12 •• On a humid day, water vapor condenses on a cold surface. During condensation, the entropy of the water (*a*) increases, (*b*) remains constant, (*c*) decreases, (*d*) may decrease or remain unchanged. Explain your answer.

13 •• An ideal gas is taken reversibly from an initial state P_i, V_i, T_i to the final state P_f, V_f, T_f. Two possible paths are (A) an isothermal expansion followed by an adiabatic compression, and (B) an adiabatic compression followed by an isothermal expansion. For these two paths, (*a*) $\Delta E_{\text{int A}} > \Delta E_{\text{int B}}$, (*b*) $\Delta S_A > \Delta S_B$, (*c*) $\Delta S_A < \Delta S_B$, (*d*) None of the above.

14 •• Figure 19-12 shows a thermodynamic cycle for an ideal gas on an *ST* diagram. Identify this cycle and sketch it on a *PV* diagram.

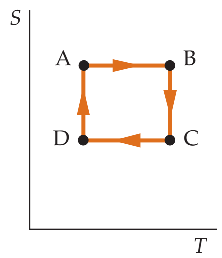

FIGURE 19-12 Problem 14, Problem 72

15 •• Figure 19-13 shows a thermodynamic cycle for an ideal gas on an *SV* diagram. Identify the type of engine represented by this diagram.

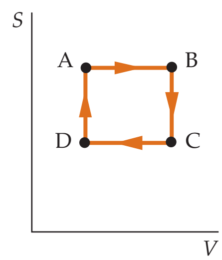

FIGURE 19-13 Problem 15

16 •• Sketch an *ST* diagram of the Otto cycle. (The Otto cycle is discussed in Section 19-1.)

17 •• Sketch an *SV* diagram of the Carnot cycle for an ideal gas. SSM

18 •• Sketch an *SV* diagram of the Otto cycle. (The Otto cycle is discussed in Section 19-1.)

19 •• Figure 19-14 shows a thermodynamic cycle for an ideal gas on an *SP* diagram. Make a sketch of this cycle on a *PV* diagram.

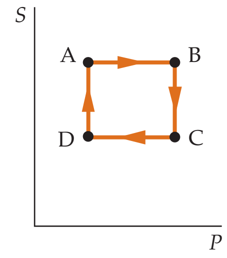

FIGURE 19-14 Problem 19

20 •• CONTEXT-RICH One afternoon, the mother of one of your friends walks into his room and finds a mess. She asks your friend how the room came to be in such a state, and your friend replies, "Well, it is the natural destiny of any closed system to degenerate toward greater and greater levels of entropy. That's all, Mom." Her reply is a sharp "Nevertheless, you'd better clean your room." Your friend retorts, "But that can't happen. It would violate the second law of thermodynamics." Critique your friend's response. Is his mother correct to ground him for not cleaning his room, or is cleaning the room really impossible?

ESTIMATION AND APPROXIMATION

21 • Estimate the change in COP of your electric food freezer when it is removed from your kitchen to its new location in your basement, which is 8°C cooler than your kitchen.

22 •• Estimate the probability that all the molecules in your bedroom are located in the (open) closet which accounts for about 10 percent of the total volume of the room.

23 •• Estimate the maximum efficiency of an automobile engine that has a compression ratio of 8.0:1.0. Assume the engine operates according to the Otto cycle and assume $\gamma = 1.4$. (The Otto cycle is discussed in Section 19-1.) SSM

24 •• CONTEXT-RICH You are working as an appliance salesperson during the summer. One day, your physics professor comes into your store to buy a new refrigerator. Wanting to buy the most efficient refrigerator possible, she asks you about the efficiencies of the available models. She decides to return the next day to buy the most efficient refrigerator. To make the sale, you need to provide her with the following estimates: (*a*) the highest COP possible for a household refrigerator, and (*b*) the highest rate possible for the heat to be released by the interior of the refrigerator if the refrigerator uses 600 W of electrical power.

25 •• The average temperature of the surface of the Sun is about 5400 K, and the average temperature of the surface of Earth is about 290 K. The solar constant (the intensity of sunlight reaching Earth's atmosphere) is about 1.37 kW/m^2. (*a*) Estimate the total power of the sunlight hitting Earth. (*b*) Estimate the net rate at which Earth's entropy is increasing due to this solar radiation. SSM

26 ••• A 1.0-L box contains *N* molecules of an ideal gas, and the positions of the molecules are observed 100 times per second. Calculate the average time it should take before we observe all *N* molecules in the left half of the box if *N* is equal to (*a*) 10, (*b*) 100, (*c*) 1000, and (*d*) 1.0 mole. (*e*) The best vacuums that have been created to date have pressures of about 10^{-12} torr. If a vacuum chamber has the same volume as the box, how long will a physicist have to wait before all of the gas molecules in the vacuum chamber occupy only the left half of it? Compare that to the expected lifetime of the universe, which is about 10^{10} years.

HEAT ENGINES AND REFRIGERATORS

27 • A heat engine with 20.0 percent efficiency does 0.100 kJ of work during each cycle. (*a*) How much heat is absorbed from the hot reservoir during each cycle? (*b*) How much heat is released to the cold reservoir during each cycle? SSM

28 • A heat engine absorbs 0.400 kJ of heat and does 0.120 kJ of work during each cycle. (*a*) What is the engine's efficiency? (*b*) How much heat is released to the cold reservoir during each cycle?

29 • A heat engine absorbs 100 J of heat from the hot reservoir and releases 60 J of heat to the cold reservoir during each cycle. (*a*) What is its efficiency? (*b*) If each cycle takes 0.50 s, find the power output of this engine.

30 • A refrigerator absorbs 5.0 kJ of heat from a cold reservoir and releases 8.0 kJ to a hot reservoir. (*a*) Find the coefficient of performance of the refrigerator. (*b*) The refrigerator is reversible. If it is run backward as a heat engine between the same two reservoirs, what is its efficiency?

31 •• The working substance of heat an engine is 1.00 mol of a monatomic ideal gas. The cycle begins at $P_1 = 1.00$ atm and $V_1 = 24.6$ L. The gas is heated at constant volume to $P_2 = 2.00$ atm. It then expands at constant pressure until it is 49.2 L. The gas is then cooled at constant volume until its pressure is again 1.00 atm. It is then compressed at constant pressure to its original state. All the steps are quasi-static and reversible. (*a*) Show this cycle on a *PV* diagram. For each step of the cycle, find the work done by the gas, the heat absorbed by the gas, and the change in the internal energy of the gas. (*b*) Find the efficiency of the cycle. SSM

32 •• The working substance of an engine is 1.00 mol of a diatomic ideal gas. The engine operates in a cycle consisting of three steps: (1) an adiabatic expansion from an initial volume of 10.0 L to a pressure of 1.00 atm and a volume of 20.0 L, (2) a compression at constant pressure to its original volume of 10.0 L, and (3) heating at constant volume to its original pressure. Find the efficiency of this cycle.

33 •• An engine using 1.00 mol of an ideal gas initially at a volume of 24.6 L and a temperature of 400 K performs a cycle consisting of four steps: (1) an isothermal expansion at a temperature of 400 K to twice its initial volume, (2) cooling at constant volume to a temperature of 300 K, (3) an isothermal compression to its original volume, and (4) heating at constant volume to its original temperature of 400 K. Assume that $C_v = 21.0$ J/K. Sketch the cycle on a *PV* diagram and find its efficiency.

34 •• Figure 19-15 shows the cycle followed by 1.00 mol of an ideal monatomic gas at an initial volume $V_1 = 25.0$ L. All the processes are quasi-static. Determine (*a*) the temperature of each numbered state of the cycle, (*b*) the heat transfer for each part of the cycle, and (*c*) the efficiency of the cycle.

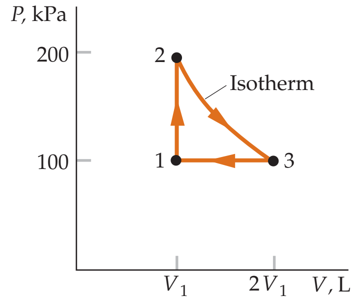

FIGURE 19-15 Problem 34

35 •• An ideal diatomic gas follows the cycle shown in Figure 19-16. The temperature of state 1 is 200 K. Determine (*a*) the temperatures of the other three numbered states of the cycle, and (*b*) the efficiency of the cycle.

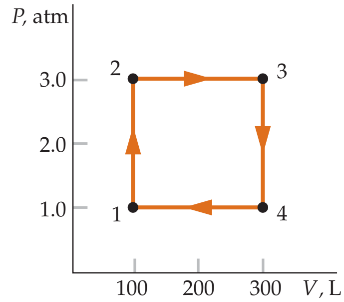

FIGURE 19-16 Problem 35

36 ••• **Engineering Application** Recently, an old design for a heat engine, known as the *Stirling engine*, has been promoted as a means of producing power from solar energy. The cycle of a Stirling engine is as follows: (1) isothermal compression of the working gas, (2) heating of the gas at constant volume, (3) an isothermal expansion of the gas, and (4) cooling of the gas at constant volume. (*a*) Sketch *PV* and *ST* diagrams for the Stirling cycle. (*b*) Find the entropy change of the gas for each step of the cycle and show that the sum of these entropy changes is equal to zero.

37 ••• **Biological Application** "As far as we know, Nature has never evolved a heat engine"—Steven Vogel, *Life's Devices* (Princeton University Press, 1988). (*a*) Calculate the efficiency of a heat engine operating between body temperature (98.6°F) and a typical outdoor temperature (70°F), and compare this to the human body's efficiency for converting chemical energy into work (approximately 20 percent). Does this efficiency comparison contradict the second law of thermodynamics? (*b*) From the result of Part (*a*), and a general knowledge of the conditions under which most warm-blooded organisms exist, give a reason why no warm-blooded organisms have evolved heat engines to increase their internal energies.

38 ••• **Engineering Application** The *diesel cycle* shown in Figure 19-17 approximates the behavior of a diesel engine. Process *ab* is an adiabatic compression, process *bc* is an expansion at constant pressure, process *cd* is an adiabatic expansion, and process *da* is cooling at constant volume. Find the efficiency of this cycle in terms of the volumes V_a, V_b, and V_c.

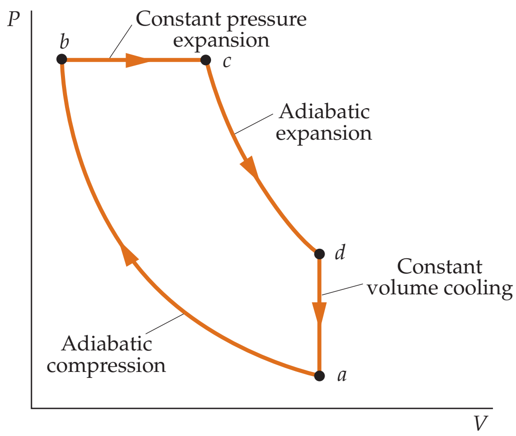

FIGURE 19-17 Problem 38

SECOND LAW OF THERMODYNAMICS

39 •• A refrigerator absorbs 500 J of heat from a cold reservoir and releases 800 J to a hot reservoir. Assume that the heat-engine statement of the second law of thermodynamics is false, and show how a perfect engine working with this refrigerator can violate the refrigerator statement of the second law of thermodynamics. SSM

40 •• If two curves that represent quasi-static adiabatic processes could intersect on a *PV* diagram, a cycle could be completed by an isothermal path between the two adiabatic curves shown in Figure 19-18. Show that such a cycle violates the second law of thermodynamics.

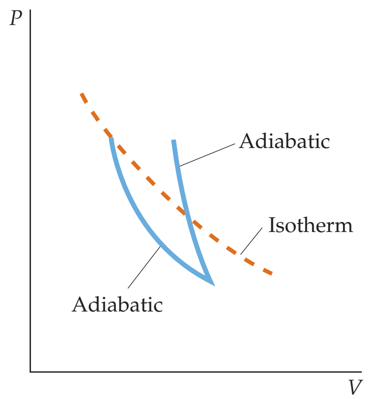

FIGURE 19-18 Problem 40

CARNOT CYCLES

41 • A Carnot engine works between two heat reservoirs at temperatures $T_h = 300$ K and $T_c = 200$ K. (*a*) What is its efficiency? (*b*) If it absorbs 100 J of heat from the hot reservoir during each cycle, how much work does it do each cycle? (*c*) How much heat does it release during each cycle? (*d*) What is the COP of this engine when it works as a refrigerator between the same two reservoirs? SSM

42 • An engine absorbs 250 J of heat per cycle from a reservoir at 300 K and releases 200 J of heat per cycle to a reservoir at 200 K. (*a*) What is its efficiency? (*b*) How much additional work per cycle could be done if the engine were reversible?

43 •• A reversible engine working between two reservoirs at temperatures T_h and T_c has an efficiency of 30 percent. Working as a heat engine, it releases 140 J per cycle of heat to the cold reservoir. A second engine working between the same two reservoirs also releases 140 J per cycle to the cold reservoir. Show that if the second engine has an efficiency greater than 30 percent, the two engines working together would violate the heat-engine statement of the second law.

44 •• A reversible engine working between two reservoirs at temperatures T_h and T_c has an efficiency of 20 percent. Working as a heat engine, it does 100 J of work per cycle. A second engine working between the same two reservoirs also does 100 J of work per cycle. Show that if the efficiency of the second engine is greater than 20 percent, the two engines working together would violate the refrigerator statement of the second law.

45 •• A Carnot engine works between two heat reservoirs as a refrigerator. During each cycle, 100 J of heat are absorbed from the cold reservoir and 150 J of heat are released to the hot reservoir. (*a*) What is the efficiency of the Carnot engine when it works as a heat engine between the same two reservoirs? (*b*) Show that no other engine working as a refrigerator between the same two reservoirs can have a COP greater than 2.00.

46 •• A Carnot engine works between two heat reservoirs at temperatures $T_h = 300$ K and $T_c = 77.0$ K. (*a*) What is its efficiency? (*b*) If it absorbs 100 J of heat from the hot reservoir during each cycle, how much work does it do? (*c*) How much heat does it release to the low-temperature reservoir during each cycle? (*d*) What is the coefficient of performance of this engine when it works as a refrigerator between these two reservoirs?

47 •• In the cycle shown in Figure 19-19, 1.00 mol of an ideal diatomic gas is initially at a pressure of 1.00 atm and a temperature of 0.0°C. The gas is heated at constant volume to $T_2 = 150$°C, and is then expanded adiabatically until its pressure is again 1.00 atm. It is then compressed at constant pressure back to its original state. Find (*a*) the temperature after the adiabatic expansion, (*b*) the heat absorbed or released by the system during each step, (*c*) the efficiency of this cycle, and (*d*) the efficiency of a Carnot cycle operating between the temperature extremes of this cycle. SSM

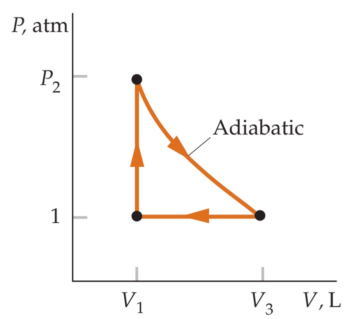

FIGURE 19-19 Problem 47

48 •• ENGINEERING APPLICATION, CONTEXT-RICH You are a part of a team that is completing a mechanical engineering project. Your team built a steam engine that takes in superheated steam at 270°C and discharges condensed steam from its cylinder at 50.0°C. Your team has measured the engine's efficiency to be 30.0 percent. (*a*) How does this efficiency compare with the maximum possible efficiency for your engine? (*b*) If the useful power output of the engine is known to be 200 kW, how much heat does the engine release to its surroundings in 1.00 h?

* HEAT PUMPS

49 • ENGINEERING APPLICATION, CONTEXT-RICH As an engineer, you are designing a heat pump that is capable of delivering heat at the rate of 20 kW to a house. The house is located where, in January, the average outside temperature is −10°C. The temperature of the air in the air handler inside the house is to be 40°C. (*a*) What is the maximum possible COP for a heat pump operating between these temperatures? (*b*) What must the minimum power of the electric motor driving the heat pump be? (*c*) In reality, the COP of the heat pump will be only 60 percent of the ideal value. What is the minimum power of the electric motor when the COP is 60 percent of the ideal value? SSM

50 • A refrigerator is rated at 370 W. (*a*) What is the maximum amount of heat it can absorb from the food compartment in 1.00 min if the food-compartment temperature of the refrigerator is 0.0°C and it releases heat into a room at 20.0°C? (*b*) If the COP of the refrigerator is 70 percent of that of a reversible refrigerator, how much heat can it absorb from the food compartment in 1.00 min under these conditions?

51 •• A refrigerator is rated at 370 W. (*a*) What is the maximum amount of heat it can absorb from the food compartment in 1.00 min if the temperature in the compartment is 0.0°C and it releases heat into a room at 35°C? (*b*) If the COP of the refrigerator is 70 percent of that of a reversible pump, how much heat can it absorb from the food compartment in 1.00 min? Is the COP for the refrigerator greater when the temperature of the room is 35°C or 20°C? Explain.

52 ••• CONTEXT-RICH You are installing a heat pump whose COP is half the COP of a reversible heat pump. You plan to use the pump on chilly winter nights to increase the air temperature in your bedroom. Your bedroom's dimensions are 5.00 m × 3.50 m × 2.50 m. The air temperature should increase from 63°F to 68°F. The outside temperature is 35°F, and the temperature at the air handler in the room is 112°F. If the pump's electric-power consumption is 750 W, how long will you have to wait for the room's air to warm if the specific heat of air is 1.005 kJ/(kg · °C)? Assume you have good window draperies and good wall insulation so that you can neglect the release of heat through windows, walls, ceilings, and floors. Also assume that the heat capacity of the floor, ceiling, walls, and furniture are negligible.

ENTROPY CHANGES

53 • You inadvertently leave a pan of water boiling on the hot stove. You return just in time to see the last drop converted into steam. The pan originally held 1.00 L of boiling water. What is the change in entropy of the water associated with its change of state from liquid to gas? SSM

54 • What is the change in entropy of 1.00 mol of liquid water at 0.0°C that freezes to ice at 0.0°C?

55 •• Consider the freezing of 50.0 g of water once it is placed in the freezer compartment of a refrigerator. Assume the walls of the freezer are maintained at −10°C. The water, initially liquid at 0.0°C, is frozen into ice and cooled to −10 °C. Show that even though the entropy of the water decreases, the net entropy of the universe increases.

56 • In this problem, 2.00 mol of an ideal gas at 400 K expand quasi-statically and isothermally from an initial volume of 40.0 L to a final volume of 80.0 L. (*a*) What is the entropy change of the gas? (*b*) What is the entropy change of the universe for this process?

57 •• A system completes a cycle consisting of six quasi-static steps, during which the total work done by the system is 100 J. During step 1 the system absorbs 300 J of heat from a reservoir at 300 K, during step 3 the system absorbs 200 J of heat from a reservoir at 400 K, and during step 5 it absorbs heat from a reservoir at temperature T_3. (During steps 2, 4 and 6 the system undergoes adiabatic processes in which the temperature of the system changes from one reservoir's temperature to that of the next.) (*a*) What is the entropy change of the system for the complete cycle? (*b*) If the cycle is reversible, what is the temperature T_3? SSM

58 •• In this problem, 2.00 mol of an ideal gas initially has a temperature of 400 K and a volume of 40.0 L. The gas undergoes a free adiabatic expansion to twice its initial volume. What are (*a*) the entropy change of the gas, and (*b*) the entropy change of the universe?

59 •• A 200-kg block of ice at 0.0°C is placed in a large lake. The temperature of the lake is just slightly higher than 0.0°C, and the ice melts very slowly. (*a*) What is the entropy change of the ice? (*b*) What is the entropy change of the lake? (*c*) What is the entropy change of the universe (the ice plus the lake)?

60 •• A 100-g piece of ice at 0.0°C is placed in an insulated calorimeter of negligible heat capacity containing 100 g of water at 100°C. (*a*) What is the final temperature of the water once thermal equilibrium is established? (*b*) Find the entropy change of the universe for this process.

61 •• A 1.00-kg block of copper at 100°C is placed in an insulated calorimeter of negligible heat capacity containing 4.00 L of liquid water at 0.0°C. Find the entropy change of (*a*) the copper block, (*b*) the water, and (*c*) the universe. SSM

62 •• If a 2.00-kg piece of lead at 100°C is dropped into a lake at 10°C, find the entropy change of the universe.

ENTROPY AND LOST WORK

63 •• A reservoir at 300 K absorbs 500 J of heat from a second reservoir at 400 K. (*a*) What is the change in entropy of the universe, and (*b*) how much work is lost during the process? SSM

64 •• In this problem, 1.00 mol of an ideal gas at 300 K undergoes a free adiabatic expansion from $V_1 = 12.3$ L to $V_2 = 24.6$ L. It is then compressed isothermally and reversibly back to its original state. (*a*) What is the entropy change of the universe for the complete cycle? (*b*) How much work is lost in this cycle? (*c*) Show that the work lost is $T\,\Delta S_u$.

GENERAL PROBLEMS

65 • A heat engine with an output of 200 W has an efficiency of 30 percent. It operates at 10.0 cycles/s. (*a*) How much work is done by the engine during each cycle? (*b*) How much heat is absorbed from the hot reservoir and how much is released to the cold reservoir during each cycle?

66 • During each cycle, a heat engine operating between two heat reservoirs absorbs 150 J from the reservoir at 100°C and releases 125 J to the reservoir at 20°C. (*a*) What is the efficiency of this engine? (*b*) What is the ratio of its efficiency to that of a Carnot engine working between the same reservoirs? (This ratio is called the *second law efficiency*.)

67 • An engine absorbs 200 kJ of heat per cycle from a reservoir at 500 K and releases heat to a reservoir at 200 K. The engine's efficiency is 85 percent of that of a Carnot engine working between the same reservoirs. (*a*) What is the efficiency of this engine? (*b*) How much work is done in each cycle? (*c*) How much heat is released to the low-temperature reservoir during each cycle? SSM

68 • Estimate the change in entropy of the universe associated with an Olympic diver diving into the water from the 10-m platform.

69 • To maintain the temperature inside a house at 20°C, the electric power consumption of the electric baseboard heaters is 30.0 kW on a day when the outside temperature is −7°C. At what rate does this house contribute to the increase in the entropy of the universe?

70 •• **ENGINEERING APPLICATION** Calvin Cliffs Nuclear Power Plant, located on the Hobbes River, generates 1.00 GW of power. In this plant, liquid sodium circulates between the reactor core and a heat exchanger located in the superheated steam that drives the turbine. Heat is absorbed by the liquid sodium in the core, and released by the liquid sodium (and into the superheated steam) in the heat exchanger. The temperature of the superheated steam is 500 K. Heat is released into the river, and the water in the river flows by at a temperature of 25°C. (*a*) What is the highest efficiency that this plant can have? (*b*) How much heat is released into the river every second? (*c*) How much heat must be released by the core to supply 1.00 GW of electrical power? (*d*) Assume that new environmental laws have been passed to preserve the unique wildlife of the river. Because of these laws, the plant is not allowed to heat the river by more than 0.50°C. What is the minimum flow rate that the water in the Hobbes River must have?

71 •• **ENGINEERING APPLICATION, CONTEXT-RICH** An inventor comes to you to explain his new invention. It is a novel heat engine using water vapor as the working substance. He claims that the water vapor absorbs heat at 100°C, does work at the rate of 125 W, and releases heat to the air at the rate of only 25.0 W, when the air temperature is 25°C. (*a*) Explain to him why he cannot be correct. (*b*) After careful analysis of the data in his prospectus folder, you decide he has made an error in the measurement of his exhausted-heat value. What is the minimum rate of exhausting heat that would make you consider believing him?

72 •• The cycle represented in Figure 19-12 (next to Problem 19-14) is for 1.00 mol of an ideal monatomic gas. The temperatures at points A and B are 300 and 750 K, respectively. What is the efficiency of the cyclic process ABCDA?

73 •• (*a*) Which of these two processes is more wasteful of available work? (1) A block moving with 0.50 J of kinetic energy being slowed to rest by sliding (kinetic) friction when the temperature of the environment is 300 K, or (2) A reservoir at 400 K releasing 1.00 kJ of heat to a reservoir at 300 K? Explain your choice. *Hint: How much of the 1.00 kJ of heat could be converted into work by an ideal cyclic process?* (*b*) What is the change in entropy of the universe for each process? SSM

74 •• Helium, a monatomic gas, is initially at a pressure of 16 atm, a volume of 1.0 L, and a temperature of 600 K. It is quasi-statically expanded at constant temperature until its volume is 4.0 L, and is then quasi-statically compressed at constant pressure until its volume and temperature are such that a quasi-static adiabatic compression will return the gas to its original state. (*a*) Sketch this cycle on a *PV* diagram. (*b*) Find the volume and temperature after the compression at constant pressure. (*c*) Find the work done during each step of the cycle. (*d*) Find the efficiency of the cycle.

75 •• A heat engine that does the work of blowing up a balloon at a pressure of 1.00 atm absorbs 4.00 kJ from a reservoir at 120°C. The volume of the balloon increases by 4.00 L, and heat is released to a reservoir at a temperature T_c, where $T_c < 120°C$. If the efficiency of the heat engine is 50 percent of the efficiency of a Carnot engine working between the same two reservoirs, find the temperature T_c. SSM

76 •• Show that the coefficient of performance of a Carnot engine run as a refrigerator is related to the efficiency of a Carnot engine operating between the same two temperatures by $\varepsilon_C \times COP_C = T_c/T_h$.

77 •• A freezer has a temperature $T_c = -23°C$. The air in the kitchen has a temperature $T_h = 27°C$. The freezer is not perfectly insulated, and heat leaks through the walls of the freezer at a rate of 50 W. Find the power of the motor that is needed to maintain the temperature in the freezer.

78 •• In a heat engine, 2.00 mol of a diatomic gas are taken through the cycle ABCA, as shown in Figure 19-20. (The *PV* diagram is not drawn to scale.) At A the pressure and temperature are 5.00 atm and 600 K. The volume at B is twice the volume at A. The segment BC is an adiabatic expansion, and the segment CA is an isothermal compression. (*a*) What is the volume of the gas at A? (*b*) What are the volume and temperature of the gas at B? (*c*) What is the temperature of the gas at C? (*d*) What is the volume of the gas at C? (*e*) How much work is done by the gas in each of the three segments of the cycle? (*f*) How much heat is absorbed or released by the gas in each segment of this cycle?

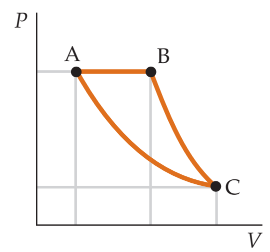

FIGURE 19-20 Problems 78, 80

79 •• In a heat engine, 2.00 mol of a diatomic gas are carried through the cycle ABCDA, shown in Figure 19-21. (The *PV* diagram is not drawn to scale.) The segment AB represents an isothermal expansion, and the segment BC is an adiabatic expansion. The pressure and temperature at A are 5.00 atm and 600 K. The volume at B is twice the volume at A. The pressure at D is 1.00 atm. (*a*) What is the pressure at B? (*b*) What is the temperature at C? (*c*) Find the total work done by the gas in one cycle. SSM

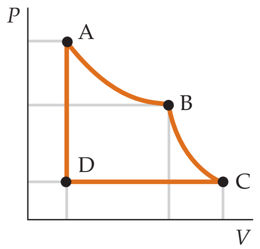

FIGURE 19-21 Problems 79, 81

80 •• In a heat engine, 2.00 mol of a monatomic gas are taken through the cycle ABCA, as shown in Figure 19-20. (The *PV* diagram is not drawn to scale.) At A the pressure and temperature are 5.00 atm and 600 K. The volume at B is twice the volume at A. The segment BC is an adiabatic expansion, and the segment CA is an isothermal compression. (*a*) What is the volume of the gas at A? (*b*) What are the volume and temperature of the gas at B? (*c*) What is the temperature of the gas at C? (*d*) What is the volume of the gas at C? (*e*) How much work is done by the gas in each of the three segments of the cycle? (*f*) How much heat is absorbed by the gas in each segment of the cycle?

81 •• In a heat engine, 2.00 mol of a monatomic gas are carried through the cycle ABCDA as shown in Figure 19-21. (The *PV* diagram is not drawn to scale.) The segment AB represents an isothermal expansion, and the segment BC is an adiabatic expansion. The pressure and temperature at A are 5.00 atm and 600 K. The volume at B is twice the volume at A. The pressure at D is 1.00 atm. (*a*) What is the pressure at B? (*b*) What is the temperature at C? (*c*) Find the total work done by the gas in one cycle.

82 •• Compare the efficiency of the Otto cycle to the efficiency of the Carnot cycle operating between the same maximum and minimum temperatures. (The Otto cycle is discussed in Section 19–1.)

83 ••• **ENGINEERING APPLICATION** A common practical cycle, often used in refrigeration, is the *Brayton cycle*, which involves (1) an adiabatic compression, (2) an isobaric (constant pressure) expansion, (3) an adiabatic expansion, and (4) an isobaric compression back to the original state. Assume the system begins the adiabatic compression at temperature T_1, and transitions to temperatures T_2, T_3, and T_4 after each leg of the cycle. (*a*) Sketch this cycle on a *PV* diagram. (*b*) Show that the efficiency of the overall cycle is given by $\varepsilon = 1 - (T_4 - T_1)/(T_3 - T_2)$. (*c*) Show that this efficiency, can be written as $\varepsilon = 1 - r^{(1-\gamma)/\gamma}$, where r is the pressure ratio $P_{\text{high}}/P_{\text{low}}$ (the ratio of the maximum and minimum pressures in the cycle). SSM

84 ••• **ENGINEERING APPLICATION** Suppose the Brayton cycle engine (see Problem 83) is run in reverse as a refrigerator in your kitchen. In this case, the cycle begins at temperature T_1 and expands at constant pressure until its temperature is T_4. Then the gas is adiabatically compressed until its temperature is T_3. And then it is compressed at constant pressure, until its temperature is T_2. Finally, it adiabatically expands until it returns to its initial state at temperature T_1. (*a*) Sketch this cycle on a *PV* diagram. (*b*) Show that the coefficient of performance, is

$$\text{COP}_{\text{B}} = \frac{(T_4 - T_1)}{(T_3 - T_2 - T_4 + T_1)}$$

(*c*) Suppose your "Brayton cycle refrigerator" is run as follows. The cylinder containing the refrigerant (a monatomic gas) has an initial volume and pressure of 60 mL and 1.0 atm. After the expansion at constant pressure, the volume and temperature are 75 mL and −25°C. The pressure ratio $r = P_{\text{high}}/P_{\text{low}}$ for the cycle is 5.0. What is the coefficient of performance for your refrigerator? (*d*) In order to absorb heat from the food compartment at the rate of 120 W, what is the rate at which electrical energy must be supplied to the motor of this refrigerator? (*e*) Assuming the refrigerator motor is actually running for only 4.0 h each day, how much does it add to your monthly electric bill. Assume 15 cents per kWh of electric energy and 30 days in a month.

85 •• Using $\Delta S = C_v \ln(T_2/T_1) - nR\ln(V_2/V_1)$ (Equation 19-16) for the entropy change of an ideal gas, show explicitly that the entropy change is zero for a quasi-static adiabatic expansion from state (V_1, T_1) to state (V_2, T_2).

86 ••• (*a*) Show that if the refrigerator statement of the second law of thermodynamics were not true, then the entropy of the universe could decrease. (*b*) Show that if the heat-engine statement of the second law were not true, then the entropy of the universe could decrease. (*c*) A third statement of the second law is that the entropy of the universe cannot decrease. Have you just proved that this statement is equivalent to the refrigerator and heat-engine statements?

87 ••• Suppose that two heat engines are connected in series, such that the heat released by the first engine is used as the heat absorbed by the second engine, as shown in Figure 19-22. The efficiencies of the engines are ε_1 and ε_2, respectively. Show that the net efficiency of the combination is given by $\varepsilon_{\text{net}} = \varepsilon_1 + \varepsilon_2 - \varepsilon_1\varepsilon_2$.

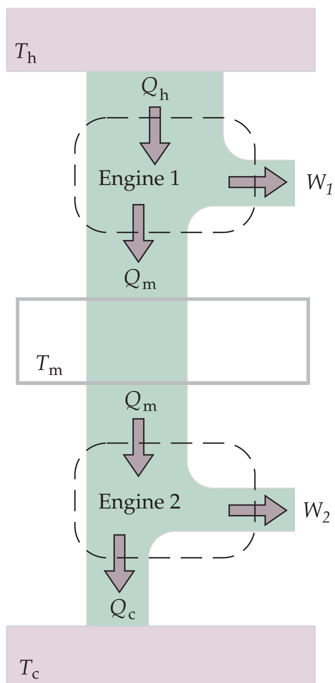

FIGURE 19-22 Problems 87, 88

88 ••• Suppose that two heat engines are connected in series, such that the heat released by the first engine is used as the heat absorbed by the second engine, as shown in Figure 19-22. Suppose that each engine is an ideal reversible heat engine. Engine 1 operates between temperatures T_h and T_m, and Engine 2 operates between T_m and T_c, where $T_h > T_m > T_c$. Show that the net efficiency of the combination is given by $\varepsilon_{net} = 1 - (T_c/T_h)$. (Note that this result means that two reversible heat engines operating "in series" are equivalent to one reversible heat engine operating between the hottest and coldest reservoirs.)

89 ••• The English mathematician and philospher Bertrand Russell (1872–1970) once said that if a million monkeys were given a million typewriters and typed away at random for a million years, they would produce all of Shakespeare's works. Let us limit ourselves to the following fragment of Shakespeare (*Julius Caesar* III:ii):

Friends, Romans, countrymen Lend me your ears.
I come to bury Caesar, not to praise him.
The evil that men do lives on after them,
The good is oft interred with the bones.
So let it be with Caesar.
The noble Brutus hath told you that Caesar was ambitious,
And, if so, it were a grievous fault,
And grievously hath Caesar answered it...

Even with this small fragment, it will take a lot longer than a million years! By what factor (roughly speaking) was Russell in error? Make any reasonable assumptions you want. (You can even assume that the monkeys are immortal.) SSM

CHAPTER 20

THE ALASKAN PIPELINE TRANSPORTS OIL THROUGH 800 MILES OF 48-IN.-DIAMETER STEEL PIPE. ZIGZAGS ARE PLACED IN THE PIPELINE TO ALLOW FOR THERMAL EXPANSION. (THE ZIGZAGS ALSO ALLOW FOR MOVEMENT DUE TO SEISMIC ACTIVITY.) THE PIPELINE WAS DESIGNED TO WITHSTAND TEMPERATURES RANGING FROM −60°F TO 145°F (THE TEMPERATURE OF THE PIPELINE WAS −60°F PRIOR TO THE START OF THE OIL FLOW.) *(Karen Kasmauski/CORBIS.)*

Thermal Properties and Processes

When an object absorbs heat, various changes may occur in the physical properties of the object. For example, its temperature may increase, accompanied by an expansion or contraction of the object, or the object may melt or vaporize, during which its temperature remains constant.

The changes in objects related to temperature are concerns scientists and engineers in many industries must deal with. Civil engineers that design bridges and roads include expansion joints that allow for more subtle changes in road lengths that arise from changes in temperature. Other engineers create products to protect objects from extreme temperature changes. Materials are used to keep thermal energy within hot water heaters, ovens, and ships' turbines, as well as to protect automobile bodies and their occupants from heat from the car's exhaust system.

In this chapter, we examine some of the thermal properties of matter and some important processes involving heat.

? What was the change in length of a 720-ft-long section of the pipeline when the temperature changed from −60°F to 145°F? (See Example 20-2.)

20-1 THERMAL EXPANSION

When the temperature of an object increases, the object typically expands. Suppose that we have a long rod of length L at a temperature T. When the temperature of a solid changes by ΔT, the fractional change in length $\Delta L/L$ is proportional to ΔT:

$$\frac{\Delta L}{L} = \alpha\,\Delta T \qquad \text{20-1}$$

where α, called the **coefficient of linear expansion,** is the ratio of the fractional change in length to the change in temperature:

$$\alpha = \frac{\Delta L/L}{\Delta T} \qquad \text{20-2}$$

The SI units for the coefficient of linear expansion are reciprocal kelvins (1/K), which are the same as reciprocal Celsius degrees (1/°C). The value of α can vary with changes in pressure and temperature. Equation 20-2 gives the average value over the temperature interval ΔT with pressure held constant. The coefficient of linear expansion at a particular temperature T is found by taking the limit as ΔT approaches zero:

$$\alpha = \lim_{\Delta T \to 0} \frac{\Delta L/L}{\Delta T} = \frac{1}{L}\frac{dL}{dT} \qquad \text{20-3}$$

DEFINITION: COEFFICIENT OF LINEAR EXPANSION

The accuracy obtained by using the average value of α over a wide temperature range is sufficient for most purposes.

For a liquid or a solid, the **coefficient of volume expansion** β is defined as the ratio of the fractional change in volume to the change in temperature (at constant pressure):

$$\beta = \lim_{\Delta T \to 0} \frac{\Delta V/V}{\Delta T} = \frac{1}{V}\frac{dV}{dT} \qquad \text{20-4}$$

DEFINITION: COEFFICIENT OF VOLUME EXPANSION

Both α and β can vary with both pressure and temperature, but any variation with pressure is typically negligible. Average values for α and β for various substances are given in Table 20-1.

For a given material, $\beta = 3\alpha$. We can show this by considering a box of dimensions L_1, L_2, and L_3. Its volume at a temperature T is

$$V = L_1 L_2 L_3$$

The rate of change of the volume with respect to temperature is

$$\frac{\partial V}{\partial T} = L_1 L_2 \frac{\partial L_3}{dT} + L_1 \frac{\partial L_2}{dT} L_3 + \frac{\partial L_1}{dT} L_2 L_3$$

Dividing each side of the equation by the volume, we obtain

$$\beta = \frac{1}{V}\frac{\partial V}{\partial T} = \frac{1}{L_3}\frac{\partial L_3}{\partial T} + \frac{1}{L_2}\frac{\partial L_2}{\partial T} + \frac{1}{L_1}\frac{\partial L_1}{\partial T}$$

We can see that each term on the right side of the preceding equation equals α, and so we have

$$\beta = 3\alpha \qquad \text{20-5}$$

Table 20-1 Approximate Values of the Coefficients of Thermal Expansion for Various Substances

Substance	Coefficient	
Air	3.67×10^{-3}	β, K^{-1}
Acetone	1.5×10^{-3}	β, K^{-1}
Alcohol	1.1×10^{-3}	β, K^{-1}
Water (20°C)	0.207×10^{-3}	β, K^{-1}
Mercury	0.18×10^{-3}	β, K^{-1}
Ice	51×10^{-6}	α, K^{-1}
Aluminum	24×10^{-6}	α, K^{-1}
Brass	19×10^{-6}	α, K^{-1}
Copper	17×10^{-6}	α, K^{-1}
Steel	11×10^{-6}	α, K^{-1}
Glass (ordinary)	9×10^{-6}	α, K^{-1}
Graphite	7.9×10^{-6}	α, K^{-1}
Glass (Pyrex)	3.2×10^{-6}	α, K^{-1}
Diamond	1.2×10^{-6}	α, K^{-1}
Invar	1×10^{-6}	α, K^{-1}

In the derivation of Equation 20-5, we have assumed that the coefficient of linear expansion is independent of direction. (This assumption is approximately true for many materials, and it will be used for the calculations in this book.) A similar derivation shows that the coefficient of area expansion is twice that of linear expansion.

Example 20-1 Do Holes Expand? *Conceptual*

Suppose we have a steel object with a circular hole through it. If the temperature of the object increases, the metal expands. Does the diameter of the hole increase or decrease?

PICTURE The increase in size of any part of an object for a given temperature increase is proportional to the original size of that part of the object (in accord with Equation 20-2). For an object, consider a steel ruler that has a 1-cm-diameter hole in it, centered on the 3.5-cm mark.

SOLVE

1. For an object, we consider a steel ruler that has a 1-cm-diameter hole in it, centered on the 3.5-cm mark:

   If a steel ruler has a 1-cm-diameter hole in it that is centered on the 3.5-cm mark, the edge of the hole will touch both the 3-cm line and the 4-cm line

2. When the temperature of the ruler increases by a given amount, the ruler expands uniformly:

   The distance between the 3-cm line and the 4-cm line will increase.

3. The edge of the hole will remain touching the 3-cm and 4-cm marks as the ruler expands.

   If the distance between the 3-cm line and the 4-cm line increases, then $\boxed{\text{the diameter of the hole increases.}}$

CHECK If the hole were made by punching out at 1-cm hole, the punched out material would be a steel disk 1-cm in diameter. If the temperature of this disk were then increased by the same amount as the temperature of the ruler was increased, then the disk would fit the hole perfectly.

TAKING IT FURTHER An apparatus for demonstrating that a hole expands when heated is shown in Figure 20-1.

FIGURE 20-1 When the ball and ring are both at room temperature, the ball is too big to pass through the ring. The ring expands when heated, and when it is hot the ball, which remains at room temperature, is able to pass through the hole. *(Richard Megna/Fundamental Photographs.)*

Most materials expand when heated and contract when cooled. Water, however, is an important exception. Figure 20-2 shows the volume occupied by 1 g of water as a function of temperature. The minimum volume, and therefore the maximum density, is at 4.00°C. Thus, when water at 4.00°C is cooled, it expands rather than contracts. This property of water has important consequences for the ecology of

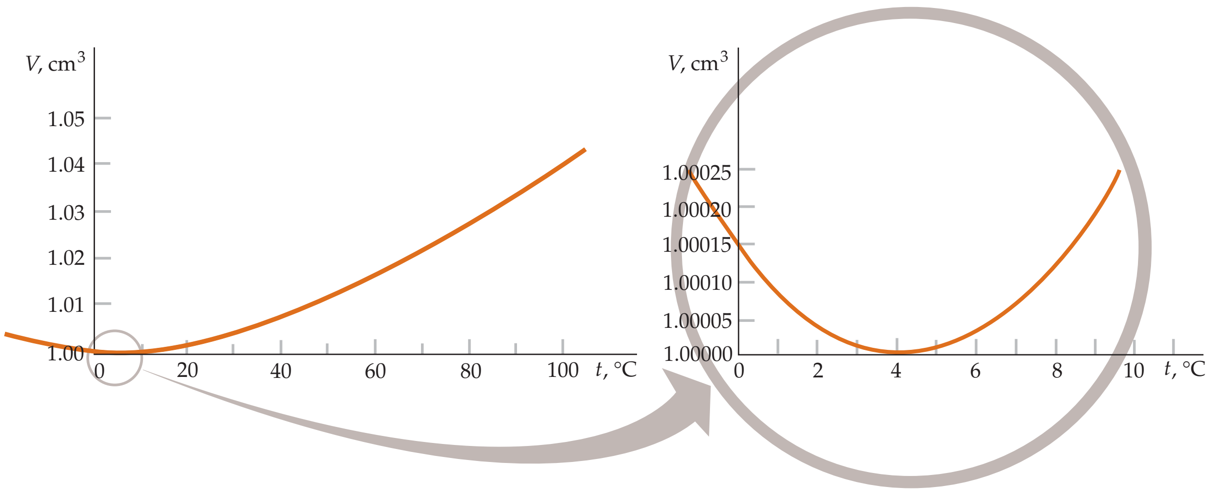

FIGURE 20-2 Volume of 1 g of water at atmospheric pressure versus temperature. The minimum volume, which corresponds to the maximum density, occurs at 4.0°C. At temperatures below 0.0°C, the curve shown is for supercooled water. (Supercooled water is water that is cooled below the normal freezing point without solidifying.)

lakes. At temperatures above 4.00°C, the water in a lake becomes denser as it cools, and therefore sinks to the bottom. But as the water cools below 4.00°C, it becomes less dense and rises to the surface. This consequence is the reason that ice forms first on the surface of a lake. Water also expands when it freezes. Because ice is less dense than liquid water, it remains at the surface and acts as insulation for the water below. If water behaved like most substances and contracted when it froze, then ice would sink and expose more water at the surface that would then freeze. Lakes would fill with ice from the bottom up and would be much more likely to freeze completely in the winter.

Example 20-2 An Expanding

A 720-ft-long straight section of the Alaskan pipeline was at a temperature of −60°F before it was filled with oil with a maximum temperature of 145°F. The pipeline is wrapped with insulation, so the oil and the steel pipe have the same temperature. (*a*) How much did the section expand when the temperature changed from −60°F to 145°F. (*b*) The sections of the pipeline that are above ground are 420 mi long. If the temperature of an entire 420-mi-long section increases from −60°F to 145°F, how much would it expand?

PICTURE Use $\alpha = 11 \times 10^{-6}\ \mathrm{K}^{-1}$ from Table 20-1 and calculate ΔL from Equation 20-1.

SOLVE

(*a*) 1. The change in length for a given change in temperature is the product of α, L, and ΔT:

$$\Delta L = \alpha L\, \Delta T$$

2. The change in temperature is 205°F. Convert this change in Fahrenheit to a change in kelvins (by multiplying by 5/9):

$$\Delta T = \frac{5\ \mathrm{K}}{9^\circ\mathrm{F}}(205^\circ\mathrm{F}) = 114\ \mathrm{K}$$

3. Calculate the change in length:

$$\Delta L = \alpha L\, \Delta T = (11 \times 10^{-6}\ \mathrm{K}^{-1})(720\ \mathrm{ft})(114\ \mathrm{K})$$
$$= \boxed{0.90\ \mathrm{ft} = 11\ \mathrm{in.}}$$

(*b*) The change in length is proportional to the length. Use this to calculate the change in length of the 420-mi section that is above ground:

$$\frac{\Delta L_2}{L_2} = \frac{\Delta L_1}{L_1} \Rightarrow \Delta L_2 = \frac{L_2}{L_1}\Delta L_1$$

$$\Delta L_2 = \frac{(420\ \mathrm{mi})(5280\ \mathrm{ft/mi})}{720\ \mathrm{ft}}(0.90\ \mathrm{ft}) = 2800\ \mathrm{ft} \approx \boxed{0.5\ \mathrm{mi}}$$

CHECK The 0.5-mi change in length is slightly more than one-tenth of one percent of the 420-mi length. That seems feasible for such a large temperature change and for such a great length.

TAKING IT FURTHER The ends of the sections of pipeline that are above ground do not move with temperature changes because the zigzagging (Figure 20-3) results in lateral movements that "absorb the expansion."

FIGURE 20-3 The zigzagging of the pipeline allows for thermal expansion of the pipes. *(Paul A. Souders/CORBIS.)*

FIGURE 20-4 Expansion joints, such as this one, allow bridges to expand with increases in temperature. *(Frank Siteman/Stock Boston, Inc./PictureQuest.)*

We can calculate the stress that would result in a 1000-m-long steel bridge without expansion joints (Figure 20-4) by using Young's modulus (Equation 12-1):

$$Y = \frac{\text{Stress}}{\text{Strain}} = \frac{F/A}{\Delta L/L}$$

Then

$$\frac{F}{A} = Y\frac{\Delta L}{L} = Y\alpha\,\Delta T$$

For $\Delta T = 30\text{ K}$, $\Delta L/L = \alpha\,\Delta T = (11 \times 10^{-6}\text{ K}^{-1})(30\text{ K}) = 3.3 \times 10^{-4} = 0.33\text{ m}/1000\text{ m}$. Then using $Y = 2.0 \times 10^{11}\text{ N/m}^2$ (from Table 12-1),

$$\frac{F}{A} = Y\frac{\Delta L}{L} = (2.0 \times 10^{11}\text{ N/m}^2)\frac{0.33\text{ m}}{1000\text{ m}} = 6.6 \times 10^{7}\text{ N/m}^2$$

This stress is about one-third of the breaking stress for steel under compression. A compression stress of this magnitude would cause a steel bridge to buckle and become permanently deformed.

Example 20-3 A Completely Filled Glass

While working in the laboratory, you fill a 1.000-L Pyrex glass flask to the brim with water at 10°C. You heat the flask, increasing the temperature of the water and flask to 30°C. How much water spills out of the flask?

PICTURE The water and the glass both expand when heated, but 1.000 L of water expands more than 1.000 L of glass, so some water spills out. We calculate the amount spilled by finding the changes in volume for $\Delta T = 20\text{ K}$ using $\Delta V_{\text{water}} = \beta V_{\text{i}}\,\Delta T$ with $\beta = 0.207 \times 10^{-3}\text{ K}^{-1}$ for water (from Table 20-1) and $\Delta V_{\text{glass}} = \beta V_{\text{i}}\,\Delta T = 3\alpha V\,\Delta T$ with $\alpha = 3.25 \times 10^{-6}\text{ K}^{-1}$ for Pyrex glass, where $V_{\text{i}} = 1.000\text{ L}$. The difference in these volume changes equals the volume spilled.

SOLVE

1. The volume of water spilled V_{spill} is the difference in the changes in volume of the water and glass:

$$V_{\text{spill}} = \Delta V_{\text{water}} - \Delta V_{\text{glass}}$$

2. Find the increase in the volume of the water:

$$\Delta V_{\text{water}} = \beta_{\text{water}} V_{\text{i}}\,\Delta T$$

3. Find the increase in the volume of the glass flask:

$$\Delta V_{\text{glass}} = \beta_{\text{glass}} V_{\text{i}}\,\Delta T = 3\alpha_{\text{Pyrex}} V_{\text{i}}\,\Delta T$$

4. Subtract to find the amount of water spilled:

$$\begin{aligned} V_{\text{spill}} &= \Delta V_{\text{water}} - \Delta V_{\text{glass}} = \beta_{\text{water}} V_{\text{i}}\,\Delta T - \beta_{\text{glass}} V_{\text{i}}\,\Delta T \\ &= (\beta_{\text{water}} - \beta_{\text{glass}})V_{\text{i}}\,\Delta T = (\beta_{\text{water}} - 3\alpha_{\text{Pyrex}})V_{\text{i}}\,\Delta T \\ &= [0.207 \times 10^{-3}\text{ K}^{-1} - 3(3.25 \times 10^{-6}\text{ K}^{-1})](1.000\text{ L})(20\text{ K}) \\ &= 3.95 \times 10^{-3}\text{ L} = \boxed{4.0\text{ mL}} \end{aligned}$$

CHECK The overflow of 4.0 mL represents only 0.4 percent of the initial volume of 1.000 L. It is feasible that this small amount would result from a 20 K temperature increase.

TAKING IT FURTHER The flask expands, making the space inside the flask larger, as if the flask were a piece of solid Pyrex glass.

Example 20-4 Breaking Copper

Context-Rich

During a home plumbing project, you heat a length of copper pipe to 300°C. Then you clamp the pipe between two fixed points so that it cannot contract. If the breaking stress of copper is 230 MN/m², at what temperature will the bar break as it cools?

PICTURE As the copper pipe cools, the change in length ΔL that would occur if it was allowed to contract is offset by an equal stretching due to tensile stress in the bar. The stress F/A is related to the stretching ΔL by $Y = (F/A)/(\Delta L/L)$, where Young's modulus for copper is $Y = 110\text{ GN/m}^2$ (from Table 12-1). The maximum allowable stretching occurs when F/A equals 230 MN/m². Thus, we find the temperature change that would produce this maximum contraction.

SOLVE

1. Calculate the change in length ΔL_1 that would occur if the pipe were allowed to contract as it cools:

$$\Delta L_1 = \alpha L\,\Delta T$$

2. A tensile stress F/A stretches the pipe by ΔL_2:

$$Y = \frac{F/A}{\Delta L_2/L} \quad \text{so} \quad \Delta L_2 = L\frac{F/A}{Y}$$

3. Substitute the step-1 and step-2 results into $\Delta L_1 + \Delta L_2 = 0$ and solve for ΔT with the stress equal to the breaking value:

$$\Delta L_1 + \Delta L_2 = 0$$

$$\alpha L\,\Delta T + L\frac{F/A}{Y} = 0$$

$$\text{so} \qquad \Delta T = -\frac{F/A}{\alpha Y} = -\frac{230 \times 10^6\text{ N/m}^2}{(17 \times 10^{-6}\text{ K}^{-1})(110 \times 10^9\text{ N/m}^2)}$$

$$= -123\text{ K} = -123°\text{C}$$

4. Add this result to the original temperature to find the final temperature at which the bar breaks:

$$t_f = t_1 + \Delta t = 300°\text{C} - 123°\text{C} = 177°\text{C} = \boxed{180°\text{C}}$$

CHECK If you look at copper plumbing you will see that the pipes are not rigidly clamped. In addition, in household plumbing the hot-water heater is almost always set so the water temperature does not exceed 60°C (140°F), and the cold water has to be at least 0°C or freezing occurs. Thus, changes in temperature greater than 60°C do not occur in home plumbing. It should not be too surprising that pipes designed for home plumbing might not hold up if expansion or contraction is not allowed for, and if temperature changes much greater than those expected in homes occur.

20-2 THE VAN DER WAALS EQUATION AND LIQUID–VAPOR ISOTHERMS

At ordinary pressures most gases behave like an ideal gas. However, this ideal behavior breaks down when the pressure is high enough or the temperature is low enough such that the density of the gas is high and the molecules are, on average, closer together. An equation of state called the **van der Waals equation** describes the behavior of many real gases over a wide range of pressures more accurately than does the ideal-gas equation of state ($PV = nRT$). The van der Waals equation for n moles of gas is

$$\left(P + \frac{an^2}{V^2}\right)(V - bn) = nRT \qquad \text{20-6}$$

THE VAN DER WAALS EQUATION OF STATE

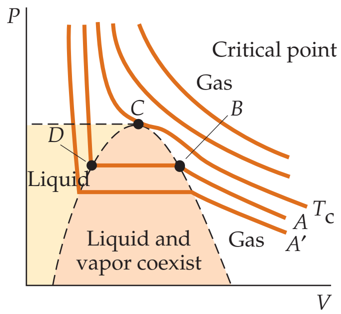

FIGURE 20-5 Isotherms on the *PV* diagram for a substance. For temperatures above the critical temperature T_c, the substance remains a gas at all pressures. Except for the region where the liquid and vapor coexist, these curves are described quite well by the van der Waals equation. The pressure for the horizontal portions of the curves in the shaded region is the vapor pressure, which is the pressure at which the vapor and liquid are in equilibrium. In the region shaded yellow, to the left of the region shaded pink, the substance is a liquid and is nearly incompressible.

The constant b in this equation arises because the gas molecules are not point particles, but objects that have a finite size; therefore, the volume available to each molecule is reduced. The magnitude of b is the volume of one mole of gas molecules. The term an^2/V^2 arises from the attraction of the gas molecules to each other. As a molecule approaches the wall of the container, it is pulled back by the molecules surrounding it with a force that is proportional to the density of those molecules n/V. Because the number of molecules that hit the wall in a given time is also proportional to the density of the molecules, the decrease in pressure due to the attraction of the molecules is proportional to the square of the density and therefore to n^2/V^2. The constant a depends on the gas and is small for inert gases, which have very weak chemical interactions. The terms bn and an^2/V^2 are both negligible when the volume V is large, so at low densities the van der Waals equation approaches the ideal-gas law. At high densities, the van der Waals equation provides a much better description of the behavior of real gases than does the ideal-gas law.

Figure 20-5 shows *PV* isothermal curves for a substance at various temperatures. Except for the region where the liquid and vapor coexist, these curves are described quite accurately by the van der Waals equation and can be used to determine the constants a and b. For example, the values of these constants that give the best fit to the experimental curves for nitrogen are $a = 1.370\ \mathrm{L^2 \cdot atm/mol^2}$ and $b = 38.7$ mL/mol. This volume of 38.7 mL/mole is about 0.2 percent of the volume of 22.4 L occupied by 1 mol of ideal gas under standard conditions. Because the molar mass of nitrogen is 28.02 g/mol, if 1 mol of nitrogen molecules were packed into a volume of 38.7 mL, then the density would be

$$\rho = \frac{M}{V} = \frac{28.0\ \mathrm{g}}{38.7\ \mathrm{mL}} = 0.724\ \mathrm{g/mL} = 0.724\ \mathrm{kg/L}$$

which is almost the same as the density of liquid nitrogen, 0.80 kg/L.

The value of the constant b can be used to estimate the size of a molecule. Because 1 mol (N_A molecules) of nitrogen has a volume of 38.7 cm³, the volume of one nitrogen molecule is

$$V = \frac{b}{N_A} = \frac{38.7\ \mathrm{cm^3/mol}}{6.02 \times 10^{23}\ \mathrm{molecules/mol}}$$
$$= 6.43 \times 10^{-23}\ \mathrm{cm^3/molecule}$$

If we assume that each molecule occupies a cube of side d, we obtain

$$d^3 = 6.43 \times 10^{-23}\ \mathrm{cm^3}$$

or

$$d = 4.0 \times 10^{-8}\ \mathrm{cm} = 0.4\ \mathrm{nm}$$

which is a plausible estimate for the "diameter" of a nitrogen molecule.

The values of the constants a and b that give the best fit to the experimental curves are listed in Table 20-2.

Table 20-2 The van der Waals *a* and *b* Coefficients for Several Gasses

	a ($\mathrm{L^2 \cdot atm/mol^2}$)	b (mL/mol)
He	0.0346	23.80
Ne	0.211	17.1
Ar	1.34	32.2
Kr	2.32	39.8
Xe	4.19	51.0
H_2	0.244	26.6
N_2	1.370	38.70
O_2	1.382	31.86
H_2O	5.46	30.5
CO_2	3.59	42.7

Example 20-5 Helium at High Density

A 20.0-L tank contains 300 mol of helium at a pressure of 400 atm. (*a*) What is the value of an^2/V^2, and what fraction of the pressure is it? (*b*) What is the value of bn, and what fraction of the volume of the container is it? (*c*) What is the temperature of the helium?

PICTURE To find the temperature use the van der Waals equation (Equation 20-6). The a and b coefficients for helium are found in Table 20-2.

SOLVE

(*a*) Calculate an^2/V^2 and compare it with 400 atm:

$$\frac{an^2}{V^2} = \frac{(0.0346\ \mathrm{L^2 \cdot atm/mol^2})(300\ \mathrm{mol})^2}{(20.0\ \mathrm{L})^2}$$

$$= 7.785\ \mathrm{atm} = \boxed{7.79\ \mathrm{atm}}$$

(7.785 atm is about 2% of 400 atm)

(*b*) Calculate bn and compare it with 20 L:

$$bn = (0.0238\ \mathrm{L/mol})(300\ \mathrm{mol}) = \boxed{7.14\ \mathrm{L}}$$

(7.14 L is about 36% of 20 L)

(*c*) 1. The van der Waals equation can be solved for the temperature:

$$\left(P + \frac{an^2}{V^2}\right)(V - bn) = nRT$$

2. Obtain the a and b coefficients for helium from Table 20-2:

$$a = 0.0346\ \mathrm{L^2 \cdot atm/mol^2}$$
$$b = 0.0238\ \mathrm{L/mol}$$

3. Enter the given values and solve for the temperature. With the pressure in atmospheres and the volume in liters, we use $R = 0.082057\ \mathrm{L \cdot atm/(mol \cdot K)}$:

$$T = \frac{\left(P + \frac{an^2}{V^2}\right)(V - bn)}{nR} = \frac{\left(400 + \frac{0.0346 \times 300^2}{20.0^2}\right)(20.0 - 0.0238 \times 300)}{300 \times 0.082057}$$

$$= \boxed{213\ \mathrm{K}}$$

CHECK In the van der Waals equation the 2% correction to the pressure term [Part (*b*)] is dwarfed by the 36% correction to the volume term [Part (*a*)]. This is as expected. The correction to the pressure term is particularly small for helium because the helium atoms attract each other more weakly than do most other atoms.

At temperatures below T_c, the van der Waals equation describes those portions of the isotherms outside the shaded region in Figure 20-5, but not those portions inside the shaded region. Suppose we have a gas at a temperature below T_c that initially has a low pressure and a large volume. We begin to compress the gas while holding the temperature constant (isotherm A in the figure). At first the pressure

Cloud forming behind an aircraft as it breaks the sound barrier. As the aircraft moves through the air, an area of low pressure forms behind it. When the pressure of this air parcel falls below the vapor pressure of gaseous water, the water in the air condenses to form the cloud. Different atmospheric conditions cause the phenomenon to occur at different aircraft speeds. *(U.S. Department of Defense/Photo Researchers, Inc.)*

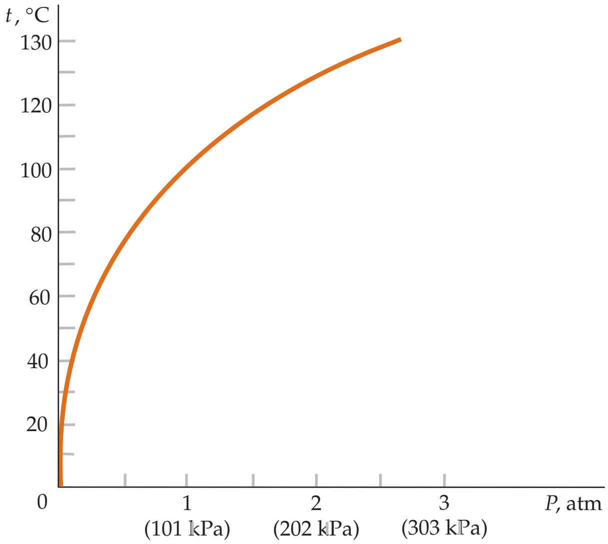

FIGURE 20-6 Boiling point of water versus pressure.

rises, but when we reach point B on the dashed curve, the pressure ceases to rise and the gas begins to liquefy at constant pressure. Along the horizontal line BD in the figure, the gas and liquid are in equilibrium. As we continue to compress the gas, more and more gas liquefies until point D on the dashed curve, at which point we have only liquid. Then, if we try to compress the substance further, the pressure rises sharply because a liquid is nearly incompressible.

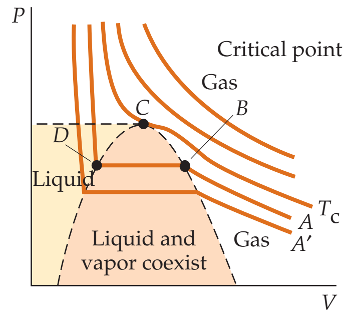

FIGURE 20-5 *(repeated)* Isotherms on the PV diagram for a substance.

Now consider injecting a liquid such as water into a sealed evacuated container. As some of the water evaporates, water-vapor molecules fill the previously empty space in the container. Some of these molecules will hit the liquid surface and rejoin the liquid water during a process called *condensation.* The rate of evaporation will initially be greater than the rate of condensation, but eventually equilibrium will be reached. The pressure at which a liquid is in equilibrium with its own vapor is called the **vapor pressure.** If we now heat the container slightly, the liquid boils, more liquid evaporates, and a new equilibrium is established at a higher vapor pressure. Vapor pressure thus depends on the temperature. We can see this from Figure 20-5. If we had started compressing the gas at a lower temperature, as with isotherm A' in Figure 20-5, the vapor pressure would be lower, as is indicated by the horizontal constant-pressure line for A' at a lower value of pressure. The temperature for which the vapor pressure for a substance equals 1 atm is the **normal boiling point** of that substance. For example, the temperature at which the vapor pressure of water is 1.00 atm is 373 K(= 100°C), so this temperature is the normal boiling point of water. At high altitudes, such as on the top of a mountain, the pressure is less than 1.00 atm, therefore, water boils at a temperature lower than 373 K. Figure 20-6 gives the vapor pressures of water at various temperatures.

At temperatures greater than the critical temperature T_c, a gas will not condense at any pressure. The critical temperature for water vapor is 647 K (374°C). The point at which the critical isotherm intersects the dashed curve in (point C) is called the **critical point.**

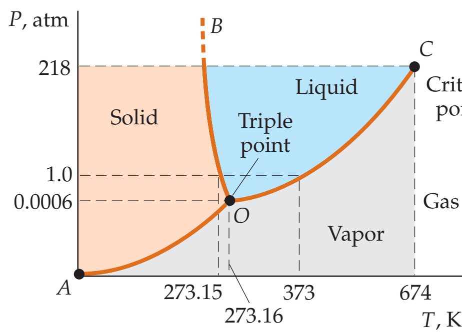

FIGURE 20-7 Phase diagram for water. The pressure and temperature scales are not linear but are compressed to show the points of interest. Curve OC is the curve of vapor pressure versus temperature. Curve OB is the melting curve, and curve OA is the sublimation curve.

20-3 PHASE DIAGRAMS

Figure 20-7 is a plot of pressure versus temperature at a constant volume for water. Such a plot is called a **phase diagram.** The portion of the diagram between points O and C shows vapor pressure versus temperature. As we continue to heat the container, the density of the liquid decreases and the density of the vapor increases. At point *C* on the diagram, these densities are equal. Point *C* is called the *critical point*. At this point and above it, there is no distinction between the liquid and the gas. Critical-point temperatures T_c for various substances are listed in Table 20-3. At temperatures greater than the critical temperature, a gas will not condense at any pressure.

If we now cool our container, some of the vapor condenses into a liquid as we move back down the curve *OC* in Figure 20-7 until the substance reaches point *O*. At this point, the liquid begins to solidify. Point *O* is the **triple point,** that one point at which the vapor, liquid, and solid phases of a substance can coexist in equilibrium. Every substance has a unique triple point at a specific temperature and pressure. The triple-point temperature for water is 273.16 K (0.01°C) and the triple-point pressure is 4.58 mmHg.

At temperatures and pressures below the triple point, the liquid cannot exist. The curve *OA* in the phase diagram of Figure 20-7 is the locus of pressures and temperatures for which the solid and vapor coexist in equilibrium. The direct change from a solid to a vapor is called **sublimation.** You can observe sublimation by putting a few loose ice cubes in the freezer compartment of a no-frost (self-defrosting) refrigerator. Over time, the ice cubes will shrink and eventually disappear due to sublimation. This happens because the atmospheric pressure is well above the triple-point pressure of water, and therefore, equilibrium is never established between the ice and water vapor. The triple-point temperature and pressure of carbon dioxide (CO_2) are 216.55 K and 3880 mmHg (5.1 atm), which means that liquid CO_2 can only exist at pressures above 5.1 atm. Thus, at ordinary atmospheric pressures, liquid CO_2 cannot exist at any temperature. When solid CO_2 "melts," it sublimates directly into gaseous CO_2 without going through the liquid phase, hence the name "dry ice."

The curve *OB* in Figure 20-7 is the melting curve separating the liquid and solid phases. For a substance like water for which the melting temperature decreases as the pressure increases, curve *OB* slopes upward to the left from the triple point, as in this figure. For most other substances, the melting temperature increases as the pressure increases. For such a substance, curve *OB* slopes upward to the right from the triple point.

For a molecule to escape (evaporate) from a substance in the liquid state, energy is required to break the intermolecular attractions at the liquid's surface. Vaporization cools the liquid left behind. If a pot of water is brought to a boil over a hot plate, this cooling effect keeps the temperature of the liquid constant at the boiling point. This is the reason that the boiling point of a substance can be used to calibrate thermometers. However, water can also be made to boil without adding heat by evacuating the air above it, thereby lowering the applied pressure. The energy needed for vaporization is then taken from the water left behind. As a result, the water will cool down, even to the point that ice forms on top of the boiling water!

Table 20-3 Critical Temperatures T_c for Various Substances

Substance	T_c, K
Water	647.4
Sulfur dioxide	430.9
Chlorine	417.12
Carbon dioxide	304.2
Nitric oxide	180.2
Oxygen	154.8
Argon	150.8
Neon	44.4
Hydrogen	33.3
Helium	5.3

20-4 THE TRANSFER OF HEAT

Heat is the transfer of energy due to a temperature difference. This transfer from one location to another takes place by way of three distinct processes: conduction, convection, and radiation.

During **conduction,** the enrgy is transferred by interactions among atoms or molecules, where the atoms or molecules are not themselves transported. For example, if one end of a solid bar is heated, the atoms in the heated end vibrate with greater energy than do those at the cooler end. The interaction of the more energetic atoms with the less energetic atoms causes this energy to be transported along the bar.*

* If the solid is a metal, the transfer of heat is made easier by *delocalized* electrons, which can move throughout the metal.

During **convection,** heat is transferred by direct transport of matter. For example, warm air in a region of a room expands, its density decreases, and the buoyant force on it due to the surrounding air causes it to rise. Energy is thus transported upward along with the molecules of warm air.

During **radiation,** the energy is transferred through space in the form of electromagnetic waves that move at the speed of light. Infrared waves, visible light waves, radio waves, television waves, and X rays are all forms of electromagnetic radiation that differ from one another in their wavelengths and frequencies.

During all mechanisms of heat transfer, the rate of cooling of a body is approximately proportional to the temperature difference between the body and its surroundings. This result is known as **Newton's law of cooling.**

During many real situations, all three mechanisms for energy transfer occur simultaneously, though one mechanism may be more dominant than the others. For example, an ordinary space heater uses both radiation and convection. If the heating element is quartz, then the main mechanism of transfer is radiation. If the heating element is metal (which does not radiate as efficiently as quartz), then convection is the main mechanism by which energy is transferred, with the heated air rising to be replaced by cooler air. Fans are often included in heaters to speed the convection process.

CONDUCTION

Figure 20-8*a* shows an insulated uniform solid bar of cross-sectional area A. If we keep one end of the bar at a high temperature and the other end at a low temperature, energy is conducted down the bar from the hot end to the cold end. In the steady state, the temperature varies linearly from the hot end to the cold end. The rate of change of the temperature along the bar dT/dx is called the **temperature gradient.***

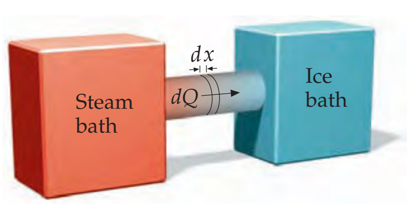
Let dT be the temperature difference across a small segment of length dx (Figure 20-8*b*). If dQ is the amount of heat conducted through a cross section of the segment during some time dt, then the rate of conduction of heat dQ/dt is called the **thermal current *I*.** It has experimentally been found that the thermal current is proportional to the temperature gradient and to the cross-sectional area A:

$$I = \frac{dQ}{dt} = -kA\frac{dT}{dx} \qquad \text{20-7}$$

DEFINITION: THERMAL CURRENT

! Heat transports energy from a higher-temperature region to a lower-temperature region, so the thermal current is in the direction of decreasing temperature.

The proportionality constant k, called the *thermal conductivity,* depends on the composition of the bar.† The heat is transferred in the direction of decreasing temperature. That is, if the temperature increases with increasing x, then the heat transfer is in the negative x direction, and vice versa. In SI units, thermal current is



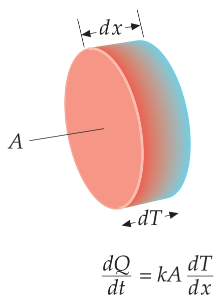


FIGURE 20-8 (*a*) An insulated conducting bar with its ends at two different temperatures. (*b*) A segment of the bar of length dx. The rate at which heat is conducted through a cross section of the segment is proportional to the cross-sectional area of the bar and the temperature drop dT across the segment, and it is inversely proportional to the length of the segment.

* The temperature gradient is actually a vector. The direction of this vector is the direction in which the temperature is increasing most rapidly, and the magnitude of this vector is the rate of change of temperature with respect to distance in this direction.

† Do not confuse the thermal conductivity with Boltzmann's constant, which is also designated by k.

Table 20-4 Thermal Conductivities *k* for Various Materials

k, Btu·in./(h·ft^2·F°)	Material	k, W/(m·K)
(2980)	Silver	(429)
(2780)	Copper	(401)
(2200)	Gold	(318)
(1644)	Aluminum	(237)
(558)	Iron	(80.4)
(319)	Steel	(46)
(20.4)	Lead	(35.3)
(6–9)	Concrete	(0.19–1.3)
(5–6)	Glass	(0.7–0.9)
(4.22)	Water at 27°C	(0.609)
(4.11)	Ice	(0.592)
(1.02)	Oak	(0.15)
(0.78)	White Pine	(0.11)
(0.18)	Air at 27°C	(0.026)

expressed in watts, and the thermal conductivity has units of W/(m · K).* In practical calculations in the United States, the thermal current is usually expressed in Btu per hour, the area is expressed in square feet, the length (or thickness) is expressed in inches, and the temperature is expressed in degrees Fahrenheit. The thermal conductivity is then given in Btu · in/(h · ft^2 · °F). Table 20-4 gives the thermal conductivities of various materials.

If we solve Equation 20-7 for the temperature difference, we obtain

$$|\Delta T| = I\frac{|\Delta x|}{kA} \qquad \text{20-8}$$

or

$$\Delta T = IR \qquad \text{20-9}$$

TEMPERATURE DROP VERSUS CURRENT

where ΔT is the *temperature drop* in the direction of the thermal current and $|\Delta x|/(kA)$ is the **thermal resistance** R:

$$R = \frac{|\Delta x|}{kA} \qquad \text{20-10}$$

DEFINITION: THERMAL RESISTANCE

CONCEPT CHECK 20-1

In a cool room, a metal tabletop feels much cooler to the touch than does a wood surface even though they both have the same temperature. Why?

* In some tables, the energy may be given in calories or kilocalories and the thickness in centimeters.

PRACTICE PROBLEM 20-1

Calculate the thermal resistance of an aluminum slab of cross-sectional area 15.0 cm^2 and thickness 2.00 cm.

PRACTICE PROBLEM 20-2

What thickness of a slab of silver would be required to give the same thermal resistance as a 1.00-cm-thick layer of dead air of the same area?

In many practical problems, we are interested in the rate of heat transfer through two or more conductors (or insulators) in series. For example, we may want to know the effect of adding insulating material of a certain thickness and thermal conductivity to the space between two layers of wallboard. Figure 20-9 shows two thermally conducting slabs of the same cross-sectional area, but of different materials and of different thicknesses. Let T_1 be the temperature on the warm side, T_2 be the temperature at the interface between the slabs, and T_3 be the temperature on the cool side. Under the conditions of steady-state heat transfer, the thermal current I through each of the slabs must be the same. This follows from energy conservation; for steady-state transfer, the rate at which energy enters any region must equal the rate at which it exits that region.

If R_1 and R_2 are the thermal resistances of the two slabs, we have by applying Equation 20-9 to each slab

$$T_1 - T_2 = IR_1$$

and

$$T_2 - T_3 = IR_2$$

Adding these equations gives

$$\Delta T = T_1 - T_3 = I(R_1 + R_2) = IR_{eq}$$

or

$$I = \frac{\Delta T}{R_{eq}} \qquad 20\text{-}11$$

where R_{eq} is the **equivalent resistance.** Thus, for thermal resistances in series, the equivalent resistance is the sum of the individual resistances:

$$R_{eq} = R_1 + R_2 + \cdots \qquad 20\text{-}12$$

THERMAL RESISTANCES IN SERIES

This result can be extended to any number of resistances in series. In Chapter 25, we will find that the same formula applies to electrical resistances in series.

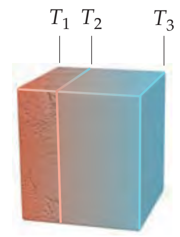

FIGURE 20-9 Two thermally conducting slabs of different materials in series. The equivalent thermal resistance of the slabs in series is the sum of their individual thermal resistances. The thermal current is the same through both slabs.

This thermogram of a house shows the heat being radiated to its surroundings. *(Alfred Pasieka/Photo Researchers, Inc.)*

To calculate the rate at which energy is leaving a room by way of heat conduction, we need to know how much heat is released through the walls, the windows, the floor, and the ceiling. For this type of problem, in which there are several paths for heat transfer, the resistances are said to be in **parallel.** The temperature difference is the same for each path, but the thermal current is different. The total thermal current is the sum of the thermal currents through each of the parallel paths:

$$I_{\text{total}} = I_1 + I_2 + \cdots = \frac{\Delta T}{R_1} + \frac{\Delta T}{R_2} + \cdots = \Delta T\left(\frac{1}{R_1} + \frac{1}{R_2} + \cdots\right)$$

or

$$I_{\text{total}} = \frac{\Delta T}{R_{\text{eq}}} \qquad \text{20-13}$$

where the equivalent thermal resistance is given by

$$\frac{1}{R_{\text{eq}}} = \frac{1}{R_1} + \frac{1}{R_2} + \cdots \qquad \text{20-14}$$

THERMAL RESISTANCES IN PARALLEL

We will encounter this equation again in Chapter 25 when we study electric conduction through parallel resistances. Note that for both resistors in series (Equation 20-11) and resistors in parallel (Equation 20-13) I is proportional to ΔT, which is in agreement with Newton's law of cooling.

PROBLEM-SOLVING STRATEGY

Calculating Thermal Current

PICTURE Determine if the group of objects for which you are finding the total thermal current are in series or in parallel.

SOLVE

1. Using $R = |\Delta x|/(kA)$ (Equation 20-10), find the thermal resistance of each object.
2. If any objects are in series, use $R_{\text{eq}} = R_1 + R_2 + \cdots$ (Equation 20-12) to calculate their equivalent resistance.
3. If any objects are in parallel, use $\frac{1}{R_{\text{eq}}} = \frac{1}{R_1} + \frac{1}{R_2} + \cdots$ (Equation 20-14) to find their equivalent resistance.
4. Repeat steps 2 and 3 until you have calculated the equivalent resistance of the entire system of conducting objects.
5. Using $\Delta T = I_{\text{total}} R_{\text{eq}}$ (Equation 20-9), calculate the total thermal current.

CHECK For each parallel combination of objects, make sure the equivalent resistance is less than the resistance of the object with the least resistance. For each series combination of objects, make sure the equivalent resistance is greater than the resistance of the object with the greatest resistance.

Example 20-6 Two Metal Bars in Series

Two insulated metal bars, each of length 5.0 cm and rectangular cross section with sides 2.0 cm and 3.0 cm, are wedged between two walls, one held at 100°C and the other at 0.0°C (Figure 20-10). The bars are lead and silver. Find (*a*) the total thermal current through the two-bar combination, and (*b*) the temperature at the interface.

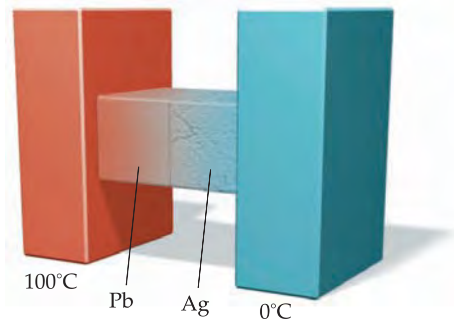

FIGURE 20-10 Two thermally conducting slabs of different materials in parallel.

PICTURE The bars are thermal resistors connected in series. (*a*) You can find the total thermal current from $I = R_{eq}/\Delta T$, where the equivalent resistance R_{eq} is the sum of the individual resistances. Using Equation 20-10 and the thermal conductivities given in Table 20-4, the individual resistances can be determined. (*b*) You can find the temperature at the interface by applying $I = R_1/\Delta T$, to the lead bar only, and solving for ΔT in terms of the value for I found in Part (*a*).

SOLVE

(*a*) 1. Use $\Delta T = IR$ (Equation 20-13) to relate the thermal current to the temperature difference:

$$I = \frac{\Delta T}{R}$$

2. Using $R = |\Delta x|/(kA)$ (Equation 20-10), write each thermal resistance in terms of the individual thermal conductivities and geometric parameters:

$$R_{Pb} = \frac{|\Delta x_{Pb}|}{k_{Pb}A_{Pb}} \qquad R_{Ag} = \frac{|\Delta x_{Ag}|}{k_{Ag}A_{Ag}}$$

$$R_{Pb} = \frac{0.050\ \text{m}}{35.3\ \text{W}/(\text{m}\cdot\text{K}) \times (0.020\ \text{m} \times 0.030\ \text{m})} = 2.36\ \text{K/W}$$

$$R_{Ag} = \frac{0.050\ \text{m}}{429\ \text{W}/(\text{m}\cdot\text{K}) \times (0.020\ \text{m} \times 0.030\ \text{m})} = 0.194\ \text{K/W}$$

3. Find R_{eq} using the formula for resistors in series:

$$R_{eq} = R_{Pb} + R_{Ag} = 2.55\ \text{K/W} + 0.194 = \ \text{K/W}$$

4. Use $\Delta T = IR$ (Equation 20-13) to find the thermal current.

$$I = \frac{\Delta T}{R_{eq}} = \frac{100\ \text{K}}{2.55\ \text{K/W}} = \boxed{39.1\ \text{W}}$$

(*b*) 1. Calculate the temperature difference across the lead bar using the current and thermal resistance found in Part (*a*).

$$\Delta T_{Pb} = IR_{Pb} = 39.1\ \text{W} \times 2.36\ \text{K/W} = 92.4\ \text{K}$$

2. Use your result from the previous step to find the temperature at the interface.

$$T_{if} = 100°\text{C} - \Delta T_{Pb} = \boxed{8°\text{C}}$$

CHECK We check our Part-(*b*) result by calculating the temperature drop across the silver bar. That is, $\Delta T_{Ag} = IR_{Ag} = 232\ \text{W} \times 0.194\ \text{K/W} = 92°\text{C}$, which agrees with our Part-(*b*) result. Note that equivalent resistance (2.55 K/W) is greater than either of the individual resistances (2.36 K/W and 0.194 K/W).

Example 20-7 The Metal Bars in Parallel

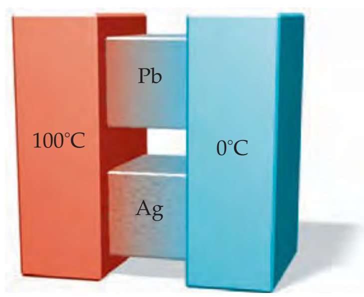

FIGURE 20-11

The metal bars in Example 20-6 are rearranged as shown in Figure 20-11. Find (*a*) the thermal current in each bar, (*b*) the total thermal current, and (*c*) the equivalent thermal resistance of the two-bar system.

PICTURE The current in each bar is found from $I = \Delta T/R$, where R is the thermal resistance of the bar (found in Example 20-6). The total current is the sum of the currents. The equivalent resistance can be found from Equation 20-14 or from $I_{total} = \Delta T/R_{eq}$.

SOLVE

(*a*) Calculate the thermal current for each bar:

$$I_{Pb} = \frac{\Delta T}{R_{Pb}} = \frac{100\ \text{K}}{2.36\ \text{K/W}} = \boxed{42.4\ \text{W}}$$

$$I_{Ag} = \frac{\Delta T}{R_{Ag}} = \frac{100\ \text{K}}{0.194\ \text{K/W}} = \boxed{515\ \text{W}}$$

(*b*) Add your results to find the total thermal current:

$$I_{\text{total}} = I_{\text{Pb}} + I_{\text{Ag}} = 42.4\text{ W} + 515\text{ W} = \boxed{557\text{ W}}$$

(*c*) 1. Use Equation 20-14 to calculate the equivalent resistance of the two bars in parallel:

$$\frac{1}{R_{\text{eq}}} = \frac{1}{R_{\text{Pb}}} + \frac{1}{R_{\text{Ag}}} = \frac{1}{2.36\text{ K/W}} + \frac{1}{0.194\text{ K/W}}$$

$$\text{so} \quad R_{\text{eq}} = \boxed{0.179\text{ K/W}}$$

2. Check your result using, $I_{\text{total}} = \Delta T/R_{\text{eq}}$:

$$I_{\text{total}} = \frac{\Delta T}{R_{\text{eq}}}$$

$$R_{\text{eq}} = \frac{\Delta T}{I_{\text{total}}} = \frac{100\text{ K}}{557\text{ W}} = \boxed{0.179\text{ K/W}}$$

CHECK With the bars in parallel the full temperature difference of 100 K is across each of them, so the thermal current through each is much higher than the thermal current was in either bar in Example 20-6, in which the bars were arranged in series so the temperature difference across either bar is considerably less than 100 K. In addition, in Example 20-7 the total current equals the sum of the currents in the bars, whereas in Example 20-6 the total current equals the current in either bar. Thus, that the total current (557 W) with the bars in parallel is more than 14 times larger than the total current (39.1 W) with the bars in series is a plausible result.

TAKING IT FURTHER Note that in part (*b*), the equivalent resistance is less than either of the individual resistances. This is always the case for resistors connected in parallel.

In the building industry, the thermal resistance of a square foot of cross-sectional area of a material is called its ***R* factor,** R_f. Consider a 32-ft^2 sheet of insulating material with thickness Δx and R factor R_f of 7.2. That is, each square foot (Figure 20-12) has a thermal resistance of 7.2°F/(Btu/h). The 32 square feet are in parallel, so the net resistance R_{net} is calculated using Equation 20-14, giving

$$\frac{1}{R_{\text{net}}} = \frac{1}{R_1} + \frac{1}{R_2} + \cdots = \frac{1}{R_f} + \frac{1}{R_f} + \cdots = \frac{32}{R_f} \qquad \text{so} \qquad R_{\text{total}} = \frac{R_f}{32}$$

Thus, the total thermal resistance R in °F/(Btu/h) equals the R factor divided by the area A in square feet. That is,

$$R_{\text{net}} = \frac{R_f}{A}$$

Because the net (total) resistance R_{net} is related to the conductivity k by $R_{\text{net}} = |\Delta x|/(kA)$ (Equation 20-10), we can express the R factor by

$$R_f = R_{\text{net}}A = \frac{|\Delta x|}{k} \qquad \text{20-15}$$

DEFINITION: *R* FACTOR

where $|\Delta x|$ is the thickness in inches and k is the conductivity in Btu·in/(h·ft^2·°F). Table 20-5 lists R factors for several materials. In terms of the R factor, Equation 20-9 for the thermal current is

$$\Delta T = IR_{\text{net}} = \frac{I}{A}R_f \qquad \text{20-16}$$

For slabs of insulating material of the same area in series, R_f is replaced by the equivalent R factor $R_{f\,\text{eq}}$

$$R_{f\,\text{eq}} = R_{f1} + R_{f2} + \cdots$$

FIGURE 20-12 For a 1-in. thickness of this material, the $R_f = 7.2$. (*Courtesy of Eugene Mosca.*)

Table 20-5 *R* **Factors for Various Building Materials**

Material	Thickness, in.	R_f, h · ft² · F°/Btu
Building board		
Gypsum or plasterboard	0.375	0.32
Plywood (Douglas fir)	0.5	0.62
Plywood or wood panels	0.75	0.93
Particle board, medium density	1.0	1.06
Finish flooring materials		
Carpet and fibrous pad	1.0	2.08
Tile		0.5
Wood, hardwood finish	0.75	0.68
Roof insulation	1.0	2.8

Asphalt roll roofing		0.15
Asphalt shingles		0.44
Windows		
Single-pane		0.9
Double pane		1.8

For parallel slabs, we calculate the thermal current through each slab and add all these currents to obtain the total current.

Example 20-8 Heat Loss Through a Roof *Context-Rich*

You are helping your friend's family put new asphalt shingles on the roof of their winter cabin. The 60-ft × 20-ft roof is made of 1.0-in-thick pine board covered with asphalt shingles. There is room for 8.0 in of roof insulation, and your friend's family is wondering how much of a difference it would make to their energy bill if they were to install two inches of insulation. Knowing that you are studying physics, they ask for your opinion.

PICTURE To assess the situation, you first calculate the *R* factor for each layer of the roof. Because the layers are in series, the equivalent *R* factor is just the sum of the individual *R* factors. The aim is to calculate the equivalent *R* factor of the roof with and without the insulation. The *R* factors for asphalt shingles and for roof insulation are found in Table 20-5. The *R* factor for the pine board is calculated from its thermal conductivity, which is found in Table 20-4. Note that when you shingle a roof you have to overlap the shingles, so there are two layers of asphalt shingling on the roof.

SOLVE

1. For a series combination, the equivalent *R* factor is the sum of the individual *R* factors:
$$R_{\text{f eq}} = R_{\text{f pine}} + R_{\text{f asph}} + R_{\text{f insul}}$$
2. The *R* factor for the double layer of shingles is twice the *R* factor for one layer:
$$R_{\text{f asph}} = 2(0.44\ \text{h}\cdot\text{ft}^2\cdot{}^\circ\text{F/Btu}) = 0.88\ \text{h}\cdot\text{ft}^2\cdot{}^\circ\text{F/Btu}$$
3. The *R* factor for 2.0 in of roof insulation is twice that for 1.0 in:
$$R_{\text{f insul}} = 2(2.8\ \text{h}\cdot\text{ft}^2\cdot{}^\circ\text{F/Btu}) = 5.6\ \text{h}\cdot\text{ft}^2\cdot{}^\circ\text{F/Btu}$$
4. The *R* factor for 1.0-in-thick pine is obtained from the conductivity:
$$R_{\text{f p}} = \frac{\Delta x_{\text{p}}}{k_{\text{p}}} = \frac{1.0\ \text{in}}{0.78\ \text{Btu}\cdot\text{in/(h}\cdot\text{ft}^2\cdot{}^\circ\text{F)}} = 1.28\ \text{h}\cdot\text{ft}^2\cdot{}^\circ\text{F/Btu}$$
5. The equivalent *R* factor without the insulation is:
$$R'_{\text{f eq}} = R_{\text{f pine}} + R_{\text{f asph}} = 1.28\ \text{h}\cdot\text{ft}^2\cdot{}^\circ\text{F/Btu} + 0.88\ \text{h}\cdot\text{ft}^2\cdot{}^\circ\text{F/Btu}$$
$$= 2.16\ \text{h}\cdot\text{ft}^2\cdot{}^\circ\text{F/Btu} = 2.2\ \text{h}\cdot\text{ft}^2\cdot{}^\circ\text{F/Btu}$$

6. The equivalent R factor with insulation is:

$$R_{\text{f eq}} = R_{\text{f pine}} + R_{\text{f asph}} + R_{\text{f insul}} = R'_{\text{f eq}} + R_{\text{f insul}}$$
$$= 2.16\ \text{h}\cdot\text{ft}^2\cdot{}^\circ\text{F/Btu} + 5.6\ \text{h}\cdot\text{ft}^2\cdot{}^\circ\text{F/Btu}$$
$$= 7.76\ \text{h}\cdot\text{ft}^2\cdot{}^\circ\text{F/Btu}$$

7. One comparison of the two equivalent R factors is their ratio:

$$\frac{R'_{\text{f eq}}}{R_{\text{f eq}}} = \frac{2.16}{7.76} = 0.28$$

8. By adding the insulation, the heat loss rate per square foot is reduced by 72 percent. Is it 72 percent of a large heat loss or a small heat loss? Using Equation 20-16 we calculate the thermal current I' through the entire roof:

$$\Delta T = IR_{\text{net}} = \frac{I}{A}R_{\text{f}}$$
$$I' = \frac{A}{R'_{\text{f eq}}}\Delta T = \frac{(60\ \text{ft})(20\ \text{ft})}{2.16\ \text{h}\cdot\text{ft}^2\cdot{}^\circ\text{F/Btu}}\Delta T = [556\ (\text{Btu/h})/{}^\circ\text{F}]\Delta T$$
$$= [5.6 \times 10^2\ (\text{Btu/h})/{}^\circ\text{F}]\Delta T$$

9. To complete the calculation, we estimate that the temperature inside the cabin is maintained at 70°F and the temperature outside the cabin during the winter is typically 40°F colder:

$$I' = [556\ (\text{Btu/h})/{}^\circ\text{F}]\Delta T$$
$$= [556\ (\text{Btu/h})/{}^\circ\text{F}](40^\circ\text{F}) = 22\,200\ \text{Btu/h}$$

and $I = 0.28I' = 0.28(22\,200\ \text{Btu/h}) = 6200\ \text{Btu/h}$

so the reduction due to the insulation is

$$I' - I = 22\,200\ \text{Btu/h} - 6200\ \text{Btu/h} = 16 \times 10^3\ \text{Btu/h}$$

10. Installing 2.0 in. of roof insulation reduces the heat loss through the roof by 16,000 Btu/h. The cabin is heated with propane, and the energy content of propane is 92,000 Btu/gal. Insulating the roof reduces consumption by approximately 4.2 gal of propane every 24 h of use.

Propane costs about $3.00/gal, so this amounts to a savings of approximately $12.60 per day, or $376 per month during the heating season. Your friend's family is impressed by the potential savings (and by the benefits of your physics knowledge). They decide to install the 2.0 in of roofing insulation.

CHECK It should come as no surprise that installing some insulation has a significant economic payback.

TAKING IT FURTHER These cost estimates do not include the cost of purchasing and installing the insulation.

PRACTICE PROBLEM 20-3 How much additional savings can possibly be had by adding even more insulation to the roof?

The thermal conductivity of air is very small compared with that of solid materials, which makes air a very good insulator. However, when there is a large air gap—say, between a storm window and the inside window—the insulating efficiency of air is greatly reduced because of convection. Whenever there is a temperature difference between different parts of the air space, convection currents act quickly to equalize the temperature, so the effective conductivity is greatly increased. For storm windows, air gaps of about 1 to 2 cm are optimal. Wider air gaps actually reduce the thermal resistance of a double-pane window due to convection.

The insulating properties of air are most effectively used when the air is trapped in small pockets that prevent convection from taking place. This is the principle underlying the excellent insulating properties of both goose down and Styrofoam.

If you touch the inside surface of a glass window when it is cold outside, you will observe that the surface is considerably colder than the inside air. The thermal resistance of windows is mainly due to thin films of insulating air that adhere to either side of the glass surface. The thickness of the glass has little effect on the overall thermal resistance. The air film on each side typically adds an R factor of about 0.45 per side. Thus, the R factor of a window with N separated glass layers is approximately $0.90N$, because of the two sides of each layer. Under windy conditions, the outside air film may be greatly decreased, leading to a smaller R factor for the window.

CONVECTION

Convection is the transfer of heat by the transport of the material medium itself. This thermal property is responsible for the great ocean currents as well as the global circulation of the atmosphere. In the simplest case, convection arises when a fluid (gas or liquid) is heated from below. The warm fluid then expands and rises as the cooler fluid sinks. The mathematical description of convection is very complex, because the flow depends on the temperature difference in different parts of the fluid, and this temperature difference is affected by the flow itself.

The heat transferred from an object to its surroundings by convection is approximately proportional to the area of the object and to the difference in temperature between the object and the surrounding fluid. It is possible to write an equation for the heat transferred by convection and to define a coefficient of convection, but the analyses of practical problems involving convection are quite complex and are not discussed here.

RADIATION

All objects emit and absorb electromagnetic radiation. When an object is in thermal equilibrium with its surroundings, it emits and absorbs radiation at the same rate. The rate at which an object radiates energy is proportional to both the surface area of the object and to the fourth power of its absolute temperature. This result, found empirically by Josef Stefan in 1879 and derived theoretically by Ludwig Boltzmann about five years later, is called the **Stefan–Boltzmann law:**

$$P_r = e\sigma AT^4 \tag{20-17}$$

STEFAN–BOLTZMANN LAW

where P_r is the power radiated, A is the surface area, σ is a universal constant called Stefan's constant, which has the value

$$\sigma = 5.6703 \times 10^{-8}\ \mathrm{W/(m^2 \cdot K^4)} \tag{20-18}$$

and e is the **emissivity** of the radiating surface, a dimensionless quantity between 0 and 1 that is dependent upon the composition of the surface of the object.

When electromagnetic radiation falls on an opaque object, part of the radiation is reflected and part is absorbed. Light-colored objects reflect most visible radiation, whereas dark objects absorb most of it. The rate at which an object absorbs radiation is given by

$$P_a = e\sigma AT_0^4 \tag{20-19}$$

where T_0 is the temperature of the source of the radiation and e is the emissivity of the surface of the absorbing object.

Suppose an object at temperature T is surrounded by objects at temperature T_0. If the object emits radiant energy at a greater rate than the object absorbs it, then the object cools, while the object's surroundings absorb radiation from the object and becomes warmer. If the object absorbs radiant energy at a greater rate than the object emits it, then the object warms and its surroundings cool. The net power radiated by an object at temperature T in an environment at temperature T_0 is

$$P_{net} = e\sigma A(T^4 - T_0^4) \tag{20-20}$$

When an object is in thermal equilibrium with its surroundings, $T = T_0$, and the object emits and absorbs radiation at the same rate.

An object that absorbs all radiation incident upon it and has an emissivity equal to 1 is called a **blackbody.** A blackbody is also an ideal radiator. The concept of a blackbody is important because the characteristics of the radiation emitted by such an ideal object can be calculated theoretically. Materials such as black velvet come close to being ideal blackbodies. The best practical approximation of an ideal blackbody is a small hole leading into a cavity, such as a keyhole in a closet door (Figure 20-13). Radiation incident on the hole has little chance of being reflected out

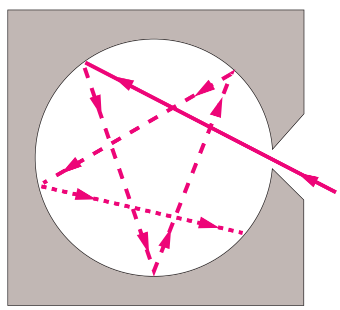

FIGURE 20-13 A hole in a cavity approximates an ideal blackbody. Radiation entering the cavity has little chance of leaving the cavity before it is completely absorbed. The radiation emitted through the hole (not shown) is therefore characteristic of the temperature of the walls of the cavity.

of the hole before the walls of the cavity absorb it. Thus, the radiation that is emitted out of the hole is characteristic of the temperature of the walls of the cavity.

The radiation emitted by an object at temperatures below approximately 600°C is not visible to the naked eye. Radiation of objects at room temperature is concentrated at wavelengths much longer than those of visible light. As an object is heated, the rate of energy emission increases, and the energy radiated extends to higher frequencies (and shorter wavelengths). Between about 600 and 700°C, enough of the radiated energy is in the visible spectrum for the object to glow a dull red. At higher temperatures, it may become bright red or even "white hot." Figure 20-14 shows the power radiated by a blackbody as a function of wavelength for three different temperatures. The wavelength at which the power is a maximum varies inversely with the temperature, a result known as Wien's displacement law:

$$\lambda_{max} = \frac{2.898\ \text{mm}\cdot\text{K}}{T} \qquad 20\text{-}21$$

WIEN'S DISPLACEMENT LAW

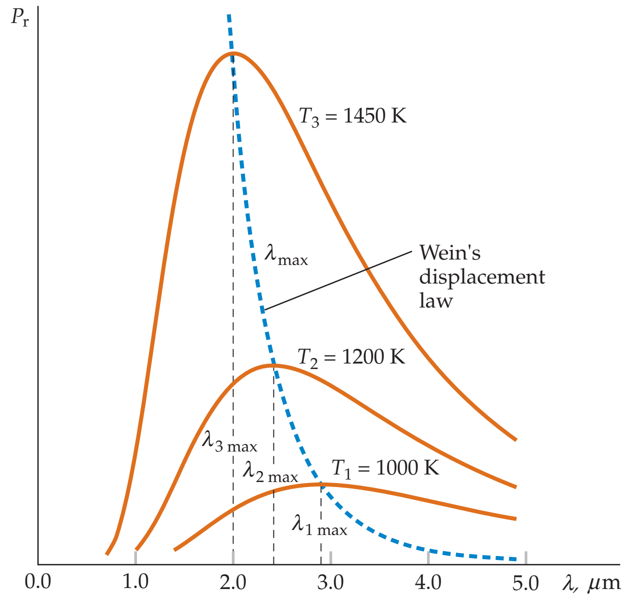

FIGURE 20-14 Radiated power versus wavelength for radiation emitted by a blackbody. The temperature of the emitting surface labels each plot on the graph. The wavelength λ_{max} at which the maximum power is emitted varies inversely with the absolute temperature T of the surface of the blackbody.

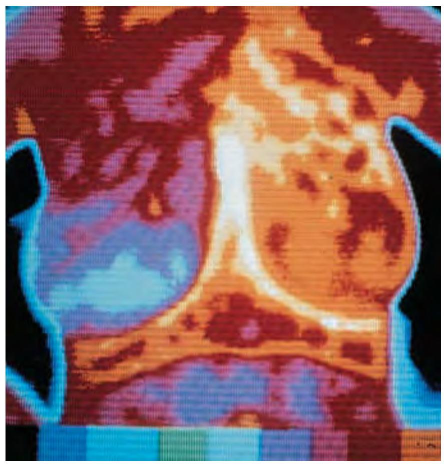
This law is used to determine the surface temperatures of stars by analyzing their radiation. It can also be used to map out the variation in temperature over different regions of the surface of an object. Such a map is called a thermograph. Thermographs can be used to detect cancer because cancerous tissue results in increased circulation, which produces a slight increase in skin temperature.

The spectral-distribution curves shown in Figure 20-14 played an important role in the history of physics. It was the discrepancy between theoretical calculations (using classic thermodynamics) that were used to generate blackbody spectral distributions and the actual experimental measurements of spectral distributions that led to Max Planck's first ideas about the quantization of energy in 1900.



A thermograph was used to detect this cancerous tumor. *(Science Photo Library/Photo Researchers, Inc.)*

Example 20-9 Radiation from the Sun

(*a*) The radiation emitted by the surface of the Sun emits maximum power at a wavelength of about 500 nm. Assuming the Sun to be a blackbody emitter, what is its surface temperature? (*b*) Calculate λ_{max} for a blackbody at room temperature, $T = 300$ K.

PICTURE The surface temperature and the wavelength at maximum emitted power are related by $\lambda_{max} = 2.898\ \text{mm}\cdot\text{K}/T$ (Equation 20-21).

SOLVE

(*a*) We can find T, given λ_{max} and using Wien's displacement law:

$$\lambda_{max} = \frac{2.898\ \text{mm}\cdot\text{K}}{T} \quad \text{so}$$

$$T = \frac{2.898\ \text{mm}\cdot\text{K}}{\lambda_{max}} = \frac{2.898\ \text{mm}\cdot\text{K}}{500\ \text{nm}} = \boxed{5800\ \text{K}}$$

(*b*) We can find λ_{max} from Wien's displacement law for $T = 300$ K:

$$\lambda_{max} = \frac{2.898\ \text{mm}\cdot\text{K}}{300\ \text{K}} = 9.66 \times 10^{-6}\ \text{m} = \boxed{9.66\ \mu\text{m}}$$

CHECK The Part-(*b*) result for λ_{max} is 19 times greater than 500 nm (the value of λ_{max} for the Sun), and the Part-(*a*) result of 5800 K for the surface temperature of the Sun is 19 times greater than 300 K, the surface temperature of the object in Part (*b*). Wien's law is that λ_{max} is inversely proportional to the temperature of the emitter, so the calculated results are as expected.

TAKING IT FURTHER The peak wavelength from the Sun is in the visible spectrum. The blackbody radiation spectrum describes the Sun's radiation spectrum fairly well, so the Sun is indeed a good example of a blackbody.

For $T = 300$ K, the spectrum peaks in the infrared at wavelengths much longer than the wavelengths visible to the eye. Surfaces that are not black to our eyes may act as blackbodies for infrared radiation and absorption. For example, it has been found experimentally that the skins of all human beings absorb all infrared radiation; hence, the emissivity of skin is 1.00 for this radiation process.

Example 20-10 Radiation from the Human Body

Try It Yourself

Calculate the net rate of heat loss in radiated energy for a naked person in a room at 20°C, assuming the person to be a blackbody with a surface area of 1.4 m^2 and a surface temperature of 33°C (= 306 K). (The surface temperature of the human body is slightly less than the internal temperature of 37°C because of the thermal resistance of the skin.)

PICTURE Use $P_{net} = e\sigma A(T^4 - T_0^4)$, with $e = 1$, $T = 306$ K, and $T_0 = 293$ K, to determine the difference between the emitted and absorbed power.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answer
Use $P_{net} = e\sigma A(T^4 - T_0^4)$, with $e = 1$, $T = 306$ K, and $T_0 = 293$ K.	$P_{net} = 111\text{ W} = \boxed{0.11\text{ kW}}$

CHECK A rate of 0.11 kW is equal to 2300 kcal/day. This is the correct order of magnitude.

TAKING IT FURTHER This large energy loss is approximately equal to the basal metabolic rate of about 120 W. We protect ourselves from this great loss of energy by wearing clothing, which, because of its low thermal conductivity, has a much lower outside temperature and therefore a much lower rate of thermal radiation.

When the temperature of an object T is not too different from the surrounding temperature T_0, a radiating object obeys Newton's law of cooling. We can see this by writing Equation 20-20 as

$$P_{net} = e\sigma A(T^4 - T_0^4) = e\sigma A(T^2 + T_0^2)(T^2 - T_0^2)$$
$$= e\sigma A(T^2 + T_0^2)(T + T_0)(T - T_0)$$

When $T - T_0$ is small, we can replace T by T_0 in the two sums with little change in the result. Then

$$P_{net} \approx e\sigma A(T_0^2 + T_0^2)(T_0 + T_0)(T - T_0) = 4e\sigma AT_0^3\,\Delta T$$

The net power radiated is approximately proportional to the temperature difference, in agreement with Newton's law of cooling. This result can also be obtained by using the differential approximation:

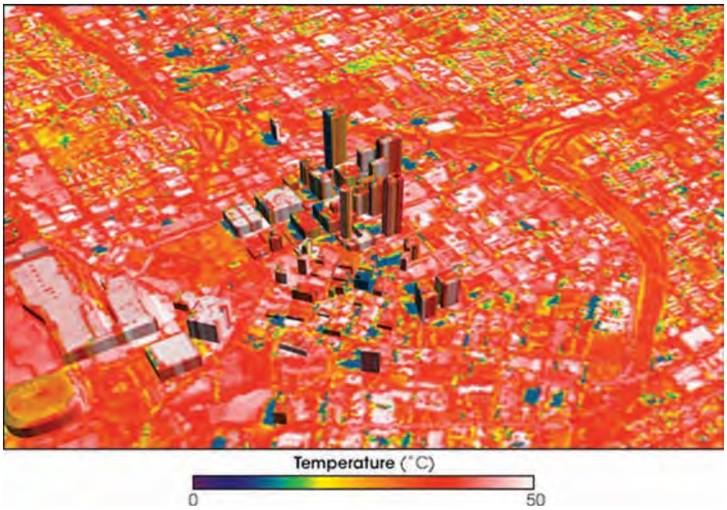
$$\Delta P_r \approx \left.\frac{dP_r}{dT}\right|_{T=T_0}(T - T_0)$$

where $P_r = e\sigma A(T^4 - T_0^4)$. For a small temperature difference $T - T_0$, we have

$$\Delta P_r = e\sigma A\, 4T^3\Big|_{T=T_0}(T - T_0) = 4e\sigma AT_0^3\,\Delta T$$

Physics Spotlight

Urban Heat Islands: Hot Nights in the City



The sides of the buildings facing away from the Sun appear dark blue or black in this thermogram of Atlanta, Georgia. This is because these sides are cooler than the sides receiving direct sunlight. Particularly hot temperatures appear white. *(NASA/Goddard Space Flight Center Scientific Visualization Studio.)*

In 1820, Luke Howard published records that listed several years of temperatures from London and its suburbs for days and nights. His records showed that London was warmer than the surrounding suburban and rural areas, and that this difference was most pronounced at nighttime. He found that London was an average of 2.1°C warmer at night than the surrounding rural area.[*] In 2004, observations showed that in the summertime Phoenix could be up to 10°C warmer at night than its surrounding area.[†] London and Phoenix are urban heat islands (UHIs). In general, cities with paved streets and many buildings are warmer than the surrounding countryside.

One important factor in the formation of UHIs is the lack of trees and other plants. During the day, plants cool the area around them because of all the water they release, which has a high latent heat. In rural areas, and even in green areas within cities, much of the energy is used to overcome the latent heat of water, rather than in increasing the surface temperature.[‡] In addition, plants reflect back much of the infrared (heat) wavelengths from solar radiation, while asphalt, steel, glass, concrete, and aluminum absorb and retain these infrared wavelengths. Another factor is the geometry of a city. Urban canyons, formed by tall buildings on either side of the streets, reflect infrared wavelengths to other absorbent surfaces.[#] Open areas allow radiation of the heat away from the ground and nearby structures.

In addition to radiated heat, rainwater runoff in urban areas can be heated by conduction. In August of 2001, a rainstorm in Cedar Rapids, Iowa, increased the temperature of a stream by 10.5°C in one hour, which killed many fish.[°] The falling rain itself was cooler than the stream, but most of the water entering the stream in that first hour ran over hot pavement. Similar sudden temperature increases have been noted in urban streams in Minnesota, Wisconsin, Oregon,[§] and California.[¶]

In 1996, in order to support the Olympics, an unprecedented weather measurement effort took place near Atlanta, Georgia.[**] One interesting revelation from this effort was that the area directly downwind of the city got more precipitation, as UHI-related convection changed weather patterns.[††] It also has been found that Dallas, San Antonio,[‡‡] and even Saint Louis[##] have more precipitation directly downwind, for up to 64 km from the city center. Convection changes caused by UHIs are complex, but the precipitation effects are measurable.

Urban planners are implementing ways to cool UHIs.[°°] In Chicago, city hall now has a "green roof" with plants and reflective walkways. The temperature of the rooftop is monitored and compared to the nearby dark asphalt roof of the Cook County building. The temperature of the planted roof can be over 33°C cooler than the asphalt roof.[§§] Several cities encourage the planting of trees,[¶¶] and others encourage the use of reflective surfaces,[***] permeable pavement, and the use of green roofs.[†††] Urban heat islands are being mediated by cool technologies.

Summary

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Thermal Expansion		
Coefficient of linear expansion	$\alpha = \frac{\Delta L/L}{\Delta T}$	20-2
Coefficient of volume expansion	$\beta = \frac{\Delta V/V}{\Delta T} = 3\alpha$	20-4, 20-5
2. The van der Waals Equation of State	The van der Waals equation of state describes the behavior of real gases over a wide range of temperatures and pressures, taking into account the space occupied by the gas molecules themselves and the attraction of the molecules to one another. $\left(P + \frac{an^2}{v^2}\right)(V - bn) = nRT$	20-6
3. Vapor Pressure	Vapor pressure is the pressure at which the liquid and gas phases of a substance are in equilibrium at a given temperature. The liquid boils at that temperature for which the external pressure equals the vapor pressure.	
4. The Triple Point	The triple point is the unique temperature and pressure at which the gas, liquid, and solid phases of a substance can coexist in equilibrium. At temperatures and pressures below the triple point, the liquid phase of a substance cannot exist.	
5. Heat Transfer	The three mechanisms by which energy is transferred due to a difference in temperature are radiation, conduction, and convection.	
Newton's law of cooling	For all mechanisms of heat transfer, if the temperature difference between the object and its surroundings is small, the rate of cooling of the object is approximately proportional to the temperature difference.	
6. Heat Conduction		
Current	The rate of conduction of heat is given by $I = \frac{dQ}{dt} = -kA\frac{dT}{dx}$ where I is the thermal current, k is the coefficient of thermal conductivity, and dT/dx is the temperature gradient.	20-7
Thermal resistance	$\Delta T = IR$ (20-9) where ΔT is the temperature decrease in the direction of the thermal current and R is the thermal resistance: $R = \frac{\|\Delta x\|}{kA}$	20-10
Equivalent resistance:		
series	$R_{eq} = R_1 + R_2 + \cdots$	20-12
parallel	$\frac{1}{R_{eq}} = \frac{1}{R_1} + \frac{1}{R_2} + \cdots$	20-14
R factor	The R factor is the thermal resistance in units of $\text{in}\cdot\text{ft}^2\cdot{}^\circ\text{F}/(\text{Btu/h})$ for a square foot of a slab of material $R_f = R_{net}A = \frac{\|\Delta x\|}{k}$	20-15
7. Thermal Radiation		
Rate of radiated power	$P_r = e\sigma AT^4$ (20-17) where $\sigma = 5.6703 \times 10^{-8}\ \text{W/m}^2\cdot\text{K}^4$ is Stefan's constant and e is the emissivity, which varies between 0 and 1 (depending on the composition of the surface of the object). Materials that are good heat absorbers are also good heat radiators.	

TOPIC	RELEVANT EQUATIONS AND REMARKS	
Net power radiated by an object at T to its environment at T_0	$P_{net} = e\sigma A(T^4 - T_0^4)$	20-20
Blackbody	A blackbody has an emissivity of 1. It is a perfect radiator, and it absorbs all radiation incident upon it.	
Wien's law	The power spectrum of electromagnetic energy radiated by a blackbody has a maximum at a wavelength λ_{max}, which varies inversely with the absolute temperature of the body: $$\lambda_{max} = \frac{2.898\ \text{mm}\cdot\text{K}}{T}$$	20-21

Answer to Concept Check

20-1 Wood is a poor conductor of heat and metal is a good conductor of heat. When your finger touches metal, the metal conducts heat away from your finger faster, and so the finger is cooled at a faster rate than if you touched wood.

Answers to Practice Problems

20-1 0.0563 K/W = 56.3 mK/W

20-2 $\Delta x = (1\text{ cm})(429)/(0.026) = 16\,500\text{ cm} = 165\text{ m}$

20-3 The thermal current is 6200 Btu/h with 2.0 in. of insulation. Thus, the maximum additional savings is 6200 Btu/h, which would save spending an additional \$146 per month during the heating season.

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • Why does the mercury level of a thermometer first decrease slightly when the thermometer is first placed in warm water?

2 • A large sheet of metal has a hole cut in the middle of it. When the sheet is heated, the area of the hole will (*a*) not change, (*b*) always increase, (*c*) always decrease, (*d*) increase if the hole is not in the exact center of the sheet, (*e*) decrease only if the hole is in the exact center of the sheet.

3 • Why is it a bad idea to place a tightly sealed glass bottle that is completely full of water, into your kitchen freezer in order to make ice? SSM

4 • The windows of your physics laboratory are left open on a night when the temperature of the outside drops well below freezing. A steel ruler and a wooden ruler were left on the window sill, and when you arrive in the morning they are both very cold. The coefficient of linear expansion of wood is about $5 \times 10^6\,\text{K}^{-1}$. Which ruler should you use to make the most accurate length measurements? Explain your answer.

5 • ENGINEERING APPLICATION Bimetallic strips are used both for thermostats and electrical circuit breakers. A bimetallic strip consists of a pair of thin strips of metal that have different coefficients of linear expansion and are bonded together to form one doubly thick strip. Suppose a bimetallic strip is constructed out of one steel strip and one copper strip, and suppose the bimetallic strip is curled in the shape of a circular arc with the steel strip on the outside. If the temperature of the strip is decreased, will the strip straighten out or curl more tightly?

6 • Metal A has a coefficient of linear expansion that is three times the coefficient of linear expansion of metal B. How do their coefficients of volume expansion β compare? (a) $\beta_A = \beta_B$, (b) $\beta_A = 3\beta_B$, (c) $\beta_A = 6\beta_B$, (d) $\beta_A = 9\beta_B$, (e) You cannot tell from the data given.

7 • The summit of Mount Rainier is 14 410 ft above sea level. Mountaineers say that you cannot hard boil an egg at the summit. This statement is true because at the summit of Mount Rainier (*a*) the air temperature is too low to boil water, (*b*) the air pressure is too low for alcohol fuel to burn, (*c*) the temperature of boiling water is not hot enough to hard boil the egg, (*d*) the oxygen content of the air is too low to support combustion, (*e*) eggs always break in climbers' backpacks.

8 • Which gases in Table 20-3 cannot be condensed by applying pressure at 20°C? Explain your answer.

9 •• The phase diagram in Figure 20-15 can be interpreted to yield information on how the boiling and melting points of water change with altitude. (*a*) Explain how this information can be obtained. (*b*) How might this information affect cooking procedures in the mountains? SSM

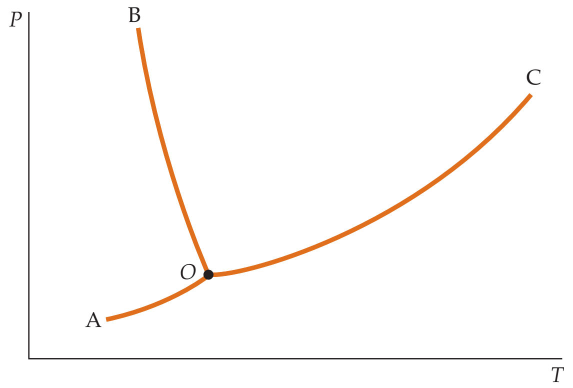

FIGURE 20-15 Problem 9

10 •• Sketch a phase diagram for carbon dioxide using information from Section 20-3.

11 •• Explain why the carbon dioxide on Mars is found in the solid state in the polar regions, even though the atmospheric pressure at the surface of Mars is only about 1 percent of the atmospheric pressure at the surface of Earth.

12 •• Explain why decreasing the temperature of your house at night in winter can save money on heating costs. Why does the cost of the fuel consumed to heat the house back to the daytime temperature in the morning not equal the savings realized by cooling it down in the evening and keeping it cool throughout the night?

13 •• Two solid cylinders made of materials A and B have the same lengths; their diameters are related by $d_A = 2d_B$. When the same temperature difference is maintained between the ends of the cylinders, they conduct heat at the same rate. Their thermal conductivities are therefore related by which of the following equations? (*a*) $k_A = k_B/4$, (*b*) $k_A = k_B/2$, (*c*) $k_A = k_B$, (*d*) $k_A = 2k_B$, (*e*) $k_A = 4k_B$ SSM

14 •• Two solid cylinders made of materials A and B have the same diameter; their lengths are related by $L_A = 2L_B$. When the same temperature difference is maintained between the ends of the cylinders, they conduct heat at the same rate. Their thermal conductivities are therefore related by which of the following equations? (*a*) $k_A = k_B/4$, (*b*) $k_A = k_B/2$, (*c*) $k_A = k_B$, (*d*) $k_A = 2k_B$, (*e*) $k_A = 4k_B$

15 •• If you feel the inside of a single-pane window during a very cold day, it is cold, even though the room temperature can be quite comfortable. Assuming the room temperature is 20.0°C and the outside temperature is 5.0°C, construct a plot of temperature versus position, starting from a point 5.0 m behind the window (inside the room) and ending at a point 5.0 m in front of the window. Explain the heat transfer mechanisms that occur along this path.

16 •• During the thermal retrofitting of many older homes in California, it was found that the 3.5-in-deep spaces between the wallboards and the outer sheathing were filled with just air (no insulation). Filling the spaces with insulating material certainly reduces heating and cooling costs; although, the insulating material is a better conductor of heat than air is. Explain why adding the insulation is a good idea.

ESTIMATION AND APPROXIMATION

17 •• You are using a cooking pot to boil water for a pasta dish. The recipe calls for at least 4.0 L of water to be used. You fill the pot with 4.0 L of room temperature water and note that this amount of water filled the pot to the brim. Knowing some physics, you are counting on the volume expansion of the steel pot to keep all of the water in the pot while the water is heated to a boil. Is your assumption correct? Explain. If your assumption is not correct, how much water runs over the sides of the pot due to the thermal expansion of the water? SSM

18 •• Liquid helium is stored in containers fitted with 7.00-cm-thick "superinsulation," consisting of numerous layers of very thin aluminized Mylar sheets. The rate of evaporation of liquid helium in a 200-L container is about 0.700 L per day when the container is stored at room temperature (20°C). The density of liquid helium is 0.125 kg/L and the latent heat of vaporization is 21.0 kJ/kg. Estimate the thermal conductivity of the superinsulation.

19 •• **BIOLOGICAL APPLICATION** Estimate the thermal conductivity of human skin. SSM

20 •• You are visiting Finland with a college friend and have met some Finnish friends. They talk you into taking part in a traditional Finnish after-sauna exercise, which consists of leaving the sauna, wearing only a bathing suit, and running out into the midwinter Finnish air. Estimate the rate at which you initially lose energy to the cold air. Compare this rate of initial energy loss to the resting metabolic rate of a typical human under normal temperature conditions. Explain the difference.

21 •• Estimate the rate of heat conduction through a 2.0-in-thick wooden door during a cold winter day in Minnesota. Include the brass doorknob. What is the ratio of the heat that escapes through the doorknob to the heat that escapes through the whole door? What is the total overall *R*-factor for the door, including the knob? The thermal conductivity of brass is 85 W/(m · K).

22 •• Estimate the effective emissivity of Earth, given the following information. The solar constant, which is the intensity of radiation incident on Earth from the Sun, is about 1.37 kW/m^2. Seventy percent of this energy is absorbed by Earth, and Earth's average surface temperature is 288 K. (Assume that the effective area that is absorbing the light is πR^2, where R is Earth's radius, while the blackbody-emission area is $4\pi R^2$.)

23 •• Black holes are highly condensed remnants of stars. Some black holes, together with a normal star, form binary systems. In such systems the black hole and the normal star orbit about the center of mass of the system. One way black holes can be detected from Earth is by observing the frictional heating of the atmospheric gases from the normal star that fall into the black hole. These gases can reach temperatures greater than 1.0×10^6 K. Assuming that the falling gas can be modeled as a blackbody radiator, estimate λ_{max} for use in an astronomical detection of a black hole. (This region is in the X-ray region of the electromagnetic spectrum.)

24 ••• **ENGINEERING APPLICATION, CONTEXT-RICH** Your cabin in northern Michigan has walls that consist of pine logs that have average thicknesses of about 20 cm. You decide to finish the interior of the cabin to improve the look and to increase the insulation of the exterior walls. You choose to buy insulation with an R-factor of 31 to cover the walls. In addition, you cover the insulation with 1.0-in.-thick gypsum wallboard. Assuming heat transfer is only due to conduction, estimate the ratio of thermal current through the walls during a cold winter night before the renovation to the thermal current through the walls following the renovation.

25 ••• **CONTEXT-RICH** You are in charge of transporting a liver from New York, New York, to Los Angeles, California, for a transplant surgery. The liver is kept cold in a styrofoam ice chest initially filled with 1.0 kg of ice. It is crucial that the liver temperature is never warmer than 5.0°C. Assuming the trip from the hospital in New York to the hospital in Los Angeles takes 7.0 h, estimate the *R*-value the styrofoam walls of the ice chest must have. SSM

THERMAL EXPANSION

26 •• You have inherited your grandfather's grandfather clock that was calibrated when the temperature of the room was 20°C. Assume that the pendulum consists of a thin brass rod of negligible mass with a compact heavy bob at its end. (*a*) During a hot day, when the temperature is 30°C, does the clock run fast or slow? Explain. (*b*) How much time does it gain or lose during this day?

27 •• **ENGINEERING APPLICATION** You need to fit a copper collar tightly around a steel shaft that has a diameter of 6.0000 cm at 20°C. The inside diameter of the collar at that temperature is 5.9800 cm. What temperature must the copper collar have so that it will just slip on the shaft, assuming the shaft itself remains at 20°C? SSM

28 •• **ENGINEERING APPLICATION** You have a copper collar and a steel shaft. At 20°C, the collar has an inside diameter of 5.9800 cm and the steel shaft has diameter of 6.0000 cm. The copper collar was heated. When its inside diameter exceeded 6.0000 cm it was slipped on the shaft. The collar fitted tightly on the shaft after they cooled to room temperature. Now, several years later, you need to remove the collar from the shaft. To do this you heat them both until you can just slip the collar off the shaft. What temperature must the collar have so that the collar will just slip off the shaft?

29 •• A container is filled to the brim with 1.4 L of mercury at 20°C. As the temperature of the container and mercury is increased to 60°C, a total of 7.5 mL of mercury spill over the brim of the container. Determine the linear expansion coefficient of the material that makes up the container.

30 •• A car with a 60.0-L steel gas tank is filled to the brim with 60.0 L of gasoline when the outside temperature is 10°C. The coefficient of volume expansion for gasoline at 20°C is $0.950 \times 10^{-3}\ \mathrm{K}^{-1}$. How much gasoline spills out of the tank when the outside temperature increases to 25°C? Take the expansion of the steel tank into account.

31 ••• What is the tensile stress in the copper collar of Problem 27 when its temperature returns to 20°C?

THE VAN DER WAALS EQUATION, LIQUID–VAPOR ISOTHERMS, AND PHASE DIAGRAMS

32 • (*a*) Calculate the volume of 1.00 mol of an ideal gas at a temperature of 100°C and a pressure of 1.00 atm. (*b*) Calculate the temperature at which 1.00 mol of steam at a pressure of 1.00 atm has the volume calculated in part (*a*). Use $a = 0.550\ \mathrm{Pa \cdot m^6/mol^2}$ and $b = 30.0\ \mathrm{cm^3/mol}$.

33 •• Using Figure 20-16, find the following quantities. (*a*) The temperature at which water boils on a mountain where the atmospheric pressure is 70.0 kPa, (*b*) the temperature at which water boils in a container where the pressure inside the container is 0.500 atm, and (*c*) the pressure at which water boils at 115°C. SSM

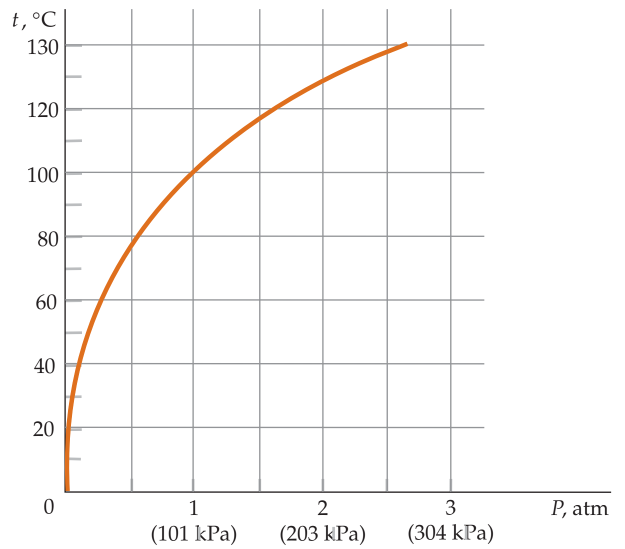

FIGURE 20-16 Problem 33

34 •• The van der Waals constants for helium are $a = 0.03412\ \mathrm{L^2 \cdot atm/mol^2}$ and $b = 0.0237$ L/mol. Use these data to find the volume in cubic centimeters occupied by one helium atom. Then, estimate the radius of the helium atom.

CONDUCTION

35 • A 20-ft × 30-ft slab of insulation has an *R* factor of 11. At what rate is heat conducted through the slab if the temperature on one side is a constant 68°F and the temperature on the other side is a constant 30°F? SSM

36 •• A copper cube and an aluminum cube, each with 3.00-cm-long edges, are arranged as shown in Figure 20-17. Find (*a*) the thermal resistance of each cube, (*b*) the thermal resistance of the two-cube combination, (*c*) the thermal current *I*, and (*d*) the temperature at the interface of the two cubes.

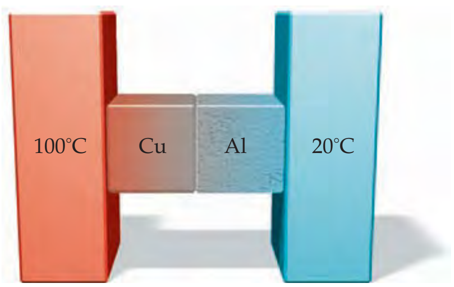

FIGURE 20-17 Problem 36

37 •• Two metal cubes, one copper and one aluminum, with 3.00-cm-long edges, are arranged in parallel, as shown in Figure 20-18. Find (*a*) the thermal current in each cube, (*b*) the total thermal current, and (*c*) the thermal resistance of the two-cube combination.

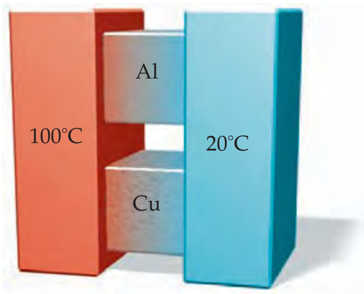

FIGURE 20-18 Problem 37

38 •• **ENGINEERING APPLICATION** The cost of air conditioning a house is approximately proportional to the rate at which heat is absorbed by the house from its surroundings divided by the coefficient of performance (COP) of the air conditioner. Let us denote the temperature difference between the inside temperature and the outside temperature as ΔT. Assuming that the rate at which heat is absorbed by a house is proportional to ΔT and that the air conditioner is operating ideally, show that the cost of air conditioning is proportional to $(\Delta T)^2$ divided by the temperature inside the house.

39 •• A spherical shell of thermal conductivity k has inside radius r_1 and outside radius r_2 (Figure 20-19). The inside of the shell is held at a temperature T_1, and the outside of the shell is held at temperature T_2, with $T_1 < T_2$. In this problem, you are to show that the thermal current through the shell is given by

$$I = -\frac{4\pi k r_1 r_2}{r_2 - r_1}(T_2 - T_1)$$

where I is positive if heat is transferred in the $+r$ direction. Here is a suggested procedure for obtaining this result: (1) obtain an expression for the thermal current I through a thin spherical shell of radius r and thickness dr when there is a temperature difference dT across the thickness of the shell; (2) explain why the thermal current is the same through each such thin shell; (3) express the thermal current I through such a shell element in terms of the area $A = 4\pi r^2$, the thickness dr, and the temperature difference dT across the element; and (4) separate variables (solve for dT in terms of r and dr) and integrate.

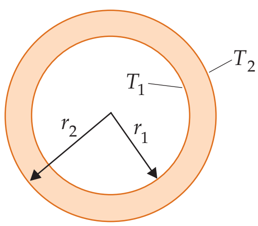

FIGURE 20-19 Problem 39

RADIATION

40 • **BIOLOGICAL APPLICATION** Calculate λ_{max} (the wavelength at which the emitted power is maximum) for a human skin. Assume the human skin is a blackbody emitter with a temperature of 33°C.

41 • The universe is filled with radiation that is believed to be left from the Big Bang. If the entire universe is considered to be a blackbody with a temperature equal to 2.3 K, what is the λ_{max} (the wavelength at which the power of the radiation is maximum) of this radiation? SSM

42 • What is the range of temperatures for star surfaces for which λ_{max} (the wavelength at which the power of the emitted radiation is maximum) is in the visible range?

43 • The heating wires of a 1.00-kW electric heater are red hot at a temperature of 900°C. Assuming that 100 percent of the heat released is due to radiation and that the wires act as blackbody emitters, what is the effective area of the radiating surface? (Assume a room temperature of 20°C.)

44 •• A blackened, solid copper sphere that has a radius equal to 4.0 cm hangs in an evacuated enclosure whose walls have a temperature of 20°C. If the sphere is initially at 0°C, find the initial rate at which its temperature changes, assuming that heat is transferred by radiation only. (Assume the sphere is a blackbody emitter.)

45 •• The surface temperature of the filament of an incandescent lamp is 1300°C. If the electric power input is doubled, what will the new temperature be? *Hint: Show that you can neglect the temperature of the surroundings.*

46 •• Liquid helium is stored at its boiling point (4.2 K) in a spherical can that is separated by an evacuated region of space from a surrounding shield that is maintained at the temperature of liquid nitrogen (77 K). If the can is 30 cm in diameter and is blackened on the outside so that it acts as a blackbody emitter, how much helium boils away per hour?

GENERAL PROBLEMS

47 • A steel tape is placed around Earth at the equator when the temperature is 0°C. What will the clearance between the tape and the ground (assumed to be uniform) be if the temperature of the tape increases to 30°C? Neglect the expansion of Earth.

48 •• Show that change in the density ρ of an isotropic material due to an increase in temperature ΔT is given by $\Delta\rho = -\beta\rho\,\Delta T$.

49 •• The solar constant is the power received from the Sun per unit area perpendicular to the Sun's rays at the mean distance of Earth from the Sun. Its value at the upper atmosphere of Earth is about 1.37 kW/m². Calculate the effective temperature of the Sun if it radiates like a blackbody. (The radius of the Sun is 6.96×10^8 m.) SSM

50 •• **ENGINEERING APPLICATION** As part of your summer job as an engineering intern at an insulation manufacturer, you are asked to determine the R-factor of insulating material. This particular material comes in $\frac{1}{2}$-in sheets. Using this material, you construct a hollow cube that has 12-in-long edges. You place a thermometer and a 100-W heater inside the box. After thermal equilibrium has been attained, the temperature inside the box is 90°C when the temperature outside the box is 20°C. Determine the R-factor of the material.

51 • (*a*) From the definition of β, the coefficient of volume expansion (at constant pressure), show that $\beta = 1/T$ for an ideal gas. (*b*) The experimentally determined value of β for N_2 gas at 0°C is $0.003673\ K^{-1}$. By what percent does this measured value of β differ from the value obtained by modeling N_2 as an ideal gas?

52 •• A rod of length L_A, made from material A, is placed next to a rod of length L_B, made from material B. The rods remain in thermal equilibrium with each other. (a) Show that even though the lengths of each rod will change with changes in the ambient temperature, the difference between the two lengths will remain constant if the lengths L_A and L_B are chosen such that $L_A/L_B = \alpha_B/\alpha_A$, where α_A and α_B are the coefficients of linear expansion, respectively. (*b*) If material B is steel, material A is brass, and $L_A = 250$ cm at 0°C, what is the value of L_B?

53 •• On average, the temperature of Earth's crust increases 1.0°C for every increase in depth of 30 m. The average thermal conductivity of Earth's crust material is 0.74 J/(m·s·K). What is the heat loss of Earth per second due to conduction from the core? How does this heat loss compare with the average power received from the Sun? SSM

54 •• A copper-bottomed saucepan containing 0.800 L of boiling water boils dry in 10.0 min. Assuming that all the heat is transferred through the flat copper bottom, which has a diameter of 15.0 cm and a thickness of 3.00 mm, calculate the temperature of the outside of the copper bottom while some water is still in the pan.

55 •• **ENGINEERING APPLICATION** A cylindrical steel hot-water tank of cylindrical shape has an inside diameter of 0.550 m and inside height of 1.20 m. The tank is enclosed by a 5.00-cm-thick insulating layer of glass wool whose thermal conductivity is 0.0350 W/(m·K). The insulation is covered by a thin sheet-metal skin. The steel tank and the sheet-metal skin have thermal conductivities that are much greater than that of the glass wool. How much electrical power must be supplied to this tank in order to maintain the water temperature at 75.0°C when the external temperature is 1.0°C?

56 •• The diameter d of a tapered rod of length L is given by $d = d_0(1 + ax)$, where a is a constant and x is the distance from one end. If the thermal conductivity of the material is k, what is the thermal resistance of the rod?

57 ••• A solid disk of radius r and mass m is spinning about a frictionless axis through its center and perpendicular to the disk, with angular velocity ω_1 at temperature T_1. The temperature of the disk decreases to T_2. Express the angular velocity ω_2, rotational kinetic energy K_2, and angular momentum L_2 in terms of their values at the temperature T_1 and the linear expansion coefficient α of the disk.

58 ••• **SPREADSHEET** Write a **spreadsheet** program to graph the average temperature of the surface of Earth as a function of emissivity, using the results of Problem 22. How much does the emissivity have to change in order for the average temperature to increase by 1 K? This result can be thought of as a model for the effect of increasing concentrations of greenhouse gases such as methane and CO_2 in Earth's atmosphere.

59 ••• A small pond has a layer of ice 1.00 cm thick floating on its surface. (*a*) If the air temperature is −10°C on a day when there is a breeze, find the rate in centimeters per hour at which ice is added to the bottom of the layer. The density of ice is 0.917 g/cm³. (*b*) How long do you and your friends have to wait for a 20.0-cm layer to be built up so you can play hockey? SSM

60 ••• A blackened copper cube that has 1.00-cm-long edges is heated to a temperature of 300°C, and then is placed in a vacuum chamber whose walls are at a temperature of 0°C. In the vacuum chamber, the cube cools radiatively. (*a*) Show that the (absolute) temperature T of the cube follows the differential equation: $(dT/dt) = -(e\sigma A/C)(T^4 - T_0^4)$, where C is the heat capacity of the cube, A is its surface area, e the emissivity, and T_0 the temperature of the vacuum chamber. (*b*) Using Euler's method (Section 5.4 of Chapter 5), numerically solve the differential equation to find $T(t)$, and graph it. Assume $e = 1.00$. How long does it take the cube to cool to a temperature of 15°C? SSM

PART IV **ELECTRICITY AND MAGNETISM**

CHAPTER 21

COPPER IS A CONDUCTOR, A MATERIAL THAT HAS SPECIFIC PROPERTIES WE FIND USEFUL BECAUSE THESE PROPERTIES MAKE IT POSSIBLE TO TRANSPORT ELECTRICITY. *(Brooks R. Dillard/www.yuprocks.com.)*

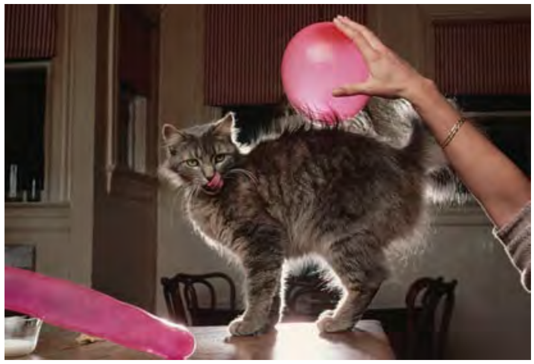
The Electric Field I: Discrete Charge Distributions

? What is the total charge of all the electrons in a penny? (See Example 21-1.)

While just a century ago we had nothing more than a few electric lights, we are now extremely dependent on electricity in our daily lives. Yet, although the use of electricity has only recently become widespread, the study of electricity has a history reaching long before the first electric lamp glowed. Observations of electrical attraction can be traced back to the ancient Greeks, who noticed that after amber was rubbed, it attracted small objects such as straw or feathers. Indeed, the word *electric* comes from the Greek word for amber, *elektron*.

Today, the study and use of electricity continue. Electrical engineers improve existing electrical technologies, increasing performance and efficiency in devices such as hybrid cars and electric power plants. Electrostatic paints are used in the auto industry for engine parts and for car frames and bodies. This painting process creates a more durable coat than does liquid paint, and is easier on the environment because no solvents are used.

In this chapter, we begin our study of electricity with electrostatics, the study of charges at rest. After introducing the concept of charge, we briefly look at conductors and insulators and how conductors can be given a net charge. We then study Coulomb's law, which describes the force exerted by one charge on another. Next, we introduce the electric field and show how it can be visualized by electric field lines that indicate the magnitude and direction of the field, just as we visualized the velocity field of a flowing fluid using streamlines (Chapter 13). Finally, we discuss the behavior of point charges and dipoles in electric fields.



A cat and a balloon. *(Roger Ressmeyer/CORBIS.)*

21-1 CHARGE

Suppose we rub a hard-rubber rod with fur and then suspend the rod from a string so that it is free to rotate. Now we bring a second hard-rubber rod that has been rubbed with fur near it. The rods repel each other (Figure 21-1*a*). Two glass rods that have been rubbed with silk (Figure 21-1*b*) also repel each other. But, when we place a hard-rubber rod rubbed with fur near a glass rod rubbed with silk (Figure 21-1*c*) they attract each other.

Rubbing a rod causes the rod to become electrically charged. If we repeat the experiment with various materials, we find that all charged objects fall into one of just two groups—those like the hard-rubber rod rubbed with fur and those like the glass rod rubbed with silk. Objects from the same group repel each other, while objects from different groups attract each other. Benjamin Franklin explained this by proposing a model in which every object has a *normal* amount of electricity that can be transferred from one object to the other when two objects are in close contact, as when they are rubbed together. One object would have an excess charge and the other object would have a deficiency of charge, and the excess charge equals the deficiency of charge. Franklin described the resulting charges as positive (plus sign) or negative (minus sign). He also chose positive to be the charge acquired by a glass rod when it is rubbed with a piece of silk. The piece of silk then acquires a negative charge of equal magnitude during the procedure. Based on Franklin's convention, if hard rubber and fur are rubbed together, the hard rubber acquires a negative charge and the fur acquires a positive charge. Two objects that have the same sign (both + or both −) repel each other, and two objects that have oppositely

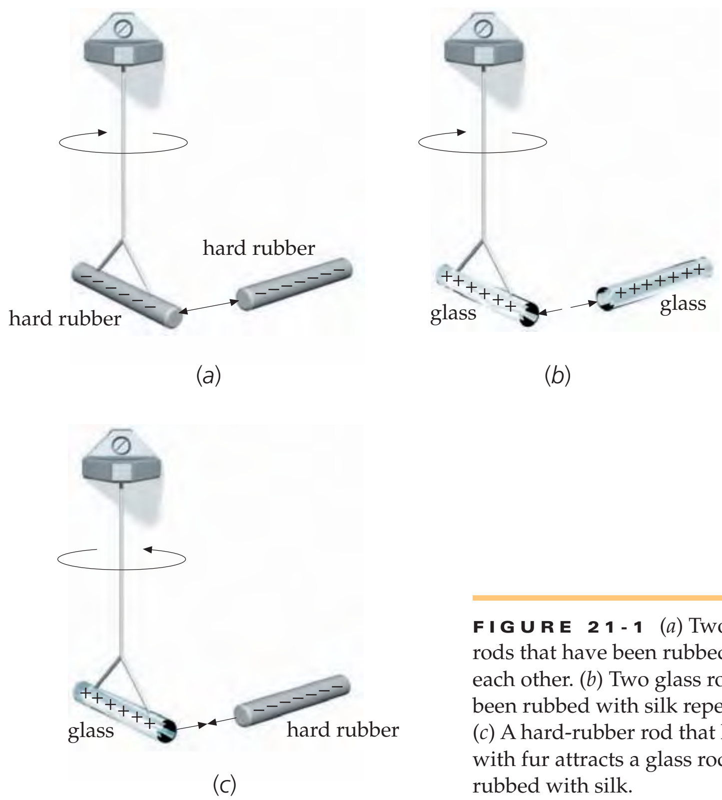


FIGURE 21-1 (*a*) Two hard-rubber rods that have been rubbed with fur repel each other. (*b*) Two glass rods that have been rubbed with silk repel each other. (*c*) A hard-rubber rod that has been rubbed with fur attracts a glass rod that has been rubbed with silk.

signed charges attract each other (Figure 21-1). An object that is neither positively nor negatively charged is said to be *electrically neutral.*

Today, we know that when glass is rubbed with silk, electrons are transferred from the glass to the silk. Because the silk is negatively charged (according to Franklin's convention, which we still use) electrons are said to have a negative charge. Table 21-1 is a short version of the **triboelectric series.** (In Greek *tribos* means "a rubbing.") The farther down the series a material is, the greater its affinity for electrons. If two of the materials are brought in contact, electrons are transferred from the material higher in the table to the one farther down the table. For example, if Teflon is rubbed with nylon, electrons are transferred from the nylon to the Teflon.

CHARGE QUANTIZATION

Matter consists of atoms that are neutral. Each atom has a tiny but massive nucleus that is composed of protons and neutrons. Protons are positively charged, whereas neutrons are neutral. The number of protons that an atom of a particular element has is the atomic number Z of that element. Surrounding the nucleus is an equal number of negatively charged electrons, leaving the atom with zero net charge. An electron is about 2000 times less massive than a proton, yet the charges of these two particles are exactly equal in magnitude. The charge of the proton is e and that of the electron is $-e$, where e is called the **fundamental unit of charge.** The charge of an electron or proton is an intrinsic property of the particle, just as mass and spin are intrinsic properties of these particles.

All observable charges occur in integral amounts of the fundamental unit of charge e; that is, *charge is quantized*. Any observable charge Q occurring in nature can be written $Q = \pm Ne$, where N is an integer.* For ordinary objects, however, N is usually very large and charge appears to be continuous, just as air appears to be continuous even though air consists of many discrete particles (molecules, atoms, and ions). To give an everyday example of N, charging a plastic rod by rubbing it with a piece of fur typically transfers 10^{10} or more electrons to the rod.

CHARGE CONSERVATION

When objects are rubbed together, one object is left with an excess of electrons and is therefore negatively charged; the other object is left with a deficit of electrons and is therefore positively charged. The net charge of the two objects remains constant; that is, *charge is conserved*. The **law of conservation of charge** is a fundamental law of nature. In certain interactions among elementary particles, charged particles such as electrons are created or annihilated. However, during these processes, equal amounts of positive and negative charge are produced or destroyed, so the net charge of the universe is unchanged.

The SI unit of charge is the coulomb, which is defined in terms of the unit of electric current, the ampere (A).† The **coulomb** (C) is the amount of charge flowing through a cross section of wire in one second when the current in the wire is one ampere. (The cross section of a solid object is the intersection of the object and a plane. Here we consider a plane that cuts across the wire.) The fundamental unit of electric charge e is related to the coulomb by

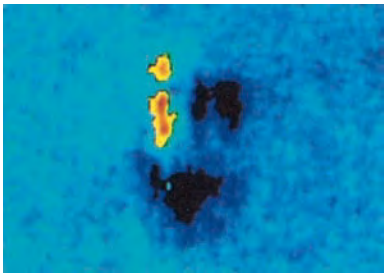
$$e = 1.602177 \times 10^{-19}\ \mathrm{C} \approx 1.60 \times 10^{-19}\ \mathrm{C} \qquad 21\text{-}1$$

FUNDAMENTAL UNIT OF CHARGE

---

* In the standard model of elementary particles, protons, neutrons, and some other elementary particles are made up of more fundamental particles called *quarks* that have charges of $\pm\frac{1}{3}e$ or $\pm\frac{2}{3}e$. Only combinations that result in a net charge of $\pm Ne$, where N is an integer, are observed.

† The ampere (A) is the unit of current used in everyday electrical work.



Charging by contact. A piece of plastic about 0.02 mm wide was charged by contact with a piece of nickel. Although the plastic carries a net positive charge, regions of negative charge (dark blue) as well as regions of positive charge (yellow) are indicated. The photograph was taken by sweeping a charged needle of width 10^{-7} m over the sample and recording the electrostatic force on the needle. *(Bruce Terris/IBM Almaden Research Center.)*

PRACTICE PROBLEM 21-1

A charge of magnitude 50 nC (1.0 nC = 10^{-9} C) can be produced in the laboratory by simply rubbing two objects together. How many electrons must be transferred to produce this charge?

Example 21-1 How Many in a Penny?

A copper penny* ($Z = 29$) has a mass of 3.10 grams. What is the total charge of all the electrons in the penny?

PICTURE The electrons have a total charge given by the number of electrons in the penny, N_e, multiplied by the charge of an electron, $-e$. The number of electrons in a copper atom is 29 (the atomic number of copper). So, the total charge of the electrons is 29 electrons multiplied by the number of copper atoms N_{at} in a penny. To find N_{at}, we use the fact that one mole of any substance has Avogadro's number ($N_A = 6.02 \times 10^{23}$) of particles (molecules, atoms, or ions), and the number of grams in one mole of copper is the molar mass M, which is 63.5 g/mol for copper.

SOLVE

1. The total charge Q is the number of electrons multiplied by the charge: $$Q = N_e(-e)$$
2. The number of electrons is Z multiplied by the number of copper atoms N_{at}: $$N_e = ZN_{at}$$
3. Compute the number of copper atoms in 3.10 g of copper: $$N_{at} = (3.10\text{ g})\frac{6.02 \times 10^{23}\text{ atoms/mol}}{63.5\text{ g/mol}} = 2.94 \times 10^{22}\text{ atoms}$$
4. Compute the number of electrons N_e: $$N_e = ZN_{at} = (29\text{ electrons/atom})(2.94 \times 10^{22}\text{ atoms}) = 8.53 \times 10^{23}\text{ electrons}$$
5. Use this value of N_e to find the total charge: $$Q = N_e \times (-e) = (8.53 \times 10^{23}\text{ electrons})(-1.60 \times 10^{-19}\text{ C/electron}) = \boxed{-1.37 \times 10^5\text{ C}}$$

CHECK There are $29 \times (6.02 \times 10^{23})$ electrons in 63.5 g of copper, so in 3.10 g of copper there are $(3.10/63.5) \times 29 \times (6.02 \times 10^{23}) = 8.53 \times 10^{23}$ electrons—in agreement with our step-4 result.

PRACTICE PROBLEM 21-2 If one million electrons were given to each person in the United States (about 300 million people), what percentage of the number of electrons in a penny would this represent?

* The penny was composed of 100 percent copper from 1793 to 1837. In 1982, the composition changed from 95 percent copper and 5 percent zinc to 2.5 percent copper and 97.5 percent zinc.

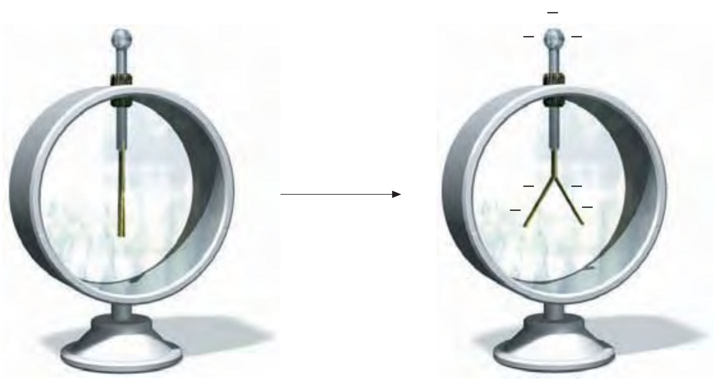


FIGURE 21-2 An electroscope. Two gold leaves are attached to a conducting post that has a conducting ball on top. The ball, post, and leaves are insulated from the container. When uncharged, the leaves hang together vertically. When the ball is touched by a negatively charged plastic rod, some of the negative charge from the rod is transferred to the ball and moves to the gold leaves, which then spread apart because of electrical repulsion between their negative charges. (Touching the ball with a positively charged glass rod would also cause the leaves to spread apart. In this case, the positively charged glass rod would remove electrons from the metal ball, leaving a net positive charge on the ball, rod, and leaves.)

21-2 CONDUCTORS AND INSULATORS

In many materials, such as copper and other metals, some of the electrons are free to move about the entire material. Such materials are called **conductors.** In other materials, such as wood or glass, all the electrons are bound to nearby atoms and none can move freely. These materials are called **insulators.**

In a single atom of copper, 29 electrons are bound to the nucleus by the electrostatic attraction between the negatively charged electrons and the positively charged nucleus. The outer (valence) electrons are more weakly bound to a nucleus than the inner (core) electrons. When a large number of copper atoms are combined in a piece of metallic copper, the strength of the attractions of electrons to a nucleus of an atom is reduced by their interactions with the electrons and nuclei of neighboring atoms. One or more of the valence electrons in each atom is no longer bound to the atom but is free to move about the whole piece of metal, much as an air molecule is free to move about in a room. The number of these free electrons depends on the particular metal, but it is typically about one per atom. (The free electrons are also referred to as conduction electrons or delocalized electrons.) An atom that has an electron removed or added, resulting in a net charge on the atom, is called an **ion.** In metallic copper, the copper ions are arranged in a regular array called a *lattice.* A conductor is neutral if for each lattice ion having a positive charge $+e$ there is a free electron having a negative charge $-e$. The net charge of the conductor can be changed by adding or removing electrons. A conductor that has a negative net charge has a surplus of free electrons, while a conductor that has a positive net charge has a deficit of free electrons.

CONCEPT CHECK 21-1

Two identical conducting spheres, one that has an initial charge $+Q$ and the other is initially uncharged, are brought into contact. (*a*) What is the new charge on each sphere? (*b*) While the spheres are in contact, a positively charged rod is moved close to one sphere, causing a redistribution of the charges on the two spheres so the charge on the sphere closest to the rod has a charge of $-Q$. What is the charge on the other sphere?

CHARGING BY INDUCTION

The conservation of charge is illustrated by a simple method of charging a conductor called **charging by induction,** as shown in Figure 21-3. Two uncharged metal spheres touch each other. When a positively charged rod (Figure 21-3*a*) is brought near one of the spheres, conduction electrons flow from one sphere to the other, toward the positively charged rod. The positively charged rod in Figure 21-3*a* attracts the negatively charged electrons, and the sphere nearest the rod acquires electrons from the sphere farther away. This leaves the near

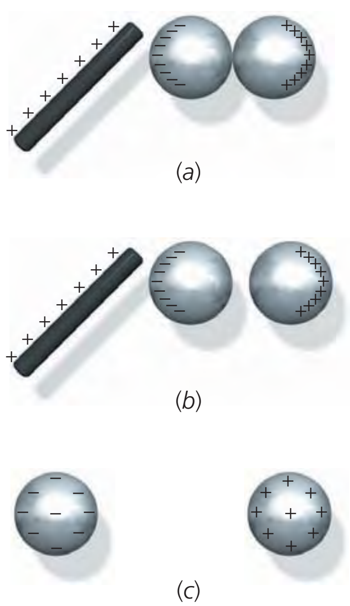

FIGURE 21-3 Charging by induction. (*a*) Neutral conductors in contact become oppositely charged when a charged rod attracts electrons to the left sphere. (*b*) If the spheres are separated before the rod is removed, they will retain their equal and opposite charges. (*c*) When the rod is removed and the spheres are far apart, the distribution of charge on each sphere approaches uniformity.

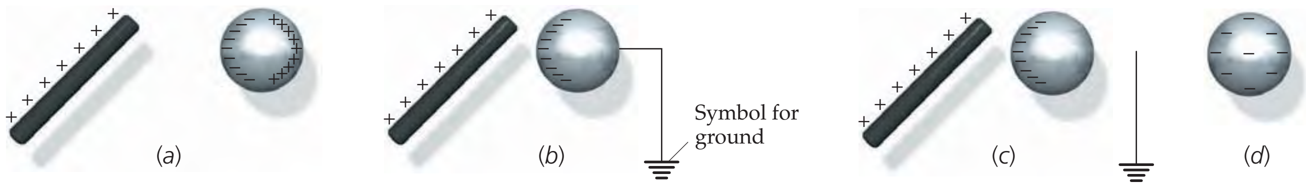

FIGURE 21-4 Induction via grounding. (*a*) The free charge on the single neutral conducting sphere is polarized by the positively charged rod, which attracts negative charges on the sphere. (*b*) When the conductor is grounded by connecting it with a wire to a very large conductor, such as Earth, electrons from the ground neutralize the positive charge on the far face. The conductor is then negatively charged. (*c*) The negative charge remains if the connection to the ground is broken before the rod is removed. (*d*) After the rod is removed, the sphere has a uniform negative charge.

sphere with a net negative charge and the far sphere with an equal net positive charge. A conductor that has *separated* equal and opposite charges is said to be **polarized.** If the spheres are separated before the rod is removed, they will be left with equal amounts of opposite charges (Figure 21-3*b*). A similar result would be obtained with a negatively charged rod, which would drive electrons from the near sphere to the far sphere.

For many purposes, Earth itself can be modeled as an infinitely large conductor that has an infinite supply of charged particles. If a conductor is electrically connected to Earth it is said to be **grounded.** Grounding a metal sphere is indicated schematically in Figure 21-4*b* by a connecting wire ending in parallel horizontal lines. Figure 21-4 demonstrates how we can induce a charge in a single conductor by transferring charge from Earth through a ground wire and then breaking the connection to the ground. (In practice, a person standing on the floor and touching the sphere with his hand provides an adequate ground for electrostatic demonstrations such the one described here.)

CONCEPT CHECK 21-2

Two identical conducting spheres are charged by induction and then separated by a large distance; sphere 1 has charge $+Q$ and sphere 2 has charge $-Q$. A third identical sphere is initially uncharged. If sphere 3 is touched to sphere 1 and separated, then touched to sphere 2 and separated, what is the final charge on each of the three spheres?

The lightning rod on this building is grounded so that it can conduct electrons from the ground to the positively charged clouds, thus neutralizing them. *(© Grant Heilman.)*

These fashionable ladies are wearing hats with metal chains that drag along the ground, which were supposed to protect them from lightning. *(Ann Roman Picture Library.)*

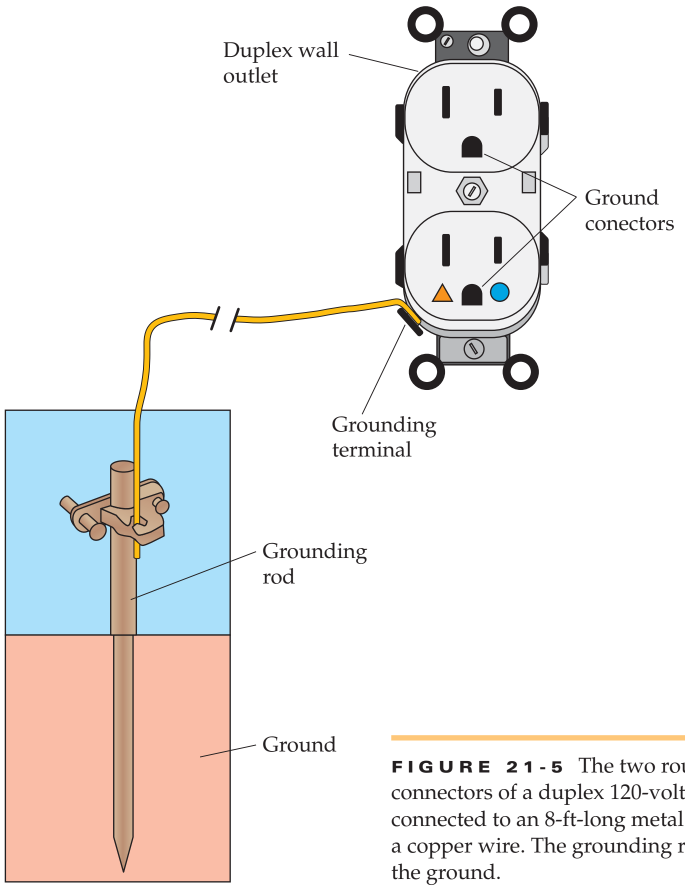

FIGURE 21-5 The two round ground connectors of a duplex 120-volt wall outlet are connected to an 8-ft-long metal grounding rod by a copper wire. The grounding rod is driven into the ground.

21-3 COULOMB'S LAW

Charles Coulomb (1736–1806) studied the force exerted by one charge on another using a torsion balance of his own invention.* In Coulomb's experiment, the charged spheres were much smaller than the distance between them so that the charges could be treated as point charges. Coulomb used the method of charging by induction to produce equally charged spheres and to vary the amount of charge on the spheres. For example, beginning with charge q_0 on each sphere, he could reduce the charge to $\frac{1}{2}q_0$ by temporarily grounding one sphere to discharge it, disconnecting it from ground, and then placing the two spheres in contact. The results of the experiments of Coulomb and others are summarized in **Coulomb's law:**

> The force exerted by one point charge on another acts along the line between the charges. It varies inversely as the square of the distance separating the charges and is proportional to the product of the charges. The force is repulsive if the charges have the same sign and attractive if the charges have opposite signs.
>
> COULOMB'S LAW

Coulomb's torsion balance. *(Bundy Library, Norwalk, CT.)*

* Coulomb's experimental apparatus was essentially the same as that described for the Cavendish experiment in Chapter 11, with the masses replaced by small charged spheres. For the magnitudes of charges easily transferred by rubbing, the gravitational attraction of the spheres is completely negligible compared with their electric attraction or repulsion.

The *magnitude* of the electric force exerted by a point charge q_1 on another point charge q_2 a distance r away is thus given by

$$F = \frac{k|q_1 q_2|}{r^2} \qquad 21\text{-}2$$

COULOMB'S LAW FOR THE MAGNITUDE OF THE FORCE EXERTED BY q_1 ON q_2

where k is an experimentally determined positive constant called the **Coulomb constant,** which has the value

$$k = 8.99 \times 10^9\ \mathrm{N \cdot m^2/C^2} \qquad 21\text{-}3$$

If q_1 is at position $\vec{r}_1$ and q_2 is at $\vec{r}_2$ (Figure 21-6), the force $\vec{F}_{12}$ exerted by q_1 on q_2 is

$$\vec{F}_{12} = \frac{kq_1q_2}{r_{12}^2}\hat{r}_{12} \qquad 21\text{-}4$$

COULOMB'S LAW (VECTOR FORM)

where $\vec{r}_{12} = \vec{r}_2 - \vec{r}_1$ is the vector pointing from q_1 to q_2, and $\hat{r}_{12} = \vec{r}_{12}/r_{12}$ is a unit vector in the same direction.

In accord with Newton's third law, the electrostatic force $\vec{F}_{21}$ exerted by q_2 on q_1 is the negative of $\vec{F}_{12}$. Note the similarity between Coulomb's law and Newton's law of gravity. (See Equation 11-3.) Both are inverse-square laws. But the gravitational force between two particles is proportional to the masses of the particles and is always attractive, whereas the electric force is proportional to the charges of the particles and is repulsive if the charges have the same sign and attractive if they have opposite signs.

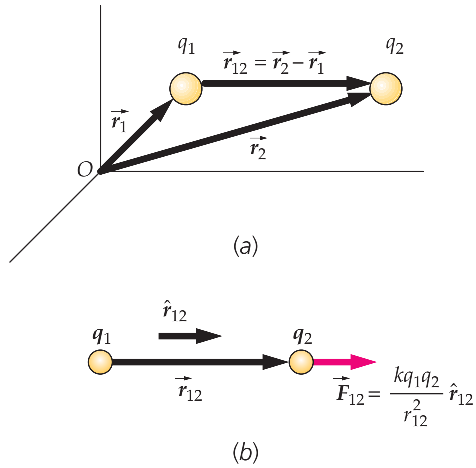

FIGURE 21-6 (*a*) Charge q_1 at position $\vec{r}_1$ and charge q_2 at $\vec{r}_2$ relative to the origin *O*. (*b*) The force $\vec{F}_{12}$ exerted by q_1 on q_2 is in the direction of the vector $\vec{r}_{12} = \vec{r}_2 - \vec{r}_1$ if both charges have the same sign, and in the opposite direction if they have opposite signs. The unit vector $\hat{r}_{12} = \vec{r}_{12}/r_{12}$ is in the direction from q_1 to q_2.

! Equation 21-4 gives the correct direction for the force, whether or not the two charges are both positive, both negative, or one positive and one negative.

Example 21-2 Electric Force in Hydrogen

In a hydrogen atom, the electron is separated from the proton by an average distance of about 5.3×10^{-11} m. Calculate the magnitude of the electrostatic force of attraction exerted by the proton on the electron.

PICTURE Assign the proton as q_1 and the electron as q_2. Use Coulomb's law to determine the magnitude of the electrostatic force of attraction exerted by the proton on the electron.

SOLVE

1. Sketch the electron and the proton and label the sketch with the suitable symbols (Figure 21-7):

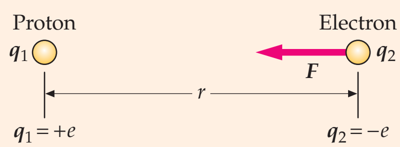

FIGURE 21-7

2. Use the given information and Equation 21-2 (Coulomb's law) to calculate the electrostatic force:

$$F = \frac{k|q_1q_2|}{r^2} = \frac{ke^2}{r^2} = \frac{(8.99 \times 10^9\ \mathrm{N \cdot m^2/C^2})(1.60 \times 10^{-19}\ \mathrm{C})^2}{(5.3 \times 10^{-11}\ \mathrm{m})^2}$$

$$= \boxed{8.2 \times 10^{-8}\ \mathrm{N}}$$

CHECK The order of magnitude is plausible. The powers of ten in the numerator combined are $10^9 \times 10^{-38} = 10^{-29}$, the power of ten in the denominator is 10^{-22}, and $10^{-29}/10^{-22} = 10^{-7}$. In comparison, $8.2 \times 10^{-8} \approx 10^{-7}$.

TAKING IT FURTHER Compared with macroscopic interactions, this is a very small force. However, because the mass of the electron is only about 10^{-30} kg, this force produces an acceleration of $F/m \approx 9 \times 10^{22}\ \mathrm{m/s^2}$. The proton is almost 2000 times more massive than the electron, so the acceleration of the proton is about $4 \times 10^{19}\ \mathrm{m/s^2}$. To put these accelerations in perspective, the acceleration due to gravity g is a mere $10^1\ \mathrm{m/s^2}$.

PRACTICE PROBLEM 21-3 Two point charges of 0.0500 μC each are separated by 10.0 cm. Find the magnitude of the force exerted by one point charge on the other.

Because the electrical force and the gravitational force between any two particles both vary inversely with the square of the distance between the particles, the ratio of these forces is independent of that distance. We can therefore compare the relative strengths of the electrical and gravitational forces for elementary particles such as the electron and proton.

Example 21-3 Ratio of Electric and Gravitational Forces

Compute the ratio of the electric force to the gravitational force exerted by a proton on an electron in a hydrogen atom.

PICTURE Use Coulomb's law and $q_1 = e$ and $q_2 = -e$ to find the electric force. Use Newton's law of gravity, the mass of the proton, $m_p = 1.67 \times 10^{-27}$ kg, and the mass of the electron, $m_e = 9.11 \times 10^{-31}$ kg, to find the gravitational force.

SOLVE

1. Express the magnitudes of the electric force F_e and the gravitational force F_g in terms of the charges, masses, separation distance r, and electrical and gravitational constants:

$$F_e = \frac{ke^2}{r^2} \qquad F_g = \frac{Gm_pm_e}{r^2}$$

2. Determine the ratio. Note that the separation distance r cancels:

$$\frac{F_e}{F_g} = \frac{ke^2}{Gm_pm_e}$$

3. Substitute numerical values:

$$\frac{F_e}{F_g} = \frac{(8.99 \times 10^9\ \mathrm{N \cdot m^2/C^2})(1.60 \times 10^{-19}\ \mathrm{C})^2}{(6.67 \times 10^{-11}\ \mathrm{N \cdot m^2/kg^2})(1.67 \times 10^{-27}\ \mathrm{kg})(9.11 \times 10^{-31}\ \mathrm{kg})}$$

$$= \boxed{2.27 \times 10^{39}}$$

CHECK In the numerator of the fraction in step 3, the coulomb units cancel out. In the denominator of the fraction, the kilogram units cancel out. The result is that both numerator and denominator have units of $\mathrm{N \cdot m^2}$. The fraction has no units, as expected for a ratio of two forces.

TAKING IT FURTHER The fact that the ratio (step 3) is so large reveals why the effects of gravity are not considered when discussing atomic or molecular interactions.

Although the gravitational force is incredibly weak compared with the electric force and plays essentially no role at the atomic level, it is the dominant force between large objects such as planets and stars. Because large objects contain almost equal numbers of positive and negative charges, the attractive and repulsive electrical forces cancel. The net force between astronomical objects is therefore essentially the force of gravitational attraction alone.

FORCE EXERTED BY A SYSTEM OF CHARGES

In a system of charges, each charge exerts a force, given by Equation 21-4, on every other charge. The net force on any charge is the vector sum of the individual forces exerted on that charge by all the other charges in the system. This result follows from the *principle of superposition* of forces.

See **Math Tutorial** *for more information on* **Trigonometry**

Example 21-4 Electric Force on a Charge

Three point charges lie on the x axis; q_1 is at the origin, q_2 is at $x = 2.0$ m, and q_0 is at position x ($x > 2.0$ m). (*a*) Find the total electric force on q_0 due to q_1 and q_2 if $q_1 = +25$ nC, $q_2 = -10$ nC, $q_0 = +20$ nC, and $x = 3.5$ m. (*b*) Find an expression for the total electric force on q_0 due to q_1 and q_2 throughout the region $2.0\text{ m} < x < \infty$.

PICTURE The total electric force on q_0 is the vector sum of the force $\vec{F}_{10}$ exerted by q_1 and the force $\vec{F}_{20}$ exerted by q_2. The individual forces are found using Coulomb's law and the principle of superposition. Note that $\hat{r}_{10} = \hat{r}_{20} = \hat{i}$ because both $\hat{r}_{10}$ and $\hat{r}_{20}$ are in the $+x$ direction.

SOLVE

(*a*) 1. Draw a sketch of the system of charges (Figure 21-8*a*). Identify the distances r_{10} and r_{20} on the graph:

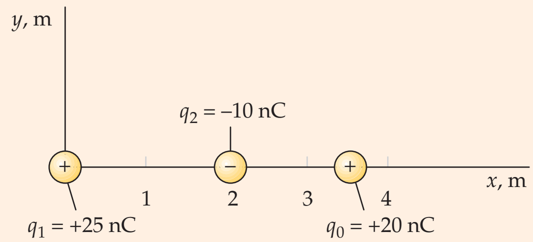

FIGURE 21-8*a*

2. Find the force exerted by q_1 on q_0. These charges have the same sign, so they repel. The force is in the $+x$ direction:

$$F_{10} = \frac{k|q_1q_0|}{r_{10}^2}$$

$$\vec{F}_{10} = +F_{10}\hat{i} = +\frac{k|q_1q_0|}{r_{10}^2}\hat{i} = \frac{(8.99 \times 10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(25 \times 10^{-9}\ \text{C})(20 \times 10^{-9}\ \text{C})}{(3.5\ \text{m})^2}\hat{i}$$

$$= (0.37 \times 10^{-6}\ \text{N})\hat{i}$$

3. Find the force exerted by q_2 on q_0. These charges have opposite signs, so they attract. The force is in the $-x$ direction:

$$F_{20} = \frac{k|q_2q_0|}{r_{20}^2}$$

$$\vec{F}_{20} = -F_{20}\hat{i} = -\frac{k|q_2q_0|}{r_{20}^2}\hat{i} = -\frac{(8.99 \times 10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(10 \times 10^{-9}\ \text{C})(20 \times 10^{-9}\ \text{C})}{(1.5\ \text{m})^2}\hat{i}$$

$$= -(0.80 \times 10^{-6}\ \text{N})\hat{i}$$

4. Combine your results to obtain the net force.

$$\vec{F}_{\text{net}} = \vec{F}_{10} + \vec{F}_{20} = \boxed{-(0.43 \times 10^{-6}\ \text{N})\hat{i}}$$

(*b*) 1. Draw a sketch of the system of charges. Label the distances r_{10} and r_{20} (Figure 21-8*b*):

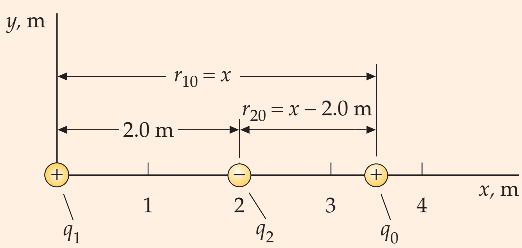

FIGURE 21-8*b*

2. Find an expression for the force on q_0 due to q_1.

$$\vec{F}_{10} = \frac{k|q_1q_0|}{x^2}\hat{i}$$

3. Find an expression for the force on q_0 due to q_2.

$$\vec{F}_{20} = -\frac{k|q_2q_0|}{(x - 2.0\text{ m})^2}\hat{i}$$

4. Combine your results to obtain an expression for the net force.

$$\vec{F}_{\text{net}} = \vec{F}_{10} + \vec{F}_{20} = \left(\frac{k|q_1q_0|}{x^2} - \frac{k|q_2q_0|}{(x - 2.0\text{ m})^2}\right)\hat{i}$$

CHECK In steps 2, 3, and 4 of Part (*b*) , both forces approach zero as $x \rightarrow \infty$, as expected. In addition, the magnitude of the step-3 result approaches infinity as $x \rightarrow 2.0$ m, also as expected.

TAKING IT FURTHER The charge q_2 is located between charges q_1 and q_0, so you might think that the presence of q_2 will affect the force $\vec{F}_{10}$ exerted by q_1 on q_0. However, this is not the case. That is, the presence of q_2 does not effect the force $\vec{F}_{10}$ exerted by q_1 on q_0. (That this is so is called the principle of superposition.) Figure 21-9 shows the x component of the force on q_0 as a function of the position x of q_0 throughout the region $2.0\text{ m} < x < \infty$. Near q_2 the force due to q_2 dominates, and because opposite charges attract the force on q_2 is in the $-x$ direction. For $x \gg 2.0$ m the force is in the $+x$ direction. This is because for large x the distance between q_1 and q_2 is negligible so the force due to the two charges is almost the same as that for a single charge of +15 nC.

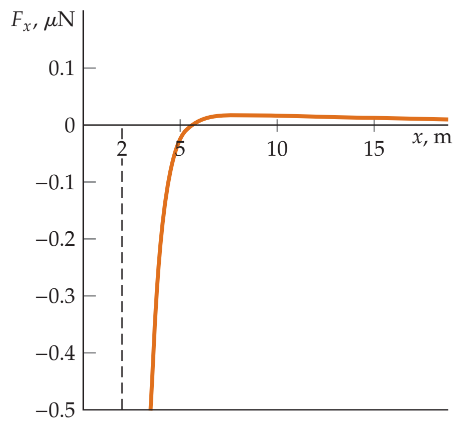

FIGURE 21-9

PRACTICE PROBLEM 21-4 If q_0 is at $x = 1.0$ m, find the total electric force acting on q_0.

For the charges in a system to remain stationary, there must be forces, other than the electric forces the charges exert on each other, acting on the charges so that the net force on each charge is zero. In the preceding example, and those that follow throughout the book, we assume that there are such forces so that all the charges remain stationary.

Example 21-5 Summing Forces in Two Dimensions

Charge $q_1 = +25$ nC is at the origin, charge $q_2 = -15$ nC is on the x axis at $x = 2.0$ m, and charge $q_0 = +20$ nC is at the point $x = 2.0$ m, $y = 2.0$ m as shown in Figure 21-10. Find the magnitude and direction of the resultant electric force on q_0.

PICTURE The resultant electric force is the vector sum of the individual forces exerted by each charge on q_0. We compute each force from Coulomb's law and write it in terms of its rectangular components.

SOLVE

1. Draw the coordinate axes showing the positions of the three charges. Show the resultant electric force $\vec{F}$ on charge q_0 as the vector sum of the forces $\vec{F}_{10}$ due to q_1 and $\vec{F}_{20}$ due to q_2 (Figure 21-10*a*):

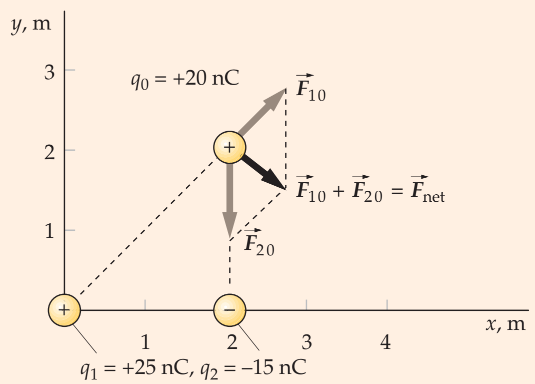

FIGURE 21-10*a*

2. The resultant force $\vec{F}$ on q_0 is the sum of the individual forces:

$$\vec{F} = \vec{F}_{10} + \vec{F}_{20}$$
so $\Sigma F_x = F_{10x} + F_{20x}$ and $\Sigma F_y = F_{10y} + F_{20y}$

3. The force $\vec{F}_{10}$ is directed away from the origin along the line from q_1 to q_0. Use $r_{10} = 2.0\sqrt{2}$ m for the distance between q_1 and q_0 to calculate its magnitude:

$$F_{10} = \frac{k|q_1q_0|}{r_{10}^2} = \frac{(8.99 \times 10^9\ \mathrm{N\cdot m^2/C^2})(25 \times 10^{-9}\ \mathrm{C})(20 \times 10^{-9}\ \mathrm{C})}{(2.0\sqrt{2}\ \mathrm{m})^2}$$
$$= 5.62 \times 10^{-7}\ \mathrm{N}$$

4. Because $\vec{F}_{10}$ makes an angle of 45° with the x and y axes, its x and y components are equal to each other:

$$F_{10x} = F_{10y} = F_{10}\cos 45° = (5.62 \times 10^{-7}\mathrm{N})\cos 45°$$
$$= 3.97 \times 10^{-7}\ \mathrm{N}$$

5. The force $\vec{F}_{20}$ exerted by q_2 on q_0 is attractive and in the $-y$ direction as shown in Figure 21-10a:

$$\vec{F}_{20} = -\frac{k|q_2q_0|}{r_{20}^2}\hat{j} = -\frac{(8.99 \times 10^9\ \mathrm{N\cdot m^2/C^2})(15 \times 10^{-9}\ \mathrm{C})(20 \times 10^{-9}\ \mathrm{C})}{(2.0\ \mathrm{m})^2}\hat{j}$$
$$= -(6.74 \times 10^{-7}\mathrm{N})\hat{j}$$

6. Calculate the components of the resultant force:

$$F_x = F_{10x} + F_{20x} = (3.97 \times 10^{-7}\ \mathrm{N}) + 0 = 3.97 \times 10^{-7}\ \mathrm{N}$$
$$F_y = F_{10y} + F_{20y} = (3.97 \times 10^{-7}\ \mathrm{N}) + (-6.74 \times 10^{-7}\ \mathrm{N})$$
$$F_y = -2.77 \times 10^{-7}\ \mathrm{N}$$

7. Draw the resultant force (Figure 21-10b) along with its two components:

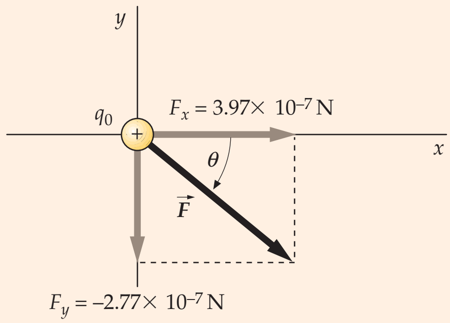

FIGURE 21-10*b*

8. The magnitude of the resultant force is found from its components:

$$F = \sqrt{F_x^2 + F_y^2} = \sqrt{(3.97 \times 10^{-7}\ \mathrm{N})^2 + (-2.77 \times 10^{-7}\ \mathrm{N})^2}$$
$$= 4.84 \times 10^{-7}\ \mathrm{N} = \boxed{4.8 \times 10^{-7}\ \mathrm{N}}$$

9. The resultant force points to the right and downward as shown in Figure 21-10b, making an angle θ with the x axis given by:

$$\tan\theta = \frac{F_y}{F_x} = \frac{-2.77}{3.97} = -0.698$$
$$\theta = \tan^{-1}(-0.698) = -34.9° = \boxed{-35°}$$

CHECK We expect the two forces to be approximately equal in magnitude because even though q_1 is a bit larger than $|q_2|$, q_2 is a bit closer to q_0 than is q_1. Comparing the results of steps 3 and 5 shows agreement with this expectation.

PRACTICE PROBLEM 21-5 Express $\hat{r}_{10}$ in Example 21-5 in terms of $\hat{i}$ and $\hat{j}$.

PRACTICE PROBLEM 21-6 In Example 21-5, is the x component of the force $\vec{F}_{10} = (kq_1q_0/r_{10}^2)\hat{r}_{10}$ equal to kq_1q_0/x_{10}^2 (where x_{10} is the x component of $\hat{r}_{10}$)?

21-4 THE ELECTRIC FIELD

The electric force exerted by one charge on another is an example of an action-at-a-distance force, similar to the gravitational force exerted by one mass on another. The idea of action at a distance presents a difficult conceptual challenge. What is the mechanism by which one particle can exert a force on another across the empty space between the particles? Suppose that a charged particle at some point is suddenly moved. Does the force exerted on the second particle some distance r away change instantaneously? To address the challenge of action at a distance, the concept of the **electric field** is introduced. One charge produces an electric field $\vec{E}$ everywhere in space, and this field exerts the force on the second charge. Thus, it is the *field* $\vec{E}$ at the location of the second charge that exerts the force on it, not the first charge itself (which is some distance away). Changes in the field propagate through space at the speed of light, c. Thus, if a charge is suddenly moved, the force it exerts on a second charge a distance r away does not change until a time r/c later.

Figure 21-11*a* shows a set of point charges q_1, q_2, and q_3 arbitrarily arranged in space. These charges produce an electric field $\vec{E}$ everywhere in space. If we place a small positive test charge q_0 at some point near the three charges, there will be a force exerted on q_0 due to the other charges. The net force on q_0 is the vector sum of the individual forces exerted on q_0 by the other charges in the system. Because each of these forces is proportional to q_0, the net force will be proportional to q_0. The electric field $\vec{E}$ at a point is this force divided by q_0:*

$$\vec{E} = \frac{\vec{F}}{q_0} \qquad (q_0 \text{ is small}) \qquad 21\text{-}5$$

DEFINITION—ELECTRIC FIELD

The SI unit of the electric field is the newton per coulomb (N/C). In addition, the test charge q_0 will exert a force on each of the other point charges (Figure 21-11*b*). Because these forces on the other charges might cause some of the other charges to move, the charge q_0 must be so small that the forces it exerts on the other charges are negligible. Thus, the electric field at the location in question is actually defined by Equation 21-5, but in the limit that q_0 approaches zero. Table 21-2 lists the magnitudes of some of the electric fields found in nature.

The electric field describes the condition in space set up by the system of point charges. By moving a test charge q_0 from point to point, we can find $\vec{E}$ at all points in space (except at any point occupied by a charge q). The electric field $\vec{E}$ is thus a vector function of position. The force exerted on a test charge q_0 at any point is related to the electric field at that point by

$$\vec{F} = q_0\vec{E} \qquad 21\text{-}6$$

PRACTICE PROBLEM 21-7

When a 5.0-nC test charge is placed at a certain point, it experiences a force of 2.0×10^{-4} N in the direction of increasing x. What is the electric field $\vec{E}$ at that point?

PRACTICE PROBLEM 21-8

What is the force on an electron placed at a point where the electric field is $\vec{E} = (4.0 \times 10^4 \text{ N/C})\hat{i}$?

The electric field due to a single point charge can be calculated from Coulomb's law. Consider a small, positive test charge q_0 at some point P a distance r_{iP} away from a charge q_i. The force on q_0 is

$$\vec{F}_{i0} = \frac{kq_iq_0}{r_{iP}^2}\hat{r}_{iP}$$

* This definition is similar to that for the gravitational field of Earth, which was defined in Section 4-3 as the force per unit mass exerted by Earth on an object.

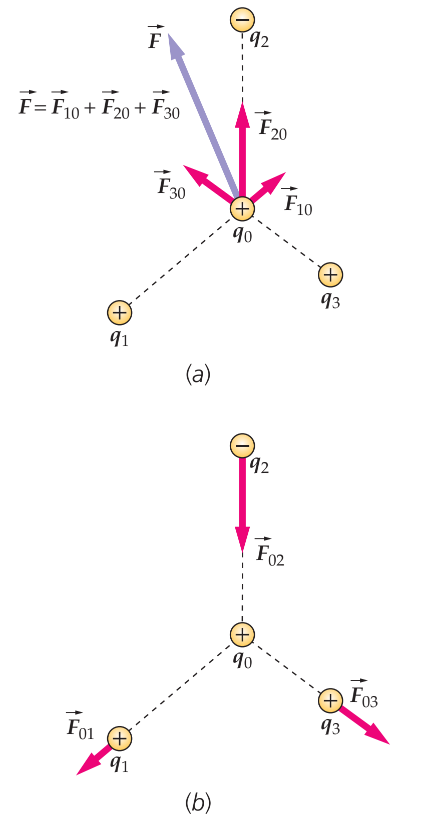

FIGURE 21-11 (*a*) A small test charge q_0 in the vicinity of a system of charges $q_1, q_2, q_3, \ldots$, experiences a resultant electric force $\vec{F}$ that is proportional to q_0. The ratio $\vec{F}/q_0$ is the electric field at that point. (*b*) The test charge q_0 also exerts a force on each of the surrounding charges, and each of these forces is proportional to q_0.

Table 21-2 Some Electric Fields in Nature

	E, N/C
In household wires	10^{-2}
In radio waves	10^{-1}
In the atmosphere	10^2
In sunlight	10^3
Under a thundercloud	10^4
In a lightning bolt	10^4
In an X-ray tube	10^6
At the electron in a hydrogen atom	5×10^{11}
At the surface of a uranium nucleus	2×10^{21}

The electric field at point P due to charge q_i (Figure 21-12) is thus

$$\vec{E}_{iP} = \frac{kq_i}{r_{iP}^2}\hat{r}_{iP} \qquad \text{21-7}$$

COULOMB'S LAW FOR $\vec{E}$

where $\hat{r}_{iP}$ is the unit vector pointing from the **source point** i to the **field point** P.

The resultant electric field at P due to a distribution of point charges is found by summing the fields due to each charge separately:

$$\vec{E}_P = \sum_i \vec{E}_{iP} \qquad \text{21-8}$$

ELECTRIC FIELD $\vec{E}$ DUE TO A SYSTEM OF POINT CHARGES

That is, electric fields follow the principle of superposition.

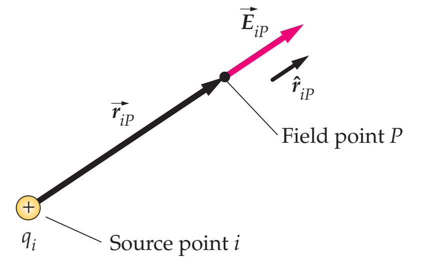

FIGURE 21-12 The electric field $\vec{E}$ at a field point P due to charge q_i at a source point i.

! Even though the expression for the electric field (Equation 21-7) does depend on the location of point P, it does *not* depend on the test charge q_0. That is, q_0 itself does not appear in Equation 21-7.

PROBLEM-SOLVING STRATEGY

Calculating the Resultant Electric Field

PICTURE To calculate the resultant electric field $\vec{E}_P$ at field point P due to a specified distribution of point charges, draw the charge configuration. Include coordinate axes and the field point on the drawing.

SOLVE

1. On the drawing label the distance r_{iP} from each charge to point P. Include an electric field vector $\vec{E}_{iP}$ for the electric field at P due to each point charge.
2. If the field point P and the point charges are not on a single line, then label the angle each individual electric field vector $\vec{E}_{iP}$ makes with one of the coordinate axes.
3. Calculate the component of each individual field vector $\vec{E}_{iP}$ along each axis and use these to calculate the components of the resultant electric field $\vec{E}_P$.

Example 21-6 Direction of Electric Field — *Conceptual*

A positive point charge $q_1 = +q$ and a negative point charge of $q_2 = -2q$ are located on the x axis at $x = a$ and $x = -a$, respectively, as shown in Figure 21-13. Consider the following regions on the x axis: region I ($x < -a$), region II ($-a < x < +a$), and region III ($x > a$). In which region, or regions, is there a point at which the resultant electric field is equal to zero?

PICTURE Let $\vec{E}_1$ and $\vec{E}_2$ be the electric fields due to q_1 and q_2, respectively. Because q_1 is positive, $\vec{E}_1$ points away from q_1 everywhere, and because q_2 is negative, $\vec{E}_2$ points toward from q_2 everywhere. The resultant electric field $\vec{E}$ is equal to the sum of the electric fields of the two charges ($\vec{E} = \vec{E}_1 + \vec{E}_2$). The resultant field is zero if $\vec{E}_1$ and $\vec{E}_2$ are equal in magnitude and oppositely directed. The magnitude of the electric field due to a point charge approaches infinity at points close to a point charge. In addition, at points far from the charge configuration, the electric field approaches the electric field of a point charge equal to $q_1 + q_2$ that is located at the center of charge. The electric field far from the charge configuration is that of a negative point charge because $q_1 + q_2$ is negative.

SOLVE

1. Sketch a figure showing the two charges, the x axis, and the electric fields due the charges at points on the x axis in each of regions I, II, and III. Label these points P_I, P_{II}, and P_{III}, respectively (Figure 21-13):

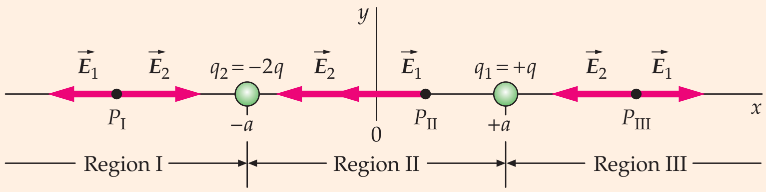

FIGURE 21-13

2. Check to see if the two electric field vectors can be equal in magnitude and opposite in direction anywhere in region I:

Throughout region I, the two electric field vectors are oppositely directed. However, each point in the region is closer to q_2 $(= -2q)$ than q_1 $(= +q)$, so E_2 is greater than E_1 at each point in the region. Thus, in region I there are no points where the electric field is equal to zero.

3. Check to see if the two electric field vectors can be equal in magnitude and opposite in direction anywhere in region II:

Throughout region II, the two electric field vectors are in the same direction at each point on the x axis. Thus, in region II there are no points where the electric field is equal to zero.

4. Check to see if the two electric field vectors can be equal in magnitude and opposite in direction anywhere in region III:

Throughout region III, the two electric field vectors are oppositely directed. At points very close to $x = a$, E_1 is greater than E_2 (because at points close to a point charge the magnitude of the electric field due to that charge approaches infinity). However, at points where $x \gg a$, E_2 is greater than E_1 (because at large distances from the two charges the field direction is determined by the sign of $q_1 + q_2$). Thus, there must be a point somewhere in region III where E_1 is equal to E_2. At that point the net electric field is zero.

CHECK The resultant electric field is zero at a point in region III, the region in which $\vec{E}_1$ and $\vec{E}_2$ are oppositely directed AND in which all points are farther from q_2, the charge with the larger magnitude, than from q_1. This result is as one would expect.

Example 21-7 Electric Field on a Line through Two Positive Point Charges

A positive point charge $q_1 = +8.0$ nC is on the x axis at $x = x_1 = -1.0$ m, and a second positive point charge $q_2 = +12$ nC is on the x axis at $x = x_2 = 3.0$ m. Find the net electric field (*a*) at point A on the x axis at $x = 6.0$ m, and (*b*) at point B on the x axis at $x = 2.0$ m.

PICTURE Let $\vec{E}_1$ and $\vec{E}_2$ be the electric fields due to q_1 and q_2, respectively. Because q_1 is positive, $\vec{E}_1$ points away from q_1 everywhere, and because q_2 is positive, $\vec{E}_2$ points away from q_2 everywhere. We calculate the resultant field using $\vec{E} = \vec{E}_1 + \vec{E}_2$.

SOLVE

(*a*) 1. Draw the charge configuration and place the field point A on the x axis at the appropriate place. Draw vectors representing the electric field at A due to each point charge. Repeat this procedure for field point B (Figure 21-14):

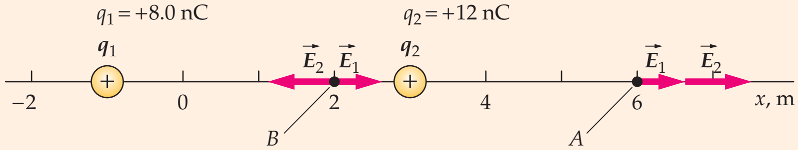

FIGURE 21-14 Because q_1 is a positive charge, $\vec{E}_1$ points away from q_1, at both point A and point B. Because q_2 is a positive charge, $\vec{E}_2$ points away from q_2 at both point A and point B.

2. Calculate $\vec{E}$ at point A, using $r_{1A} = |x_A - x_1| = 6.0\text{ m} - (-1.0\text{ m}) = 7.0$ m and $r_{2A} = |x_A - x_2| = 6.0\text{ m} - (3.0\text{ m}) = 3.0$ m:

$$\vec{E} = \vec{E}_1 + \vec{E}_2 = \frac{kq_1}{r_{1A}^2}\hat{r}_{1A} + \frac{kq_2}{r_{2A}^2}\hat{r}_{2A} = \frac{kq_1}{(x_A - x_1)^2}\hat{i} + \frac{kq_2}{(x_A - x_2)^2}\hat{i}$$

$$= \frac{(8.99 \times 10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(8.0 \times 10^{-9}\text{ C})}{(7.0\text{ m})^2}\hat{i} + \frac{(8.99 \times 10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(12 \times 10^{-9}\text{ C})}{(3.0\text{ m})^2}\hat{i}$$

$$= (1.47\text{ N/C})\hat{i} + (12.0\text{ N/C})\hat{i} = \boxed{(13\text{ N/C})\hat{i}}$$

(*b*) Calculate $\vec{E}$ at point B, where
$r_{1B} = |x_B - x_1| = 2.0\text{ m} - (-1.0\text{ m}) = 3.0\text{ m}$
and $r_{2B} = |x_B - x_2| = |2.0\text{ m} - (3.0\text{ m})| = 1.0\text{ m}$:

$$\vec{E} = \vec{E}_1 + \vec{E}_2 = \frac{kq_1}{r_{1B}^2}\hat{r}_{1B} + \frac{kq_2}{r_{2B}^2}\hat{r}_{2B} = \frac{kq_1}{(x_B - x_1)^2}\hat{i} + \frac{kq_2}{(x_B - x_2)^2}(-\hat{i})$$

$$= \frac{(8.99\times 10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(8.0\times 10^{-9}\text{ C})}{(3.0\text{ m})^2}\hat{i} - \frac{(8.99\times 10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(12\times 10^{-9}\text{ C})}{(1.0\text{ m})^2}\hat{i}$$

$$= (7.99\text{ N/C})\hat{i} - (108\text{ N/C})\hat{i} = \boxed{-(100\text{ N/C})\hat{i}}$$

CHECK The Part (*b*) result is large and in the $-x$ direction. This result is expected because point B is close to q_2, and q_2 is a large positive charge (+12 nC) that produces electric field $\vec{E}_2$ in the $-x$ direction at B.

TAKING IT FURTHER The resultant electric field at source points close to $q_1 = +8.0$-nC is dominated by the field $\vec{E}_1$ due to q_1. There is one point between q_1 and q_2 where the resultant electric field is zero. A test charge placed at this point would experience no electric force. A sketch of E_x versus x for this charge configuration is shown in Figure 21-15.

PRACTICE PROBLEM 21-9 Regarding Example 21-7, find the point on the x axis where the electric field is zero.

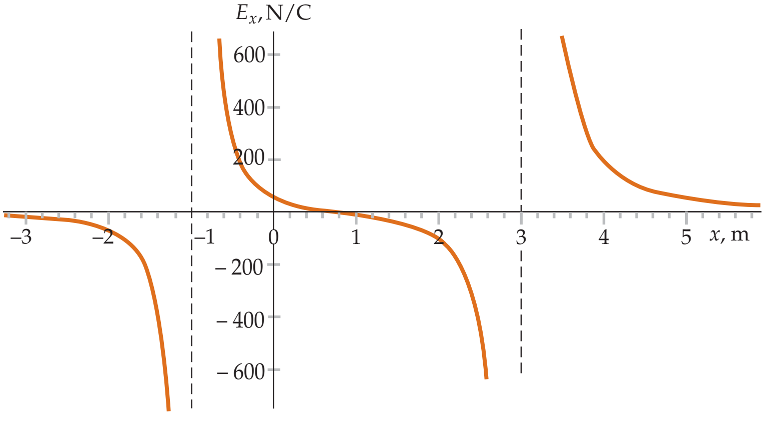

FIGURE 21-15

Example 21-8 Electric Field Due to Point Charges on the *x* Axis — *Try It Yourself*

A point charge $q_1 = +8.0$ nC is at the origin and a second point charge $q_2 = +12.0$ nC is on the x axis at $x = 4.0$ m. Find the electric field on the y axis at $y = 3.0$ m.

PICTURE As in Example 21-7, $\vec{E} = \vec{E}_1 + \vec{E}_2$. At points on the y axis, the electric field $\vec{E}_1$ due to charge q_1 is directed along the y axis, and the field $\vec{E}_2$ due to charge q_2 is in the second quadrant. To find the resultant field $\vec{E}$, we first find the x and y components of $\vec{E}$.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps

1. Sketch the two charges and the field point. Include the coordinate axes. Draw the electric field due to each charge at the field point and label distances and angles appropriately (Figure 21-16*a*):

Answers

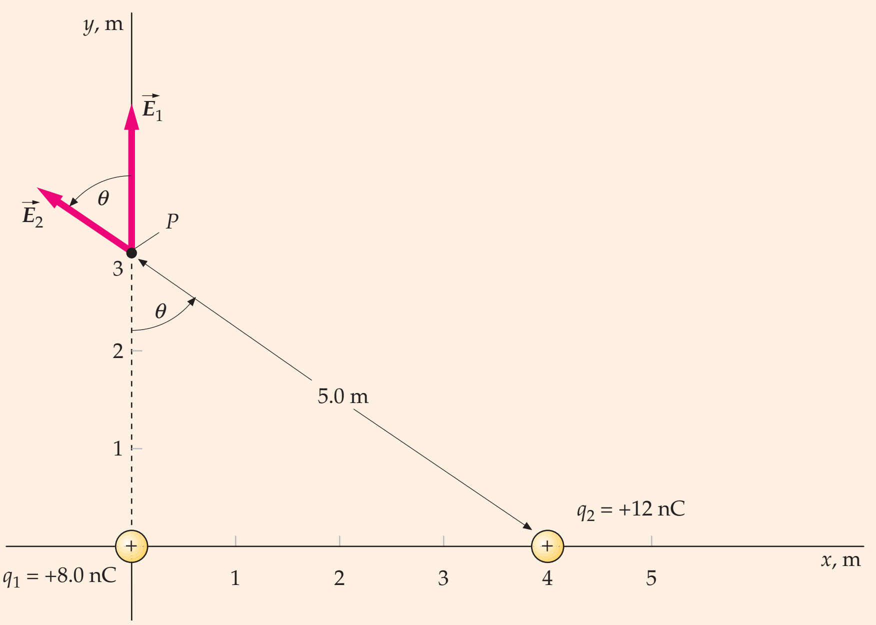

FIGURE 21-16*a*

2. Calculate the magnitude of the field $\vec{E}_1$ at (0, 3.0 m) due to q_1. Find the x and y components of $\vec{E}_1$ — $E_1 = kq_1/y^2 = 7.99$ N/C; $E_{1x} = 0$, $E_{1y} = E_1 = 7.99$ N/C

3. Calculate the magnitude of the field $\vec{E}_2$ at $(0, y)$ due to q_2. — $E_2 = 4.32$ N/C

4. Write the x and y components of $\vec{E}_2$ in terms of the angle θ. — $E_{2x} = -E_2 \sin\theta$; $E_{2y} = E_2 \cos\theta$

5. Compute $\sin\theta$ and $\cos\theta$. — $\sin\theta = 0.80$; $\cos\theta = 0.60$

6. Calculate E_{2x} and E_{2y}. — $E_{2x} = -3.46$ N/C; $E_{2y} = 2.59$ N/C

7. Sketch the components of the resultant field. Include both the vector $\vec{E}$ and the angle $\vec{E}$ makes with the x axis (Figure 21-16b):

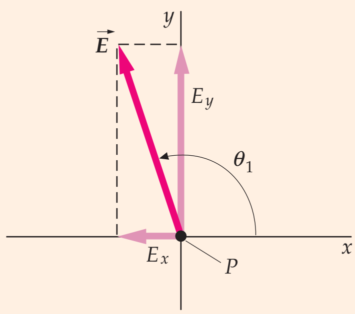

FIGURE 21-16*b*

8. Find the x and y components of the resultant field $\vec{E}$. — $E_x = E_{1x} + E_{2x} = -3.46$ N/C; $E_y = E_{1y} + E_{2y} = 10.6$ N/C

9. Calculate the magnitude of $\vec{E}$ from its components. — $E = \sqrt{E_x^2 + E_y^2} = 11.2 \text{ N/C} = \boxed{11 \text{ N/C}}$

10. Find the angle θ_1 made by $\vec{E}$ with the x axis. — $\theta_1 = \tan^{-1}\left(\frac{E_y}{E_x}\right) = \boxed{108^\circ}$

CHECK As expected, E is larger than either E_1 or E_2, but less than $E_1 + E_2$. (This result is expected because the angle between $\vec{E}_1$ and $\vec{E}_2$ is less than 90°.)

Example 21-9 Electric Field Due to Two Equal and Opposite Charges

A charge $+q$ is at $x = a$ and a second charge $-q$ is at $x = -a$ (Figure 21-17). (a) Find the electric field on the x axis at an arbitrary point $x > a$. (b) Find the limiting form of the electric field for $x \gg a$.

PICTURE We calculate the electric field at point P using the principle of superposition, $\vec{E}_P = \vec{E}_{1P} + \vec{E}_{2P}$. For $x > a$, the electric field $\vec{E}_+$ due to the positive charge is in the $+x$ direction and the electric field $\vec{E}_-$ due to the negative charge is in the $-x$ direction. The distances are $x - a$ to the positive charge and $x - (-a) = x + a$ to the negative charge.

SOLVE

(a) 1. Draw the charge configuration on a coordinate axis and label the distances from each charge to the field point (Figure 21-17):

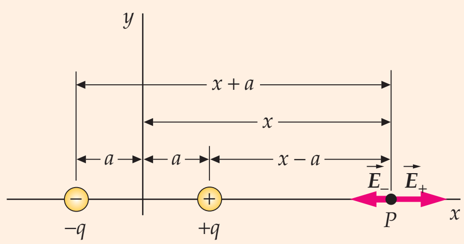

FIGURE 21-17

2. Calculate $\vec{E}$ due to the two charges for $x > a$: (*Note:* The equation on the right holds only for $x > a$.

$$\vec{E} = \vec{E}_+ + \vec{E}_- = \frac{kq}{[x-a]^2}\hat{i} + \frac{kq}{[x-(-a)]^2}\left(-\hat{i}\right)$$
$$= kq\left[\frac{1}{(x-a)^2} - \frac{1}{(x+a)^2}\right]\hat{i}$$

3. Put the terms in square brackets under a common denominator and simplify:

$$\vec{E} = kq\left[\frac{(x+a)^2 - (x-a)^2}{(x+a)^2(x-a)^2}\right]\hat{i} = \boxed{kq\frac{4ax}{(x^2-a^2)^2}\hat{i} \qquad x > a}$$

(*b*) In the limit $x \gg a$, we can neglect a^2 compared with x^2 in the denominator:

$$\vec{E} = kq\frac{4ax}{(x^2-a^2)^2}\hat{i} \approx kq\frac{4ax}{x^4}\hat{i} = \boxed{\frac{4kqa}{x^3}\hat{i} \qquad x \gg a}$$

CHECK Both boxed answers approach zero as x approaches infinity, which is as expected.

TAKING IT FURTHER Figure 21-18 shows E_x versus x for all x, for $q = 1.0\,\text{nC}$ and $a = 1.0\,\text{m}$. For $|x| \gg a$ (far from the charges), the field is given by

$$\vec{E} = \frac{4kqa}{|x|^3}\hat{i} \qquad |x| \gg a$$

Between the charges, the contribution from each charge is in the negative direction. An expression for $\vec{E}$ is

$$\vec{E} = \frac{kq}{(x-a)^2}\hat{e}_+ + \frac{k(-q)}{(x+a)^2}\hat{e}_- \qquad -a < x < a$$

where $\hat{e}_+$ is a unit vector that points away from the point $x = a$ for all values of x (except $x = a$) and $\hat{e}_-$ is a unit vector that points away from the point $x = -a$ for all values of x (except $x = -a$). (Note that $\hat{e}_+ = \frac{x-a}{|x-a|}\hat{i}$ and $\hat{e}_- = \frac{x+a}{|x+a|}\hat{i}$.)

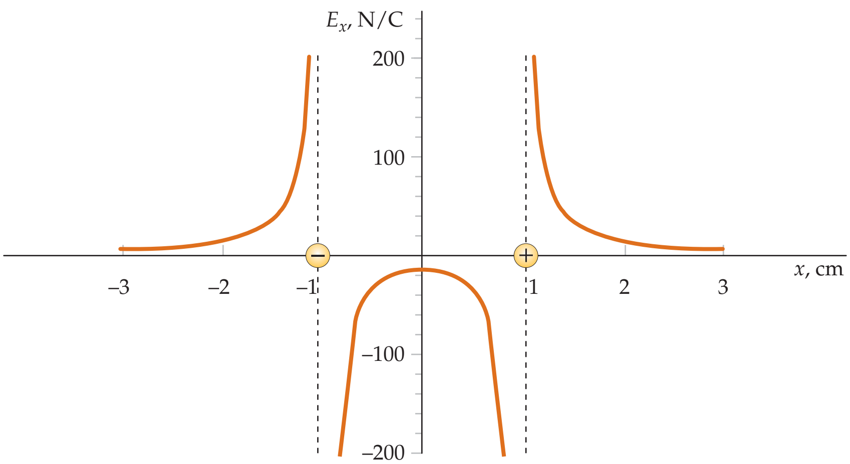

FIGURE 21-18 A plot of E_x versus x on the x axis for the charge distribution in Example 21-9.

ELECTRIC DIPOLES

A system of two equal and opposite charges q separated by a small distance L is called a **dipole.** Its strength and orientation are described by the **dipole moment $\vec{p}$,** which is a vector that points from the negative charge $-q$ toward the positive charge $+q$ and has the magnitude $q\vec{L}$ (Figure 21-19):

$$\vec{p} = q\vec{L} \tag{21-9}$$

DEFINITION—DIPOLE MOMENT

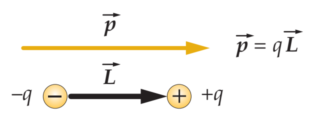

FIGURE 21-19 A dipole consists of a pair of equal and opposite charges. The dipole moment is $\vec{p} = q\vec{L}$, where q is the magnitude of one of the charges and $\vec{L}$ is the position of the negative charge relative to the positive charge.

where $\vec{L}$ is the position of the positive charge relative to the negative charge.

For the system of charges in Figure 21-17, $\vec{L} = 2a\hat{i}$ and the dipole moment is

$$\vec{p} = 2aq\hat{i}$$

In terms of the dipole moment $\vec{p}$, the electric field on the axis of the dipole at a point a great distance $|x|$ away is in the same direction as $\vec{p}$ and has magnitude

$$E = \frac{2kp}{|x|^3} \tag{21-10}$$

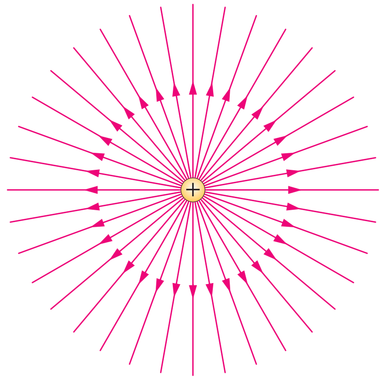
(see Example 21-9). At a point far from a dipole in any direction, the magnitude of the electric field is proportional to the magnitude of the dipole moment and decreases with the cube of the distance. If a system has a nonzero net charge, the electric field decreases as $1/r^2$ at large distances. In a system that has zero net charge, the electric field falls off more rapidly with distance. In the case of a dipole, the field falls off as $1/r^3$ in all directions.

21-5 ELECTRIC FIELD LINES

We can visualize the electric field by drawing a number of directed curved lines, called **electric field lines,** to indicate both the magnitude and the direction of the field. At any given point, the field vector $\vec{E}$ is tangent to the line through that point. (Electric field lines are also called *lines of force* because they show the direction of the electric force exerted on a positive test charge.) At points very near a positive point charge, the electric field $\vec{E}$ points directly away from the charge. Consequently, the electric field lines very near a positive charge also point directly away from the charge. Similarly, very near a negative point charge the electric field lines point directly toward the charge.

Figure 21-20 shows the electric field lines of a single positive point charge. The spacing of the lines is related to the strength of the electric field. As we move away from the charge, the field becomes weaker and the lines become farther apart. Consider an imaginary spherical surface of radius r that has its center at the charge. Its area is $4\pi r^2$. Thus, as r increases, the density of the field lines (the number of lines per unit area through a surface element normal to the field lines) decreases as $1/r^2$, the same rate of decrease as E. So, we adopt the convention of drawing a fixed number of lines from a point charge, the number being proportional to the charge q, and if we draw the lines equally spaced very near the point charge, the field strength is indicated by the density of the lines. The more closely spaced the lines, the stronger the electric field. The magnitude of the electric field is also called the **electric field strength.**

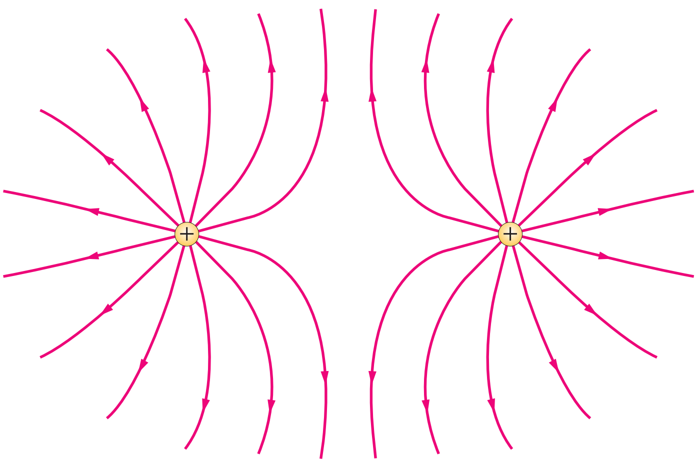
Figure 21-21 shows the electric field lines for two equal positive point charges q separated by a small distance. Near each point charge, the field is approximately that due to that charge alone. This is because the magnitude of the field of a single point charge is extremely large at points very close to the charge, and because the second charge is relatively far away. Consequently, the field lines near either charge are radial



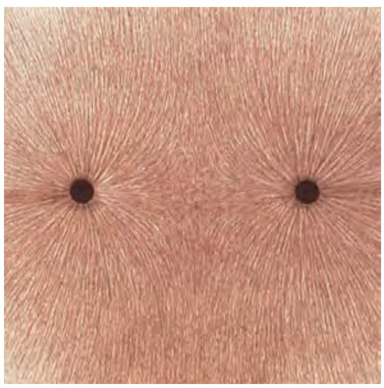
(*a*)

(*b*)

FIGURE 21-20 (*a*) Electric field lines of a single positive point charge. If the charge were negative, the arrows would be reversed. (*b*) The same electric field lines shown by bits of thread suspended in oil. The electric field of the charged object in the center induces opposite charges on the ends of each bit of thread, causing the threads to align themselves parallel to the field. *(Harold M. Waage.)*



(*a*)



(*b*)

FIGURE 21-21 (*a*) Electric field lines due to two positive point charges. The arrows would be reversed if both charges were negative. (*b*) The same electric field lines shown by bits of thread in oil. *(Harold M. Waage.)*

and equally spaced. Because the charges are of equal magnitude, we draw an equal number of lines originating from each charge. At very large distances, the details of the charge configuration are not important and the electric field lines are indistinguishable from those of a point charge of magnitude $2q$ a very large distance away. (For example, if the two charges were 1 mm apart and we look at the field lines near a point 100 km away, the field lines would look like those of a single charge of magnitude $2q$ a distance 100 km away.) So at a large distance from the charges, the field is approximately the same as that due to a point charge $2q$ and the lines are approximately equally spaced. Looking at Figure 21-21, we see that the density of field lines in the region between the two charges is small compared to the density of lines in the region just to the left and just to the right of the charges. This indicates that the magnitude of the electric field is weaker in the region between the charges than it is in the region just to the right or left of the charges, where the lines are more closely spaced. This information can also be obtained by direct calculation of the field at points in these regions.

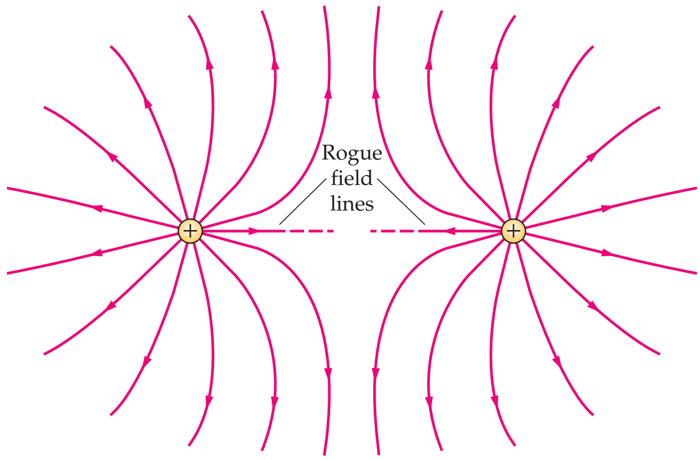


FIGURE 21-22 There are infinitely many field lines emanating from the two charges, two of which are rogue field lines. These rogue field lines terminate at the point midway between the two charges.

We can apply this reasoning to sketch the electric field lines for any system of point charges. Very near each charge, the field lines are equally spaced and emanate from or terminate on the charge radially, depending on the sign of the charge. Very far from all the charges, the detailed configuration of the system of charges is not important, so the field lines are like those of a single point charge having the net charge of the system. The rules for drawing electric field lines are summarized in the following Problem-Solving Strategy.

PROBLEM-SOLVING STRATEGY

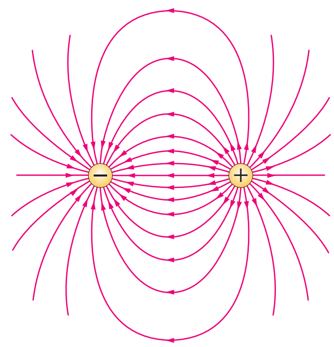
Drawing Field Lines

PICTURE Electric field lines emanate from positive charges and terminate on negative charges.*

SOLVE

1. The lines emanating from (or terminating on) an isolated point charge are drawn uniformly spaced as they emanate (or terminate).
2. The number of lines emanating from a positive charge (or terminating on a negative charge) is proportional to the magnitude of the charge.
3. The density of the lines at any point (the number of lines per unit area through a surface element normal to the lines) is proportional to the magnitude of the field there.
4. At large distances from a system of charges that has a nonzero net charge, the field lines are equally spaced and radial, as if they emanated from (or terminated on) a single point charge equal to the total charge of the system.

CHECK Make sure that the field lines never intersect each other. (If two field lines intersected, that would indicate two directions for $\vec{E}$ at the point of intersection.)



(a)

(b)

FIGURE 21-23 (a) Electric field lines for a dipole. (b) The same field lines shown by bits of thread in oil. *(Harold M. Waage.)*

Figure 21-23 shows the electric field lines due to a dipole. Very near the positive charge, the lines are directed radially outward. Very near the negative charge, the

* Rogue field lines are field lines that do not follow this rule. An example of a rogue field line is a line that leaves one of the positive charges in Figure 21-22 and is directed toward the other charge. This field line terminates at the point midway between the two charges-as does a corresponding field line emanating from the second positive charge in the figure. For these two charges there are infinitely many field lines, two of which are rogue field lines.

lines are directed radially inward. Because the charges have equal magnitudes, the number of lines that begin at the positive charge equals the number that end at the negative charge. In this case, the field is strong in the region between the charges, as indicated by the high density of field lines in this region.

Figure 21-24*a* shows the electric field lines for a negative charge $-q$ at a small distance from a positive charge $+2q$. Twice as many lines emanate from the positive charge as terminate on the negative charge. Thus, half the lines emanating from the positive charge $+2q$ terminate on the negative charge $-q$; the other half of the lines emanating from the positive charge continue on indefinitely. Very far from the charges (Figure 21-24*b*), the lines are approximately symmetrically spaced and point radially away from a single point, just as they would for a single positive point charge $+q$.

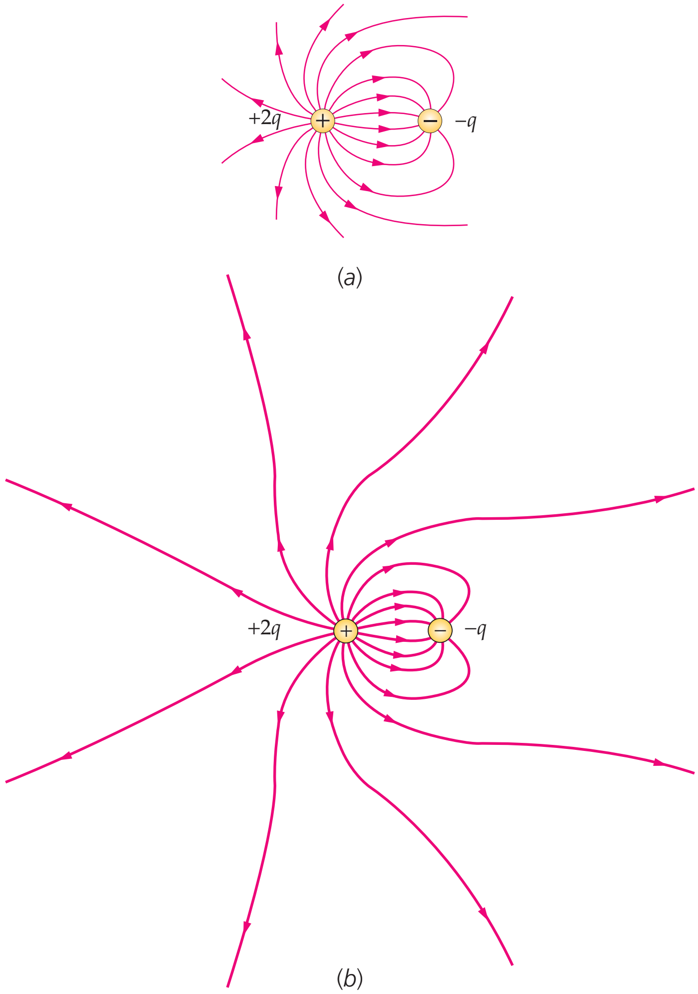


FIGURE 21-24 (*a*) Electric field lines for a point charge $+2q$ and a second point charge $-q$. (*b*) At great distances from the charges, the field lines approach those for a single point charge $+q$ located at the center of charge.

Example 21-10 Field Lines for Two Conducting Spheres — *Conceptual*

The electric field lines for two conducting spheres are shown in Figure 21-25. What is the sign of the charge on each sphere, and what are the relative magnitudes of the charges on the spheres?

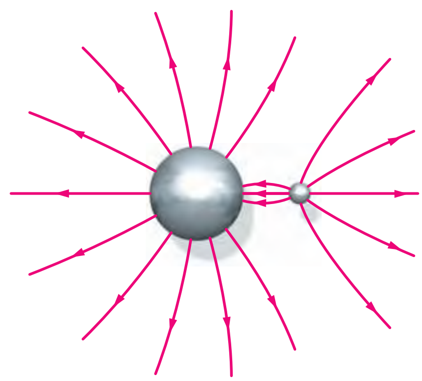

FIGURE 21-25

PICTURE The charge on an object is positive if more field lines emanate from it than terminate on it, and negative if more terminate on it than emanate from it. The ratio of the magnitudes of the charges equals the ratio of the net number of lines emanating from or terminating on the spheres.

SOLVE

1. By counting field lines, determine the net number of field lines emanating from the larger sphere:	Because 11 electric field lines emanate from the larger sphere and 3 lines terminate on it, the net number of lines emanating from it is 8.
2. By counting field lines, determine the net number of field lines emanating from the smaller sphere:	Because 8 electric field lines emanate from the smaller sphere and no lines terminate on it, the net number of lines emanating from it is 8.
3. Determine the sign of the charge on each sphere:	Because both spheres have more field lines emanating from than terminating on them, $\boxed{\text{both spheres are positively charged.}}$
4. Determine the relative magnitudes of the charges on the two spheres:	Because both spheres have the same net number of lines emanating from them, the $\boxed{\text{charges on them are equal in magnitude.}}$

The convention relating the electric field strength to the density of the electric field lines works only because the electric field varies inversely as the square of the distance from a point charge. Because the gravitational field of a point mass also varies inversely as the square of the distance, field-line drawings are also useful for picturing gravitational fields. Near a point mass, the gravitational field lines terminate on the mass just as electric field lines terminate on a negative charge. However, unlike electric field lines near a positive charge, there are no points in space from which gravitational field lines emanate. That is because the gravitational force between two masses is never repulsive.

Schematic drawing of a cathode-ray-tube display used for color television. The beams of electrons from the electron gun on the right activate phosphors on the screen at the left, giving rise to bright spots whose colors depend on the relative intensity of each beam. Electric fields between deflection plates in the gun (or magnetic fields from coils surrounding the gun) deflect the beams. The beams sweep across the screen in a horizontal line, are deflected downward, then sweep across again. The entire screen is covered in this way 30 times per second. *(Courtesy of Hulon Forrester/Video Display Corporation, Tucker Georgia.)*

21-6 ACTION OF THE ELECTRIC FIELD ON CHARGES

A uniform electric field can exert a force on a single charged particle and can exert both a torque and a net force on an electric dipole.

MOTION OF POINT CHARGES IN ELECTRIC FIELDS

When a particle that has a charge q is placed in an electric field $\vec{E}$, it experiences a force $q\vec{E}$. If the electric force is the only force acting on the particle, the particle has acceleration

$$\vec{a} = \frac{\Sigma\vec{F}}{m} = \frac{q}{m}\vec{E}$$

where m is the mass of the particle. (If the particle is an electron, its speed in an electric field is often a significant fraction of the speed of light. In such cases, Newton's laws of motion must be modified by Einstein's special theory of relativity.) If the electric field is known, the charge-to-mass ratio of the particle can be determined from the measured acceleration. J. J. Thomson used the deflection of electrons in a uniform electric field in 1897 to demonstrate the existence of electrons and to measure their charge-to-mass ratio. Familiar examples of devices that rely on the motion of electrons in electric fields are oscilloscopes, computer monitors, and television sets that use cathode-ray-tube displays.

Example 21-11 Electron Moving Parallel to a Uniform Electric Field

An electron is projected into a uniform electric field $\vec{E} = (1000\text{ N/C})\hat{i}$ with an initial velocity $\vec{v}_0 = (2.00 \times 10^6\text{ m/s})\hat{i}$ in the direction of the field (Figure 21-26). How far does the electron travel before it is brought momentarily to rest?

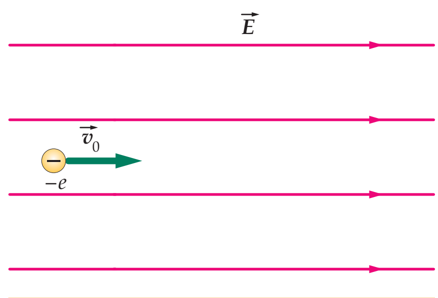

FIGURE 21-26

PICTURE Because the charge of the electron is negative, the force $\vec{F} = -e\vec{E}$ acting on the electron is in the direction opposite that of the field. Because $\vec{E}$ is constant, the force is constant and we can use constant acceleration formulas from Chapter 2. We choose the field to be in the $+x$ direction.

SOLVE

1. The displacement Δx is related to the initial and final velocities: $\quad v_x^2 = v_{0x}^2 + 2a_x\Delta x$

2. The acceleration is obtained from Newton's second law: $\quad a_x = \dfrac{F_x}{m} = \dfrac{-eE_x}{m}$

3. When $v_x = 0$, the displacement is:

$$\Delta x = \frac{v_x^2 - v_{0x}^2}{2a_x} = \frac{0 - v_{0x}^2}{2(-eE_x/m)} = \frac{mv_0^2}{2eE} = \frac{(9.11 \times 10^{-31}\text{ kg})(2.00 \times 10^6\text{ m/s})^2}{2(1.60 \times 10^{-19}\text{ C})(1000\text{ N/C})}$$

$$= 1.14 \times 10^{-2}\text{ m} = \boxed{1.14\text{ cm}}$$

CHECK The displacement Δx is positive, as is expected for something moving in the $+x$ direction.

Example 21-12 Electron Moving Perpendicular to a Uniform Electric Field

An electron enters a uniform electric field $\vec{E} = (-2.0\text{ kN/C})\hat{j}$ with an initial velocity $\vec{v}_0 = (1.0 \times 10^6\text{ m/s})\hat{i}$ perpendicular to the field (Figure 21-27). (*a*) Compare the gravitational force acting on the electron to the electric force acting on it. (*b*) By how much has the electron been deflected after it has traveled 1.0 cm in the x direction?

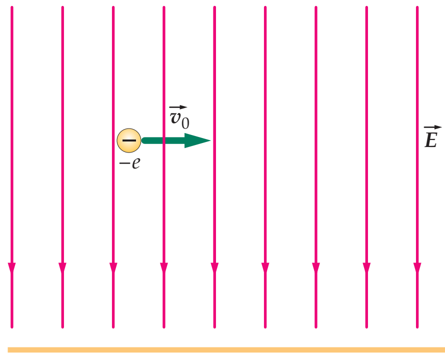

FIGURE 21-27

PICTURE (*a*) Calculate the ratio of the magnitude of the electric force $|q|E = eE$ to that of the gravitational force mg. (*b*) Because mg is, by comparison, negligible, the net force on the electron is equal to the vertically upward electric force. The electron thus moves with constant horizontal velocity v_x and is deflected upward by an amount $\Delta y = \frac{1}{2}at^2$, where t is the time to travel 1.0 cm in the x direction.

SOLVE

(*a*) 1. Calculate the ratio of the magnitude of the electric force, F_e, to the magnitude of the gravitational force, F_g:

$$\frac{F_e}{F_g} = \frac{eE}{mg} = \frac{(1.60 \times 10^{-19}\text{ C})(2000\text{ N/C})}{(9.11 \times 10^{-31}\text{ kg})(9.81\text{ N/kg})} = \boxed{3.6 \times 10^{13}}$$

(*b*) 1. Express the vertical deflection in terms of the acceleration a and time t:

$$\Delta y = \frac{1}{2}a_y t^2$$

2. Express the time required for the electron to travel a horizontal distance Δx with constant horizontal velocity v_0:

$$t = \frac{\Delta x}{v_0}$$

3. Use this result for t and eE/m for a_y to calculate Δy:

$$\Delta y = \frac{1}{2}\frac{eE}{m}\left(\frac{\Delta x}{v_0}\right)^2 = \frac{1}{2}\frac{(1.6 \times 10^{-19}\text{ C})(2000\text{ N/C})}{9.11 \times 10^{-31}\text{ kg}}\left(\frac{0.010\text{ m}}{10^6\text{ m/s}}\right)^2$$

$$= \boxed{1.8\text{ cm}}$$

CHECK The step-4 result is positive (upward), as is expected for an object accelerating upward that was initially moving horizontally.

TAKING IT FURTHER (*a*) As is usually the case, the electric force is huge compared with the gravitational force. Thus, it is not necessary to consider gravity when designing a cathode-ray tube, for example, or when calculating the deflection in the problem above. In fact, a television picture tube works equally well upside down and right side up, as if gravity were not even present. (*b*) The path of an electron moving in a uniform electric field is a parabola, the same as the path of a neutral particle moving in a uniform gravitational field.

Example 21-13 The Electric Field in an Ink-Jet Printer *Context-Rich*

You have just finished printing out a long essay for your English professor, and you wonder about how the ink-jet printer knows where to place the ink. You search the Internet and find a picture (Figure 21-28) showing that the ink drops are given a charge and pass between a pair of oppositely charged metal plates that provide a uniform electric field in the region between the plates. Because you have been studying the electric field in physics class, you wonder if you can determine how large a field is used in this type of printer. You search further and find that the 40.0-μm-diameter ink drops have an initial velocity of 40.0 m/s, and that a drop that has a 2.00-nC charge is deflected upward a distance of 3.00 mm as the drop travels through the 1.00-cm-long region between the plates. Find the magnitude of the electric field. (Neglect any effects of gravity on the motion of the drops.)

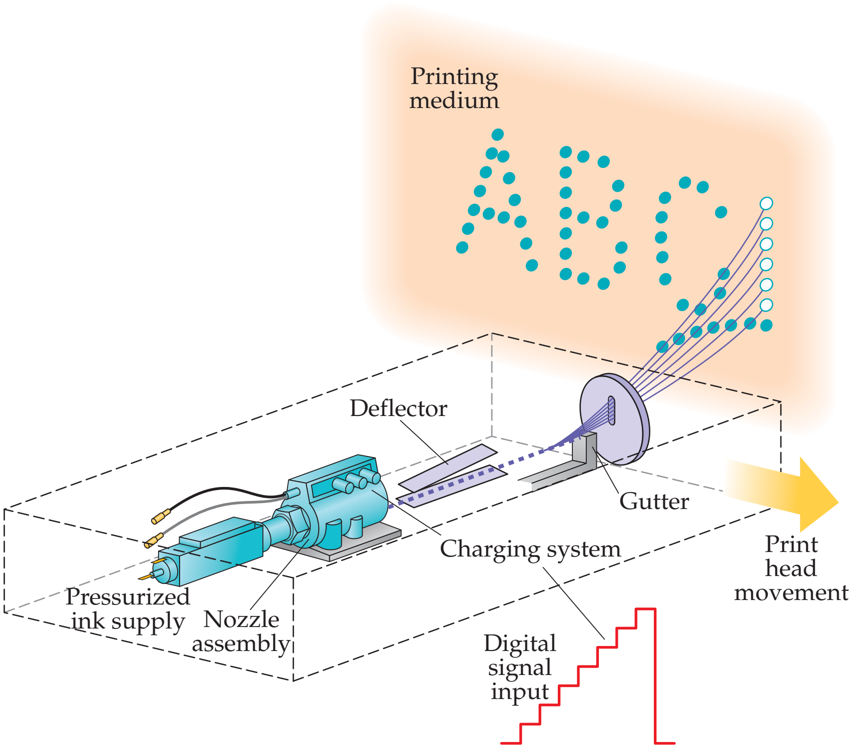

FIGURE 21-28 An ink-jet used for printing. The ink exits the nozzle in discrete droplets. Any droplet destined to form a dot on the image is given a charge. The deflector consists of a pair of oppositely charged plates. The greater the charge a drop receives, the higher the drop is deflected as it passes between the deflector plates. Drops that do not receive a charge are not deflected upward. These drops end up in the gutter, and the ink is returned to the ink reservoir. *(Courtesy of Videojet Systems International.)*

PICTURE The electric field $\vec{E}$ exerts a constant electric force $\vec{F}$ on the drop as it passes between the two plates, where $\vec{F} = q\vec{E}$. We are looking for E. We can get the force $\vec{F}$ by determining the mass and acceleration $\vec{F} = m\vec{a}$. The acceleration can be found from kinematics and mass can be found using the radius. Assume the density ρ of ink is 1000 kg/m³ (the same as the density of water).

SOLVE

1. The electric field strength equals the force to charge ratio: $E = \dfrac{F}{q}$
2. The force, which is in the $+y$ direction (upward), equals the mass multiplied by the acceleration: $F = ma_y$
3. The vertical displacement is obtained using a constant-acceleration kinematic formula with $v_{0y} = 0$: $\Delta y = v_{0y}t + \frac{1}{2}a_y t^2 = 0 + \frac{1}{2}a_y t^2$
4. The time is how long it takes for the drop to travel the $\Delta x = 1.00$ cm at $v_0 = 40.0$ m/s: $\Delta x = v_{0x}t = v_0 t \quad \text{so} \quad t = \Delta x/v_0$
5. Solving for a_y gives: $a_y = \dfrac{2\Delta y}{t^2} = \dfrac{2\Delta y}{(\Delta x/v_0)^2} = \dfrac{2v_0^2\Delta y}{(\Delta x)^2}$
6. The mass equals the density multiplied by the volume: $m = \rho V = \rho\frac{4}{3}\pi r^3$
7. Solve for E:

$$E = \frac{F}{q} = \frac{ma}{q} = \frac{\rho\frac{4}{3}\pi r^3}{q}\frac{2v_0^2\Delta y}{(\Delta x)^2} = \frac{8\pi}{3}\frac{\rho r^3 v_0^2 \Delta y}{q(\Delta x)^2}$$

$$= \frac{8\pi}{3}\frac{(1000\ \text{kg/m}^3)(20.0 \times 10^{-6}\ \text{m})^3(40.0\ \text{m/s})^2(3.00 \times 10^{-3}\ \text{m})}{(2.00 \times 10^{-9}\ \text{C})(0.0100\ \text{m})^2} = \boxed{1.61\ \text{kN/C}}$$

CHECK The units in last line of step 7 are $\text{kg}\cdot\text{m}/(\text{C}\cdot\text{s}^2)$. The units work out because $1\ \text{N} = 1\ \text{kg}\cdot\text{m/s}^2$.

TAKING IT FURTHER The ink-jet in this example is called a multiple-deflection continuous ink-jet. It is used in some industrial printers. The low-cost ink-jet printers sold for home use do not use charged droplets deflected by an electric field.

DIPOLES IN ELECTRIC FIELDS

In Example 21-9 we found the electric field produced by a dipole, a system of two equal and opposite point charges that are close together. Here we consider the behavior of a dipole in an external electric field. Some molecules have permanent dipole moments due to a nonuniform distribution of charge within the molecule. Such molecules are called **polar molecules.** An example is HCl, which is essentially a positive hydrogen ion of charge $+e$ combined with a negative chloride ion of charge $-e$. The center of charge of the positive ion does not coincide with the center of charge for the negative ion, so the molecule has a permanent dipole moment. Another example is water (Figure 21-29).

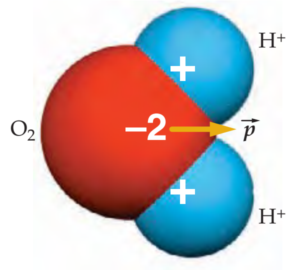

FIGURE 21-29 An H_2O molecule has a permanent dipole moment that points in the direction from the center of negative charge to the center of positive charge.

A uniform external electric field exerts no net force on a dipole, but it does exert a torque that tends to rotate the dipole so as to align it with the direction of the external field. We see in Figure 21-30 that the torque $\vec{\tau}$ calculated about the position of either charge has the magnitude $F_1L\sin\theta = qEL\sin\theta = pE\sin\theta$.* The direction of the torque vector is into the paper such that it tends to rotate the dipole moment vector $\vec{p}$ so it aligns with the direction of $\vec{E}$. The torque can be expressed most concisely as the cross product:

$$\vec{\tau} = \vec{p} \times \vec{E} \qquad 21\text{-}11$$

If the dipole rotates through angle $d\theta$, the electric field does work:

$$dW = -\tau d\theta = -pE\sin\theta\, d\theta$$

(The minus sign arises because the torque opposes any increase in θ.) Setting the negative of this work value equal to the change in potential energy, we have

$$dU = -dW = +pE\sin\theta\, d\theta$$

Integrating, we obtain

$$U = -pE\cos\theta + U_0$$

If we choose the potential energy U to be zero when $\theta = 90°$, then $U_0 = 0$ and the potential energy of the dipole is

$$U = -pE\cos\theta = -\vec{p}\cdot\vec{E} \qquad 21\text{-}12$$

POTENTIAL ENERGY OF A DIPOLE IN AN ELECTRIC FIELD

Microwave ovens take advantage of the dipole moment of water molecules to cook food. Like other electromagnetic waves, microwaves have oscillating electric fields that exert torques on dipoles, torques that cause the water molecules to rotate with significant rotational kinetic energy. In this manner, energy is transferred from the microwave radiation to the water molecules at a high rate, accounting for the rapid cooking times that make microwave ovens so convenient.

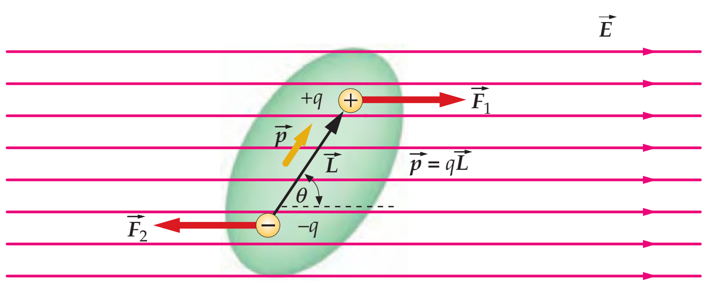

FIGURE 21-30 A dipole in a uniform electric field experiences equal and opposite forces that tend to rotate the dipole so that its dipole moment $\vec{p}$ is aligned with the electric field $\vec{E}$.

* The torque produced by two equal and opposite forces (an arrangement called a couple) is the same about any point in space.

Nonpolar molecules have no permanent dipole moment. However, all neutral molecules have equal amounts of positive and negative charge. In the presence of an external electric field $\vec{E}$, the positive and negative charge centers become separated in space. The positive charges are pushed in the direction of $\vec{E}$ and the negative charges are pushed in the opposite direction. The molecule thus acquires an induced dipole moment parallel to the external electric field and is said to be **polarized.**

In a nonuniform electric field, a dipole experiences a net force because the electric field has different magnitudes at the positive and negative charge centers. Figure 21-31 shows how a positive point charge polarizes a nonpolar molecule and then attracts it. A familiar example is the attraction that holds an electrostatically charged balloon against a wall. The nonuniform field produced by the charge on the balloon polarizes molecules in the wall and attracts them. An equal and opposite force is exerted by the wall molecules on the balloon.

The diameter of an atom or molecule is of the order of 10^{-12} m = 1 pm (one picometer). A convenient unit for the dipole moment of atoms and molecules is the fundamental charge e multiplied by the distance 1 pm. For example, the dipole moment of H_2O in these units has a magnitude of about 40 $e \cdot$pm.

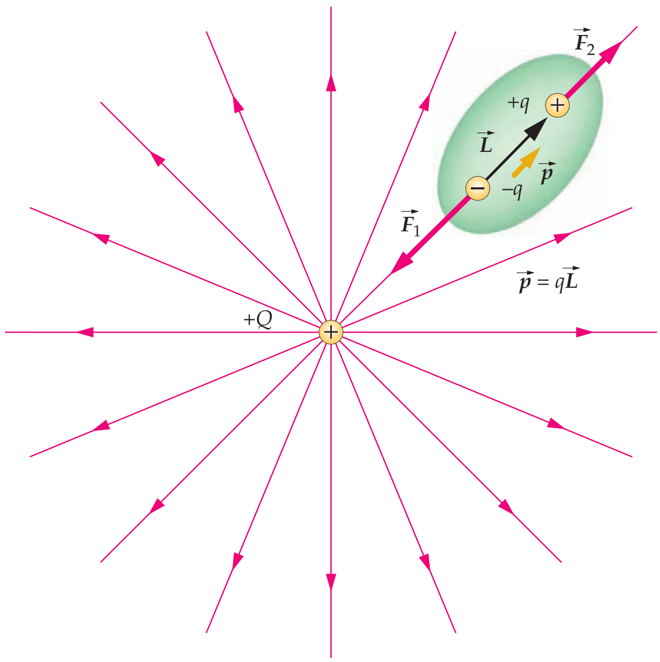

FIGURE 21-31 A nonpolar molecule in the nonuniform electric field of a positive point charge $+Q$. The point charge attracts the negative charges (the electrons) in the molecule and repels the positive charges (the protons). As a result the center of negative charge $-q$ is closer to $+Q$ than is the center of positive charge $+q$ and the induced dipole moment $\vec{p}$ is parallel to the field of the point charge. Because $-q$ is closer to $+Q$ than is $+q$, F_1 is greater than F_2 and the molecule is attracted to the point charge. In addition, if the point charge were negative, the induced dipole moment would be reversed, and the molecule would again be attracted to the point charge.

Example 21-14 Torque and Potential Energy

A polar molecule has a dipole moment of magnitude 20 $e \cdot$pm that makes an angle of 20° with a uniform electric field of magnitude 3.0×10^3 N/C (Figure 21-32). Find (*a*) the magnitude of the torque on the dipole, and (*b*) the potential energy of the system.

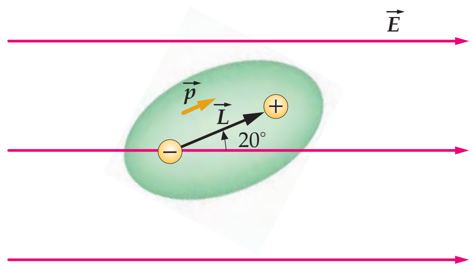

FIGURE 21-32

PICTURE The torque is found from $\vec{\tau} = \vec{p} \times \vec{E}$ and the potential energy is found from $U = -\vec{p} \cdot \vec{E}$.

SOLVE

1. Calculate the magnitude of the torque:

$$\tau = |\vec{p} \times \vec{E}| = pE\sin\theta = (20\,e\cdot\text{pm})(3 \times 10^3\ \text{N/C})(\sin 20°)$$
$$= (0.02)(1.6 \times 10^{-19}\ \text{C})(10^{-9}\ \text{m})(3 \times 10^3\ \text{N/C})(\sin 20°)$$
$$= \boxed{3.3 \times 10^{-27}\ \text{N}\cdot\text{m}}$$

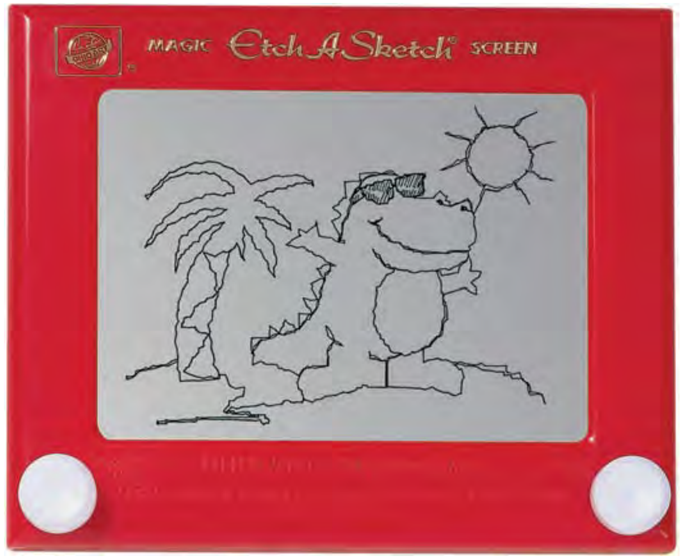
2. Calculate the potential energy:

$$U = -\vec{p} \cdot \vec{E} = -pE\cos\theta$$
$$= -(0.02)(1.6 \times 10^{-19}\ \text{C})(10^{-9}\ \text{m})(3 \times 10^3\ \text{N/C})\cos 20°$$
$$= \boxed{-9.0 \times 10^{-27}\ \text{J}}$$

CHECK The sign of the potential energy is negative. That is because the reference orientation of the potential energy function $U = -\vec{p} \cdot \vec{E}$ is $U = 0$ for $\theta = 90°$. For $\theta = 20°$ the potential energy is less than zero. The system has more potential energy if $\theta = 20°$ than it does if $\theta = 90°$.

Physics Spotlight

Powder Coating—Industrial Static



A fine powder is attracted to the back of the screen by electrostatic. Turning the knobs results in the power being rubbed off by a small stylus. *(Courtesy of The Ohio Art Company.)*

Children around the world take advantage of triboelectric properties. The Ohio Art Company introduced the Etch A Sketch™ at about 1960.[*] Styrene beads provide a charge to very fine aluminum powder when shaken. The charged powder is attracted to the translucent screen of the toy. A stylus is then used to draw lines in the powder. The toy is based on the fact that the aluminum and screen attract each other with opposite charges.

Although charged powder can be a toy, it is serious business in many industries. Unprotected metal tends to corrode, so to prevent corrosion, metal parts of automobiles, metal appliances, and other metal objects are coated. In the past, coating involved paints, lacquers, varnishes, and enamels that were put on as liquids and dried. These liquids have disadvantages.[†] The solvents take a long time to dry or release unwanted volatile compounds. Surfaces at different angles can be coated unevenly. Liquid spray causes waste and cannot be easily recycled. Electrostatic powder coating reduces many of these problems.[‡] This coating process was first used in the 1950s and is now popular with manufacturers adhering to environmental regulations by reducing the use of volatile chemicals.

Powder coating is applied by giving a charge to the item that will be coated.[#] To do this reliably, it is simplest if the object to be coated is conductive. Then very small (from 1 μm to 100 μm) particles[°] in a powder are given an opposite charge. The coating particles are strongly attracted to the object to be coated. Loose particles can be recycled and used again. Once the particles are on the object, the coating is then cured, either by increased temperature or by ultraviolet light. The curing process locks the molecules of the coating together, and the particles and the object lose their charges.

Coating particles are given a charge by either corona discharge or triboelectric charging.[§] Corona discharge blows the particles through a plasma of electrons, giving them a negative charge. Triboelectric charging blows the particles through a tube that is made from a material on the opposite end of the triboelectric spectrum, often Teflon. The coating particles are given a positive charge from this rapid contact. The item to be coated is given a charge that depends on the coating method used. Depending on the coating and additives, coating charges range from 500 to 1000 μC/kg.[¶] The curing process differs according to the coating materials and the coated item. The curing time can be anywhere from 1 to 30 minutes.[**]

Although powder coating is economical and environmentally friendly, it has difficulties. The abilities of the coating particles to hold a charge[††] can vary with humidity, which must be precisely controlled.[‡‡] If the electric field for corona discharge is too strong, the powder sprays too quickly toward the item to be coated, leaving a bare spot in the middle of a built-up ring, which gives an uneven "orange peel" finish.[##] Electrostatic powders can be child's play, but electrostatic powder coating is a complex, useful, and evolving process.

Summary

1. Quantization and conservation are fundamental properties of electric charge.
2. Coulomb's law is the fundamental law of interaction between charges at rest.
3. The electric field describes the condition in space set up by a charge distribution.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Charge	There are two kinds of charge, positive and negative. Charges of like sign repel, those of opposite sign attract.	
Quantization	Charge is quantized—it always occurs in integer multiples of the fundamental charge unit e. The charge of the electron is $-e$ and that of the proton is $+e$.	
Magnitude	$e = 1.60 \times 10^{-19}\ \mathrm{C}$	
Conservation	Charge is conserved. When charged particles are created or annihilated, the total amount of charge carried by the created or annihilated particles is zero.	
2. Conductors and Insulators	In metals, about one electron per atom is delocalized (free to move about the entire material). In insulators, all the electrons are bound to nearby atoms.	
Ground	A very large conductor (such as Earth) that can supply or absorb a virtually unlimited amount of charge is called a ground.	
3. Charging by Induction	To charge a conductor by induction: connect a ground to the conductor, hold an external charge near the conductor (to attract or repel the conduction electrons), then disconnect the conductor from ground, and finally move the external charge away from the conductor.	
4. Coulomb's Law	The force exerted by point charge q_1 on point charge q_2 a distance r_{12} away is given by $\vec{F}_{12} = \frac{kq_1q_2}{r_{12}^2}\hat{r}_{12}$ where unit vector $\hat{r}_{12}$ points from q_1 toward q_2.	21-4
Coulomb constant	$k = 8.99 \times 10^9\ \mathrm{N \cdot m^2/C^2}$	21-3
5. Electric Field	The electric field due to a system of charges at a point is defined as the net force $\vec{F}$, exerted by those charges on a very small positive test charge q_0, divided by q_0: $\vec{E} = \frac{\vec{F}}{q_0}$	21-5
Due to a point charge	$\vec{E}_{iP} = \frac{kq_i}{r_{iP}^2}\hat{r}_{iP}$	21-7
Due to a system of point charges	The electric field at P due to several charges is the vector sum of the fields at P due to the individual charges: $\vec{E}_P = \sum_i \vec{E}_{iP}$	21-8
6. Electric Field Lines	The electric field can be represented by electric field lines that emanate from positive charges and terminate on negative charges. The strength of the electric field is indicated by the density of the electric field lines.	
7. Dipole	A dipole is a system of two equal but opposite charges separated by a small distance.	
Dipole moment	$\vec{p} = q\vec{L}$ where $\vec{L}$ is the position of the positive charge relative to the negative charge.	21-9
Field due to dipole	The electric field strength far from a dipole is proportional to the magnitude of the dipole moment and decreases with the cube of the distance.	
Torque on a dipole	In a uniform electric field, the net force on a dipole is zero, but there is a torque that tends to align the dipole in the direction of the field. $\vec{\tau} = \vec{p} \times \vec{E}$	21-11

TOPIC	RELEVANT EQUATIONS AND REMARKS	
Potential energy of a dipole	$U = -\vec{p} \cdot \vec{E} + U_0$ where U_0 is usually taken to be zero.	21-12
8. Polar and Nonpolar Molecules	Polar molecules, such as H_2O and HCl, have permanent dipole moments because their centers of positive and negative charge do not coincide. They behave like simple dipoles in an electric field. Nonpolar molecules do not have permanent dipole moments, but they acquire induced dipole moments in the presence of an electric field.	

Answers to Concept Checks

21-1 (*a*) $+\frac{1}{2}Q$. Because the spheres are identical, they must share the total charge equally. (*b*) $+2Q$, which is necessary to satisfy the conservation of charge

21-2 $Q_1 = +Q/2$, $Q_2 = -Q/4$, and $Q_3 = -Q/4$

Answers to Practice Problems

21-1 $N = Q/e = (50 \times 10^{-9}\ \mathrm{C})/(1.6 \times 10^{-19}\ \mathrm{C}) = 3.1 \times 10^{11}$. Charge quantization cannot be detected in a charge of this size; even adding or subtracting a million electrons produces a negligibly small effect.

21-2 About 3.5×10^{-8} percent

21-3 2.25×10^{-3} N

21-4 $+(6.3\ \mu\mathrm{N})\hat{\boldsymbol{i}}$

21-5 $\hat{\boldsymbol{r}}_{10} = (\hat{\boldsymbol{i}} + \hat{\boldsymbol{j}})/\sqrt{2}$

21-6 No, but suppose it were. Because the x component of $\vec{r}_{10}$ is less than the magnitude of $\vec{r}_{10}$, the denominator of kq_1q_0/x_{10}^2 is less than the denominator of kq_1q_0/r_{10}^2. This would imply that the x component of $\vec{F}_{10}$ is greater than the magnitude of $\vec{F}_{10}$, an impossibility because the component of a vector is never greater than the magnitude of the vector. Therefore, the x component of the force $\vec{F}_{10} = (kq_1q_0/r_{10}^2)\hat{\boldsymbol{r}}_{10}$ is not necessarily equal to $F_{10x} = kq_1q_0/x_{10}^2$.

21-7 $\vec{E} = \vec{F}/q_0 = (4.0 \times 10^4\ \mathrm{N/C})\hat{\boldsymbol{i}}$

21-8 $\vec{F} = -(6.4 \times 10^{-15}\ \mathrm{N})\hat{\boldsymbol{i}}$

21-9 $x = 1.80$ m

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • Objects are composed of atoms which are composed of charged particles (protons and electrons); however, we rarely observe the effects of the electrostatic force. Explain why we do not observe these effects.

2 • A carbon atom can become a carbon *ion* if it has one or more of its electrons removed during a process called *ionization.* What is the net charge on a carbon atom that has had two of its electrons removed? (*a*) $+e$, (*b*) $-e$, (*c*) $+2e$, (*d*) $-2e$

3 •• You do a simple demonstration for your high school physics teacher in which you claim to disprove Coulomb's law. You first run a rubber comb through your dry hair, then use it to attract tiny neutral pieces of paper on the desk. You then say, "Coulomb's law states that for there to be electrostatic forces of attraction between two objects, both objects need to be charged. However, the paper was not charged. So according to Coulomb's law, there should be no electrostatic forces of attraction between them, yet there clearly was." You rest your case. (*a*) What is wrong with your assumptions? (*b*) Does attraction between the paper and the comb require that the net charge on the comb be negative? Explain your answer.

4 •• You have a positively charged insulating rod and two metal spheres on insulating stands. Give step-by-step directions of how the rod, without actually touching either sphere, can be used to give one of the spheres (*a*) a negative charge and (*b*) a positive charge.

5 •• (*a*) Two point particles that have charges of $+4q$ and $-3q$ are separated by distance d. Use field lines to draw a visualization of the electric field in the neighborhood of this system. (*b*) Draw the field lines at distances much greater than d from the charges.

6 •• A metal sphere is positively charged. Is it possible for the sphere to electrically attract another positively charged ball? Explain your answer.

7 •• A simple demonstration of electrostatic attraction can be done by dangling a small ball of crumpled aluminum foil on a string and bringing a charged rod near the ball. The ball initially will be attracted to the rod, but once they touch, the ball will be strongly repelled from it. Explain these observations.

8 •• Two positive point charges that are equal in magnitude are fixed in place, one at $x = 0.00$ m and the other at $x = 1.00$ m, on the x axis. A third positive point charge is placed at an equilibrium position. (*a*) Where is this equilibrium position? (*b*) Is the equilibrium position stable if the third particle is constrained to move parallel with the x axis? (*c*) What if it is constrained to move parallel with the y axis? Explain your answer.

9 •• Two neutral conducting spheres are in contact and are supported on a large wooden table by insulated stands. A positively charged rod is brought up close to the surface of one of the spheres on the side opposite its point of contact with the other sphere. (*a*) Describe the induced charges on the two conducting spheres and sketch the charge distributions on them. (*b*) The two spheres are separated and then the charged rod is removed. The spheres are then separated far apart. Sketch the charge distributions on the separated spheres.

10 •• Three point charges, $+q$, $+Q$, and $-Q$, are placed at the corners of an equilateral triangle as shown in Figure 21-33. No other charged objects are nearby. (*a*) What is the direction of the net force on charge $+q$ due to the other two charges? (*b*) What is the total electric force on the system of three charges? Explain.

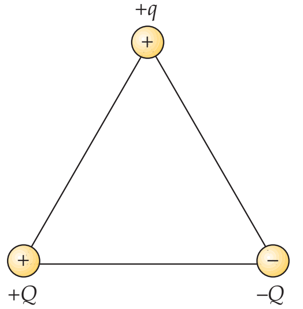

FIGURE 21-33 Problem 10

11 •• A positively charged particle is free to move in a region with a nonzero electric field $\vec{E}$. Which statement(s) must be true?

(*a*) The particle is accelerating in the direction perpendicular to $\vec{E}$.
(*b*) The particle is accelerating in the direction of $\vec{E}$.
(*c*) The particle is moving in the direction of $\vec{E}$.
(*d*) The particle could be momentarily at rest.
(*e*) The force on the particle is opposite the direction of $\vec{E}$.
(*f*) The particle is moving opposite the direction of $\vec{E}$.

12 •• Four charges are fixed in place at the corners of a square as shown in Figure 21-34. No other charges are nearby. Which of the following statements is true?

(*a*) $\vec{E}$ is zero at the midpoints of all four sides of the square.
(*b*) $\vec{E}$ is zero at the center of the square.
(*c*) $\vec{E}$ is zero midway between the top two charges and midway between the bottom two charges.

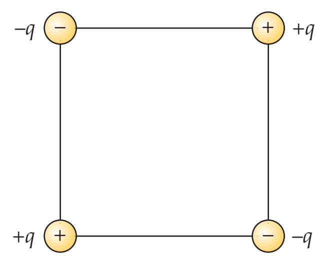

FIGURE 21-34 Problem 12

13 •• Two point particles that have charges of $+q$ and $-3q$ are separated by distance d. (*a*) Use field lines to sketch the electric field in the neighborhood of this system. (*b*) Draw the field lines at distances much greater than d from the charges. SSM

14 •• Three equal positive point charges (each charge $+q$) are fixed at the vertices of an equilateral triangle that has sides of length a. The origin is at the midpoint of one side the triangle, the center of the triangle on the x axis at $x = x_1$, and the vertex opposite the origin is on the x axis at $x = x_2$. (*a*) Express x_1 and x_2 in terms of a. (*b*) Write an expression for the electric field on the x axis a distance x from the origin on the interval $0\ x < x_2$. (*c*) Show that the expression you obtained in (*b*) gives the expected results for $x = 0$ and for $x = x_1$.

15 •• A molecule has a dipole moment given by $\vec{p}$. The molecule is momentarily at rest with $\vec{p}$ making an angle θ with a uniform electric field $\vec{E}$. Describe the subsequent motion of the dipole moment.

16 •• True or false:

(*a*) The electric field of a point charge always points away from the charge.
(*b*) The electric force on a charged particle in an electric field is always in the same direction as the field.
(*c*) Electric field lines never intersect.
(*d*) All molecules have dipole moments in the presence of an external electric field.

17 •• Two molecules have dipole moments of equal magnitude. The dipole moments are oriented in various configurations as shown in Figure 21-35. Determine the electric-field direction at each of the numbered locations. Explain your answers. SSM

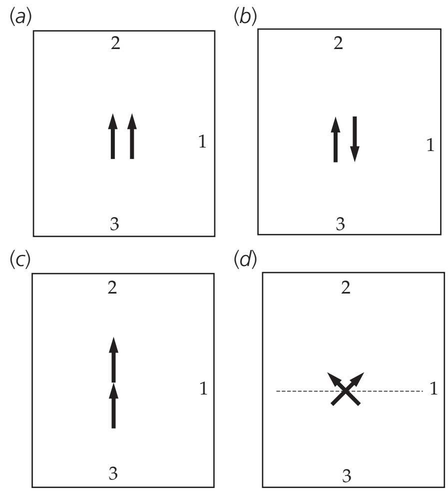

FIGURE 21-35 Problem 17

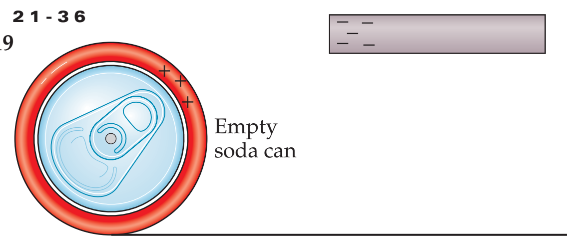
ESTIMATION AND APPROXIMATION

18 •• Estimate the force required to bind the two protons in the He nucleus together. *Hint: Model the protons as point charges. You will need to have an estimate of the distance between them.*

19 •• A popular classroom demonstration consists of rubbing a plastic rod with fur to give the rod charge, and then placing the rod near an empty soda can that is on its side (Figure 21-36). Explain why the can will roll toward the rod.

FIGURE 21-36 Problem 19



20 •• Sparks in air occur when ions in the air are accelerated to such a high speed by an electric field that when the ions impact on neutral gas molecules, the neutral molecules become ions. If the electric field strength is large enough, the ionized collision products are themselves accelerated and produce more ions on impact, and so forth. This avalanche of ions is what we call a spark. (*a*) Assume that an ion moves, on average, exactly one mean free path through the air before hitting a molecule. If the ion needs to acquire approximately 1.0 eV of kinetic energy in order to ionize a molecule, estimate the

minimum strength of the electric field required at standard room pressure and temperature. Assume that the cross-sectional area of an air molecule is about 0.10 nm^2. (*b*) How does the strength of the electric field in Part (*a*) depend on temperature? (*c*) How does the strength of the electric field in Part (*a*) depend on pressure?

CHARGE

21 • A plastic rod is rubbed against a wool shirt, thereby acquiring a charge of $-0.80\ \mu C$. How many electrons are transferred from the wool shirt to the plastic rod?

22 • A charge equal to the charge of Avogadro's number of protons ($N_A = 6.02 \times 10^{23}$) is called a *faraday*. Calculate the number of coulombs in a faraday.

23 • What is the total charge of all of the protons in 1.00 kg of carbon? SSM

24 •• Suppose a cube of aluminum which is 1.00 cm on a side accumulates a net charge of +2.50 pC. (*a*) What percentage of the electrons originally in the cube was removed? (*b*) By what percentage has the mass of the cube decreased because of this removal?

25 •• During a process described by the *photoelectric effect*, ultraviolet light can be used to charge a piece of metal. (*a*) If such light is incident on a slab of conducting material and electrons are ejected with enough energy that they escape the surface of the metal, how long before the metal has a net charge of +1.50 nC if 1.00×10^6 electrons are ejected per second? (*b*) If 1.3 eV is needed to eject an electron from the surface, what is the power rating of the light beam? (Assume this process is 100% efficient.)

COULOMB'S LAW

26 • A point charge $q_1 = 4.0\ \mu C$ is at the origin and a point charge $q_2 = 6.0\ \mu C$ is on the x axis at $x = 3.0$ m. (*a*) Find the electric force on charge q_2. (*b*) Find the electric force on q_1. (*c*) How would your answers for Parts (*a*) and (*b*) differ if q_2 were $-6.0\ \mu C$?

27 • Three point charges are on the x axis: $q_1 = -6.0\ \mu C$ is at $x = -3.0$ m, $q_2 = 4.0\ \mu C$ is at the origin, and $q_3 = -6.0\ \mu C$ is at $x = 3.0$ m. Find the electric force on q_1. SSM

28 •• A 2.0-μC point charge and a 4.0-μC point charge are a distance L apart. Where should a third point charge be placed so that the electric force on that third charge is zero?

29 •• A -2.0-μC point charge and a 4.0-μC point charge are a distance L apart. Where should a third point charge be placed so that the electric force on that third charge is zero?

30 •• Three point charges, each of magnitude 3.00 nC, are at separate corners of a square of edge length 5.00 cm. The two point charges at opposite corners are positive, and the third point charge is negative. Find the force exerted by these point charges on a fourth point charge $q_4 = +3.00$ nC at the remaining corner.

31 •• A point charge of 5.00 μC is on the y axis at $y = 3.00$ cm, and a second point charge of $-5.00\ \mu C$ is on the y axis at $y = -3.00$ cm. Find the electric force on a point charge of 2.00 μC on the x axis at $x = 8.00$ cm.

32 •• A point particle that has a charge of $-2.5\ \mu C$ is located at the origin. A second point particle that has a charge of 6.0 μC is at $x = 1.0$ m, $y = 0.50$ m. A third point particle, an electron, is at a point that has coordinates (x, y). Find the values of x and y such that the electron is in equilibrium.

33 •• A point particle that has a charge of $-1.0\ \mu C$ is located at the origin; a second point particle that has a charge of 2.0 μC is located at $x = 0$, $y = 0.10$ m; and a third point particle that has a charge of 4.0 μC is located at $x = 0.20$ m, $y = 0$. Find the total electric force on each of the three point charges.

34 •• A point particle that has a charge of 5.00 μC is located at $x = 0$, $y = 0$ and a point particle that has a charge q is located at $x = 4.00$ cm, $y = 0$. The electric force on a point particle at $x = 8.00$ cm, $y = 0$ that has a charge of 2.00 μC is $-(19.7\ \mathrm{N})\hat{\boldsymbol{i}}$. Determine the charge q.

35 ••• Five identical point charges, each having charge Q, are equally spaced on a semicircle of radius R as shown in Figure 21-37. Find the force (in terms of k, Q, and R) on a charge q located equidistant from the five other charges. SSM

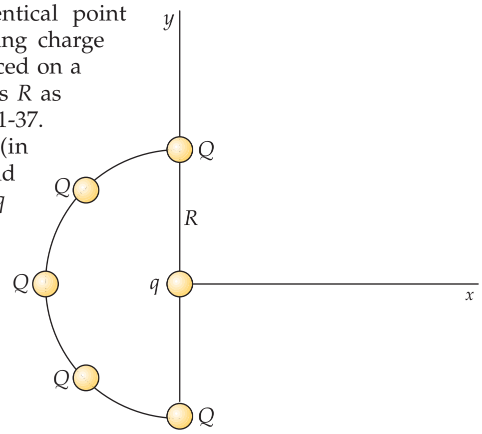


FIGURE 21-37
Problem 35

36 ••• The structure of the NH_3 molecule is approximately that of an equilateral tetrahedron, with three H^+ ions forming the base and an N^{3-} ion at the apex of the tetrahedron. The length of each side is 1.64×10^{-10} m. Calculate the electric force that acts on each ion.

THE ELECTRIC FIELD

37 • A point charge of 4.0 μC is at the origin. What are the magnitude and direction of the electric field on the x axis at (*a*) $x = 6.0$ m and (*b*) $x = -10$ m? (*c*) Sketch the function E_x versus x for both positive and negative values of x. (Remember that E_x is negative when $\vec{E}$ points in the $-x$ direction.) SSM

38 • Two point charges, each $+4.0\ \mu C$, are on the x axis; one point charge is at the origin and the other is at $x = 8.0$ m. Find the electric field on the x axis at (*a*) $x = -2.0$ m, (*b*) $x = 2.0$ m, (*c*) $x = 6.0$ m, and (*d*) $x = 10$ m. (*e*) At what point on the x axis is the electric field zero? (*f*) Sketch E_x versus x for $-3.0\ \mathrm{m} < x < 11$ m.

39 • When a 2.0-nC point charge is placed at the origin, it experiences an electric force of 8.0×10^{-4} N in the $+y$ direction. (*a*) What is the electric field at the origin? (*b*) What would be the electric force on a -4.0-nC point charge placed at the origin? (*c*) If this force is due to the electric field of a point charge on the y axis at $y = 3.0$ cm, what is the value of that charge?

40 • The electric field near the surface of Earth points downward and has a magnitude of 150 N/C. (*a*) Compare magnitude of the upward electric force on an electron with the magnitude of gravitational force on the electron. (*b*) What charge should be placed on a Ping-Pong ball of mass 2.70 g so that the electric force balances the weight of the ball near Earth's surface?

41 •• Two point charges q_1 and q_2 both have a charge equal to +6.0 nC and are on the y axis at $y_1 = +3.0$ cm and $y_2 = -3.0$ cm, respectively. (*a*) What are the magnitude and direction of the electric field on the x axis at $x = 4.0$ cm? (*b*) What is the force exerted on a third charge $q_0 = 2.0$ nC when it is placed on the x axis at $x = 4.0$ cm? SSM

42 •• A point charge of +5.0 μC is located on the x axis at $x = -3.0$ cm, and a second point charge of $-8.0\ \mu C$ is located on the x axis at $x = +4.0$ cm. Where should a third charge of +6.0 μC be placed so that the electric field at the origin is zero?

43 •• A -5.0-μC point charge is located at $x = 4.0$ m, $y = -2.0$ m, and a 12-μC point charge is located at $x = 1.0$ m, $y = 2.0$ m. (*a*) Find the magnitude and direction of the electric field at $x = -1.0$ m, $y = 0$. (*b*) Calculate the magnitude and direction of the electric force on an electron that is placed at $x = -1.0$ m, $y = 0$.

44 •• Two equal positive charges q are on the y axis; one point charge is at $y = +a$ and the other is at $y = -a$. (*a*) Show that on the x axis the x component of the electric field is given by $E_x = 2kqx/(x^2 + a^2)^{3/2}$. (*b*) Show that near the origin, where x is much smaller than a, $E_x \approx 2kqx/a^3$. (*c*) Show that for values of x much larger than a, $E_x \approx 2kq/x^2$. Explain why a person might expect this result even without deriving it by taking the appropriate limit.

45 •• A 5.0-μC point charge is located at $x = 1.0$ m, $y = 3.0$ m, and a -4.0-μC point charge is located at $x = 2.0$ m, $y = -2.0$ m. (*a*) Find the magnitude and direction of the electric field at $x = -3.0$ m, $y = 1.0$ m. (*b*) Find the magnitude and direction of the force on a proton placed at $x = -3.0$ m, $y = 1.0$ m.

46 •• Two positive point charges, each having charge Q, are on the y axis—one at $y = +a$ and the other at $y = -a$. (*a*) Show that the electric field strength on the x axis is greatest at $x = a/\sqrt{2}$ and $x = -a/\sqrt{2}$ by computing $\partial E_x/\partial x$ and setting the derivative equal to zero. (*b*) Sketch the function E_x versus x using your results for Part (*a*) of this problem and the facts that E_x is approximately $2kqx/a^3$ when x is much smaller than a and E_x is approximately $2kq/x^2$ when x is much larger than a.

47 •• Two point particles, each having a charge q, sit on the base of an equilateral triangle that has sides of length L as shown in Figure 21-38. A third point particle that has a charge equal to $2q$ sits at the apex of the triangle. Where must a fourth point particle that has a charge equal to q be placed in order that the electric field at the center of the triangle be zero? (The center is in the plane of the triangle and equidistant from the three vertices.) SSM

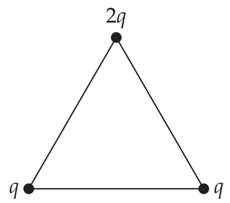

FIGURE 21-38 Problems 47 and 48

48 •• Two point particles, each having a charge equal to q, sit on the base of an equilateral triangle that has sides of length L as shown in Figure 21-38. A third point particle that has a charge equal to $2q$ sits at the apex of the triangle. A fourth point particle that has charge q' is placed at the midpoint of the baseline making the electric field at the center of the triangle equal to zero. What is the value of q'? (The center is in the plane of the triangle and equidistant from all three vertices.)

49 •• Two equal positive point charges $+q$ are on the y axis; one is at $y = +a$ and the other is at $y = -a$. The electric field at the origin is zero. A test charge q_0 placed at the origin will therefore be in equilibrium. (*a*) Discuss the stability of the equilibrium for a positive test charge by considering small displacements from equilibrium along the x axis and small displacements along the y axis. (*b*) Repeat Part (*a*) for a negative test charge. (*c*) Find the magnitude and sign of a charge q_0 that when placed at the origin results in a net force of zero on each of the three charges.

50 ••• Two positive point charges $+q$ are on the y axis at $y = +a$ and $y = -a$. A bead of mass m and charge $-q$ slides without friction along a taut thread that runs along the x axis. Let x be the position of the bead. (*a*) Show that for $x \ll a$, the bead experiences a linear restoring force (a force that is proportional to x and directed toward the equilibrium position at $x = 0$) and therefore undergoes simple harmonic motion. (*b*) Find the period of the motion.

POINT CHARGES IN ELECTRIC FIELDS

51 •• The acceleration of a particle in an electric field depends on q/m (the charge-to-mass ratio of the particle). (*a*) Compute q/m for an electron. (*b*) What are the magnitude and direction of the acceleration of an electron in a uniform electric field that has a magnitude of 100 N/C? (*c*) Compute the time it takes for an electron placed at rest in a uniform electric field that has a magnitude of 100 N/C to reach a speed 0.01c. (When the speed of an electron approaches the speed of light c, relativistic kinematics must be used to calculate its motion, but at speeds of 0.01c or less, nonrelativistic kinematics is sufficiently accurate for most purposes.) (*d*) How far does the electron travel in that time? SSM

52 • The acceleration of a particle in an electric field depends on the charge-to-mass ratio of the particle. (*a*) Compute q/m for a proton, and find its acceleration in a uniform electric field that has a magnitude of 100 N/C. (*b*) Find the time it takes for a proton initially at rest in such a field to reach a speed of 0.01c (where c is the speed of light). (When the speed of a proton approaches the speed of light c, relativistic kinematics must be used to calculate its motion, but at speeds of 0.01c or less, nonrelativistic kinematics is sufficiently accurate for most purposes.)

53 • An electron has an initial velocity of 2.00×10^6 m/s in the $+x$ direction. It enters a region that has a uniform electric field $\vec{E} = (300\ \mathrm{N/C})\hat{j}$. (*a*) Find the acceleration of the electron. (*b*) How long does it take for the electron to travel 10.0 cm in the $+x$ direction in the region that has the field? (*c*) Through what angle, and in what direction, is the electron deflected while traveling the 10.0 cm in the x direction?

54 •• An electron is released from rest in a weak electric field given by $\vec{E} = -1.50 \times 10^{-10}\ \mathrm{N/C}\hat{j}$. After the electron has traveled a vertical distance of 1.0 μm, what is its speed? (Do not neglect the gravitational force on the electron.)

55 •• A 2.00-g charged particle is released from rest in a region that has a uniform electric field $\vec{E} = (300\ \mathrm{N/C})\hat{i}$. After traveling a distance of 0.500 m in this region, the particle has a kinetic energy of 0.120 J. Determine the charge of the particle.

56 •• A charged particle leaves the origin with a speed of 3.00×10^6 m/s at an angle of 35° above the x axis. A uniform electric field, given by $\vec{E} = -E_0\hat{j}$, exists throughout the region. Find E_0 such that the particle will cross the x axis at $x = 1.50$ cm if the particle is (*a*) an electron and (*b*) a proton.

57 •• An electron starts at the position shown in Figure 21-39 with an initial speed $v_0 = 5.00 \times 10^6$ m/s at 45° to the x axis. The electric field is in the $+y$ direction and has a magnitude of 3.50×10^3 N/C. The black lines in the figure are charged metal plates. On which plate and at what location will the electron strike? SSM

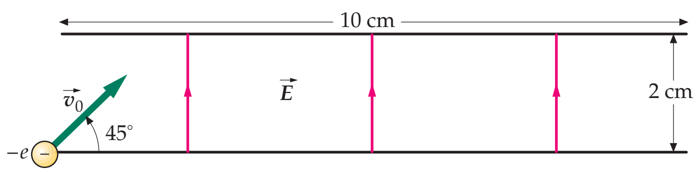

FIGURE 21-39 Problem 57

58 •• **ENGINEERING APPLICATION** An electron that has a kinetic energy equal to 2.00×10^{-16} J is moving to the right along the axis of a cathode-ray tube as shown in Figure 21-40. An electric field $\vec{E} = (2.00 \times 10^4\ \mathrm{N/C})\hat{j}$ exists in the region between the deflection plates, and no electric field ($\vec{E} = 0$) exists outside this region. (*a*) How far is the electron from the axis of the tube when it exits the region between the plates? (*b*) At what angle is the electron moving, with respect to the axis, after exiting the region between the plates? (*c*) At what distance from the axis will the electron strike the fluorescent screen?

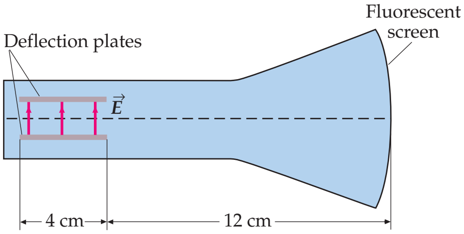

FIGURE 21-40
Problem 58

DIPOLES

59 • Two point charges, $q_1 = 2.0$ pC and $q_2 = -2.0$ pC, are separated by 4.0 μm. (*a*) What is the magnitude of the dipole moment of this pair of charges? (*b*) Sketch the pair and show the direction of the dipole moment.

60 • A dipole of moment 0.50 $e \cdot$nm is placed in a uniform electric field that has a magnitude of 4.0×10^4 N/C. What is the magnitude of the torque on the dipole when (*a*) the dipole is aligned with the electric field, (*b*) the dipole is transverse to (perpendicular to) the electric field, and (*c*) the direction of dipole makes an angle of 30° with the direction of electric field? (*d*) Defining the potential energy to be zero when the dipole is transverse to the electric field, find the potential energy of the dipole for the orientations specified in Parts (*a*) and (*c*).

GENERAL PROBLEMS

61 • Show that it is only possible to place one isolated proton in an ordinary empty coffee cup by considering the following situation. Assume the first proton is fixed at the bottom of the cup. Determine the distance directly above this proton where a second proton would be in equilibrium. Compare this distance to the depth of an ordinary coffee cup to complete the argument. SSM

62 •• Point charges of -5.00 μC, $+3.00$ μC, and $+5.00$ μC are located on the x axis at $x = -1.00$ cm, $x = 0$, and $x = +1.00$ cm, respectively. Calculate the electric field on the x axis at $x = 3.00$ cm and at $x = 15.0$ cm. Are there any points on the x axis where the magnitude of the electric field is zero? If so, where are those points?

63 •• Point charges of -5.00 μC and $+5.00$ μC are located on the x axis at $x = -1.00$ cm and $x = +1.00$ cm, respectively. (*a*) Calculate the electric field strength at $x = 10.00$ cm. (*b*) Estimate the electric field strength at $x = 10.00$ cm by modeling the two charges as an electric dipole located at the origin and using $E = 2kp/|x|^3$ (Equation 21-10). Compare your result with the result obtained in Part (*a*), and explain the reason for the difference between the two results.

64 •• A fixed point charge of $+2q$ is connected by strings to point charges of $+q$ and $+4q$, as shown in Figure 21-41. Find the tensions T_1 and T_2.

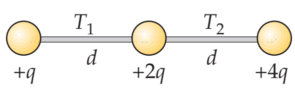

FIGURE 21-41 **Problem 64**

65 •• A positive charge Q is to be divided into two positive point charges q_1 and q_2. Show that, for a given separation D, the force exerted by one charge on the other is greatest if $q_1 = q_2 = \frac{1}{2}Q$. SSM

66 •• A point charge Q is located on the x axis at $x = 0$, and a point charge $4Q$ is located at $x = 12.0$ cm. The electric force on a point charge of -2.00 μC is zero if that charge is placed at $x = 4.00$ cm, and is 126 N in the $+x$ direction if placed at $x = 8.00$ cm. Determine the charge Q.

67 •• Two point particles separated by 0.60 m have a total charge of 200 μC. (*a*) If the two particles repel each other with a force of 80 N, what is the charge on each of the two particles? (*b*) If the two particles attract each other with a force of 80 N, what are the charges on the two particles?

68 •• A point particle that has charge $+q$ and unknown mass m is released from rest in a region that has a uniform electric field $\vec{E}$ that is directed vertically downward. The particle hits the ground at a speed $v = 2\sqrt{gh}$, where h is the initial height of the particle. Find m in terms of E, q, and g.

69 •• A rigid 1.00-m-long rod is pivoted about its center (Figure 21-42). A charge $q_1 = 5.00 \times 10^{-7}$ C is placed on one end of the rod, and a charge $q_2 = -q_1$ is placed a distance $d = 10.0$ cm directly below it. (*a*) What is the force exerted by q_2 on q_1? (*b*) What is the torque (measured about the rotation axis) due to that force? (*c*) To counterbalance the attraction between the two charges, we hang a block 25.0 cm from the pivot as shown. What value should we choose for the mass m of the block? (*d*) We now move the block and hang it a distance of 25.0 cm from the balance point, on the same side of the balance as the charge. Keeping q_1 the same, and d the same, what value should we choose for q_2 to keep this apparatus in balance? SSM

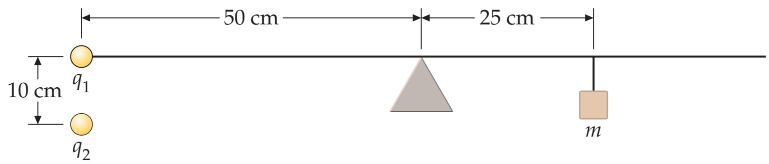

FIGURE 21-42 **Problem 69**

70 •• Two 3.0-μC point charges are located at $x = 0$, $y = 2.0$ m and at $x = 0$, $y = -2.0$ m. Two other point charges, each with charge Q, are located at $x = 4.0$ m, $y = 2.0$ m and at $x = 4.0$ m, $y = -2.0$ m (Figure 21-43). The electric field at $x = 0, y = 0$ due to the presence of the four charges is $(4.0 \times 10^3\ \text{N/C})\hat{\boldsymbol{i}}$. Determine Q.

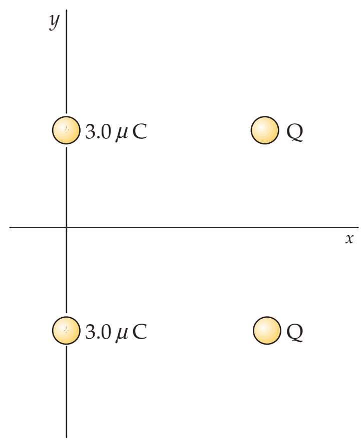

FIGURE 21-43
Problem 70

71 •• Two point charges have a total charge equal to 200 μC and are separated by 0.600 m. (*a*) Find the charge of each particle if the particles repel each other with a force of 120 N. (*b*) Find the force on each particle if the charge on each particle is 100 μC. SSM

72 •• Two point charges have a total charge equal to 200 μC and are separated by 0.600 m. (*a*) Find the charge of each particle if the particles attract each other with a force of 120 N. (*b*) Find the force on each particle if the charge on each particle is 100 μC. SSM

73 •• A point charge of -3.00 μC is located at the origin; a point charge of 4.00 μC is located on the x axis at $x = 0.200$ m; a third point charge Q is located on the x axis at $x = 0.320$ m. The electric force on the 4.00–μC charge is 240 N in the $+x$ direction. (*a*) Determine the charge Q. (*b*) With this configuration of three charges, at what location(s) is the electric field zero?

74 •• Two point particles, each of mass m and charge q, are suspended from a common point by threads of length L. Each thread makes an angle θ with the vertical as shown in Figure 21-44. (*a*) Show that $q = 2L\sin\theta\sqrt{(mg/k)\tan\theta}$ where k is the Coulomb constant. (*b*) Find q if $m = 10.0$ g, $L = 50.0$ cm, and $\theta = 10.0°$.

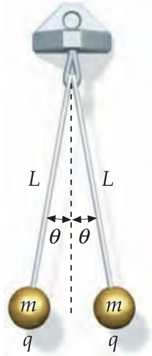

FIGURE 21-44 Problem 74

75 •• Suppose that in Problem 74 $L = 1.5$ m and $m = 0.010$ kg. (*a*) What is the angle that each string makes with the vertical if $q = 0.75\ \mu$C? (*b*) What is the angle that each string makes with the vertical if one particle has a charge of 0.50 μC and the other has a charge of 1.0 μC?

76 •• Four point charges of equal magnitude are arranged at the corners of a square of side L as shown in Figure 21-45. (*a*) Find the magnitude and direction of the force exerted on the charge in the lower left corner by the other three charges. (*b*) Show that the electric field at the midpoint of one of the sides of the square is directed along that side toward the negative charge and has a magnitude E given by

$$E = k\frac{8q}{L^2}\left(1 - \frac{1}{5\sqrt{5}}\right).$$

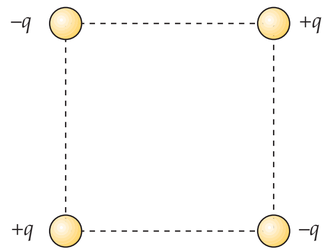

FIGURE 21-45 Problem 76

77 •• Figure 21-46 shows a dumbbell consisting of two identical small particles, each of mass m, attached to the ends of a thin (massless) rod of length a that is pivoted at its center. The particles have charges of $+q$ and $-q$, and the dumbbell is located in a uniform electric field $\vec{E}$. Show that for small values of the angle θ between the direction of the dipole and the direction of the electric field, the system displays a rotational form of simple harmonic motion, and obtain an expression for the period of that motion. SSM

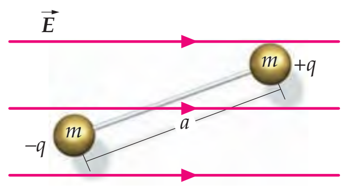

FIGURE 21-46 Problems 77 and 78

78 •• For the dumbbell in Problem 77, let $m = 0.0200$ kg, $a = 0.300$ m, and $\vec{E} = (600\text{ N/C})\hat{i}$. The dumbbell is initially at rest and makes an angle of 60° with the x axis. The dumbbell is then released, and when it is momentarily aligned with the electric field, its kinetic energy is 5.00×10^{-3} J. Determine the magnitude of q.

79 •• An electron (charge $-e$, mass m) and a positron (charge $+e$, mass m) revolve around their common center of mass under the influence of their attractive coulomb force. Find the speed v of each particle in terms of e, m, k, and their separation distance L. SSM

80 ••• A simple pendulum of length 1.0 m and mass 5.0×10^{-3} kg is placed in a uniform, electric field $\vec{E}$ that is directed vertically upward. The bob has a charge of $-8.0\ \mu$C. The period of the pendulum is 1.2 s. What are the magnitude and direction of $\vec{E}$?

81 ••• A point particle of mass m and charge q is constrained to move vertically inside a narrow, frictionless cylinder (Figure 21-47). At the bottom of the cylinder is a point charge Q having the same sign as q. (*a*) Show that the particle whose mass is m will be in equilibrium at a height $y_0 = (kqQ/mg)^{1/2}$. (*b*) Show that if the particle is displaced from its equilibrium position by a small amount and released, it will exhibit simple harmonic motion with angular frequency $\omega = (2g/y_0)^{1/2}$.

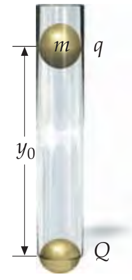

FIGURE 21-47 Problem 81

82 ••• Two neutral molecules on the x axis attract each other. Each molecule has a dipole moment $\vec{p}$, and these dipole moments are on the $+x$ direction and are separated by a distance d. Derive an expression for the force of attraction in terms of p and d.

83 ••• Two equal positive point charges Q are on the x axis at $x = \frac{1}{2}a$ and $x = -\frac{1}{2}a$. (*a*) Obtain an expression for the electric field on the y axis as a function of y. (*b*) A bead of mass m, which has a charge q, moves along the y axis on a thin frictionless taut thread. Find the electric force that acts on the bead as a function of y and determine the sign of q such that this force always points away from the origin. (*c*) The bead is initially at rest at the origin. If it is given a slight nudge in the $+y$ direction, how fast will the bead be traveling the instant the net force on it is a maximum? (Assume any effects due to gravity are negligible.)

84 ••• A gold nucleus is 100 fm (1 fm $= 10^{-15}$ m) from a proton, which initially is at rest. When the proton is released, it speeds away because of the repulsion that it experiences due to the charge on the gold nucleus. What is the proton's speed a large distance (assume to be infinity) from the gold nucleus? (Assume the gold nucleus remains stationary.)

85 ••• During a famous experiment in 1919, Ernest Rutherford shot doubly ionized helium nuclei (also known as alpha particles) at a gold foil. He discovered that virtually all of the mass of an atom resides in an extremely compact nucleus. Suppose that during such an experiment, an alpha particle far from the foil has a kinetic energy of 5.0 MeV. If the alpha particle is aimed directly at the gold nucleus, and the only force acting on it is the electric force of repulsion exerted on it by the gold nucleus, how close will it approach the gold nucleus before turning back? That is, what is the minimum center-to-center separation of the alpha particle and the gold nucleus? SSM

86 ••• During the Millikan experiment used to determine the charge on the electron, a charged polystyrene microsphere is released in still air in a known vertical electric field. The charged microsphere will accelerate in the direction of the net force until it reaches terminal speed. The charge on the microsphere is determined by measuring the terminal speed. During one such experiment, the microsphere has radius $r = 5.50 \times 10^{7}$ m, and the field has a magnitude $E = 6.00 \times 10^{4}$ N/C. The magnitude of the drag force on the sphere is given by $F_D = 6\pi\eta r v$, where v is the speed of the sphere and η is the viscosity of air ($\eta = 1.8 \times 10^{-5}\ \text{N}\cdot\text{s/m}^2$). Polystyrene has density $1.05 \times 10^{3}\ \text{kg/m}^3$. (*a*) If the electric field is pointing down and the polystyrene microsphere is rising with a terminal speed of 1.16×10^{-4} m/s, what is the charge on the sphere? (*b*) How many excess electrons are on the sphere? (*c*) If the direction of the electric field is reversed but its magnitude remains the same, what is the new terminal speed?

87 ••• In Problem 86, there is a description of the Millikan experiment used to determine the charge on the electron. During the experiment, a switch is used to reverse the direction of the electric field without changing its magnitude, so that one can measure the terminal speed of the microsphere both as it is moving upward and as it is moving downward. Let v_u represent the terminal speed when the particle is moving up and v_d the terminal speed when moving down. (*a*) If we let $u = v_u + v_d$, show that $q = 3\pi\eta r u/E$, where q is the microsphere's net charge. For the purpose of determining q, what advantage does measuring both v_u and v_d have over measuring only one terminal speed? (*b*) Because charge is quantized, u can only change by steps of magnitude $N\Delta$, where N is an integer. Using the data from Problem 86, calculate Δ. SSM

CHAPTER 22

LIGHTNING IS AN ELECTRIC PHENOMENA. DURING A LIGHTNING STRIKE, CHARGES ARE TRANSFERRED BETWEEN THE CLOUDS AND THE GROUND. THE VISIBLE LIGHT GIVEN OFF COMES FROM AIR MOLECULES RETURNING TO LOWER ENERGY STATES. *(Photo Disc.)*

The Electric Field II: Continuous Charge Distributions

? How would you calculate the charge on the surface of Earth? (See Example 22-15.)

On a microscopic scale, charge is quantized. However, there are often situations in which many charges are so close together that the charge can be thought of as continuously distributed. We apply the concept of density to charge similarly to the way we use it to describe matter.

In addition to continuous charge distributions, we examine the importance of symmetry within the electric field. The mathematical findings of Carl Friedrich Gauss show that every electric field maintains symmetric properties. It is an understanding of charge distribution and symmetry within the electric field that aids scientists in a vast array of fields.

In this chapter, we show how Coulomb's law is used to calculate the electric field produced by various types of continuous charge distributions. We then introduce Gauss's law and use it to calculate the electric fields produced by charge distributions that have certain symmetries.

22-1 CALCULATING FROM COULOMB'S LAW

Figure 22-1 shows an element of charge $dq = \rho\, dV$ that is small enough to be considered a point charge. The element of charge dq is the amount of charge in volume element dV and ρ is the charge per unit volume. Coulomb's law states that the electric field $d\vec{E}$ at a field point P due to this element of charge is

$$d\vec{E} = dE_r\,\hat{r} = \frac{k\,dq}{r^2}\,\hat{r} \qquad \text{22-1}a$$

where $\hat{r}$ is a unit vector directed away from the charge element dq and toward point P, and dE_r (the component of $d\vec{E}$ in the direction of $\hat{r}$) is given by $k\,dq/r^2$.

The total field $\vec{E}$ at P is calculated by integrating this expression over the entire charge distribution. That is,

$$\vec{E} = \int d\vec{E} = \int \frac{k\hat{r}}{r^2}\,dq \qquad \text{22-1}b$$

ELECTRIC FIELD DUE TO A CONTINUOUS CHARGE DISTRIBUTION

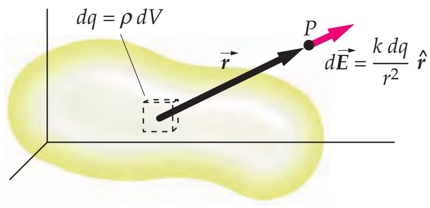

FIGURE 22-1 An element of charge dq produces a field $d\vec{E} = (k\,dq/r^2)\hat{r}$ at point P. The field at P is calculated by integrating Equation 22-1a over the entire charge distribution.

The use of a continuous charge density to describe a large number of discrete charges is similar to the use of a continuous mass density to describe air, which actually consists of a large number of discrete atoms and molecules. In both cases, it is usually easy to find a volume element ΔV that is large enough to contain a multitude of individual charge carriers and yet is small enough that replacing ΔV with a differential dV and using calculus introduces negligible error. If the charge is distributed over a surface or along a line, we use $dq = \sigma\, dA$ or $dq = \lambda\, dL$ and integrate over the surface or line. (In these cases σ and λ are the charge per unit area and charge per unit length, respectively.) The integration usually is done by expressing $\hat{r}$ in terms of its Cartesian components, and then integrating one component at a time.

! The x component of $\hat{r}$ is $\hat{r}\cdot\hat{i} = \cos\theta$, where θ is the angle between $\hat{r}$ and $\hat{i}$.* The y and z components of $\hat{r}$ are calculated in like manner.

PROBLEM-SOLVING STRATEGY

Calculating $\vec{E}$ Using Equations 22-1a and 22-1b

PICTURE Sketch the charge configuration along with a field point P (the point where $\vec{E}$ is to be calculated). In addition, the sketch should include an increment of charge dq at an arbitrary source point S.

SOLVE

1. Add coordinate axes to the sketch. The choice of axes should exploit any symmetry of the charge configuration. For example, if the charge is along a straight line, then select that line as one of the coordinate axes. Draw a second axis that passes through the field point P. In addition, include the coordinates of both P and S, the distance r between P and S, and the unit vector $\hat{r}$ directed away from S toward P.
2. To compute the electric field $\vec{E}$ using Equation 22-1b, we express $d\vec{E} = dE_r\,\hat{r}$ in component form. The x component of $d\vec{E}$ is $dE_x = dE_r\,\hat{r}\cdot\hat{i} = dE_r\cos\theta$, where θ is the angle between $\hat{r}$ and $\hat{i}$ (see Figure 22-2), and the y component of $d\vec{E}$ is $dE_y = dE_r\,\hat{r}\cdot\hat{j} = dE_r\sin\theta$.

* The componet of a vector in a given direction is equal to the scalar product of the vector with the unit vector in the given direction. Scalar products are discussed in Section 6-3.

3. Express $\vec{E}$ in Equation 22-1*b* in terms of its *x* and *y* components:

$$E_x = \int dE_x = \int dE_r \cos\theta = \int \frac{k\,dq}{r^2}\cos\theta$$

$$E_y = \int dE_y = \int dE_r \sin\theta = \int \frac{k\,dq}{r^2}\sin\theta$$

4. To calculate E_x, express dq as $\rho\,dV$ or $\sigma\,dA$ or $\lambda\,dL$ (whichever is appropriate) and integrate. To calculate E_y, follow a procedure similar to that used for calculating E_x.
5. Symmetry arguments are sometimes used to show that one or more components of $\vec{E}$ are equal to zero. (For example, a symmetry argument is used to show $E_y = 0$ in Example 22-5.)

CHECK If the charge distribution is confined to a finite region of space at points far from the charge distribution, the expression for the electric field will approach that of a point charge located at the center of charge. (If the charge configuration is sufficiently symmetric then the location of the center of charge can be obtained by inspection.)

See **Math Tutorial** *for more information on* **Trigonometry**

Example 22-1 Electric Field Due to a Line Charge of Finite Length

A thin rod of length *L* and charge *Q* is uniformly charged, so it has a linear charge density $\lambda = Q/L$. Find the electric field at point *P*, where *P* is an arbitrarily positioned point.

PICTURE Choose the *x* axis so the rod is on the *x* axis between points x_1 and x_2, and choose the *y* axis to be through the field point *P*. Let y_P be the radial distance of *P* from the *x* axis. To calculate the electric field $\vec{E}$ at *P*, we separately calculate E_x and E_y. Using Equations 22-1, first find the field increment $d\vec{E}$ at *P* due to an arbitrary increment *dq* of the charge distribution. Then integrate each component of $d\vec{E}$ over the entire charge distribution. (Because *Q* is distributed uniformly, the linear charge density λ equals Q/L.)

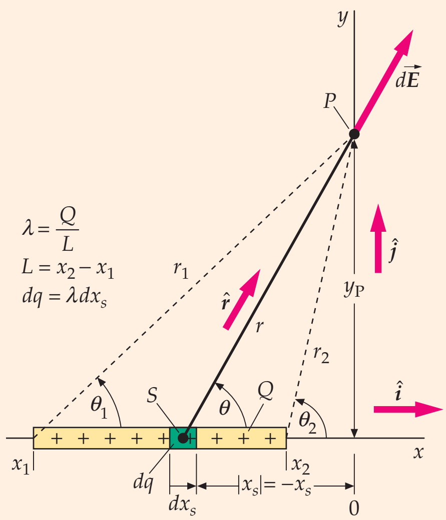

FIGURE 22-2 Geometry for the calculation of the electric field at field point *P* due to a uniformly charged rod.

SOLVE

1. Sketch the charge configuration and the field point *P*. Include the *x* and *y* axes with the *x* axis lying along the line of charge and the *y* axis passing through *P*. In addition, sketch an *arbitrary* increment of the line charge at point *S* (at $x = x_S$) that has a length dx_S and a charge *dq*, and the electric field at *P* due to *dq*. Sketch the electric field vector $d\vec{E}$ as if *dq* is positive (Figure 22-2):

2. $\vec{E} = E_x\hat{i} + E_y\hat{j}$. Find expressions for dE_x and dE_y in terms of dE_r and θ, where dE_r is the component of $d\vec{E}$ in the direction away from *S* toward *P*:

$$d\vec{E} = dE_r\,\hat{r}$$

so $$dE_x = dE_r\,\hat{r}\cdot\hat{i} = dE_r\cos\theta$$

$$dE_y = dE_r\,\hat{r}\cdot\hat{j} = dE_r\sin\theta$$

3. First we solve for E_x. Express dE_r using Equation 21-1*a*, where *r* is the distance from the source point *S* to the field point *P*. We see (Figure 22-2) that $\cos\theta = |x_S|/r = -x_S/r$. In addition, use $dq = \lambda\,dx_S$:

$$dE_r = \frac{k\,dq}{r^2} \text{ and } \cos\theta = \frac{-x_S}{r}$$

so

$$dE_x = \frac{k\,dq}{r^2}\cos\theta = \frac{k\cos\theta\,\lambda\,dx_S}{r^2}$$

4. Integrate the step-3 result:

$$dE_x = \int_{x_1}^{x_2}\frac{k\cos\theta\,\lambda\,dx_S}{r^2} = k\lambda\int_{x_1}^{x_2}\frac{\cos\theta\,dx_S}{r^2}$$

5. Next change the integration variable from x_S to θ. From Figure 22-2, find the relation between x_S and θ and between r and θ.

$$\tan\theta = \frac{y_P}{|x_S|} = \frac{y_P}{-x_S}, \quad \text{so} \quad x_S = -\frac{y_P}{\tan\theta} = -y_P \cot\theta$$

$$\sin\theta = \frac{y_P}{r}, \quad \text{so} \quad r = \frac{y_P}{\sin\theta}$$

6. Differentiate the step 5 result to obtain an expression for dx_S (the field point P remains fixed, so y_P is constant):

$$dx_S = -y_P \frac{d\cot\theta}{d\theta} = y_P \csc^2\theta \, d\theta$$

7. Substitute $y_P \csc^2\theta \, d\theta$ for dx_S and $y_P/\sin\theta$ for r in the integral in step 4 and simplify:

$$\int_{x_1}^{x_2} \frac{\cos\theta \, dx_S}{r^2} = \int_{\theta_1}^{\theta_2} \frac{\cos\theta \, y_P \csc^2\theta \, d\theta}{y_P^2/\sin^2\theta} = \frac{1}{y_P}\int_{\theta_1}^{\theta_2} \cos\theta \, d\theta \qquad (y_P \neq 0)$$

8. Evaluate the integral and solve for E_x:

$$E_x = k\lambda \frac{1}{y_P}\int_{\theta_1}^{\theta_2} \cos\theta \, d\theta = \frac{k\lambda}{y_P}(\sin\theta_2 - \sin\theta_1) = \frac{k\lambda}{y_P}\left(\frac{y_P}{r_2} - \frac{y_P}{r_1}\right)$$

$$= k\lambda\left(\frac{1}{r_2} - \frac{1}{r_1}\right) \qquad (r_1 > 0 \text{ and } r_2 > 0)$$

9. E_y can be found using a procedure that parallels the one in steps 3–7 for finding E_x (to find E_y, see Problem 22-21):

$$E_y = -\frac{k\lambda}{y_P}(\cos\theta_2 - \cos\theta_1) = -k\lambda\left(\frac{\cot\theta_2}{r_2} - \frac{\cot\theta_1}{r_1}\right) \qquad (y_P \neq 0)$$

and

$$E_y = 0 \qquad (y_P = 0)$$

10. Combine steps 8 and 9 to obtain and expression for the electric field at P:

$$\vec{E} = \boxed{E_x \hat{i} + E_y \hat{j}}$$

CHECK Consider the plane that is perpendicular to and bisecting the rod. At points on this plane, symmetry dictates that $\vec{E}$ points directly away from the center of the rod. That is, we expect that $E_x = 0$ throughout this plane. At all points on this plane $r_1 = r_2$. The step-8 result gives $E_x = 0$ if $r_1 = r_2$, as expected.

TAKING IT FURTHER The first expression for E_y in the step 9 result is valid everywhere in the xy plane but on the x axis. The two cotangent functions in the expression for E_y are given by

$$\cot\theta_1 = \frac{-x_1}{y_P} \quad \text{and} \quad \cot\theta_2 = \frac{-x_2}{y_P}$$

and neither of these functions is defined on the x axis (where $y_P = 0$). The second expression for E_y in the step-9 result is obtained using Equation 22-1*a*. By recognizing that on the x axis $\hat{r} = \pm\hat{i}$, we can see that Equation 22-1*a* tells us that $d\vec{E} = \pm dE\,\hat{i}$, which implies $E_y = 0$.

PRACTICE PROBLEM 22-1 Using the expression for E_x in step 8, show that $E_x > 0$ at all points on the x axis in the region $x > x_2$.

The electric field at point P due to a thin uniformly charged rod (see Figure 22-3) located on the z axis is given by $\vec{E} = E_z\hat{k} + E_R\hat{R}$, where

$$E_z = \frac{k\lambda}{R}(\sin\theta_2 - \sin\theta_1) = k\lambda\left(\frac{1}{r_2} - \frac{1}{r_1}\right) \qquad (r_1 \neq 0) \text{ and } (r_2 \neq 0) \qquad \text{22-2}a$$

$$E_R = -\frac{k\lambda}{R}(\cos\theta_2 - \cos\theta_1) = -k\lambda\left(\frac{\cot\theta_2}{r_2} - \frac{\cot\theta_1}{r_1}\right) \qquad (R \neq 0) \qquad \text{22-2}b$$

These equations are derived in Example 22-1. The expressions for E_z (Equation 22-2*a*) are undefined at the end points of the thin charged rod and the expressions for E_R (Equation 22-2*b*) are undefined at all points on the z axis (where $R = 0$). However, $E_R = 0$ at all points where $R = 0$.

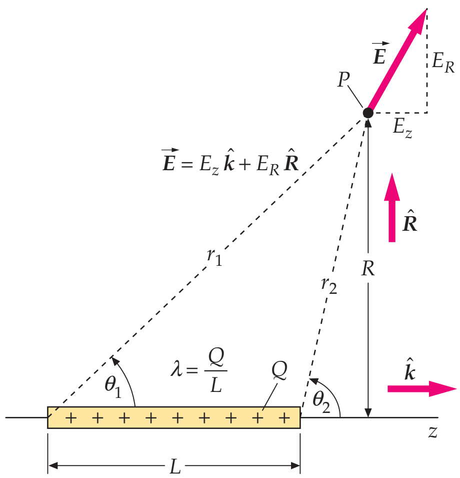

FIGURE 22-3 The electric field due to a uniformly charged thin rod.

Example 22-2 $\vec{E}$ of a Finite Line Charge and Far from the Charge

A charge Q is uniformly distributed along the z axis, from $z = -\frac{1}{2}L$ to $z = +\frac{1}{2}L$. Show that for large values of z the expression for the electric field of the line charge on the z axis approaches the expression for the electric field of a point charge Q at the origin.

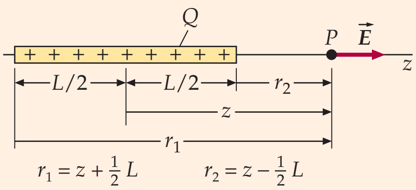

FIGURE 22-4 Geometry for the calculation of the electric field on the axis of a uniform line charge of length L, charge Q, and linear charge density $\lambda = Q/L$.

PICTURE Use Equation 22-2*a* to show that for large values of z the expression for the electric field of the line charge on the z axis approaches that of a point charge Q at the origin.

SOLVE

1. The electric field on the z axis has only a z component, given by Equation 22-2a:
$$E_z = k\lambda\left(\frac{1}{r_2} - \frac{1}{r_1}\right)$$

2. Sketch the line charge. Include the z axis, the field point P, and r_1 and r_2 (Figure 22-4):

3. Substitute with $r_1 = z + \frac{1}{2}L$ and $r_2 = z - \frac{1}{2}L$ into the step 1 result and simplify:
$$E_z = k\lambda\left(\frac{1}{z - \frac{1}{2}L} - \frac{1}{z + \frac{1}{2}L}\right) = \frac{kQ}{L}\frac{L}{z^2 - \left(\frac{1}{2}L\right)^2} = \frac{kQ}{z^2 - \left(\frac{1}{2}L\right)^2} \qquad \left(z > \tfrac{1}{2}L\right)$$

4. Find an approximate expression for E_z for $z \gg L$, which is done by neglecting $(\frac{1}{2}L)^2$ in comparison with z^2 in the step 3 result.
$$\boxed{E_z \approx \frac{kQ}{z^2} \qquad (z \gg L)}$$

CHECK The approximate expression (step 4) falls off inversely as the square of z, the distance from the origin. This expression is the same as the expression for the electric field of a point charge Q located at the origin.

PRACTICE PROBLEM 22-2 The validity of the step 3 result is established for the region $L/2 > z > \infty$. Is the step 3 result also valid in the region $-L/2 < z < +L/2$? Explain your answer.

Example 22-3 $\vec{E}$ Due to an Infinite Line Charge

Find the electric field due to a uniformly charged line that extends to infinity in both directions and has linear charge density λ.

PICTURE A line charge is considered infinite if the distances between the ends of the line charge and the field points of interest are much much greater than the distances between any of the radial distances of the field points from the line charge. To calculate the electric field due to such a line charge we take the limit (see Figure 22-2) both as $x_1 \to -\infty$ and as $x_2 \to +\infty$. From the figure, we see that taking the limit as both $\theta_1 \to 0$ and as $\theta_2 \to \pi$ is needed. See Equations 22-2*a* and 22-2*b* for expressions for the electric field.

SOLVE

1. Choose the first expression for the electric field in each of Equations 22-2*a* and 22-2*b*:
$$E_z = \frac{k\lambda}{R}(\sin\theta_2 - \sin\theta_1)$$
$$E_R = -\frac{k\lambda}{R}(\cos\theta_2 - \cos\theta_1)$$

2. Take the limit as both $\theta_1 \to 0$ and as $\theta_2 \to \pi$.
$$E_z = \frac{k\lambda}{R}(\sin\pi - \sin 0) = \frac{k\lambda}{R}(0 - 0) = 0$$
$$E_R = -\frac{k\lambda}{R}(\cos\pi - \cos 0) = -\frac{k\lambda}{R}(-1 - 1) = 2\frac{k\lambda}{R}$$

3. Express the electric field in vector form:
$$\vec{E} = E_z\hat{k} + E_R\hat{R} = 0\hat{k} + \frac{2k\lambda}{R}\hat{R} = \boxed{\frac{2k\lambda}{R}\hat{R}}$$

CHECK The electric field is in the radial direction as expected. We expected this due to the symmetry. (The line charge is uniformly distributed and extends to infinity in both directions.)

TAKING IT FURTHER The magnitude of the electric field decreases inversely with the radial distance from the line charge.

The electric field due to a uniformly charged line that extends to infinity in both directions is given by

$$\vec{E} = \frac{2k\lambda}{R}\hat{\boldsymbol{R}} \qquad 22\text{-}3$$

where λ is the linear charge density, R is the radial distance from the line charge to the field point, and $\hat{\boldsymbol{R}}$ is the unit vector in the radial direction. Equation 22-3 is derived in Example 22-3.

PRACTICE PROBLEM 22-3

Show that if k, λ, and R are in SI units then Equation 22-3 gives the electric field in newtons per coulomb.

It is customary to write the Coulomb constant k in terms of another constant, ϵ_0, called the **electric constant (permittivity of free space):**

$$k = \frac{1}{4\pi\epsilon_0} \qquad 22\text{-}4$$

Using this notation, Coulomb's law for $\vec{E}$ (Equation 21-7) is written

$$\vec{E} = k\frac{q}{r^2}\hat{\boldsymbol{r}} = \frac{1}{4\pi\epsilon_0}\frac{q}{r^2}\hat{\boldsymbol{r}} \qquad 22\text{-}5$$

and $\vec{E}$ for a uniformly charged infinite line (Equation 22-3) with linear charge density λ is written

$$\vec{E} = \frac{1}{2\pi\epsilon_0}\frac{\lambda}{R}\hat{\boldsymbol{R}} \qquad 22\text{-}6$$

The value of ϵ_0 in SI units is

$$\epsilon_0 = \frac{1}{4\pi k} = 8.85 \times 10^{-12}\,\mathrm{C^2/(N\cdot m^2)} \qquad 22\text{-}7$$

Example 22-4 Approximating Equations 22-2*a* and 22-2*b* on the Symmetry Plane

A charge Q is uniformly distributed along the z axis, from $z = -\frac{1}{2}L$ to $z = +\frac{1}{2}L$. (*a*) Find an expression for the electric field on the $z = 0$ plane as a function of R, the radial distance of the field point from the z axis. (*b*) Show that for $R \gg L$, the expression found in Part (*a*) approaches that of a point charge at the origin of charge Q. (*c*) Show that for $R \ll L$, the expression found in Part (*a*) approaches that of an infinitely long line charge on the z axis with a uniform linear charge density $\lambda = Q/L$.

PICTURE The charge configuration is the same as that in Example 22-2, and the linear charge density is $\lambda = Q/L$. Sketch the line charge on the z axis and put the field point in the $z = 0$ plane. Then use Equations 22-2*a* and 22-2*b* to find the electric field expression for Part (*a*). The electric field due to a point charge decreases inversely with the square of the distance from the charge. Examine the Part (*a*) result to see how it approaches that of a point charge at the origin for $R \gg L$. The electric field due to a uniform line charge of infinite length decreases inversely with the radial distance from the line (Equation 22-3). Examine the Part (*a*) result to see how it approaches the expression for the electric field of a line charge of infinite length for $R \ll L$.

SOLVE

(*a*) 1. Choose the first expression for the electric field in each of Equations 22-2*a* and 22-2*b*:

$$E_z = \frac{k\lambda}{R}(\sin\theta_2 - \sin\theta_1)$$

$$E_R = -\frac{k\lambda}{R}(\cos\theta_2 - \cos\theta_1)$$

2. Sketch the charge configuration with the line charge on the z axis from $z = -\frac{1}{2}L$ to $z = +\frac{1}{2}L$. Show the field point P in the $z = 0$ plane a distance R from the origin (Figure 22-5):

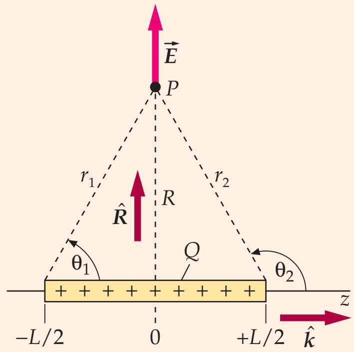

FIGURE 22-5

3. From the figure, we see that $\theta_2 + \theta_1 = \pi$, so $\sin\theta_2 = \sin(\pi - \theta_1) = \sin\theta_1$ and $\cos\theta_2 = \cos(\pi - \theta_1) = -\cos\theta_1$. Substitute into the step 1 results:

$$E_z = \frac{k\lambda}{R}(\sin\theta_1 - \sin\theta_1) = 0$$

$$E_R = -\frac{k\lambda}{R}(-\cos\theta_1 - \cos\theta_1) = \frac{2k\lambda}{R}\cos\theta_1$$

4. Express $\cos\theta_1$ in terms of R and L and substitute into the step-3 result:

$$\cos\theta_1 = \frac{\frac{1}{2}L}{\sqrt{R^2 + \left(\frac{1}{2}L\right)^2}}$$

so

$$E_R = \frac{2k\lambda}{R}\frac{\frac{1}{2}L}{\sqrt{R^2 + \left(\frac{1}{2}L\right)^2}} = \frac{k\lambda L}{R\sqrt{R^2 + \left(\frac{1}{2}L\right)^2}}$$

5. Express the electric field in vector form, and substitute Q for λL:

$$\vec{E} = E_z\hat{k} + E_R\hat{R} = 0\hat{k} + E_R\hat{R}$$

so $$\vec{E} = E_R\hat{R} = \boxed{\frac{kQ}{R\sqrt{R^2 + \left(\frac{1}{2}L\right)^2}}\hat{R}}$$

(*b*) 1. Examine the step-5 result. If $R \gg L$ then $R^2 + (\frac{1}{2}L)^2 \approx R^2$. Substitute R^2 for $R^2 + (\frac{1}{2}L)^2$:

$$\vec{E} \approx \frac{kQ}{R\sqrt{R^2}}\hat{R} = \frac{kQ}{R^2}\hat{R} \quad (R \gg L)$$

2. This (approximate) expression for the electric field decreases inversely with the square of the distance from the origin, just as it would for a point charge Q at the origin.

$$\vec{E} \approx \boxed{\frac{kQ}{R^2}\hat{R} \quad (R \gg L)}$$

(*c*) 1. Examine the Part (*a*), step-5 result. If $R \ll L$ then $R^2 + (\frac{1}{2}L)^2 \approx (\frac{1}{2}L)^2$. Substitute $(\frac{1}{2}L)^2$ for $R^2 + (\frac{1}{2}L)^2$. This (approximate) expression for the electric field falls off inversely with the radial distance from the line charge, just as the exact expression for an infinite line charge (Equation 22-3) would.

$$\vec{E} \approx \frac{k\lambda L}{R\sqrt{\left(\frac{1}{2}L\right)^2}}\hat{R} = \boxed{\frac{2k\lambda}{R}\hat{R}} \quad (R \ll L)$$

CHECK Parts (*b*) and (*c*) are themselves plausibility checks for the Part (*a*) result. They reveal the validity of the Part (*a*) result in two limiting cases, $R \gg L$ and $R \ll L$.

TAKING IT FURTHER Figure 22-6 shows the exact result for a line charge of length $L = 10$ cm and a linear charge density of $\lambda = 4.5$ nC/m. It also shows the limiting cases of an infinite line charge of the same charge density and a point charge $Q = \lambda L$.

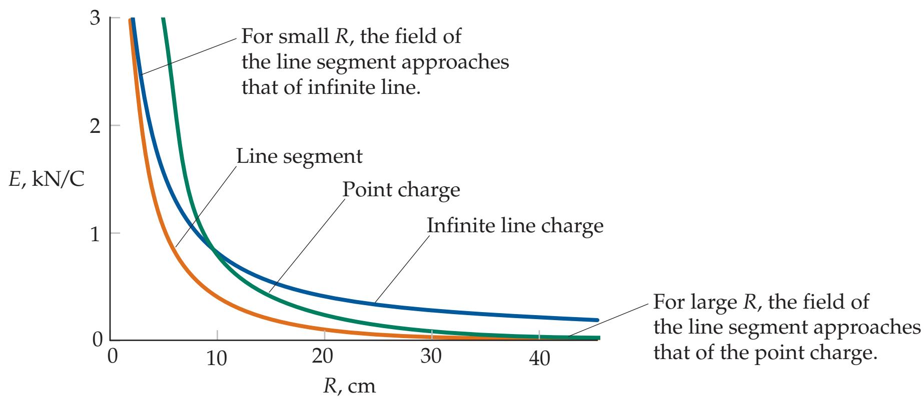

FIGURE 22-6 The magnitude of the electric field is plotted versus distance for a 10-cm-long line charge, a point charge, and an infinite line charge.

Example 22-5 $\vec{E}$ on the Axis of a Charged Ring

A thin ring (a circle) of radius a is uniformly charged with total charge Q. Find the electric field due to this charge at all points on the axis perpendicular to the plane and through the center of the ring.

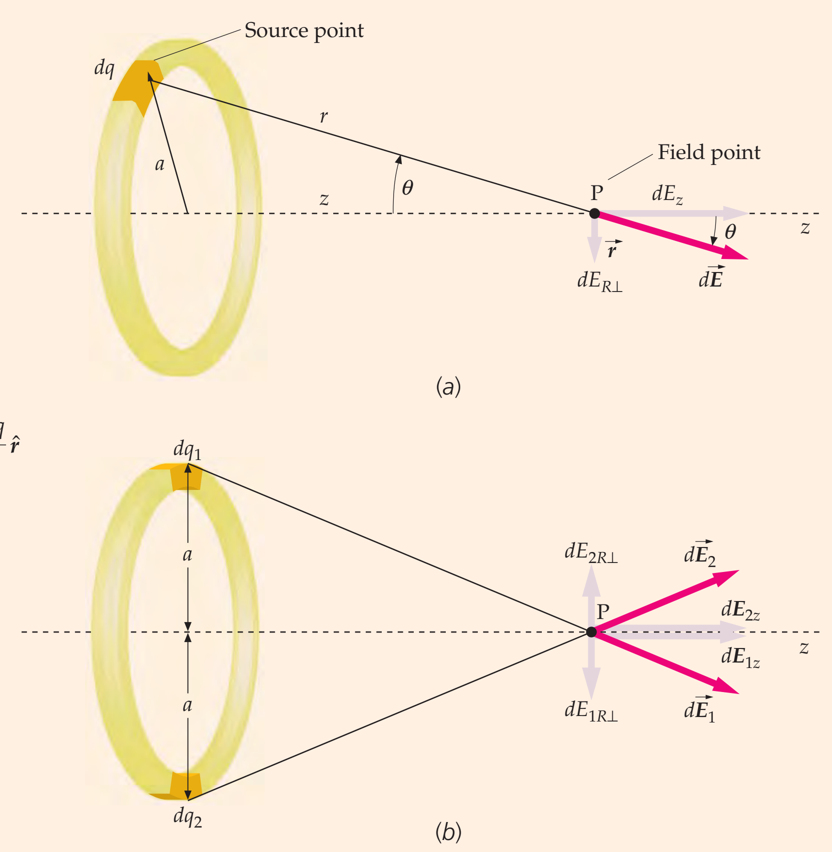

FIGURE 22-7 (*a*) A ring charge of radius a. The electric field at point P on the z axis due to the charge element dq shown has one component along the z axis and one perpendicular to the z axis. (*b*) For any charge element dq_1 there is an equal charge element dq_2 opposite it, and the electric field components perpendicular to the z axis sum to zero.

PICTURE Starting with $d\vec{E} = (k\,dq/r^2)\hat{r}$ (Equation 22-1*a*), calculate the electric field at an arbitrarily positioned field point on the axis. Sketch the charged ring. Choose the z axis to coincide with the axis of the ring with the ring in the $z = 0$ plane. Label a field point P somewhere on the $+z$ axis, and place a source point S on the ring.

SOLVE

1. Write the equation (Equation 22-1*a*) giving the electric field due to an element of charge dq:
$$d\vec{E} = \frac{k\,dq}{r^2}\hat{r}$$

2. Sketch the ring (Figure 22-7*a*) and the axis (the z axis), and show the electric field vector at field point P due to an increment of charge dq at source point:

3. Sketch the ring (Figure 22-7*b*) and show the axial and radial components of $\vec{E}$ for identical charge elements on opposite sides of the ring. The radial components cancel in pairs, as can be seen, so the resultant field is axial:
$$E_R = 0$$

4. Express the z component of the electric field from the step-1 result:
$$dE_z = \frac{k\,dq}{r^2}\cos\theta = \frac{k\,dq}{r^2}\frac{z}{r} = \frac{k\,dq\,z}{r^3}$$

5. Integrate both sides of the step-4 result. Factor constant terms from the integral:
$$E_z = \int \frac{kz\,dq}{r^3} = \frac{kz}{r^3}\int dq = \frac{kz}{r^3}Q$$

6. Using the Pythagorean theorem gives $r = \sqrt{z^2 + a^2}$:
$$\vec{E} = E_z\hat{k} + E_R\hat{R} = E_z\hat{k} + 0 = \boxed{\frac{kQz}{(z^2 + a^2)^{3/2}}\hat{k}}$$

CHECK We expect the direction of the electric field at points on the z axis to be directed away from the origin for $Q > 0$. The step-6 result meets this expectation as z is positive on the $+z$ axis and negative on the $-z$ axis. In addition, for $z \gg a$ we expect E to decrease inversely as the square of the distance from the origin. The step-6 result meets this expectation, giving $E_z \approx kQ/z^2$ if a^2 is negligibly small relative to z^2.

PRACTICE PROBLEM 22-4 A plot of E_z versus z along the axis using the step-6 result is shown in Figure 22-8. Find the point on the axis of the ring where E_z is maximum. *Hint*: $dE_z/dz = 0$ *where* E_z *is maximum.*

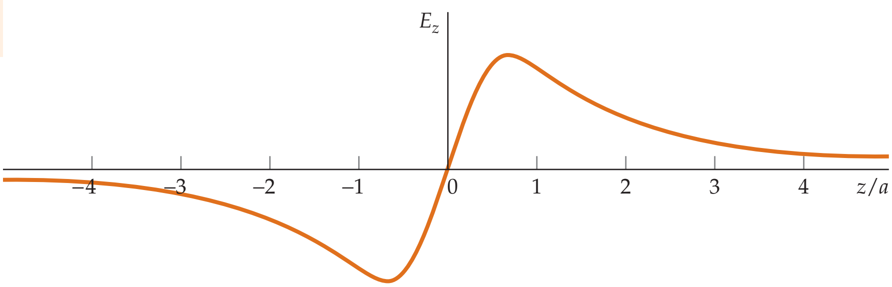

FIGURE 22-8

Example 22-6 $\vec{E}$ on the Axis of a Charged Ring — *Conceptual*

For the charged ring in Example 22-5, why is the magnitude of the electric field small near the origin, even though the origin is closer to the ring than any other points on the z axis (see Figure 22-9)?

PICTURE The key to solving this problem can be found in Figure 22-7*b*. Redraw this figure with the field point P on the z axis, but near the origin.

SOLVE

1. Redraw Figure 22-7*b* with the field point P near the origin:

2. The electric fields near the origin due to the two elements of charge (shown in Figure 22-9) are large but are of equal magnitude and nearly oppositely directed, so they nearly sum to zero.

   Near the origin the resultant electric field is axial and small.

CHECK At the origin, the two electric fields are large, but are oppositely directed and so add to zero. Far from the origin ($|z| \gg a$), the two electric fields (Figure 22-7*b*) are in almost the same direction so they do not add to zero.

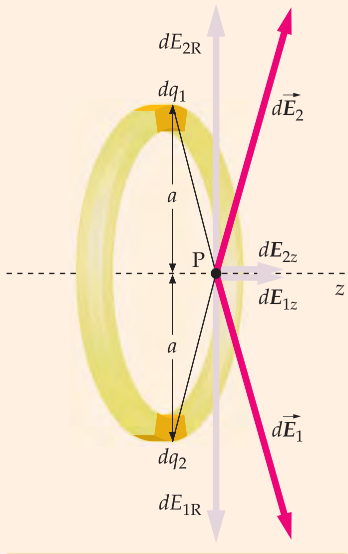

FIGURE 22-9

The electric field on the axis of a uniformly charged circular ring of radius a and charge Q is given by $\vec{E} = E_z\hat{k}$, where

$$E_z = \frac{kQz}{(z^2 + a^2)^{3/2}} \qquad 22\text{-}8$$

Equation 22-8 is derived in Example 22-5.

See **Math Tutorial** *for more information on*

Binomial Expansion

Example 22-7 $\vec{E}$ on the Axis of a Charged Disk

Consider a uniformly charged thin disk of radius b and surface charge density σ. (*a*) Find the electric field at all points on the axis of the disk. (*b*) Show that for points on the axis and far from the disk, the electric field approaches that of a point charge at the origin with the same charge as the disk. (*c*) Show that for a uniformly charged disk of infinite radius, the electric field is uniform throughout the region on either side of the disk.

PICTURE We can calculate the field on the axis of the disk by treating the disk as a set of concentric, uniformly charged rings.

SOLVE

(*a*) 1. Calculate the field on the axis of the disk by treating the disk as a set of concentric rings of charge. The field of a single uniformly charged ring that has a charge Q and a radius a is shown in Equation 22-8:

$$\vec{E} = E_z\hat{k}, \text{ where } E_z = \frac{kQz}{(z^2 + a^2)^{3/2}}$$

2. Sketch the disk (Figure 22-10) and illustrate the electric field $d\vec{E}$ on its axis due to a single ring of charge dq, radius a, and width da:

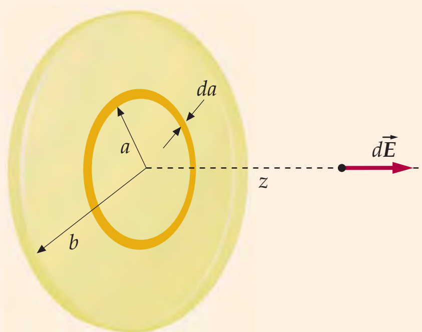

FIGURE 22-10 A uniform disk of charge can be treated as a set of ring charges, each of radius a.

3. Substitute dq for Q and dE_z for E_z in the step-1 result. Then integrate both sides to calculate the resultant field for the entire disk. The field point remains fixed, so z is constant:

$$dE_z = \frac{kz\,dq}{(z^2 + a^2)^{3/2}}$$

$$\text{so} \quad E_z = \int \frac{kz\,dq}{(z^2 + a^2)^{3/2}} = kz\int \frac{dq}{(z^2 + a^2)^{3/2}}$$

4. To evaluate this integral we change integration variables from q to a. The charge $dq = \sigma\, dA$, where $dA = 2\pi a\, da$ is the area of a ring of radius a and width da:

$$dq = \sigma\, dA = \sigma 2\pi a da$$

so $$E_z = \pi k z \sigma \int_0^b \frac{2ada}{(z^2 + a^2)^{3/2}} = \pi k z \sigma \int_{z^2+0^2}^{z^2+b^2} u^{-3/2}\, du$$

where $u = z^2 + a^2$, so $du = 2ada$.

5. Evaluate the integral and simplify the result:

$$E_z = \pi k z \sigma \frac{u^{-1/2}}{-\frac{1}{2}}\Bigg|_{z^2}^{z^2+b^2} = -2\pi k z \sigma \left(\frac{1}{\sqrt{z^2+b^2}} - \frac{1}{\sqrt{z^2}}\right)$$

$$= \boxed{\operatorname{sign}(z) \cdot 2\pi k \sigma \left(1 - \frac{1}{\sqrt{1 + \dfrac{b^2}{z^2}}}\right)}$$

where $\operatorname{sign}(z) = z/|z|$. By definition*:

$$\operatorname{sign}(z) = \begin{cases} +1 & z > 0 \\ 0 & z = 0 \\ -1 & z < 0 \end{cases}$$

(*b*) 1. For $z \gg b$ (on the $+z$ axis far from the disk) we expect the electric field to decrease inversely with z^2, like that of a point charge. To show this we use the binomial expansion:

The binomial expansion (to first order) is $(1 + x)^n \approx 1 + nx$ for $|x| \ll 1$.

2. Apply the binomial expansion to the rightmost term in the step-5 result:

$$\frac{1}{\sqrt{1 + \dfrac{b^2}{z^2}}} = \left(1 + \frac{b^2}{z^2}\right)^{-1/2} \approx 1 - \frac{1}{2}\frac{b^2}{z^2} \qquad z^2 \gg b^2$$

3. Substitute into the step-5 result and simplify. [For $z \gg b$, sign $(z) = 1$.] Thus, the approximate expression for the field for $z \gg b$ is the same as that of a point charge $Q = \sigma\pi b^2$ at the origin:

$$E_z \approx 2\pi k \sigma\left(1 - \left[1 - \frac{1}{2}\frac{b^2}{z^2}\right]\right) = 2\pi k \sigma \frac{1}{2}\frac{b^2}{z^2} = \boxed{\frac{kQ}{z^2}} \qquad z \gg b$$

where $Q = \sigma\pi b^2$.

(*c*) 1. Take the limit of the Part (*a*), step-5 result as $b \to \infty$. This result is an expression for E_z that is uniform, both in the region $z > 0$ and in the region $z < 0$:

$$E_z = \operatorname{sign}(z) \cdot 2\pi k \sigma \left(1 - \frac{1}{\sqrt{1 + \infty}}\right) = \boxed{\operatorname{sign}(z) \cdot 2\pi k \sigma}$$

CHECK We expect the electric field be in opposite directions on opposite sides of the disk. The Part (*a*), step-5 result meets this expectation.

TAKING IT FURTHER According to the Part (*c*) result the electric field is discontinuous at $z = 0$ (Figure 22-11) where the field jumps from $-2\pi k\sigma\hat{i}$ to $+2\pi k\sigma\hat{i}$ as we cross the $z = 0$ plane. There is thus a discontinuity in E_z in the amount $4\pi k\sigma = \sigma/\epsilon_0$.

PRACTICE PROBLEM 22-5 The electric field due to a uniform surface charge on the entire $z = 0$ plane is given by the Part (*c*) result. What fraction of the field on the z axis at $z = a$ is due to the surface charge within a circle that has a radius $r = 5a$ centered at the origin? *Hint: Divide the Part (a), step 5 result by the Part (c) result after substituting* 5a *for* b *and* a *for z.*

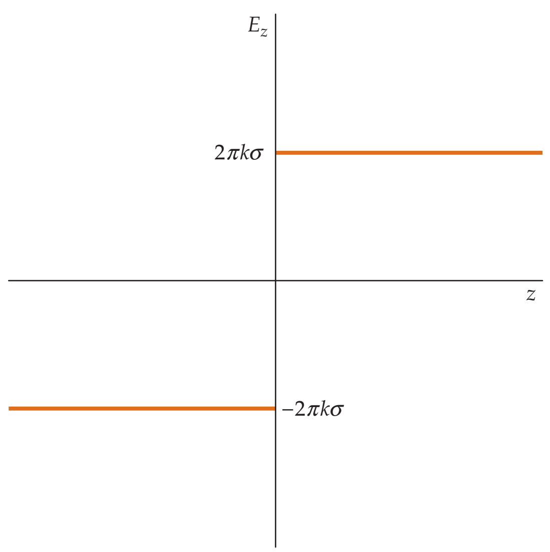

FIGURE 22-11 Graph showing the discontinuity of $\vec{E}$ at a plane charge. Can you see the similarity between this graph and the one in Figure 22-8?

* Both Excel and Mathematica use the definition of the sign function given here. Texas Instruments, however, uses a definition in which sign(0) returns ±1 instead of 0.

The answer to Practice Problem 22-5 depends not on a, but on the ratio $r/a = 5$. Eighty percent of the field at any distance a from a uniformly charged plane surface is due to the charge within a circle whose radius is equal to $5a$ multiplied by that distance.

The formula for the electric field on the axis of a uniformly charged circular disk, established in Example 22-7, is

$$E_z = \text{sign}(z) \cdot 2\pi k\sigma\left(1 - \frac{1}{\sqrt{1 + \frac{R^2}{z^2}}}\right) \qquad 22\text{-}9$$

ELECTRIC FIELD ON AXIS OF A UNIFORM DISK OF CHARGE

where sign(z) is defined in Part (a), step 5 of Example 22-7 and R is the radius of the disk. The field of a uniformly charged electric plane of charge can be obtained from Equation 22-9 by letting the ratio R/z go to infinity. Then

$$E_z = \text{sign}(z) \cdot 2\pi k\sigma = \text{sign}(z) \cdot \frac{\sigma}{2\epsilon_0} \qquad 22\text{-}10$$

ELECTRIC FIELD OF A UNIFORM PLANE OF CHARGE

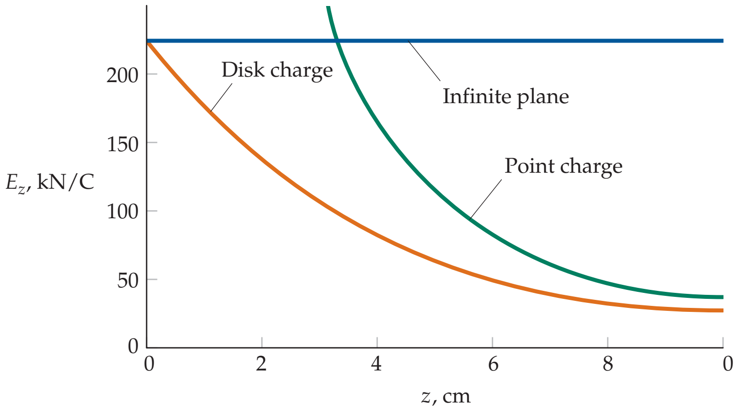

FIGURE 22-12 A disk and a point have equal charges, and an infinite plane and the disk have equal uniform surface-charge densities. Note that the field of the disk charge converges with the field of the point charge as z approaches infinity, and equals the field of the infinite plane charge as z approaches zero.

Figure 22-12 shows the electric fields of a point charge, a uniform disk of charge, and an infinite plane of charge as a function of position.

As we move along the z axis, the electric field jumps from $-2\pi k\sigma\hat{i}$ to $+2\pi k\sigma\hat{i}$ when we pass through the $z = 0$ plane (Figure 22-11). Thus, at $z = 0$ there is a discontinuity in E_z in the amount $4\pi k\sigma$.

Example 22-8 Electric Field Due to Two Infinite Planes

In Figure 22-13, an infinite plane of surface charge density $\sigma = +4.5$ nC/m^2 lies in the $x = 0.00$ m plane, and a second infinite plane of surface charge density $\sigma = -4.50$ nC/m^2 lies in the $x = 2.00$ m plane. Find the electric field at (a) $x = 1.80$ m and (b) $x = 5.00$ m.

PICTURE Each charged plane produces a uniform electric field of magnitude $E = \sigma/(2\epsilon_0)$. We use superposition to find the resultant field. Between the planes the fields add, producing a net field of magnitude σ/ϵ_0 in the $+x$ direction. For $x > 2.00$ m and for $x < 0$, the two fields point in opposite directions and thus sum to zero.

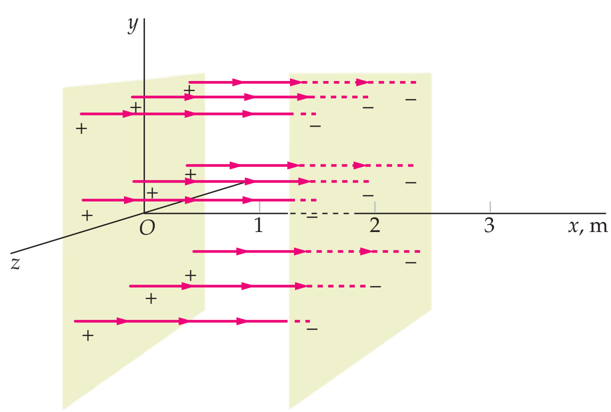

FIGURE 22-13

SOLVE

(a) 1. Calculate the magnitude of the field E produced by each plane:

$$E = |\sigma|/(2\epsilon_0) = (4.50 \times 10^{-9}\ \text{N/C})/(2 \cdot 8.85 \times 10^{-12}) = 254\ \text{N/C}$$

2. At $x = 1.80$ m, between the planes, the field due to each plane points in the $+x$ direction:

$$E_{x\,\text{net}} = E_1 + E_2 = 254\ \text{N/C} + 254\ \text{N/C} = \boxed{508\ \text{N/C}}$$

(*b*) At $x = 5.00$ m, the fields due to the two planes are oppositely directed:

$$E_{x\,\text{net}} = E_1 - E_2 = \boxed{0.00\ \text{N/C}}$$

CHECK Because the two planes have equal and opposite charge densities, electric field lines originate on the positive plane and terminate on the negative plane. $\vec{E}$ is equal to zero except between the planes.

TAKING IT FURTHER Note that $E_{x\,\text{net}} = 508$ N/C not just at $x = 1.8$ m but at any point in the region between the charged planes. The charge configuration described in this example is that of a parallel-plate capacitor. Capacitors are discussed in Chapter 24.

22-2 GAUSS'S LAW

In Chapter 21, the electric field is described visually by using electric field lines. Here that description is put in rigorous mathematical language called Gauss's law. Gauss's law is one of Maxwell's equations—the fundamental equations of electromagnetism—which are the topic of Chapter 30. In electrostatics, Gauss's law and Coulomb's law are equivalent. Electric fields arising from some symmetrical charge distributions, such as a uniformly charged spherical shell or uniformly charged infinite line, can be easily calculated using Gauss's law. In this section, we give an argument for the validity of Gauss's law based on the properties of electric field lines. A more rigorous derivation of Gauss's law is presented in Section 22-6.

A closed surface—like the surface of a soap bubble—is one that divides the universe into two distinct regions, the region enclosed by surface and the region outside the surface. Figure 22-14 shows a closed surface of arbitrary shape enclosing a dipole. The number of electric field lines beginning on the positive charge and penetrating the surface from the inside depends on where the surface is drawn, but any line penetrating the surface from the inside also penetrates it from the outside. To count the net number of lines out of any closed surface, count any penetration from the inside as +1, and any penetration from the outside as −1. Thus, for the surface shown (Figure 22-14), the net number of lines out of the surface is zero. For surfaces enclosing other types of charge distributions, such as that shown in Figure 22-15, *the net number of lines out of any surface enclosing the charges is proportional to the net charge enclosed by the surface.* This rule is a statement of Gauss's law.

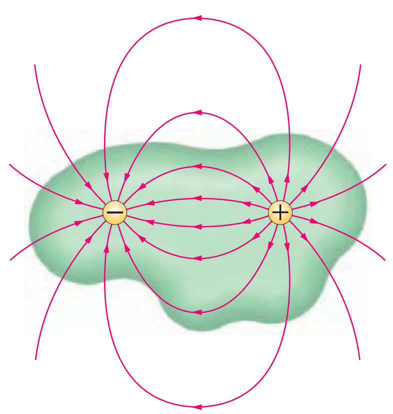

FIGURE 22-14 A surface of arbitrary shape enclosing an electric dipole. As long as the surface encloses both charges, the number of lines penetrating the surface from the inside is exactly equal to the number of lines penetrating the surface from the outside no matter where the surface is drawn.

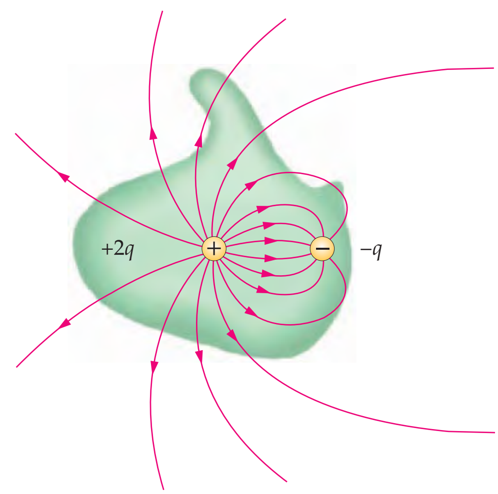

FIGURE 22-15 A surface of arbitrary shape enclosing the charges $+2q$ and $-q$. Either the field lines that end on $-q$ do not pass through the surface or they penetrate it from the inside the same number of times as from the outside. The net number that exit, the same as that for a single charge of $+q$, is equal to the net charge enclosed by the surface.

ELECTRIC FLUX

The mathematical quantity that corresponds to the number of field lines penetrating a surface is called the **electric flux** ϕ. For a surface perpendicular to $\vec{E}$ (Figure 22-16), the electric flux is the product of the magnitude of the field E and the area A:

$$\phi = EA$$

The units of electric flux are $N \cdot m^2/C$. Because E is proportional to the number of field lines per unit area, the flux is proportional to the number of field lines penetrating the surface.

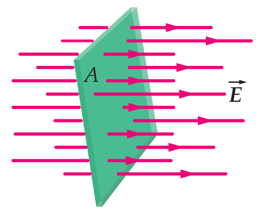

FIGURE 22-16 Electric field lines of a uniform field penetrating a surface of area A that is oriented perpendicular to the field. The product EA is the electric flux through the surface.

In Figure 22-17, the surface of area A_2 is not perpendicular to the electric field $\vec{E}$. However, the number of lines that penetrate the surface of area A_2 is the same as the number that penetrate the surface of area A_1, which is normal (perpendicular) to $\vec{E}$. These areas are related by

$$A_2 \cos\theta = A_1 \qquad \text{22-11}$$

where θ is the angle between $\vec{E}$ and the unit vector $\hat{n}$ that is normal to the surface A_2, as shown in the figure. The electric flux through a surface is defined to be

$$\phi = \vec{E} \cdot \hat{n} A = EA\cos\theta = E_n A \qquad \text{22-12}$$

where $E_n = \vec{E} \cdot \hat{n}$ is the component of $\vec{E}$ normal to the surface.

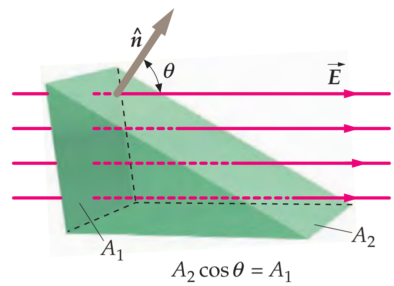

FIGURE 22-17 Electric field lines of a uniform electric field that is perpendicular to the surface of area A_1 but makes an angle θ with the unit vector $\hat{n}$ that is normal to the surface of area A_2. Where $\vec{E}$ is not perpendicular to the surface, the flux is $E_n A$, where $E_n = E\cos\theta$ is the component of $\vec{E}$ that is perpendicular to the surface. The flux through the surface of area A_2 is the same as that through the surface of area A_1.

Figure 22-18 shows a curved surface over which $\vec{E}$ may vary. If the area ΔA_i of the surface element that we choose is small enough, it can be modeled as a plane, and the variation of the electric field across the element can be neglected. The flux of the electric field through this element is

$$\Delta\phi_i = E_{ni}\,\Delta A_i = \vec{E}_i \cdot \hat{n}_i\,\Delta A_i$$

where $\hat{n}_i$ is the unit vector perpendicular to the surface element and $\vec{E}_i$ is the electric field on the surface element. If the surface is curved, the unit vectors for the different small surface elements will have different directions. The total flux through the surface is the sum of $\Delta\phi_i$ over all the elements making up the surface. In the limit, as the number of elements approaches infinity and the area of each element approaches zero, this sum becomes an integral. The general definition of electric flux is thus

$$\phi = \lim_{\Delta A_i \to 0} \sum_i \vec{E}_i \cdot \hat{n}_i\,\Delta A_i = \int_S \vec{E} \cdot \hat{n}\,dA \qquad \text{22-13}$$

DEFINITION—ELECTRIC FLUX

where the S stands for the surface we are integrating over.* The sign of the flux depends on the choice for the direction of the unit normal $\hat{n}$. By choosing $\hat{n}$ to be out of one side of a surface we are determining the sign of $\vec{E} \cdot \hat{n}$, and thus the sign of the flux through the surface.

On a *closed* surface we are interested in the electric flux through the surface, and by convention, we always choose the unit vector $\hat{n}$ to be out of the surface at each point. The integral over a closed surface is indicated by the symbol $\oint$. The total or net flux through a closed surface S is therefore written

$$\phi_{\text{net}} = \oint_S \vec{E} \cdot \hat{n}\,dA = \oint_S E_n\,dA \qquad \text{22-14}$$

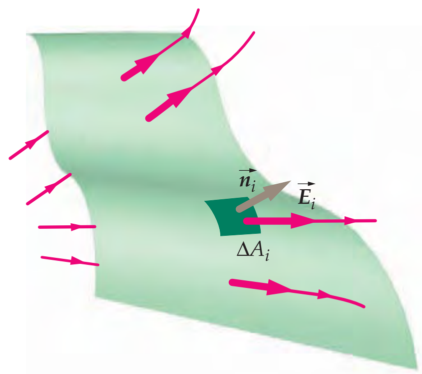

FIGURE 22-18 If E_n varies from place to place on a surface, either because the magnitude E varies or because the angle between $\vec{E}$ and $\hat{n}$ varies, the area of the surface is divided into small elements of area ΔA_i. The flux through the surface is computed by summing $\vec{E}_i \cdot \hat{n}_i\,\Delta A_i$ over all the area elements.

* The flux of a vector field through a surface is a mathematical operation used to describe the flow rates of fluids and rates of heat transfers. In addition, it is used to relate electric fields with the charges that produce them.

The net flux ϕ_{net} through the closed surface is positive or negative, depending on whether $\vec{E}$ is predominantly outward or inward at the surface. At points on the surface where $\vec{E}$ is inward, E_n is negative.

QUANTITATIVE STATEMENT OF GAUSS'S LAW

Figure 22-19 shows a spherical surface of radius R that has a point charge Q at its center. The electric field everywhere on this surface is normal to the surface and has the magnitude

$$E_n = \frac{kQ}{R^2}$$

The net flux of $\vec{E}$ out of this spherical surface is

$$\phi_{\text{net}} = \oint_S E_n\, dA = E_n \oint_S dA$$

where we have taken E_n out of the integral because it is constant everywhere on the surface. The integral of dA over the surface is just the total area of the surface, which for a sphere of radius R is $4\pi R^2$. Using this and substituting kQ/R^2 for E_n, we obtain

$$\phi_{\text{net}} = \frac{kQ}{R^2}4\pi R^2 = 4\pi kQ = Q/\epsilon_0 \qquad \text{22-15}$$

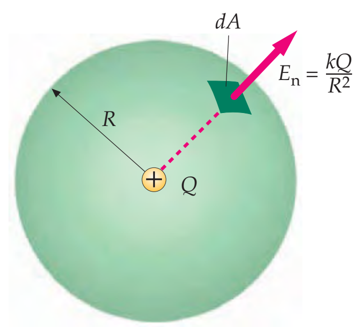

FIGURE 22-19 A spherical surface enclosing a point charge Q. The net flux is easily calculated for a spherical surface. It equals E_n multiplied by the surface area, or $E_n 4\pi R^2$.

Thus, the net flux out of a spherical surface that has a point charge Q at its center is independent of the radius R of the sphere and is equal to Q divided by ϵ_0. This is consistent with our previous observation that the net number of lines through a closed surface is proportional to the net charge inside the surface. *This number of lines is the same for all closed surfaces surrounding the charge, independent of the shape of the surface.* Thus, the net flux out of *any surface* surrounding a point charge Q equals Q/ϵ_0.

We can extend this result to systems containing multiple charges. In Figure 22-20, the surface encloses two point charges, q_1 and q_2, and there is a third point charge q_3 outside the surface. Because the electric field at any point on the surface is the vector sum of the electric fields produced by each of the three charges, the net flux $\phi_{\text{net}} = \oint_S (\vec{E}_1 + \vec{E}_2 + \vec{E}_3)\cdot\hat{n}\, dA$ out of the surface is just the sum of the fluxes ($\phi_{\text{net}} = \Sigma\phi_i$, where $\phi_i = \oint_S \vec{E}_i\cdot\hat{n}\, dA$) due to the individual charges. The flux ϕ_3 (due to charge q_3 which is outside the surface) is zero because every field line from q_3 that enters the region bounded by the surface at one point leaves the region surface at some other point. The flux out of the surface due to charge q_1 is $\phi_1 = q_1/\epsilon_0$ and the flux due to charge q_2 is $\phi_2 = q_2/\epsilon_0$. The net flux out of the surface therefore equals $\phi_{\text{net}} = (q_1 + q_2)/\epsilon_0$, which may be positive, negative, or zero depending on the signs and magnitudes of q_1 and q_2.

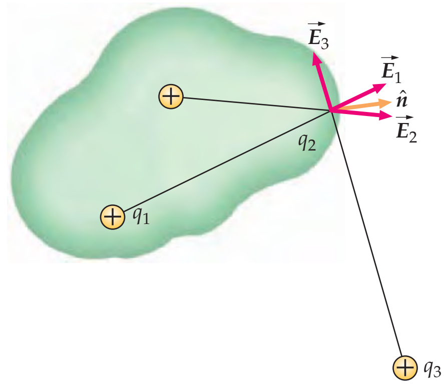

FIGURE 22-20 A surface enclosing point charges q_1 and q_2, but not q_3. The net flux out of this surface is $4\pi k(q_1 + q_2)$.

> The net outward flux through any closed surface equals the net charge inside the surface divided by ϵ_0:
>
> $$\phi_{\text{net}} = \oint_S \vec{E}\cdot\hat{n}\, dA = \oint_S E_n\, dA = \frac{Q_{\text{inside}}}{\epsilon_0} \qquad \text{22-16}$$
>
> GAUSS'S LAW

This is **Gauss's law.** It reflects the fact that the electric field due to a single point charge varies inversely with the square of the distance from the charge. It was this property of the electric field that made it possible to draw a fixed number of electric field lines from a charge and have the density of lines be proportional to the field strength.

Gauss's law is valid for all surfaces and all charge distributions. For charge distributions that have high degrees of symmetry, it can be used to calculate the electric field, as we illustrate in the next section. For static charge distributions, Gauss's law and Coulomb's law are equivalent. However, Gauss's law is more general in that it is always valid whereas the validity of Coulomb's law is restricted to static charge distributions.

Example 22-9 Flux through a Piecewise-Continuous Closed Surface

An electric field is given by $\vec{E} = +(200\ \mathrm{N/C})\hat{k}$ throughout the region $z > 0$ and by $\vec{E} = -(200\ \mathrm{N/C})\hat{k}$ throughout the region $z < 0$. An imaginary soup-can-shaped surface that has a length equal to 20 cm and a radius R equal to 5.00 cm has its center at the origin and its axis along the z axis, so that one end is at $z = +10$ cm and the other is at $z = -10$ cm (Figure 22-21). (*a*) What is the net outward flux through the closed surface? (*b*) What is the net charge inside the closed surface?

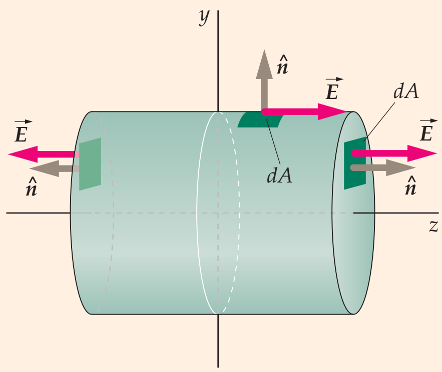

FIGURE 22-21

PICTURE The closed surface described, which is piecewise continuous, consists of three pieces—two flat ends and a curved side. Separately calculate the flux of $\vec{E}$ out of each piece of this surface. To calculate the flux out of a piece draw the outward normal $\hat{n}$ at an arbitrarily chosen point on the piece and draw the vector $\vec{E}$ at the same point. If $E_n = \vec{E}\cdot\hat{n}$ is the same everywhere on the piece, then the outward flux through the piece is E_nA, where A is the area of the piece. The net outward flux through the entire closed surface is obtained by summing the fluxes through the individual pieces. The net outward flux is related to the charge inside by Gauss's law (Equation 22-16).

SOLVE

(*a*) 1. Sketch the soup-can-shaped surface. On each piece of the surface draw the outward normal $\hat{n}$ and the vector $\vec{E}$ (Figure 22-21):

2. Calculate the outward flux through the right end of the "can" (the piece of the surface at $z = +10$ cm). On this piece $\hat{n} = \hat{k}$:

$$\phi_{\text{right}} = \vec{E}_{\text{right}}\cdot\hat{n}_{\text{right}}A = \vec{E}_{\text{right}}\cdot\hat{k}\pi R^2 = +(200\ \mathrm{N/C})\hat{k}\cdot\hat{k}(\pi)(0.0500\ \mathrm{m})^2$$
$$= 1.57\ \mathrm{N\cdot m^2/C}$$

3. Calculate the outward flux through the left end of the "can" (the piece of the surface at $z = -10$ cm), where $\hat{n} = -\hat{k}$:

$$\phi_{\text{left}} = \vec{E}_{\text{left}}\cdot\hat{n}_{\text{left}}A = \vec{E}_{\text{left}}\cdot(-\hat{k})\pi R^2$$
$$= -(200\ \mathrm{N/C})\hat{k}\cdot(-\hat{k})(\pi)(0.0500\ \mathrm{m})^2$$
$$= 1.57\ \mathrm{N\cdot m^2/C}$$

4. Calculate the outward flux through the curved surface. On the curved surface $\hat{n}$ is in the radial direction, perpendicular to the z axis:

$$\phi_{\text{curved}} = \vec{E}_{\text{curved}}\cdot\hat{n}_{\text{curved}}A = 0$$

($\phi_{\text{curved}} = 0$ because $\vec{E}\cdot\hat{n} = 0$ everywhere on the curved piece.)

5. The net outward flux is the sum through all the individual surfaces:

$$\phi_{\text{net}} = \phi_{\text{right}} + \phi_{\text{left}} + \phi_{\text{curved}} = 1.57\ \mathrm{N\cdot m^2/C} + 1.57\ \mathrm{N\cdot m^2/C} + 0$$
$$= \boxed{3.14\ \mathrm{N\cdot m^2/C}}$$

(*b*) Gauss's law relates the charge inside to the net flux:

$$Q_{\text{inside}} = \epsilon_0\phi_{\text{net}} = (8.85\times10^{-12}\ \mathrm{C^2/N\cdot m^2})(3.14\ \mathrm{N\cdot m^2/C})$$
$$= \boxed{2.78\times10^{-11}\ \mathrm{C} = 27.8\ \mathrm{pC}}$$

CHECK The flux through either end of the can does not depend on the length of the can. This result is expected for an electric field that does not vary with distance from the $z = 0$ plane.

TAKING IT FURTHER The net flux does not depend on the length of the can. Thus, the charge inside resides entirely on the $z = 0$ plane.

22-3 USING SYMMETRY TO CALCULATE $\vec{E}$ WITH GAUSS'S LAW

Given a highly symmetrical charge distribution, the electric field can often be calculated more easily by using Gauss's law than it can by using Coulomb's law. There are three classes of symmetry to consider. A charge configuration has **cylindrical (or line) symmetry** if the charge density depends only on the distance from a line, **plane symmetry** if the charge density depends only on the distance from a plane, and **spherical (or point) symmetry** if the charge density depends only on the distance from a point.

PROBLEM-SOLVING STRATEGY

Calculating $\vec{E}$ Using Gauss's Law

PICTURE Determine if the charge configuration belongs to one of the three symmetry classes. If it does not, then try another method to calculate the electric field. If is does, then sketch the charge configuration and establish the magnitude and direction of the electric field $\vec{E}$ using symmetry considerations.

SOLVE

1. On the sketch draw an imaginary closed surface, called a **Gaussian surface** (for example, the soup can in Example 22-9). This surface is chosen so that on each piece of the surface $\vec{E}$ is either zero, normal to the surface with E_n the same everywhere on the piece, or parallel to the surface ($E_n = 0$) everywhere on the piece. For a configuration that has cylindrical (line) symmetry, the Gaussian surface is a cylinder coaxial with the symmetry line. For a configuration that has plane symmetry, the Gaussian surface is a cylinder bisected by the symmetry plane and with its symmetry axis normal to the symmetry plane. For a configuration that has spherical (point) symmetry, the Gaussian surface is a sphere centered on the symmetry point. On each piece of the Gaussian surface sketch an area element dA, an outward normal $\hat{n}$, and the electric field $\vec{E}$.
2. Closed cylindrical surfaces are piecewise continuous, with the surface divided into three pieces. Spherical surfaces consist of a single piece. The flux through each piece of a properly chosen Gaussian surface equals E_nA, where E_n is the component of $\vec{E}$ normal to the piece and A is the area of the piece. Add the fluxes to obtain the total outward flux through the closed surface.
3. Calculate the total charge inside the Gaussian surface.
4. Apply Gauss's law to relate E_n to the charges inside the closed surface and solve for E_n.

CONCEPT CHECK 22-1

Is the electric field $\vec{E}$ in Gauss's law only that part of the electric field due to the charges inside a surface, or is it the total electric field due to all the charges both inside and outside the surface?

$\vec{E}$ Due to a Uniformly Charged Slab

A very large (infinite), uniformly charged slab of plastic of thickness $2a$ occupies the region between the $z = -a$ plane and the $z = +a$ plane. Find the electric field everywhere due this charge configuration. The charge per unit volume of the plastic is ρ.

PICTURE The charge configuration has plane symmetry, with the $z = 0$ plane as the symmetry plane. Use symmetry arguments to determine the direction of the electric field everywhere. Then, apply Gauss's law and solve for the electric field.

SOLVE

1. Use symmetry considerations to determine the direction of $\vec{E}$. Because the sheet is infinite, there is no preferred direction parallel to the sheet:

For $\rho > 0$, $\vec{E}$ points directly away from the $z = 0$ plane, and for $\rho < 0$, $\vec{E}$ points directly toward the $z = 0$ plane. On the $z = 0$ plane $\vec{E} = 0$.

2. Sketch the charge configuration that has a suitable Gaussian surface—a cylinder bisected by the symmetry plane (the $z = 0$ plane with its axis normal to the $z = 0$ plane). The cylinder extends from $-z$ to $+z$ (Figure 22-22):

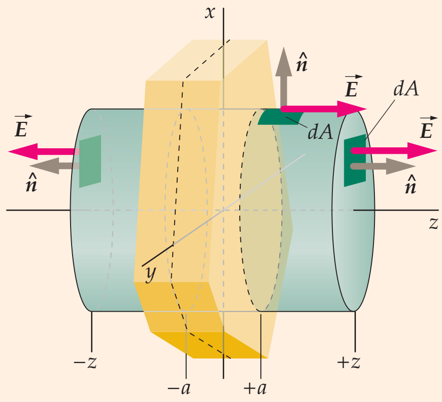

FIGURE 22-22 Gaussian surface for the calculation of $\vec{E}$ due to an infinite plane of charge. (Only the part of the plane that is inside the Gaussian surface is shown.) On the flat faces of this soup-can-shaped surface, $\vec{E}$ is perpendicular to the surface and constant in magnitude. On the curved surface $\vec{E}$ is parallel with the surface.

3. Write down Gauss's law (Equation 22-16):

$$\phi_{\text{net}} = \oint_S \vec{E} \cdot \hat{n}\, dA = \frac{Q_{\text{inside}}}{\epsilon_0}$$

4. The outward flux $\vec{E}$ through the surface is equal to the sum of the fluxes through each piece of the surface. Draw both $\hat{n}$ and $\vec{E}$ at an area element on each piece of the surface (Figure 22-22):

$$\phi_{\text{net}} = \phi_{\text{left end}} + \phi_{\text{right end}} + \phi_{\text{curved side}}$$

where
$$\phi_{\text{left end}} = \int_{\text{left end}} \vec{E} \cdot \hat{n} dA$$
$$\phi_{\text{right end}} = \int_{\text{right end}} \vec{E} \cdot \hat{n}\, dA$$
$$\phi_{\text{curved side}} = \int_{\text{curved side}} \vec{E} \cdot \hat{n}\, dA$$

5. Because $\vec{E} \cdot \hat{n}$ is zero everywhere on the curved piece of the surface, the flux through the curved piece is zero:

$$\phi_{\text{curved side}} = 0$$

6. $\vec{E}$ is uniform on the right end of the surface, so $\vec{E} \cdot \hat{n} = E_n$ can be factored from the integral. Let A be the area of the end of right end of the surface:

$$\phi_{\text{right end}} = \int_{\text{right end}} \vec{E} \cdot \hat{n}\, dA = \int_{\text{right end}} E_n\, dA$$
$$= E_n \int_{\text{right end}} dA = E_n A$$

7. The two ends of the surface are the same distance from the symmetry plane (the $z = 0$ plane), so $\vec{E}$ on the left end is equal and opposite to $\vec{E}$ on the right end. The normals on the two ends are equal and opposite as well. Thus, $\vec{E} \cdot \hat{n} = E_n$ is the same on both ends. It follows that the flux out of both ends is the same as well:

$\vec{E} \cdot \hat{n} = E_n$ is the same on the two ends,
$$\therefore\ \phi_{\text{left end}} = \phi_{\text{right end}} = E_n A$$

8. Add the individual fluxes to get the net flux out of the surface:

$$\phi_{\text{net}} = \phi_{\text{left end}} + \phi_{\text{right end}} + \phi_{\text{curved side}} = E_n A + E_n A + 0 = 2E_n A$$

9. Solve for the charge inside the Gaussian surface. The volume of a cylinder is the cross-sectional area multiplied by the length. The cylinder has a length of $2z$.

$$Q_{\text{inside}} = \rho A 2a \qquad (z \geq a)$$
$$Q_{\text{inside}} = \rho A 2z \qquad (z \leq a)$$

10. Substitute the step-8 and step-9 results into $\phi_{\text{net}} = Q_{\text{inside}}/\epsilon_0$ (the step-3 result) and solve for E_n on the right end of the surface:

For $|z| \geq a$, $2E_n A = \rho A 2a/\epsilon_0$, so $E_n = \rho a/\epsilon_0$.
For $-a \leq z \leq a$, $2E_n A = \rho A 2|z|/\epsilon_0$, so $E_n = \rho|z|/\epsilon_0$.

11. Solve for $\vec{E}$ as a function of z. In the region $z < 0$, $\hat{n} = -\hat{k}$, so $E_z = -E_n$; this means $\vec{E}$ is in the $-z$ direction so E_z is negative:

$$\vec{E} = E_z \hat{k} = \boxed{\begin{cases} -(\rho a/\epsilon_0)\hat{k} & (z \leq -a) \\ (\rho z/\epsilon_0)\hat{k} & (-a \leq z \leq a) \\ +(\rho a/\epsilon_0)\hat{k} & (z \geq +a) \end{cases}}$$

or

$$\vec{E} = E_z \hat{k} = \boxed{\begin{cases} \text{sign}(z) \cdot (\rho a/\epsilon_0)\hat{k} & (|z| \geq a) \\ \text{sign}(z) \cdot (\rho |z|/\epsilon_0)\hat{k} & (|z| \leq a) \end{cases}}$$

CHECK The electric field has units of N/C. According to our step 11 results, $\rho a/\epsilon_0$ should have the same units. It does, as $\epsilon_0 = 8.85 \times 10^{-12}\ \text{C}^2/(\text{N} \cdot \text{m}^2)$, ρ has units of C/m^3, and a has units of m.

TAKING IT FURTHER Outside the slab the electric field is the same as that of the uniformly charged plane of Equation 22-10, with $\sigma = 2\rho a$. Figure 22-23 shows a graph of E_z versus z for the charged slab. Compare this graph with that of Figure 22-11 which shows a graph of E_z versus z for the charged plane. These graphs are readily compared if you recognize that $2\pi k = 1/(2\epsilon_0)$.

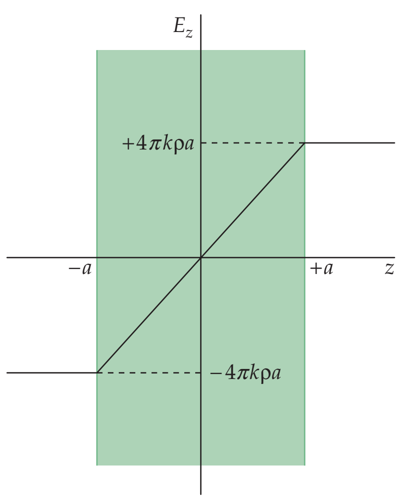

FIGURE 22-23 A graph of E_z versus z for a uniformly charged infinite slab of thickness $2a$ and charge density ρ.

We can use Gauss's law to derive Coulomb's law. This is accomplished by applying Gauss's law to find the electric field a distance r from a point charge q. Place the origin at the location of the point charge and choose a spherical Gaussian surface of radius r centered on the point charge. The outward normal $\hat{\boldsymbol{n}}$ to this surface is equal to the unit vector $\hat{\boldsymbol{r}}$. By symmetry, $\vec{E}$ is directed either radially outward or radially inward, so $\vec{E} = E_r\hat{\boldsymbol{r}}$. It follows that E_n, the component of $\vec{E}$ normal to the surface, equals the radial component $\vec{E}$. That is, $E_n = \vec{E}\cdot\hat{\boldsymbol{n}} = \vec{E}\cdot\hat{\boldsymbol{r}} = E_r$. Also, the magnitude of $\vec{E}$ can depend on the distance from the charge but not on the direction from the charge. It follows that E_n has the same value everywhere on the surface. The net flux of $\vec{E}$ through the spherical surface of radius r is thus

$$\phi_{\text{net}} = \oint_S \vec{E}\cdot\hat{\boldsymbol{n}}\,dA = \oint_S E_n\,dA = E_n\oint_S dA = E_r 4\pi r^2$$

where $\oint_S dA = 4\pi r^2$ (the area of the spherical surface). Because the total charge inside the surface is just the point charge q, Gauss's law gives

$$E_r 4\pi r^2 = \frac{q}{\epsilon_0}$$

Solving for E_r gives

$$E_r = \frac{1}{4\pi\epsilon_0}\frac{q}{r^2}$$

which is Coulomb's law. We have thus derived Coulomb's law from Gauss's law. Because for static charges Gauss's law can also be derived from Coulomb's law (see Section 22-6), we have shown that the two laws are equivalent (for static charges).

Example 22-11 $\vec{E}$ Due to a Thin Spherical Shell of Charge

Find the electric field due to a uniformly charged thin spherical shell of radius R and total charge Q.

PICTURE This charge configuration depends only on the distance from a single point—the center of the spherical shell. Thus, the configuration has spherical (point) symmetry. This symmetry dictates that $\vec{E}$ must be radial and have a magnitude that depends only on the distance r from the center of the spherical shell. A spherical Gaussian surface that has an arbitrary radius r and is concentric with the charge configuration is needed.

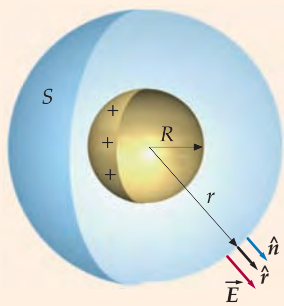

FIGURE 22-24 Spherical Gaussian surface of radius $r > R$ for the calculation of the electric field outside a uniformly charged thin spherical shell of radius R.

SOLVE

1. Sketch the charge configuration and a spherical Gaussian surface S of radius $r > R$. Include an area element dA, the normal $\hat{\boldsymbol{n}}$, and the electric field $\vec{E}$ on the area element (Figure 22-24):

2. Express Gauss's law (Equation 22-16): $$\phi_{\text{net}} = \oint_S E_n\,dA = \frac{Q_{\text{inside}}}{\epsilon_0}$$

3. The value of E_n is the same everywhere on S. Thus we can factor it from the integral: $$E_n\oint_S dA = \frac{Q_{\text{inside}}}{\epsilon_0}$$

4. The integral of the area element over the surface S is just the area of the sphere. The area of the sphere is $4\pi r^2$:

$$E_n 4\pi r^2 = \frac{Q_{\text{inside}}}{\epsilon_0}$$

5. Due to the symmetry, $E_n = E_r$. Substitute E_r for E_n and solve for E_r:

$$E_r = \frac{1}{4\pi\epsilon_0}\frac{Q_{\text{inside}}}{r^2}$$

6. For $r > R$, $Q_{\text{inside}} = Q$. For $r < R$, $Q_{\text{inside}} = 0$:

$\vec{E} = E_r\hat{\boldsymbol{r}}$, where

$$\boxed{\begin{array}{ll} E_r = \dfrac{1}{4\pi\epsilon_0}\dfrac{Q}{r^2} & r > R \\ E_r = 0 & r < R \end{array}}$$

CHECK Outside the charged shell, the electric field is the same as that of a point charge Q at the shell's center. This result is expected for $r \gg R$.

TAKING IT FURTHER The step-6 result can also be obtained by direct integration of Coulomb's law, but that calculation is much more challenging.

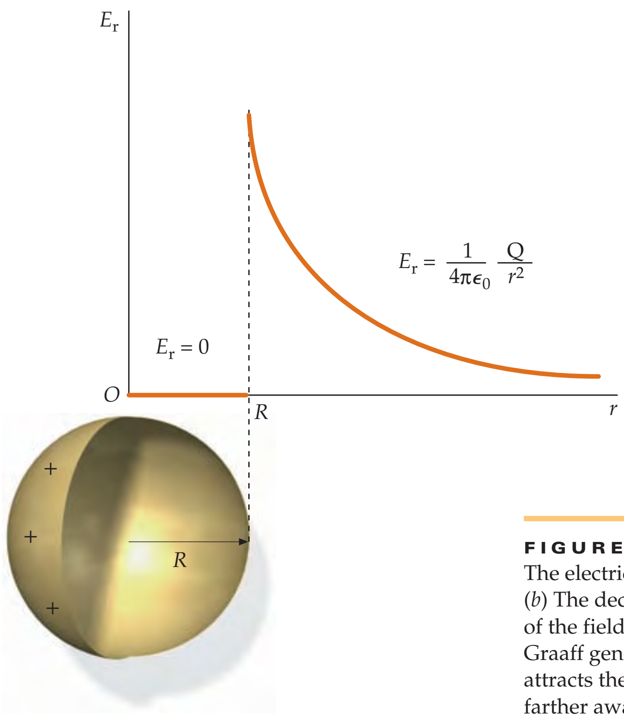
Figure 22-25 shows E_r versus r for a spherical-shell charge distribution. Again, note that the electric field is discontinuous at $r = R$, where the surface charge density is $\sigma = Q/(4\pi R^2)$. Just outside the shell, the electric field is $E_r = Q/(4\pi\epsilon_0 R^2) = \sigma/\epsilon_0$, because $\sigma = Q/4\pi R^2$. Because the field just inside the shell is zero, the electric field is discontinuous at $r = R$ by the amount σ/ϵ_0.

The electric field of a uniformly charged thin spherical shell is given by $\vec{E} = E_r\hat{\boldsymbol{r}}$, where

$$E_r = \frac{1}{4\pi\epsilon_0}\frac{Q}{r^2} \qquad r > R \qquad \text{22-17}a$$

$$E_r = 0 \qquad r < R \qquad \text{22-17}b$$

(*a*)



(*b*)

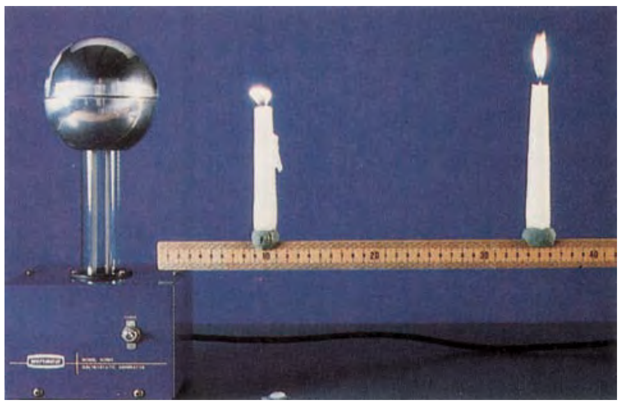


FIGURE 22-25 (*a*) A plot of E_r versus r for a thin spherical shell charge distribution. The electric field is discontinuous at $r = R$, where there is a surface charge of density σ. (*b*) The decrease in E_r over distance due to a charged spherical shell is evident by the effect of the field on the flames of two candles. The spherical shell at the left (part of a Van de Graaff generator, a device that is discussed in Chapter 23) has a large negative charge that attracts the positive ions in the nearby candle flame. The flame at right, which is much farther away, is not noticeably affected. *(Runk/Schoenberger from Grant Heilmann.)*

Example 22-12 Electric Field Due to a Point Charge and a Charged Spherical Shell

A spherical shell of radius $R = 3.00$ m has its center at the origin and has a surface charge density of $\sigma = 3.00\ \text{nC/m}^2$. A point charge $q = 250$ nC is on the y axis at $y = 2.00$ m. Find the electric field on the x axis at (*a*) $x = 2.00$ m and (*b*) $x = 4.00$ m.

PICTURE We separately find the field due to the point charge and that due to the spherical shell and sum the field vectors in accord with the principle of superposition. For Part (*a*), the field point is inside the shell, so the field is due only to the point charge (Figure 22-26*a*). For Part (*b*), the field point is outside the shell, so the field due to the shell can be calculated as if the charge were a point charge at the origin. We then add the fields due to the two point charges (Figure 22-26*b*).

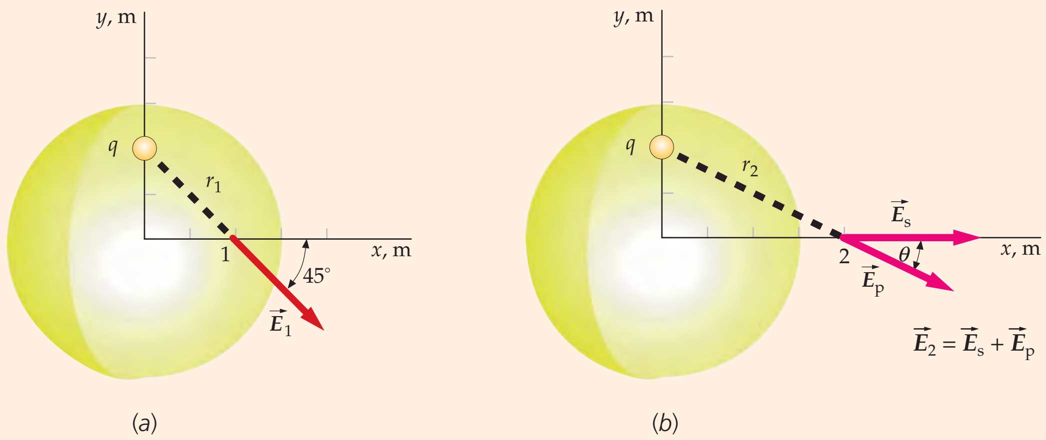

FIGURE 22-26

SOLVE

(*a*) 1. Inside the shell, $\vec{E}_1$ is due only to the point charge: $\quad \vec{E}_1 = \dfrac{kq}{r_1^2}\hat{r}_1$

2. Calculate the square of the distance r_1: $\quad r_1^2 = (2.00\ \text{m})^2 + (2.00\ \text{m})^2 = 8.00\ \text{m}^2$

3. Use r_1 to calculate the magnitude of the field:
$$E_1 = \frac{kq}{r_1^2} = \frac{(8.99 \times 10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(250 \times 10^{-9}\ \text{C})}{8.00\ \text{m}^2} = 281\ \text{N/C}$$

4. From Figure 22-26*a*, we can see that the field makes an angle of 45° with the x axis: $\quad \theta_1 = 45.0°$

5. Express $\vec{E}_1$ in terms of its components:
$$\vec{E}_1 = E_{1x}\hat{i} + E_{1y}\hat{j} = E_1\cos 45.0°\ \hat{i} - E_1 \sin 45.0°\ \hat{j}$$
$$= (281\ \text{N/C})\cos 45.0°\ \hat{i} - (281\ \text{N/C})\sin 45.0°\ \hat{j}$$
$$= \boxed{(199\hat{i} - 199\hat{j})\ \text{N/C}}$$

(*b*) 1. Outside of its perimeter, the field of the shell can be calculated as if the shell were a point charge at the origin, and the field due to the shell $\vec{E}_S$ is therefore along the x axis: $\quad \vec{E}_S = \dfrac{kQ}{x_2^2}\hat{i}$

2. Calculate the total charge Q on the shell: $\quad Q = \sigma 4\pi R^2 = (3.00\ \text{nC/m}^2)4\pi(3.00\ \text{m})^2 = 339\ \text{nC}$

3. Use Q to calculate the field due to the shell:
$$E_S = \frac{kQ}{x_2^2} = \frac{(8.99 \times 10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(339 \times 10^{-9}\text{C})}{(4.00\ \text{m})^2} = 190\ \text{N/C}$$

4. The field due to the point charge is: $\quad \vec{E}_P = \dfrac{kq}{r_2^2}\hat{r}_2$

5. Calculate the square of the distance from the point charge q on the y axis to the field point at $x = 4.00$ m:

$$r_2^2 = (2.00\text{ m})^2 + (4.00\text{ m})^2 = 20.0\text{ m}^2$$

6. Calculate the magnitude of the field due to the point charge:

$$E_P = \frac{kq}{r_2^2} = \frac{(8.99 \times 10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(250 \times 10^{-9}\text{ C})}{20.0\text{ m}^2} = 112\text{ N/C}$$

7. This field makes an angle θ with the x axis, where:

$$\tan\theta = \frac{2.00\text{ m}}{4.00\text{ m}} = 0.500 \Rightarrow \theta = \tan^{-1}0.500 = 26.6°$$

8. The x and y components of the net electric field are thus:

$$E_x = E_{Px} + E_{Sx} = E_P\cos\theta + E_S$$
$$= (112\text{ N/C})\cos 26.6° + 190\text{ N/C} = 290\text{ N/C}$$
$$E_y = E_{Py} + E_{Sy} = -E_P\sin\theta + 0$$
$$= -(112\text{ N/C})\sin 26.6° = -50.0\text{ N/C}$$
$$\vec{E}_2 = \boxed{(290\hat{i} - 50.0\hat{j})\text{ N/C}}$$

CHECK The Part (*b*), step 8 result is qualitatively in agreement with Figure 22-26*b*. That is, E_x is positive, E_y is negative, and $|E_y| < E_x$.

TAKING IT FURTHER Specifying the x, y, and z components of a vector completely specifies the vector. In these cases, the z component is zero.

$\vec{E}$ DUE TO A UNIFORMLY CHARGED SPHERE

Example 22-13 $\vec{E}$ Due to a Uniformly Charged Solid Sphere

Find the electric field everywhere for a uniformly charged solid sphere that has a radius R and a total charge Q that is uniformly distributed throughout the volume of the sphere that has a charge density $\rho = Q/V$, where $V = \frac{4}{3}\pi R^3$ is the volume of the sphere.

PICTURE The charge configuration has spherical symmetry. By symmetry, the electric field must be radial. We choose a spherical Gaussian surface of radius r (Figure 22-27*a* and Figure 22-27*b*). On the Gaussian surface, E_n is the same everywhere, and $E_n = E_r$. Gauss's law thus relates E_r to the total charge inside the Gaussian surface.

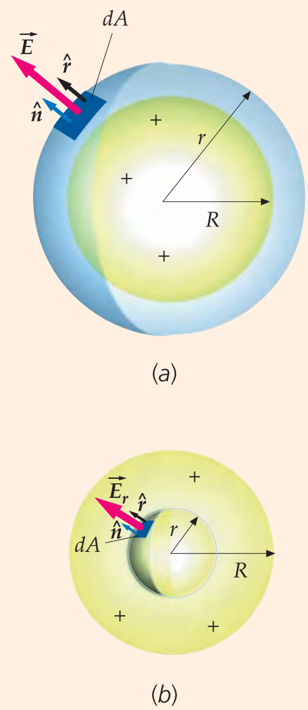

FIGURE 22-27

SOLVE

1. Draw a charged sphere of radius R and draw a spherical Gaussian surface with radius r (Figure 22-27*a* for $r > R$ and Figure 22-27*b* for $r < R$):

2. Relate the flux through the Gaussian surface to the electric field E_r on it. At every point on this surface $\hat{n} = \hat{r}$ and E_r has the same value:

$$\phi_{\text{net}} = \vec{E}\cdot\hat{n}A = \vec{E}\cdot\hat{r}A = E_r 4\pi r^2$$

(The surface area of a sphere of radius r is $4\pi r^2$.)

3. Apply Gauss's law to relate the field to the total charge inside the surface:

$$E_r 4\pi r^2 = \frac{Q_{\text{inside}}}{\epsilon_0}$$

4. Find Q_{inside} for all values of r. The charge density $\rho = Q/V$, where $V = \frac{4}{3}\pi R^3$:

For $r \geq R$, $Q_{\text{inside}} = Q$

For $r \leq R$, $Q_{\text{inside}} = \rho V'$,

where $V' = \frac{4}{3}\pi r^3$

so

$$Q_{\text{inside}} = \frac{Q}{V}V' = \frac{Q}{\frac{4}{3}\pi R^3}\frac{4}{3}\pi r^3 = Q\frac{r^3}{R^3}$$

5. Substitute into the step 3 result and solve for $\vec{E}$:

$\vec{E} = E_r\hat{r}$, where

$$\boxed{E_r = \frac{1}{4\pi\epsilon_0}\frac{Q}{r^2} \qquad r \geq R}$$

$$\boxed{E_r = \frac{1}{4\pi\epsilon_0}\frac{Q}{r^2}\frac{r^3}{R^3} = \frac{1}{4\pi\epsilon_0}\frac{Q}{R^3}r \qquad r \leq R}$$

CHECK At the center of the charged sphere the electric field is zero, as symmetry suggests. For $r > R$, the field is identical to the field of a point charge Q at the center of the sphere, also as expected.

TAKING IT FURTHER Figure 22-28 shows E_r versus r for the charge distribution in this example. Inside the sphere of charge, E_r increases with r. Note that E_r is continuous at $r = R$. A uniformly charged sphere is sometimes used as a model to describe the electric field of an atomic nucleus.

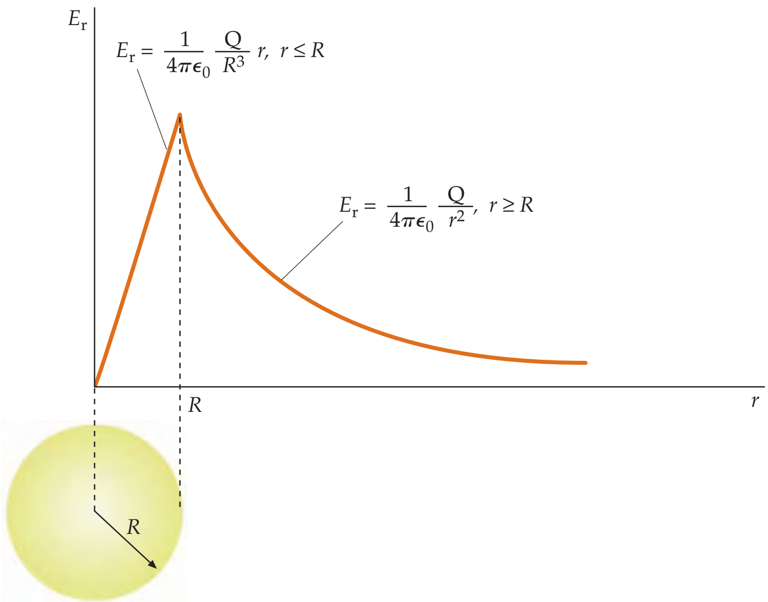

FIGURE 22-28

We see from Example 22-13 that the electric field a distance r from the center of a uniformly charged sphere of radius R is given by $\vec{E} = E_r\hat{r}$, where

$$E_r = \frac{1}{4\pi\epsilon_0}\frac{Q}{r^2} \qquad r \geq R \tag{22-18a}$$

$$E_r = \frac{1}{4\pi\epsilon_0}\frac{Q}{R^3}r \qquad r \leq R \tag{22-18b}$$

and Q is the total charge of the sphere.

Example 22-14 Electric Field Due to Infinite Line Charge

Use Gauss's law to find the electric field everywhere due to an infinitely long line charge of uniform charge density λ. (This problem was already solved in Example 22-3 using Coulomb's law.)

PICTURE Because of the symmetry, we know the electric field is directed away from the line if λ is positive (directly toward it if λ is negative), and we know the magnitude of the field depends only on the radial distance from the line charge. We therefore choose a cylindrical Gaussian surface coaxial with the line charge. We calculate the outward flux of $\vec{E}$ through each piece of the surface, and, using Gauss's law, relate the net outward flux of $\vec{E}$ to the charge inside the cylinder.

SOLVE

1. Sketch the wire and a coaxial cylindrical Gaussian surface (Figure 22-29) that has a length L and a radius R. The closed surface consists of three pieces: the two flat ends and the curved side. At a randomly chosen point on each piece, draw an area element and the vectors $\vec{E}$ and $\hat{n}$. Because of the symmetry, we know that the direction of $\vec{E}$ is radial (either toward or away from the line charge), and we know that the magnitude E depends only on the distance from the line charge.

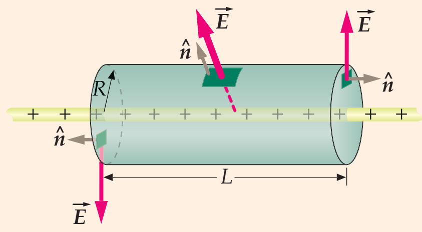

FIGURE 22-29

2. Calculate the outward flux through the curved piece of the Gaussian surface. At each point on the curved piece $\hat{R} = \hat{n}$, where $\hat{R}$ is the unit vector in the radial direction.

$$\phi_{\text{curved}} = \vec{E}\cdot\hat{n}A_{\text{curved}} = \vec{E}\cdot\hat{R}A_{\text{curved}} = E_R 2\pi RL$$

3. Calculate the outward flux through each of the flat ends of the Gaussian surface. On these pieces the direction of $\hat{n}$ is parallel with the line charge (and thus perpendicular to $\vec{E}$):

$$\phi_{\text{left}} = \vec{E}\cdot\hat{n}A_{\text{left}} = 0$$

$$\phi_{\text{right}} = \vec{E}\cdot\hat{n}A_{\text{right}} = 0$$

4. Apply Gauss's law to relate the field to the total charge inside the surface Q_{inside}. The net flux out of the Gaussian surface is the sum of the fluxes out of the three pieces of the surface, and Q_{inside} is the charge on a length L of the line charge:

$$\phi_{\text{net}} = \frac{Q_{\text{inside}}}{\epsilon_0}$$

$$E_R 2\pi RL = \frac{\lambda L}{\epsilon_0} \quad \text{so} \quad \vec{E} = E_R\hat{R}, \quad \text{where} \quad E_R = \boxed{\frac{1}{2\pi\epsilon_0}\frac{\lambda}{R}}$$

CHECK Because $1/(2\pi\epsilon_0) = 2k$, the step-4 result can also be written $2k\lambda/R$. This is the same expression for E_R that was obtained by using Coulomb's law (see Example 22-3).

In the calculation of $\vec{E}$ for a line charge (Example 22-14), we needed to assume that the field point was very far from the ends of the line charge so that E_n would be constant everywhere on the cylindrical Gaussian surface. If we are near the end of a finite line charge, we cannot assume that $\vec{E}$ is perpendicular to the curved surface of the cylinder, or that E_n is constant everywhere on it, so we cannot use Gauss's law to calculate the electric field.

It is important to realize that although Gauss's law holds for any closed surface and any charge distribution, it is particularly useful for calculating the electric fields of charge distributions that have cylindrical, spherical, or plane symmetry. It is also particularly useful doing calculations involving conductors in electrostatic equilibrium, as we shall see in Section 22-5.

22-4 DISCONTINUITY OF

We have seen that the electric field for an infinite plane of charge and a thin spherical shell of charge is discontinuous by the amount σ/ϵ_0 at a surface having charge density σ. We now show that this is a general result for the component of the electric field that is perpendicular to a surface having a charge density of σ.

Figure 22-30 shows an arbitrary surface having a surface charge density σ. The surface is arbitrary in that it is arbitrarily curved, although it does not have any sharp folds where the normal direction is ambiguous, and σ may vary continuously on the surface from place to place. We consider electric field $\vec{E}$ in the vicinity of a point P on the surface as the superposition of electric field $\vec{E}_{\text{disk}}$, due just to the charge on a small disk centered at point P, and the electric field $\vec{E}'$ due to all other charges in the universe. Thus,

$$\vec{E} = \vec{E}_{\text{disk}} + \vec{E}' \qquad 22\text{-}19$$

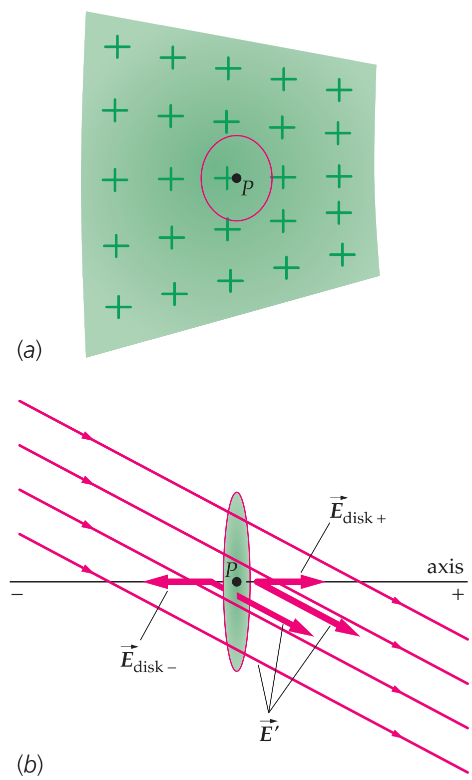

FIGURE 22-30 (a) A surface having surface charge. (b) The electric field $\vec{E}_{\text{disk}}$ due to the charge on a circular disk, plus the electric field $\vec{E}'$ due to all other charges.

The disk is small enough that it may be considered both flat and uniformly charged. On the axis of the disk, the electric field $\vec{E}_{\text{disk}}$ is given by Equation 22-9. At points on the axis very close to the disk, the magnitude of this field is given by $E_{\text{disk}} = |\sigma|/(2\epsilon_0)$. The direction of $\vec{E}_{\text{disk}}$ is away from the disk if σ is positive, and toward it if σ is negative. The magnitude and direction of the electric field $\vec{E}\,'$ are unknown. In the vicinity of point P, however, this field is continuous. Thus, at points on the axis of the disk and very close to it, $\vec{E}\,'$ is essentially uniform.

The axis of the disk is normal to the surface, so vector components along this axis can be referred to as normal components. The normal components of the vectors in Equation 22-19 are related by $E_n = E_{\text{disk}\,n} + E'_n$. If we refer to one side of the surface as the $+$ side, and the other side as the $-$ side, then $E_{n+} = \dfrac{\sigma}{2\epsilon_0} + E'_{n+}$ and $E_{n-} = -\dfrac{\sigma}{2\epsilon_0} + E'_{n+}$. Thus, E_n changes discontinuously from one side of the surface to the other. That is,

$$\Delta E_n = E_{n+} - E_{n-} = \frac{\sigma}{2\epsilon_0} - \left(-\frac{\sigma}{2\epsilon_0}\right) = \frac{\sigma}{\epsilon_0} \qquad 22\text{-}20$$

DISCONTINUITY OF E_n AT A SURFACE CHARGE

where we have made use of the fact that near the disk $E'_{n+} = E'_{n-}$ (because $\vec{E}\,'$ is continuous and uniform).

Note that the discontinuity of E_n occurs at a finite disk of charge, an infinite plane of charge (see Figure 22-12), and a thin spherical shell of charge (see Figure 22-25). However, it does not occur at the perimeter of a solid sphere of charge (see Figure 22-28). The electric field is discontinuous at any location with an infinite volume charge density. These include locations that each have a finite point charge, locations that each have a finite line charge density, and locations that each have a finite surface charge density. At all locations with a finite surface charge density, the normal component of the electric field is discontinuous—in accord with Equation 22-20.

22-5 CHARGE AND FIELD AT CONDUCTOR SURFACES

A conductor contains an enormous amount of charge that can move freely within the conductor. If there is an electric field within a conductor, there will be a net force on this free charge causing a momentary electric current (electric currents are discussed in Chapter 25). However, unless there is a source of energy to maintain this current, the free charge in a conductor will merely redistribute itself to create an electric field that cancels the external field within the conductor. The conductor is then said to be in **electrostatic equilibrium.** Thus, in electrostatic equilibrium, the electric field inside a conductor is zero everywhere. The time taken to reach equilibrium depends on the conductor. For copper and other metal conductors, the time is so small that in most cases electrostatic equilibrium is reached in a few nanoseconds.*

We can use Gauss's law to show that for a conductor in electrostatic equilibrium, any net electric charge on the conductor resides entirely on the surface of the conductor. Consider a Gaussian surface completely inside the material of a conductor in electrostatic equilibrium (Figure 22-31). The size and shape of the Gaussian surface do not matter, as long as the entire surface is embedded within the material of the conductor. The electric field is zero everywhere on the Gaussian surface because the surface is completely within the conductor, where the field is everywhere zero. The net flux of the electric field through the surface must therefore be zero, and, by Gauss's law, the net charge inside the surface must be zero. Thus, there can be no

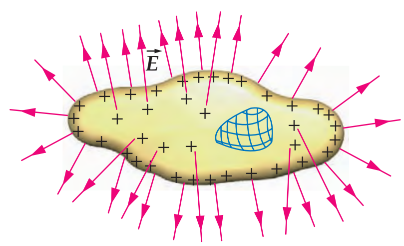

FIGURE 22-31 A Gaussian surface completely within the material of a conductor. Because the electric field is zero inside the material a conductor in electrostatic equilibrium, the net flux through this surface must also be zero. Therefore, the net charge density ρ must be zero everywhere within the material of a conductor.

* At very low temperatures some metals become superconducting. In a superconductor, a current is sustained for a much longer time, even without an energy source. Superconducting metals are discussed in Chapters 27 and 38.

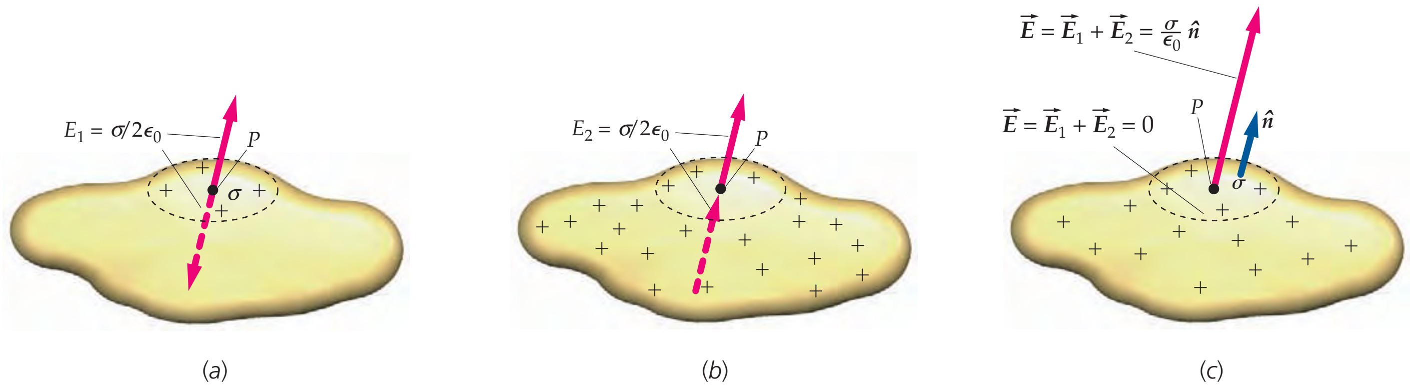

FIGURE 22-32 An arbitrarily shaped conductor having a charge on its surface. (*a*) The charge in the vicinity of point P near the surface looks like a small uniformly charged circular disk centered at P, giving an electric field of magnitude $\sigma/(2\epsilon_0)$ pointing away from the surface both inside and outside the surface. Inside the conductor, this field points away from point P in the opposite direction. (*b*) Because the net field inside the conductor is zero, the rest of the charges in the universe must produce a field of magnitude $\sigma/(2\epsilon_0)$ in the outward direction. The field due to these charges is the same just inside the surface as it is just outside the surface. (*c*) Inside the surface, the fields shown in (*a*) and (*b*) cancel, but outside they add to give $E_n = \sigma/\epsilon_0$.

net charge inside any surface lying completely within the material of the conductor. Therefore, if a conductor has a net charge, it must reside on the conductor's surface. At the surface of a conductor in electrostatic equilibrium, $\vec{E}$ must be perpendicular to the surface. (If the electric field did have a tangential component at the surface, the free charge would be accelerated tangential to the surface until electrostatic equilibrium was reestablished.)

Because E_n is discontinuous at any charged surface by the amount σ/ϵ_0, and because $\vec{E}$ is zero inside the material of a conductor, the field just outside the surface of a conductor is given by

$$E_n = \frac{\sigma}{\epsilon_0} \qquad \text{22-21}$$

E_n JUST OUTSIDE THE SURFACE OF A CONDUCTOR

This result is exactly twice the field produced by a uniform disk of surface charge density σ. We can understand this result from Figure 22-32. The charge on the conductor consists of two parts: (1) the charge near point P and (2) all the rest of the charge. The charge near point P looks like a small, uniformly charged circular disk centered at P that produces a field near P of magnitude $\sigma/(2\epsilon_0)$ just inside and just outside the conductor. The rest of the charges in the universe must produce a field of magnitude $\sigma/(2\epsilon_0)$ that exactly cancels the field inside the conductor. This field due to the rest of the charge in the universe adds to the field due to the small charged disk just outside the conductor to give a total field of σ/ϵ_0.

Example 22-15 The Charge of Earth *Context-Rich*

While watching a science show on the atmosphere, you find out that on average the electric field of Earth is about 100 N/C directed vertically downward. Given that you have been studying electric fields in your physics class, you wonder if you can determine what the total charge on Earth's surface is.

PICTURE Earth is a conductor, so any charge it has resides on the surface of Earth. The surface charge density σ is related to the normal component of the electric field E_n by Equation 22-21. The total charge Q equals the charge density σ multiplied by the surface area A.

SOLVE

1. The surface charge density σ is related to the normal component of the electric field E_n by Equation 22-21: $\quad E_n = \dfrac{\sigma}{\epsilon_0}$

2. On the surface of Earth, $\hat{n}$ is upward and $\vec{E}$ is downward so E_n is negative: $\quad E_n = \vec{E}\cdot\hat{n} = E\cos 180° = -E = -100\text{ N/C}$

3. The charge Q is the charge per unit area multiplied by the area. Combine this with the step 1 and 2 results to obtain an expression for Q: $\quad Q = \sigma A = \epsilon_0 E_n A = -\epsilon_0 EA$

4. The surface area of a sphere of radius r is given by $A = 4\pi r^2$:

$$Q = -\epsilon_0 EA = -\epsilon_0 E4\pi R_E^2 = -4\pi\epsilon_0 ER_E^2$$

5. The radius of Earth is 6.37×10^6 m:

$$Q = -4\pi\epsilon_0 ER_E^2$$
$$= -4\pi(8.85 \times 10^{-12}\ \mathrm{C^2/N\cdot m^2})(100\ \mathrm{N/C})(6.37 \times 10^6\ \mathrm{m})^2$$
$$= \boxed{-4.51 \times 10^5\ \mathrm{C}}$$

CHECK We will check to see if units in the step 5 calculation are correct. In multiplying the three quantities, both the newtons and the meters cancel out, leaving only coulombs as expected.

TAKING IT FURTHER Is -4.53×10^5 C a large amount of charge? In Example 21-1 we calculated that the total charge of all the electrons in a copper penny amounts to -1.37×10^5 C, so the total charge on the surface of Earth is only 3.3 times larger than the total charge of all the electrons in a single copper penny.

Figure 22-33 shows a positive point charge q at the center of a spherical cavity inside a spherical conductor. Because the net charge must be zero within any Gaussian surface drawn within the material of the conductor, there must be a negative charge $-q$ induced on the surface of the cavity. In Figure 22-34, the point charge has been moved so that it is no longer at the center of the cavity. The field lines in the cavity are altered, and the surface charge density of the induced negative charge on the inner surface is no longer uniform. However, the positive surface charge density on the outside surface is not disturbed—it is still uniform—because it is electrically shielded from the cavity by the conducting material. The electric field of the point charge q and that of the surface charge $-q$ on the inner surface of the cavity superpose to produce an electric field that is exactly zero everywhere outside the cavity. This is obviously true if the point charge is at the center of the cavity, but it is true even if the point charge is somewhere else in the cavity. In addition, the surface charge on the outer surface of the conductor produces an electric field that is exactly zero everywhere inside the outer surface of the conductor. Furthermore, these statements are valid even if both the outer surface and the inner surface of the conductor are nonspherical.

Electric field lines for an oppositely charged cylinder and plate, shown by bits of fine thread suspended in oil. Note that the field lines are normal to the surfaces of the conductors and that there are no lines inside the cylinder. The region inside the cylinder is electrically shielded from the region outside the cylinder. *(Harold M. Waage.)*

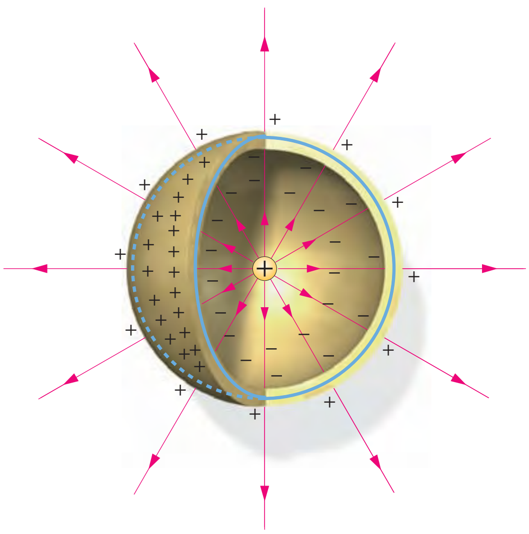

FIGURE 22-33 A point charge q in the cavity at the center of a thick spherical conducting shell. Because the net charge within the Gaussian surface (indicated in blue) must be zero, we know a surface charge $-q$ is induced on the inner surface of the shell, and because the conductor is neutral, an equal but opposite charge $+q$ is induced on the outer surface. Electric field lines begin on the point charge and end on the inner surface. Field lines begin again on the outer surface.

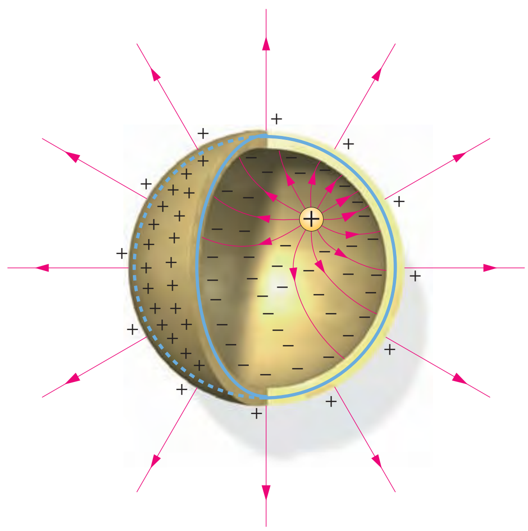

FIGURE 22-34 The same conductor as in Figure 22-33 with the point charge moved away from the center of the sphere. The charge on the outer surface and the electric field lines outside the sphere are not affected.

* 22-6 THE EQUIVALENCE OF GAUSS'S LAW AND COULOMB'S LAW IN ELECTROSTATICS

Gauss's law can be derived mathematically from Coulomb's law for the electrostatic case using the concept of the **solid angle.** Consider an area element ΔA on a spherical surface. The solid angle $\Delta\Omega$ subtended by ΔA at the center of the sphere is defined to be

$$\Delta\Omega = \frac{\Delta A}{r^2}$$

where r is the radius of the sphere. Because ΔA and r^2 both have dimensions of length squared, the solid angle is dimensionless. The SI unit of the solid angle is the **steradian** (sr). Because the total area of a sphere is $4\pi r^2$, the total solid angle subtended by a spherical surface is

$$\frac{4\pi r^2}{r^2} = 4\pi \text{ steradians}$$

There is a close analogy between the solid angle and the ordinary plane angle $\Delta\theta$, which is defined to be the ratio of an element of arc length of a circle Δs to the radius of the circle:

$$\Delta\theta = \frac{\Delta s}{r} \text{ radians}$$

The total plane angle subtended by a circle is 2π radians.

In Figure 22-35, the area element ΔA is not perpendicular to the radial lines from point O. The unit vector $\hat{\boldsymbol{n}}$ normal to the area element makes an angle θ with the radial unit vector $\hat{\boldsymbol{r}}$. In this case, the solid angle subtended by ΔA at point O is

$$\Delta\Omega = \frac{\Delta A\, \hat{\boldsymbol{n}} \cdot \hat{\boldsymbol{r}}}{r^2} = \frac{\Delta A \cos\theta}{r^2} \qquad \text{22-22}$$

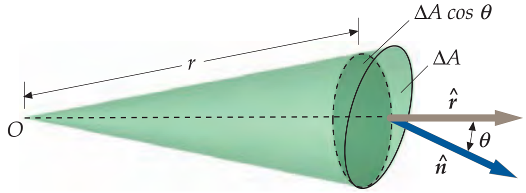

FIGURE 22-35 An area element ΔA whose normal is not parallel to the radial line from O to the center of the element. The solid angle subtended by this element at O is defined to be $(\Delta A \cos\theta)/r^2$.

The solid angle $\Delta\Omega$ is the same as that subtended by the corresponding area element of a spherical surface of any radius.

Figure 22-36 shows a point charge q surrounded by a surface of arbitrary shape. To calculate the flux of $\vec{E}$ through this surface, we want to find $\vec{E} \cdot \hat{\boldsymbol{n}}\Delta A$ for each element of area on the surface and sum over the entire surface. The electric field at the area element shown is given by

$$\vec{E} = \frac{kq}{r^2}\hat{\boldsymbol{r}}$$

so the flux through the element is

$$\Delta\phi = \vec{E} \cdot \hat{\boldsymbol{n}}\Delta A = \frac{kq}{r^2}\hat{\boldsymbol{r}} \cdot \hat{\boldsymbol{n}}\Delta A = kq\, \Delta\Omega$$

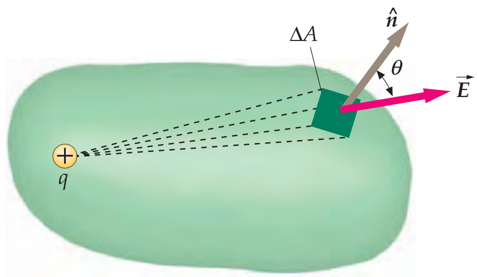

FIGURE 22-36 A point charge enclosed by an arbitrary surface. The flux through an area element ΔA is proportional to the solid angle subtended by the area element at the charge. The net flux through the surface, found by summing over all the area elements, is proportional to the total solid angle 4π at the charge, which is independent of the shape of the surface.

The sum of the fluxes through the entire surface is kq multiplied by the total solid angle subtended by the closed surface, which is 4π steradians:

$$\phi_{\text{net}} = \oint_S \vec{E} \cdot \hat{\boldsymbol{n}}\, dA = kq \oint d\Omega = kq4\pi = 4\pi kq = \frac{q}{\epsilon_0} \qquad \text{22-23}$$

which is Gauss's law.

Physics Spotlight

Charge Distribution—Hot and Cold

Electrical dipole moment, or *polarity*, affects the solubility of substances. Because water has such a strong electric dipole moment, it works very well as a solvent for other molecules that have both weak and strong dipole moments and ions. On the other hand, molecules without dipole moments, or molecules that are so big that they have large regions without dipole moments, do not dissolve well in water. Some oils, for example, do not have dipole moments and are immiscible with water.

Charge distributions that molecules can have also control whether substances that are not strictly classified as oils dissolve well in water. Anyone who has ever bitten into a very spicy-hot pepper and then taken a large drink of water can testify that water does not wash away the sensation of pain. Capsaicin, the active chemical in spicy-hot peppers such as habañeros, serranos, and piquins, does not dissolve well in cold water because of its charge distribution.* However, capsaicin's solubility in water is increased with the addition of ethyl alcohol, as demonstrated by people who cool their mouths with beer after spicy-hot peppers. Alcohol molecules have weak dipole moments, and mix well with both water and capsaicin. Capsaicin also mixes well with oils, some starches, and proteins. In many cultures, rice or meat, rather than alcohol, is used to dissolve capsaicin.

The molecules of the active ingredient in these spicy hot peppers do not dissolve in water because they do not have electric dipole moments. *(Stockbyte Platinum/Getty Images.)*

The sensation of pain that people who eat peppers feel is also due to the charge distributions in molecules. The protein TRPV1 is a neuron receptor in humans that signals how hot—temperature wise—something is. This protein has a charge distribution that is changed by a temperature above 43°C. Proteins change their shapes (fold and unfold) as the charge distribution changes across the molecule.† Many protein functions are determined by folding and unfolding caused by changes in charge distributions.‡ A change in charge distribution on a TRPV1 protein folds the protein and passes information about how hot a human's surroundings are to neurons. Capsaicin creates the same changes as heat does in the charge distributions of TRPV1 proteins,# which is why people perceive peppers as hot. Ginger, a "warm" spice, contains gingerols, which trigger similar receptors by means of changing charge distributions.° Menthol causes similar charge distribution changes in proteins that are neuron receptors in humans and signal how cold surroundings are.§ This is why people perceive mint as cool.

Changes in charge distributions of proteins can cause textural changes in proteins. The salting of caviar, for example, changes the charge distribution of proteins inside the fish eggs. As the proteins unfold, they thicken the formerly thin fluid inside the egg to a creamy texture.¶

Summary

1. Gauss's law is a fundamental law of physics that is equivalent to Coulomb's law for static charges.
2. For highly symmetric charge distributions, Gauss's law can be used to calculate the electric field.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Electric Field for a Continuous Charge Distribution	$\vec{E} = \int d\vec{E} = \int \frac{k\hat{r}}{r^2}\,dq$ (Coulomb's law)	22-1*b*
	where $dq = \rho\,dV$ for a charge distributed throughout a volume, $dq = \sigma\,dA$ for a charge distributed on a surface, and $dq = \lambda\,dL$ for a charge distributed along a line.	
2. Electric Flux	$\phi = \lim_{\Delta A_i \to 0} \sum_i \vec{E}_i \cdot \hat{n}_i\,\Delta A_i = \int_S \vec{E} \cdot \hat{n}\,dA$	22-13
3. Gauss's Law	$\phi_{\text{net}} = \oint_S \vec{E} \cdot \hat{n}\,dA = \oint_S E_n\,dA = \frac{Q_{\text{inside}}}{\epsilon_0}$	22-16
	The net outward electric flux through a closed surface equals the net charge within the surface divided by ϵ_0.	
4. Coulomb Constant k and Electric Constant (Permittivity of Free Space) ϵ_0	$k = \frac{1}{4\pi\epsilon_0} = 8.99 \times 10^9\ \text{N}\cdot\text{m}^2/\text{C}^2$	
	$\epsilon_0 = \frac{1}{4\pi k} = 8.85 \times 10^{-12}\ \text{C}^2/(\text{N}\cdot\text{m}^2)$	22-7
5. Coulomb's Law and Gauss's Law	$\vec{E} = \frac{1}{4\pi\epsilon_0}\frac{q}{r^2}\hat{r}$	22-5
	$\phi_{\text{net}} = \oint_S E_n\,dA = \frac{Q_{\text{inside}}}{\epsilon_0}$	22-16
6. Discontinuity of E_n	At a surface having a surface charge density σ, the component of the electric field normal to the surface is discontinuous by σ/ϵ_0.	
	$E_{n+} - E_{n-} = \frac{\sigma}{\epsilon_0}$	22-20
7. Charge on a Conductor	In electrostatic equilibrium, the charge density is zero throughout the material of the conductor. All excess or deficit charge resides on the surfaces of the conductor.	
8. $\vec{E}$ Just Outside a Conductor	The resultant electric field just outside the surface of a conductor is normal to the surface and has the magnitude σ/ϵ_0, where σ is the local surface charge density on the conductor:	
	$E_n = \frac{\sigma}{\epsilon_0}$	22-21
9. Electric Fields for Selected Uniform Charge Distributions		
Of a line charge of infinite length	$E_R = 2k\frac{\lambda}{R} = \frac{1}{2\pi\epsilon_0}\frac{\lambda}{R}$	22-6
On the axis of a charged ring	$E_z = \frac{kQz}{(z^2 + a^2)^{3/2}}$	22-8
On the axis of a charged disk	$E_z = \text{sign}(z)\cdot\frac{\sigma}{2\epsilon_0}\left[1 - \left(1 + \frac{R^2}{z^2}\right)^{-1}\right]$	22-9

TOPIC	RELEVANT EQUATIONS AND REMARKS	
Of a charged infinite plane	$E_z = \text{sign}(z) \cdot \frac{\sigma}{2\epsilon_0}$	22-10
Of a charged thin spherical shell	$E_r = \frac{1}{4\pi\epsilon_0}\frac{Q}{r^2} \quad r > R$	22-17*a*
	$E_r = 0 \quad r < R$	22-17*b*

Answers to Concept Checks

22-1 The $\vec{E}$ in Gauss's law is the electric field due to all charges. However, the flux of the electric field due to all the charges outside the surface equals zero, so the flux of the electric field due to all charges equals the flux of the field due to the charges inside the surface alone.

Answers to Practice Problems

22-1 $E_x = k\lambda\left(\frac{1}{r_2} - \frac{1}{r_1}\right)$. For $x > x_2$, $r_2 < r_1$ so $\frac{1}{r_2} > \frac{1}{r_1}$ which means $E_x > 0$.

22-2 No. Symmetry dictates that E_z is zero at $z = 0$ whereas the equation in step 3 gives a negative value for E_z at $z = 0$. These contradictory results cannot both be valid.

22-3 The SI units for k, λ, and R are $\text{N} \cdot \text{m}^2/\text{C}^2$, C/m, and m, respectively. It follows that $k\lambda/R$ has units of $(\text{N} \cdot \text{m}^2/\text{C}^2)(\text{C/m})(1/\text{m}) = \text{N/C}$.

22-4 $z = a/\sqrt{2}$

22-5 80%

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • Figure 22-37 shows an L-shaped object that has sides which are equal in length. Positive charge is distributed uniformly along the length of the object. What is the direction of the electric field along the dashed 45° line? Explain your answer. SSM

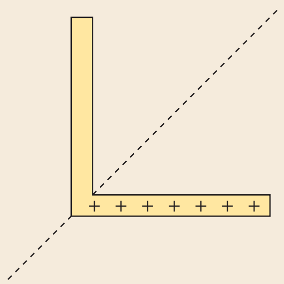

FIGURE 22-37 **Problem 1**

2 • Positive charge is distributed uniformly along the entire length of the x axis, and negative charge is distributed uniformly along the entire length of the y axis. The charge per unit length on the two axes is identical, except for the sign. Determine the direction of the electric field at points on the lines defined by $y = x$ and $y = -x$. Explain your answer.

3 • True or false:

(*a*) The electric field due to a hollow uniformly charged thin spherical shell is zero at all points inside the shell.
(*b*) In electrostatic equilibrium, the electric field everywhere inside the material of a conductor must be zero.
(*c*) If the net charge on a conductor is zero, the charge density must be zero at every point on the surface of the conductor.

4 • If the electric flux through a closed surface is zero, must the electric field be zero everywhere on that surface? If not, give a specific example. From the given information can the net charge inside the surface be determined? If so, what is it?

5 • True or false:

(*a*) Gauss's law holds only for symmetric charge distributions.
(*b*) The result that $E = 0$ everywhere inside the material of a conductor under electrostatic conditions can be derived from Gauss's law.

6 •• A single point charge q is located at the center of both an imaginary cube and an imaginary sphere. How does the electric flux through the surface of the cube compare to that through the surface of the sphere? Explain your answer.

7 •• An electric dipole is completely inside a closed imaginary surface and there are no other charges. True or false:

(*a*) The electric field is zero everywhere on the surface.
(*b*) The electric field is normal to the surface everywhere on the surface.
(*c*) The electric flux through the surface is zero.
(*d*) The electric flux through the surface could be positive or negative.
(*e*) The electric flux through a portion of the surface might not be zero. SSM

8 •• Explain why the electric field strength increases linearly with r, rather than decreases inversely with r^2, between the center and the surface of a uniformly charged solid sphere.

9 •• Suppose that the total charge on the conducting spherical shell in Figure 22-38 is zero. The negative point charge at the center has a magnitude given by Q. What is the direction of the electric field in the following regions? (*a*) $r < R_1$, (*b*) $R_2 > r > R_1$, (*c*) and $r > R_2$. Explain your answer. SSM

10 •• The conducting shell in Figure 22-38 is grounded, and the negative point charge at the center has a magnitude given by Q. Which of the following statements is correct?

(*a*) The charge on the inner surface of the shell is $+Q$ and the charge on the outer surface is $-Q$.
(*b*) The charge on the inner surface of the shell is $+Q$ and the charge on the outer surface is zero.
(*c*) The charge on both surfaces of the shell is $+Q$.
(*d*) The charge on both surfaces of the shell is zero.

11 •• The conducting shell in Figure 22-38 is grounded, and the negative point charge at the center has a magnitude given by Q. What is the direction of the electric field in the following regions? (*a*) $r < R_1$, (*b*) $R_2 > r > R_1$, (*c*) and $r > R_2$. Explain your answers.

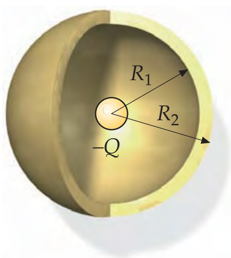

FIGURE 22-38 Problems 9, 10, and 11

ESTIMATION AND APPROXIMATION

12 •• In the chapter, the expression for the electric field due to a uniformly charged disk (on its axis), was derived. At any location on the axis, the field magnitude is given by $|E| = 2\pi k\sigma\left[1 - \left(1 + \frac{R^2}{z^2}\right)^{-1/2}\right]$. At large distances ($|z| \gg R$), it was shown that this equation approaches $E \approx kQ/z^2$. Very near the disk ($|z| \ll R$), the field strength is approximately that of an infinite plane of charge or $|E| \approx 2\pi k\sigma$. Suppose you have a disk of radius 2.5 cm that has a uniform surface charge density of 3.6 μC/m^2. Use both the exact and approximate expression from those given above to find the electric field strength on the axis at distances of (*a*) 0.010 cm, (*b*) 0.040 cm, and (*c*) 5.0 m. Compare the two values in each case and comment on how well the approximations work in their region of validity.

CALCULATING $\vec{E}$ FROM COULOMB'S LAW

13 • A uniform line charge that has a linear charge density λ equal to 3.5 nC/m is on the x axis between $x = 0$ and $x = 5.0$ m. (*a*) What is its total charge? Find the electric field on the x axis at (*b*) $x = 6.0$ m, (*c*) $x = 9.0$ m, and (*d*) $x = 250$ m. (*e*) Estimate the electric field at $x = 250$ m, using the approximation that the charge is a point charge on the x axis at $x = 2.5$ m, and compare your result with the result calculated in Part (*d*). (To do this, you will need to assume that the values given in this problem statement are valid to more than two significant figures.) Is your approximate result greater or smaller than the exact result? Explain your answer. SSM

14 • Two infinite nonconducting sheets of charge are parallel to each other, with sheet A in the $x = -2.0$ m plane and sheet B in the $x = +2.0$ m plane. Find the electric field in the region $x < -2.0$ m, in the region $x > +2.0$ m, and between the sheets for the following situations. (*a*) When each sheet has a uniform surface charge density equal to $+3.0\ \mu$C/m^2 and (*b*) when sheet A has a uniform surface charge density equal to $+3.0\ \mu$C/m^2 and sheet B has a uniform surface charge density equal to $-3.0\ \mu$C/m^2. (c) Sketch the electric field line pattern for each case.

15 • A charge of 2.75 μC is uniformly distributed on a ring of radius 8.5 cm. Find the electric field strength on the axis at distances of (*a*) 1.2 cm, (*b*) 3.6 cm, and (*c*) 4.0 m from the center of the ring. (*d*) Find the field strength at 4.0 m using the approximation that the ring is a point charge at the origin, and compare your results for Parts (*c*) and (*d*). Is your approximate result a good one? Explain your answer.

16 • A nonconducting disk of radius R lies in the $z = 0$ plane with its center at the origin. The disk has a uniform surface charge density σ. Find the value of z for which $E_z = \sigma/(4\epsilon_0)$. Note that at this distance, the magnitude of the electric field strength is half the electric field strength at points on the x axis that are very close to the disk.

17 • A ring that has radius a lies in the $z = 0$ plane with its center at the origin. The ring is uniformly charged and has a total charge Q. Find E_z on the z axis at (*a*) $z = 0.2a$, (*b*) $z = 0.5a$, (*c*) $z = 0.7a$, (*d*) $z = a$, and (*e*) $z = 2a$. (*f*) Use your results to plot E_z versus z for both positive and negative values of z. (Assume that these distances are exact.) SSM

18 • A nonconducting disk of radius a lies in the $z = 0$ plane with its center at the origin. The disk is uniformly charged and has a total charge Q. Find E_z on the z axis at (*a*) $z = 0.2a$, (*b*) $z = 0.5a$, (*c*) $z = 0.7a$, (*d*) $z = a$, and (*e*) $z = 2a$. (*f*) Use your results to plot E_z versus z for both positive and negative values of z. (Assume that these distances are exact.)

19 •• **SPREADSHEET** (*a*) Using a **spreadsheet** program or graphing calculator, make a graph of the electric field strength on the axis of a disk that has a radius $a = 30.0$ cm and a surface charge density $\sigma = 0.500$ nC/m^2. (*b*) Compare your results to the results based on the approximation $E = 2\pi k\sigma$ (the formula for the electric field strength of a uniformly charged infinite sheet). At what distance does the solution based on approximation differ from the exact solution by 10.0 percent?

20 •• (*a*) Show that the electric field strength E on the axis of a ring charge of radius a has maximum values at $z = \pm a/\sqrt{2}$. (*b*) Sketch the field strength E versus z for both positive and negative values of z. (*c*) Determine the maximum value of E.

21 •• A line charge that has a uniform linear charge density λ lies along the x axis from $x = x_1$ to $x = x_2$ where $x_1 < x_2$. Show that the x component of the electric field at a point on the y axis is given by $E_x = \frac{k\lambda}{y}(\cos\theta_2 - \cos\theta_1)$ where $\theta_1 = \tan^{-1}(x_1/y)$, $\theta_2 = \tan^{-1}(x_2/y)$, and $y \neq 0$.

22 •• A ring of radius a has a charge distribution on it that varies as $\lambda(\theta) = \lambda_0 \sin\theta$, as shown in Figure 22-39. (*a*) What is the direction of the electric field at the center of the ring? (*b*) What is the magnitude of the field at the center of the ring?

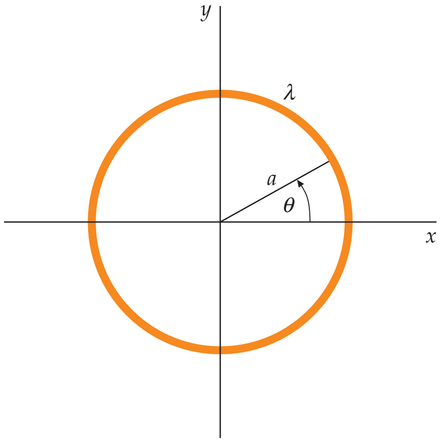

FIGURE 22-39 Problem 22

23 •• A line of charge that has uniform linear charge density λ lies on the x axis from $x = 0$ to $x = a$. Show that the y component of the electric field at a point on the y axis is given by $E_y = \frac{k\lambda}{y}\frac{a}{\sqrt{y^2 + a^2}}$, $y \neq 0$.

24 ••• Calculate the electric field a distance z from a uniformly charged infinite flat nonconducting sheet by modeling the sheet as a continuum of infinite straight lines of charge.

25 •• Calculate the electric field a distance z from a uniformly charged infinite flat nonconducting sheet by modeling the sheet as a continuum of infinite circular rings of charge. SSM

26 ••• A thin hemispherical shell of radius R has a uniform surface charge σ. Find the electric field at the center of the base of the hemispherical shell.

GAUSS'S LAW

27 • A square that has 10-cm-long edges is centered on the x axis in a region where there exists a uniform electric field given by $\vec{E} = (2.00\ \text{kN/C})\hat{i}$. (*a*) What is the electric flux of this electric field through the surface of a square if the normal to the surface is in the $+x$ direction? (*b*) What is the electric flux through the same square surface if the normal to the surface makes a 60° angle with the y axis and an angle of 90° with the z axis?

28 • A single point charge ($q = +2.00\ \mu\text{C}$) is fixed at the origin. An imaginary spherical surface of radius 3.00 m is centered on the x axis at $x = 5.00$ m. (*a*) Sketch electric field lines for this charge (in two dimensions) assuming twelve equally spaced field lines in the xy plane leave the charge location, with one of the lines in the $+x$ direction. Do any lines enter the spherical surface? If so, how many? (*b*) Do any lines leave the spherical surface? If so, how many? (*c*) Counting the lines that enter as negative and the ones that leave as positive, what is the net number of field lines that penetrate the spherical surface? (*d*) What is the net electric flux through this spherical surface?

29 • An electric field is given by $\vec{E} = \text{sign}(x) \cdot (300\ \text{N/C})\hat{i}$, where sign (x) equals -1 if $x < 0$, 0 if $x = 0$, and $+1$ if $x > 0$. A cylinder of length 20 cm and radius 4.0 cm has its center at the origin and its axis along the x axis such that one end is at $x = +10$ cm and the other is at $x = -10$ cm. (*a*) What is the electric flux through each end? (*b*) What is the electric flux through the curved surface of the cylinder? (*c*) What is the electric flux through the entire closed surface? (*d*) What is the net charge inside the cylinder? SSM

30 • Careful measurement of the electric field at the surface of a black box indicates that the net outward electric flux through the surface of the box is $6.0\ \text{kN}\cdot\text{m}^2/\text{C}$. (*a*) What is the net charge inside the box? (*b*) If the net outward electric flux through the surface of the box were zero, could you conclude that there were no charges inside the box? Explain your answer.

31 • A point charge ($q = +2.00\ \mu\text{C}$) is at the center of an imaginary sphere that has a radius equal to 0.500 m. (*a*) Find the surface area of the sphere. (*b*) Find the magnitude of the electric field at all points on the surface of the sphere. (*c*) What is the flux of the electric field through the surface of the sphere? (*d*) Would your answer to Part (*c*) change if the point charge were moved so that it was inside the sphere but not at its center? (*e*) What is the flux of the electric field through the surface of an imaginary cube that has 1.00-m-long edges and encloses the sphere?

32 • What is the electric flux through one side of a cube that has a single point charge of $-3.00\ \mu\text{C}$ placed at its center? *Hint: You do not need to integrate any equations to get the answer.*

33 • A single point charge is placed at the center of an imaginary cube that has 20-cm-long edges. The electric flux out of one of the cube's sides is $-1.50\ \text{kN}\cdot\text{m}^2/\text{C}$. How much charge is at the center? SSM

34 •• Because the formulas for Newton's law of gravity and for Coulomb's law have the same inverse-square dependence on distance, a formula analogous to the formula for Gauss's law can be found for gravity. The gravitational field $\vec{g}$ at a location is the force per unit mass on a test mass m_0 placed at that location. (Then, for a point mass m at the origin, the gravitational field g at some position $\hat{r}$ is $\vec{g} = -(Gm/r^2)\hat{r}$.) Compute the flux of the gravitational field through a spherical surface of radius R centered at the origin, and verify that the gravitational analog of Gauss's law is $\phi_{\text{net}} = -4\pi G m_{\text{inside}}$.

35 •• An imaginary right circular cone (Figure 22-40) that has a base angle θ and a base radius R is in charge free region that has a uniform electric field $\vec{E}$ (field lines are vertical and parallel to the cone's axis). What is the ratio of the number of field lines per unit area penetrating the base to the number of field lines per unit area penetrating the conical surface of the cone? Use Gauss's law in your answer. (The field lines in the figure are only a representative sample.)

36 •• In the atmosphere and at an altitude of 250 m, you measure the electric field to be 150 N/C directed downward, and you measure the electric field to be 170 N/C directed downward at an altitude of 400 m. Calculate the volume charge density of the atmosphere in the region between altitudes of 250 m and 400 m, assuming it to be uniform. (You may neglect the curvature of Earth. Why?)

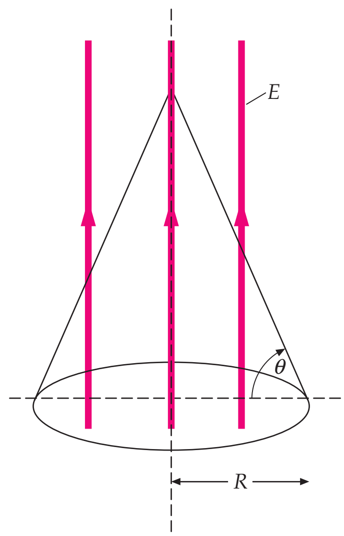

FIGURE 22-40 Problem 35

GAUSS'S LAW APPLICATIONS IN SPHERICAL SYMMETRY SITUATIONS

37 • A thin nonconducting spherical shell of radius R_1 has a total charge q_1 that is uniformly distributed on its surface. A second, larger thin nonconducting spherical shell of radius R_2 that is coaxial with the first has a charge q_2 that is uniformly distributed on its surface. (*a*) Use Gauss's law to obtain expressions for the electric field in each of the three regions: $r < R_1$, $R_1 < r < R_2$, and $r > R_2$. (*b*) What should the ratio of the charges q_1/q_2 and the relative signs for q_1 and q_2 be for the electric field to be zero throughout the region $r > R_2$? (*c*) Sketch the electric field lines for the situation in Part (*b*) when q_1 is positive.

38 • A nonconducting thin spherical shell of radius 6.00 cm has a uniform surface charge density of 9.00 nC/m^2. (*a*) What is the total charge on the shell? Find the electric field at the following distances from the sphere's center: (*b*) 2.00 cm, (*c*) 5.90 cm, (*d*) 6.10 cm, and (*e*) 10.0 cm.

39 •• A nonconducting sphere of radius 6.00 cm has a uniform volume charge density of 450 nC/m^3. (*a*) What is the total charge on the sphere? Find the electric field at the following distances from the sphere's center: (*b*) 2.00 cm, (*c*) 5.90 cm, (*d*) 6.10 cm, and (*e*) 10.0 cm. SSM

40 •• Consider the solid conducting sphere and the concentric conducting spherical shell in Figure 22-41. The spherical shell has a charge $-7Q$. The solid sphere has a charge $+2Q$. (*a*) How much charge is on the outer surface and how much charge is on the inner surface of the spherical shell? (*b*) Suppose a metal wire is now connected between the solid sphere and the shell. After electrostatic equilibrium is reestablished, how much charge is on the solid sphere and on each surface of the spherical shell? Does the electric field at the surface of the solid sphere change when the wire is connected? If so, in what way? (*c*) Suppose we return to the conditions in Part (*a*), with $+2Q$ on the solid sphere and $-7Q$ on the spherical shell. We next connect the solid sphere to ground with a metal wire, and then disconnect it. Then how much total charge is on the solid sphere and on each surface of the spherical shell?

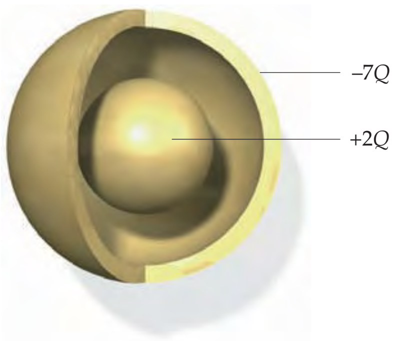

FIGURE 22-41
Problem 40

41 •• A nonconducting solid sphere of radius 10.0 cm has a uniform volume charge density. The magnitude of the electric field at 20.0 cm from the sphere's center is 1.88×10^3 N/C. (*a*) What is the sphere's volume charge density? (*b*) Find the magnitude of the electric field at a distance of 5.00 cm from the sphere's center.

42 •• A nonconducting solid sphere of radius R has a volume charge density that is proportional to the distance from the center. That is, $\rho = Ar$ for $r \leq R$, where A is a constant. (*a*) Find the total charge on the sphere. (*b*) Find the expressions for the electric field inside the sphere ($r < R$) and outside the sphere ($r > R$). (*c*) Sketch the magnitude of the electric field as a function of the distance r from the sphere's center.

43 •• A sphere of radius R has volume charge density $\rho = B/r$ for $r < R$, where B is a constant and $\rho = 0$ for $r > R$. (*a*) Find the total charge on the sphere. (*b*) Find the expressions for the electric field inside and outside the charge distribution. (*c*) Sketch the magnitude of the electric field as a function of the distance r from the sphere's center. SSM

44 •• A sphere of radius R has volume charge density $\rho = C/r^2$ for $r < R$, where C is a constant and $\rho = 0$ for $r > R$. (*a*) Find the total charge on the sphere. (*b*) Find the expressions for the electric field inside and outside the charge distribution. (*c*) Sketch the magnitude of the electric field as a function of the distance r from the sphere's center.

45 ••• A nonconducting spherical shell of inner radius R_1 and outer radius R_2 has a uniform volume charge density ρ. (*a*) Find the total charge on the shell. (*b*) Find expressions for the electric field everywhere.

GAUSS'S LAW APPLICATIONS IN CYLINDRICAL SYMMETRY SITUATIONS

46 • **Context-Rich, Engineering Application** For your senior project, you are designing a Geiger tube for detecting radiation in the nuclear physics laboratory. This instrument will consist of a long metal cylindrical tube that has a long straight metal wire running down its central axis. The diameter of the wire will be 0.500 mm and the inside diameter of the tube will be 4.00 cm. The tube is to be filled with a dilute gas in which an electrical discharge (breakdown of the gas) occurs when the electric field reaches 5.50×10^6 N/C. Determine the maximum linear charge density on the wire if breakdown of the gas is not to happen. Assume that the tube and the wire are infinitely long.

47 ••• In Problem 46, suppose ionizing radiation produces an ion and an electron at a distance of 1.50 cm from the long axis of the central wire of the Geiger tube. Suppose that the central wire is positively charged and has a linear charge density equal to 76.5 pC/m. (*a*) In this case, what will be the electron's speed as it impacts the wire? (*b*) How will the electron's speed compare to the ion's final speed when it impacts the outside cylinder? Explain your answer.

48 •• Show that the electric field due to an infinitely long, uniformly charged thin cylindrical shell of radius a having a surface charge density σ is given by the following expressions: $E = 0$ for $0 \leq R < a$ and $E_R = \sigma a/(\epsilon_0 R)$ for $R > a$.

49 • A thin cylindrical shell of length 200 m and radius 6.00 cm has a uniform surface charge density of 9.00 nC/m^2. (*a*) What is the total charge on the shell? Find the electric field at the following radial distances from the long axis of the cylinder: (*b*) 2.00 cm, (*c*) 5.90 cm, (*d*) 6.10 cm, and (*e*) 10.0 cm. (Use the results of Problem 48.)

50 •• An infinitely long nonconducting solid cylinder of radius a has a uniform volume charge density of ρ_0. Show that the electric field is given by the following expressions: $E_R = \rho_0 R/(2\epsilon_0)$ for $0 \leq R < a$ and $E_R = \rho_0 a^2/(2\epsilon_0 R)$ for $R > a$, where R is the distance from the long axis of the cylinder.

51 •• A solid cylinder of length 200 m and radius 6.00 cm has a uniform volume charge density of 300 nC/m^3. (*a*) What is the total charge of the cylinder? Use the formulas given in Problem 50 to calculate the electric field at a point equidistant from the ends at the following radial distances from the cylindrical axis: (*b*) 2.00 cm, (*c*) 5.90 cm, (*d*) 6.10 cm, and (*e*) 10.0 cm. SSM

52 •• Consider two infinitely long, coaxial thin cylindrical shells. The inner shell has a radius a_1 and has a uniform surface charge density of σ_1, and the outer shell has a radius a_2 and has a uniform surface charge density of σ_2. (*a*) Use Gauss's law to find expressions for the electric field in the three regions: $0 \le R < a_1$, $a_1 < R < a_2$, and $R > a_2$, where R is the distance from the axis. (*b*) What is the ratio of the surface charge densities σ_2/σ_1 and their relative signs if the electric field is to be zero everywhere outside the largest cylinder? (*c*) For the case in Part (*b*), what would be the electric field between the shells? (*d*) Sketch the electric field lines for the situation in Part (*b*) if σ_1 is positive.

53 •• Figure 22-42 shows a portion of an infinitely long, concentric cable in cross section. The inner conductor has a linear charge density of 6.00 nC/m and the outer conductor has no net charge. (*a*) Find the electric field for all values of R, where R is the perpendicular distance from the common axis of the cylindrical system. (*b*) What are the surface charge densities on the inside and the outside surfaces of the outer conductor?

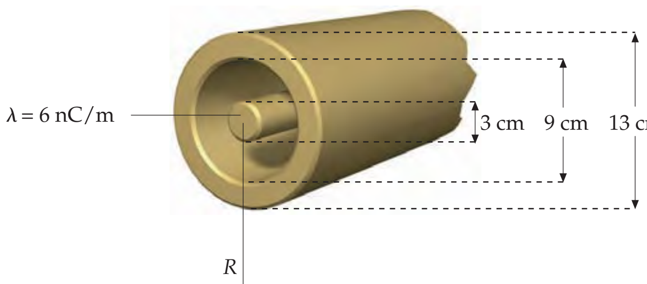

FIGURE 22-42
Problems 53 and 57

54 •• An infinitely long nonconducting solid cylinder of radius a has a nonuniform volume charge density. This density varies linearly with R, the perpendicular distance from its axis, according to $\rho(R) = \beta R$, where β is a constant. (*a*) Show that the linear charge density of the cylinder is given by $\lambda = 2\pi\beta a^3/3$. (*b*) Find expressions for the electric field for $R < a$ and $R > a$.

55 •• An infinitely long nonconducting solid cylinder of radius a has a nonuniform volume charge density. This density varies with R, the perpendicular distance from its axis, according to $\rho(R) = bR^2$, where b is a constant. (*a*) Show that the linear charge density of the cylinder is given by $\lambda = \pi b a^4/2$. (*b*) Find expressions for the electric field for $R < a$ and $R > a$. SSM

56 ••• An infinitely long, nonconducting cylindrical shell of inner radius a_1 and outer radius a_2 has a uniform volume charge density ρ. Find expressions for the electric field everywhere.

57 ••• The inner cylinder of Figure 22-42 is made of nonconducting material and has a volume charge distribution given by $\rho(R) = C/R$, where $C = 200\ \text{nC/m}^2$. The outer cylinder is metallic, and both cylinders are infinitely long. (*a*) Find the charge per unit length (that is, the linear charge density) on the inner cylinder. (*b*) Calculate the electric field for all values of R. SSM

ELECTRIC CHARGE AND FIELD AT CONDUCTOR SURFACES

58 • An uncharged penny is in a region that has a uniform electric field of magnitude 1.60 kN/C directed perpendicular to its faces. (*a*) Find the charge density on each face of the penny, assuming the faces are planes. (*b*) If the radius of the penny is 1.00 cm, find the total charge on one face.

59 • A thin metal slab has a net charge of zero and has square faces that have 12-cm-long sides. It is in a region that has a uniform electric field that is perpendicular to its faces. The total charge induced on one of the faces is 1.2 nC. What is the magnitude of the electric field?

60 • A charge of −6.00 nC is uniformly distributed on a thin square sheet of nonconducting material of edge length 20.0 cm. (*a*) What is the surface charge density of the sheet? (*b*) What are the magnitude and direction of the electric field next to the sheet and proximate to the center of the sheet?

61 • A conducting spherical shell that has zero net charge has an inner radius R_1 and an outer radius R_2. A positive point charge q is placed at the center of the shell. (*a*) Use Gauss's law and the properties of conductors in electrostatic equilibrium to find the electric field in the three regions: $0 \le r < R_1$, $R_1 < r < R_2$, and $r > R_2$, where r is the distance from the center. (*b*) Draw the electric field lines in all three regions. (*c*) Find the charge density on the inner surface ($r = R_1$) and on the outer surface ($r = R_2$) of the shell.

62 •• The electric field just above the surface of Earth has been measured to typically be 150 N/C pointing downward. (*a*) What is the sign of the net charge on Earth's surface under typical conditions? (*b*) What is the total charge on Earth's surface implied by this measurement?

63 •• A positive point charge of 2.5 μC is at the center of a conducting spherical shell that has a net charge of zero, an inner radius equal to 60 cm, and an outer radius equal to 90 cm. (*a*) Find the charge densities on the inner and outer surfaces of the shell and the total charge on each surface. (*b*) Find the electric field everywhere. (*c*) Repeat Part (*a*) and Part (*b*) with a net charge of +3.5 μC placed on the shell. SSM

64 •• If the magnitude of an electric field in air is as great as 3.0×10^6 N/C, the air becomes ionized and begins to conduct electricity. This phenomenon is called *dielectric breakdown.* A charge of 18 μC is to be placed on a conducting sphere. What is the minimum radius of a sphere that can hold this charge without breakdown?

65 •• A thin square conducting sheet that has 5.00-m-long edges has a net charge of 80.0 μC. The square is in the $x = 0$ plane and is centered at the origin. (Assume the charge on each surface is uniformly distributed.) (*a*) Find the charge density on each side of the sheet and find the electric field on the x axis in the region $|x| \ll 5.00$ m. (*b*) A thin but infinite nonconducting sheet that has a uniform charge density of 2.00 $\mu\text{C/m}^2$ is now placed in the $x = -2.50$ m plane. Find the electric field on the x axis on each side of the square sheet in the region $|x| \ll 2.50$ m. Find the charge density on each surface of the square sheet. SSM

GENERAL PROBLEMS

66 •• Consider the concentric metal sphere and spherical shells that are shown in Figure 22-43. The innermost is a solid sphere that has a radius R_1. A spherical shell surrounds the sphere and has an

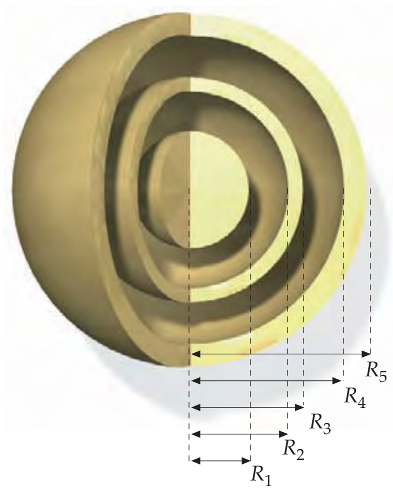

FIGURE 22-43
Problem 66

inner radius R_2 and an outer radius R_3. The sphere and the shell are both surrounded by a second spherical shell that has an inner radius R_4 and an outer radius R_5. None of the three objects initially have a net charge. Then, a negative charge $-Q_0$ is placed on the inner sphere and a positive charge $+Q_0$ is placed on the outermost shell. (*a*) After the charges have reached equilibrium, what will be the direction of the electric field between the inner sphere and the middle shell? (*b*) What will be the charge on the inner surface of the middle shell? (*c*) What will be the charge on the outer surface of the middle shell? (*d*) What will be the charge on the inner surface of the outermost shell? (*e*) What will be the charge on the outer surface of the outermost shell? (*f*) Plot E as a function of r for all values of r.

67 •• A large, flat, nonconducting, nonuniformly charged surface lies in the $x = 0$ plane. At the origin, the surface charge density is $+3.10\ \mu\text{C/m}^2$. A small distance away from the surface on the positive x axis, the x component of the electric field is 4.65×10^5 N/C. What is E_x a small distance away from the surface on the negative x axis? SSM

68 •• An infinitely long line charge that has a uniform linear charge density equal to $-1.50\ \mu\text{C/m}$ lies parallel to the y axis at $x = -2.00$ m. A positive point charge that has a magnitude equal to 1.30 μC is located at $x = 1.00$ m, $y = 2.00$ m. Find the electric field at $x = 2.00$ m, $y = 1.50$ m.

69 •• A thin, nonconducting, uniformly charged spherical shell of radius R (Figure 22-44*a*) has a total positive charge of Q. A small circular plug is removed from the surface. (*a*) What are the magnitude and direction of the electric field at the center of the hole? (*b*) The plug is now put back in the hole (Figure 22-44*b*). Using the result of Part (*a*), find the electric force acting on the plug. (*c*) Using the magnitude of the force, calculate the "electrostatic pressure" (force/unit area) that tends to expand the sphere. SSM

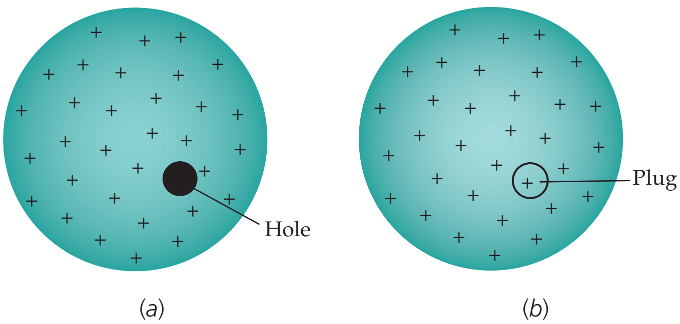

FIGURE 22-44 Problem 69

70 •• An infinite thin sheet in the $y = 0$ plane has a uniform surface charge density $\sigma_1 = +65\ \text{nC/m}^2$. A second infinite thin sheet has a uniform charge density $\sigma_2 = +45\ \text{nC/m}^2$ and intersects the $y = 0$ plane at the z axis and makes an angle of 30° with the xz plane, as shown in Figure 22-45. Find the electric field at (*a*) $x = 6.0$ m, $y = 2.0$ m and (*b*) $x = 6.0$ m, $y = 5.0$ m.

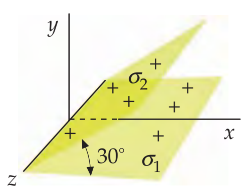

FIGURE 22-45 Problem 70

71 ••• Two identical square parallel metal plates each have an area of 500 cm². They are separated by 1.50 cm. They are both initially uncharged. Now a charge of +1.50 nC is transferred from the plate on the left to the plate on the right and the charges then establish electrostatic equilibrium. (Neglect edge effects.) (*a*) What is the electric field between the plates at a distance of 0.25 cm from the plate on the right? (*b*) What is the electric field between the plates a distance of 1.00 cm from the plate on the left? (*c*) What is the electric field just to the left of the plate on the left? (*d*) What is the electric field just to the right of the plate on the right? SSM

72 •• Two infinite nonconducting uniformly charged planes lie parallel to each other and to the yz plane. One is at $x = -2.00$ m and has a surface charge density of $-3.50\ \mu\text{C/m}^2$. The other is at $x = 2.00$ m and has a surface charge density of $6.00\ \mu\text{C/m}^2$. Find the electric field in the region: (*a*) $x < -2.00$ m (*b*) $-2.00\ \text{m} < x < 2.00$ m, and (*c*) $x > 2.00$ m.

73 ••• A quantum-mechanical treatment of the hydrogen atom shows that the electron in the atom can be treated as a smeared-out distribution of negative charge of the form $\rho(r) = -\rho_0 e^{-2r/a}$. Here r represents the distance from the center of the nucleus and a represents the *first Bohr radius*, which has a numerical value of 0.0529 nm. Recall that the nucleus of a hydrogen atom consists of just one proton and treat this proton as a positive point charge. (*a*) Calculate ρ_0, using the fact that the atom is neutral. (*b*) Calculate the electric field at any distance r from the nucleus. SSM

74 •• A uniformly charged ring has a radius a, lies in a horizontal plane, and has a negative charge given by $-Q$. A small particle of mass m has a positive charge given by q. The small particle is located on the axis of the ring. (*a*) What is the minimum value of q/m such that the particle will be in equilibrium under the action of gravity and the electrostatic force? (*b*) If q/m is twice the value calculated in Part (*a*) , where will the particle be when it is in equilibrium? Express your answer in terms of a.

75 •• A long, thin, nonconducting plastic rod is bent into a circular loop that has a radius a. Between the ends of the rod a short gap of length ℓ, where $\ell \ll a$, remains. A positive charge of magnitude Q is evenly distributed on the loop. (*a*) What is the direction of the electric field at the center of the loop? Explain your answer. (*b*) What is the magnitude of the electric field at the center of the loop?

76 •• A nonconducting solid sphere that is 1.20 m in diameter and has its center on the x axis at $x = 4.00$ m has a uniform volume charge of density of $+5.00\ \mu\text{C/m}^3$. Concentric with the sphere is a thin nonconducting spherical shell that has a diameter of 2.40 m and a uniform surface charge density of $-1.50\ \mu\text{C/m}^2$. Calculate the magnitude and direction of the electric field at (*a*) $x = 4.50$ m, $y = 0$, (*b*) $x = 4.00$ m, $y = 1.10$ m, and (*c*) $x = 2.00$ m, $y = 3.00$ m.

77 •• An infinite nonconducting plane sheet of charge that has a surface charge density $+3.00\ \mu\text{C/m}^2$ lies in the $y = -0.600$ m plane. A second infinite nonconducting plane sheet of charge that has a surface charge density of $-2.00\ \mu\text{C/m}^2$ lies in the $x = 1.00$ m plane. Lastly, a nonconducting thin spherical shell that has a radius of 1.00 m and its center in the $z = 0$ plane at the intersection of the two charged planes has a surface charge density of $-3.00\ \mu\text{C/m}^2$. Find the magnitude and direction of the electric field on the x axis at (*a*) $x = 0.400$ m and (*b*) $x = 2.50$ m.

78 •• An infinite nonconducting plane sheet lies in the $x = 2.00$ m plane and has a uniform surface charge density of $+2.00\ \mu\text{C/m}^2$. An infinite nonconducting line charge of uniform linear charge density 4.00 μC/m passes through the origin at an angle of 45.0° with the x axis in the xy plane. A solid nonconducting sphere of volume charge density $-6.00\ \mu\text{C/m}^3$ and radius 0.800 m is centered on the x axis at $x = 1.00$ m. Calculate the magnitude and direction of the electric field in the $z = 0$ plane at $x = 1.50$ m, $y = 0.50$ m.

79 •• A uniformly charged, infinitely long line of negative charge has a linear charge density of $-\lambda$ and is located on the z axis. A small positively charged particle that has a mass m and a charge q is in a circular orbit of radius R in the xy plane centered on the line of charge. (*a*) Derive an expression for the speed of the particle. (*b*) Obtain an expression for the period of the particle's orbit. SSM

80 •• A stationary ring of radius a lies in the yz plane and has a uniform positive charge Q. A small particle that has mass m and a negative charge $-q$ is located at the center of the ring. (*a*) Show that if $x \ll a$, the electric field along the axis of the ring is proportional to x. (*b*) Find the force on the particle as a function of x. (*c*) Show that if the particle is given a small displacement in the $+x$ direction, it will perform simple harmonic motion. (*d*) What is the frequency of that motion?

81 •• The charges Q and q of Problem 80 are $+5.00\ \mu$C and $-5.00\ \mu$C, respectively, and the radius of the ring is 8.00 cm. When the particle is given a small displacement in the x direction, it oscillates about its equilibrium position at a frequency of 3.34 Hz. (*a*) What is the particle's mass? (*b*) What is the frequency if the radius of the ring is doubled to 16.0 cm and all other parameters remain unchanged? SSM

82 •• If the radius of the ring in Problem 80 is doubled while keeping the linear charge density on the ring the same, does the frequency of oscillation of the particle change? If so, by what factor does it change?

83 ••• A uniformly charged nonconducting solid sphere of radius R has its center at the origin and has a volume charge density of ρ. (*a*) Show that at a point within the sphere a distance r from the center $\vec{E} = \frac{\rho}{3\epsilon_0} r\hat{\boldsymbol{r}}$. (*b*) Material is removed from the sphere leaving a spherical cavity that has a radius $b = R/2$ and its center at $x = b$ on the x axis (Figure 22-46). Calculate the electric field at points 1 and 2 shown in Figure 22-46. *Hint: Model the sphere-with-cavity as two uniform spheres of equal positive and negative charge densities.*

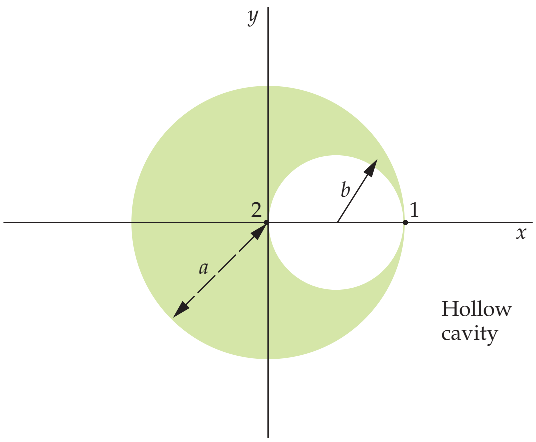

FIGURE 22-46 Problems 83 and 85

84 ••• Show that the electric field throughout the cavity of Problem 83*b* is uniform and is given by $\vec{E} = \frac{\rho}{3\epsilon_0} b\hat{\boldsymbol{i}}$.

85 ••• The cavity in Problem 83*b* is now filled with a uniformly charged nonconducting material with a total charge of Q. Calculate the new values of the electric field at points 1 and 2 shown in Figure 22-46.

86 ••• A *small* Gaussian surface in the shape of a cube has faces parallel to the xy, xz, and yz planes (Figure 22-47) and is in a region in which the electric field is parallel to the x axis. (*a*) Using the differential approximation, show that the net electric flux of the electric field out of the Gaussian surface is given by $\phi_{\text{net}} \approx \frac{\partial E_x}{\partial x}\Delta V$, where ΔV is the volume enclosed by the Gaussian surface. (*b*) Using Gauss's law and the results of Part (*a*) show that $\frac{\partial E_x}{\partial x} = \frac{\rho}{\epsilon_0}$, where ρ is the volume charge density inside the cube. (This equation is the one-dimensional version of the point form of Gauss's law.)

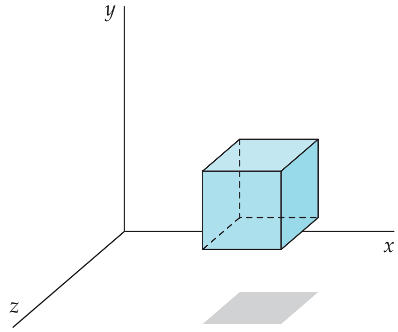

FIGURE 22-47 Problem 86

87 ••• Consider a simple but surprisingly accurate model for the hydrogen molecule: two positive point charges, each having charge $+e$, are placed inside a uniformly charged sphere of radius R, which has a charge equal to $-2e$. The two point charges are placed symmetrically, equidistant from the center of the sphere (Figure 22-48). Find the distance from the center, a, where the net force on either point charge is zero. SSM

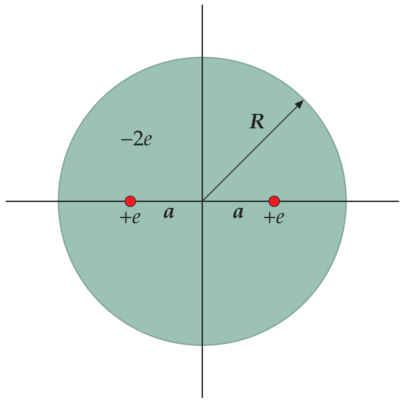

FIGURE 22-48 Problem 87

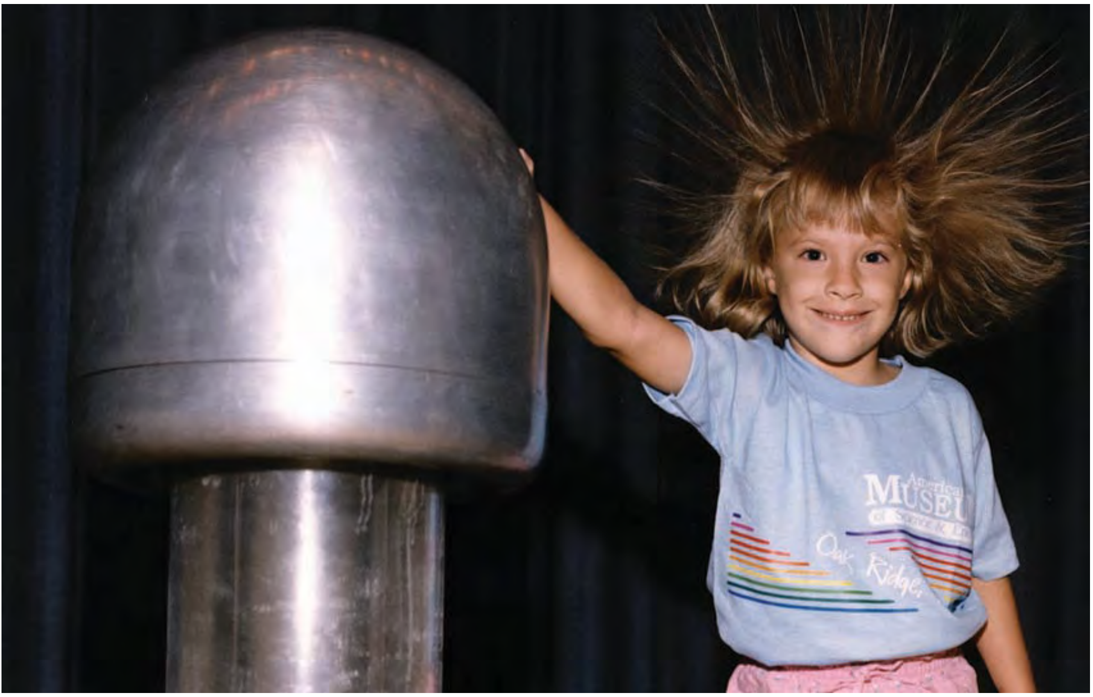
88 ••• An electric dipole that has a dipole moment of $\vec{p}$ is located at a perpendicular distance R from an infinitely long line charge that has a uniform linear charge density λ. Assume that the dipole moment is in the same direction as the field of the line of charge. Determine an expression for the electric force on the dipole.



CHAPTER 23

THIS GIRL HAS BEEN INCREASED TO A HIGH ELECTRIC POTENTIAL THROUGH CONTACT WITH THE DOME OF A VAN DE GRAAFF GENERATOR. SHE IS STANDING ON A PLATFORM THAT ELECTRICALLY INSULATES HER FROM THE FLOOR, SO SHE ACCUMULATES CHARGE FROM THE VAN DE GRAAFF. HER HAIR STANDS UP BECAUSE THE CHARGES ON HER HAIR STRANDS HAVE THE SAME SIGN, AND LIKE CHARGES REPEL EACH OTHER. *(Courtesy of the U.S. Department of Energy.)*

Electric Potential

? Did you know that the maximum potential that the dome of a Van de Graaff generator can be increased to is determined by the radius of the dome? (See Example 23-14.)

Gravitational potential energy, introduced in Chapter 7, is a powerful conceptual and computational aid. In this chapter, we introduce electrical potential energy, and like gravitational potential energy, we will find electrical potential energy to be a powerful conceptual and computational aid. In addition, we continue to develop the concept of the electric field. Electric fields are discussed in Chapters 21 and 22, and we continue this discussion in this chapter by introducing the electric potential—a scalar field that is directly related to the electric field. Because it is a scalar field, it is easier to use during calculations than the electric field (a vector) in many circumstances. Also, the potential is usually much easier to measure—using a voltmeter—than is the electric field. Both electric potential energy and the electrical potential field will be essential tools in the analysis of capacitance, resistance, and electric circuits—topics that are developed in Chapters 24 and 25.

In this chapter, we will establish the relationship between the electric field and electric potential and calculate the electric potential of various continuous charge distributions. We will also calculate the electrical potential energy of a system of point charges and a system of charged conductors.

23-1 POTENTIAL DIFFERENCE

The electrostatic force exerted by a point charge on another point charge is directed along the line joining the charges and varies inversely with the square of their separation distance. This same dependence can be seen when analyzing the gravitational force between two masses. Like the gravitational force, the electric force is conservative, so there is a potential energy function U associated with it. If the point of application of a conservative force $\vec{F}$ undergoes a displacement $d\vec{\ell}$, the change in the potential energy function dU associated with this displacement is given by

$$dU = -\vec{F} \cdot d\vec{\ell}$$

If the conservative force is exerted by electrostatic field $\vec{E}$ on point charge q, then the force is given by

$$\vec{F} = q\vec{E}$$

and if the point charge q undergoes a displacement $d\vec{\ell}$, the corresponding change in the electrostatic potential energy is given by

$$dU = -q\vec{E} \cdot d\vec{\ell} \qquad 23\text{-}1$$

In Section 21-4, we revealed that the electrostatic force $\vec{F}$ on a test charge q_0 is proportional to q_0, and this relationship led to defining a quantity (the force per unit charge at the location of the test charge) called the electric field $\vec{E}$. There is an analogous situation here. The potential energy change associated with the displacement of a test charge q_0 that undergoes a displacement $d\vec{\ell}$ is given by $dU = -q_0\vec{E} \cdot d\vec{\ell}$. Thus, the potential energy change is proportional to the test charge. This relation suggests that we define a quantity—the potential energy change per unit charge—called the **potential difference** dV:

$$dV = \frac{dU}{q_0} = -\vec{E} \cdot d\vec{\ell} \qquad 23\text{-}2a$$

DEFINITION—POTENTIAL DIFFERENCE

For a finite displacement from point a to point b, the change in potential is

$$\Delta V = V_b - V_a = \frac{\Delta U}{q_0} = -\int_a^b \vec{E} \cdot d\vec{\ell} \qquad 23\text{-}2b$$

DEFINITION—FINITE POTENTIAL DIFFERENCE

The potential difference $V_b - V_a$ is the negative of the work per unit charge done by the electric field on a test charge when the test charge moves from point a to point b (along *any* path). During this calculation, the positions of any and all other charges remain fixed. (Recall that a test charge is a point charge whose magnitude is so small that it exerts only negligible forces on any and all other charges. For convenience, test charges are invariably considered to be positive charges.)

The function V is called the **electric potential;** it is often referred to as the **potential.** Like the electric field, the potential V is a function of position. Unlike the electric field, V is a scalar function, whereas $\vec{E}$ is a vector function. As with potential energy U, only *differences* in the potential V are physically significant. We are free to choose the potential to be zero at any convenient point, just as we are when dealing with potential energy. For convenience, the electric potential and the potential energy of a test charge are chosen to be zero at the same reference point. Under this restriction they are related by

$$U = q_0V \qquad 23\text{-}3$$

RELATION BETWEEN POTENTIAL ENERGY AND POTENTIAL

CONTINUITY OF *V*

In Chapter 22, we saw that the electric field is discontinuous by σ/ϵ_0 at points where there is a surface charge density σ. The potential function, on the other hand, is continuous everywhere, except at points where the electric field is infinite (points occupied by a point charge or a line charge). We can see this result from the definition of potential. Consider a region occupied by an electric field $\vec{E}$. The difference in potential between two nearby points separated by displacement $d\vec{\ell}$ is related to the electric field by $dV = -\vec{E} \cdot d\vec{\ell}$ (Equation 23-2*a*). The dot product can be expressed as $E_{\parallel}\, d\ell$, where $E_{\parallel}$ is the component of $\vec{E}$ in the direction of $d\vec{\ell}$ and $d\ell$ is the magnitude of $d\vec{\ell}$. Substituting into Equation 23-2*a* gives $dV = -E_{\parallel}\, d\ell$. If $\vec{E}$ is finite at each of the two points and along the line segment of infinitesimal length $d\ell$ joining them, then dV is infinitesimal. Thus, the potential function V is continuous at any point not occupied by a point charge or a line charge.

UNITS

Because electric potential is the potential energy per unit charge, the SI unit for potential and potential difference is the joule per coulomb, called the **volt** (V):

$$1\ \text{V} = 1\ \text{J/C} \qquad 23\text{-}4$$

The potential difference between two points (measured in volts) is commonly referred to as the **voltage** between the two points. In a 12-V car battery, the positive terminal has a potential 12 V higher than the negative terminal. If we attach an external circuit to the battery and one coulomb of charge is transferred from the positive terminal through the circuit to the negative terminal, the potential energy of the charge decreases by $Q\,\Delta V = (1\ \text{C})(12\ \text{V}) = 12\ \text{J}$.

We can see from Equation 23-2 that the dimensions of potential are also those of the product of electric field and distance. Thus, the unit of the electric field is equal to one volt per meter:

$$1\ \text{N/C} = 1\ \text{V/m} \qquad 23\text{-}5$$

so we may think of the magnitude of the electric field E as either a force per unit charge or as a rate of change of potential (V) with respect to distance in a given direction. In atomic and nuclear physics, we often have particles that have charges of magnitude e, such as electrons and protons, moving through potential differences of several thousands or even millions of volts. Because energy has dimensions of electric charge multiplied by electric potential, a unit of energy is defined as the product of the fundamental charge unit e and a volt. This particularly useful unit is called an **electron volt** (eV). Energies used in atomic and molecular physics are typically a few eV, making the electron volt a convenient-sized unit for atomic and molecular processes. The conversion between electron volts and joules is obtained by expressing the fundamental charge unit in coulombs:

$$1\ \text{eV} = 1.60 \times 10^{-19}\ \text{C} \cdot \text{V} = 1.60 \times 10^{-19}\ \text{J} \qquad 23\text{-}6$$

THE ELECTRON VOLT

For example, an electron moving from the negative terminal to the positive terminal of a 12-V car battery loses 12 eV of potential energy.

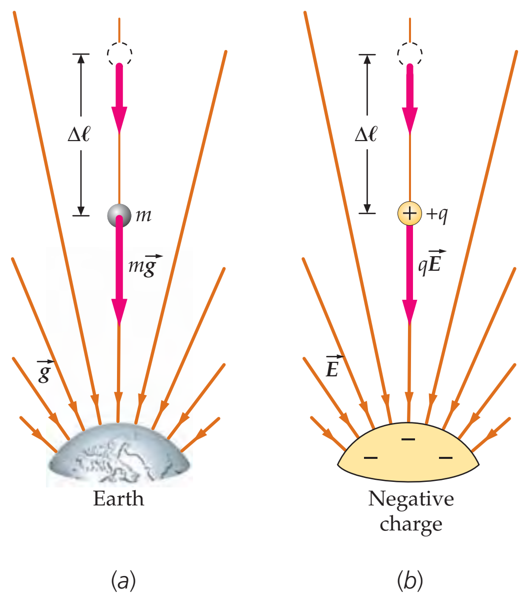


FIGURE 23-1 (*a*) The work done by the gravitational field $\vec{g}$ on a mass m is equal to the decrease in the gravitational potential energy. (*b*) The work done by the electric field $\vec{E}$ on a charge q is equal to the decrease in the electric potential energy.

POTENTIAL AND ELECTRIC FIELDS

If we place a positive charge q_0 in an electric field $\vec{E}$ and release it, it accelerates in the direction of $\vec{E}$. As the kinetic energy of the charge increases, its potential energy decreases. The charge therefore accelerates toward a region where its electric potential energy is less, just as a mass in a gravitational field accelerates toward a region where its gravitational potential energy is less (Figure 23-1).

The electric potential energy U is related to the electric potential V by $U = qV$, so *for a positive charge* a region where the charge has lower potential energy U is also a region of lower electric potential V. In summary, a positive charge accelerates in the direction of $\vec{E}$ (Figure 23-2) toward a region of lower electric potential V. Thus,

> The electric field $\vec{E}$ points in the direction in which the potential V decreases most rapidly.

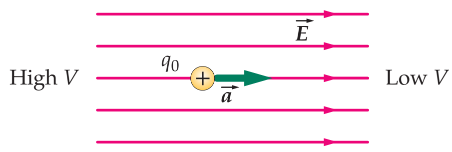

FIGURE 23-2 The electric field points in the direction in which the potential decreases most rapidly. If a positive test charge q_0 is in an electric field, it accelerates in the direction of the field. If it is released from rest, its kinetic energy increases and its potential energy decreases.

PRACTICE PROBLEM 23-1
If you place a negative charge in an electric field, would the negative charge accelerate in the direction of increasing or decreasing potential?

Example 23-1 Find V for Uniform $\vec{E}$

A uniform electrostatic field points in the $+x$ direction and has a magnitude of $E = 10\text{ N/C} = 10\text{ V/m}$. Find the potential as a function of x, assuming that $V = 0$ at $x = 0$.

PICTURE We can solve for V by using $V_b - V_a = -\int_a^b \vec{E}\cdot d\vec{\ell}$ (Equation 23-2*b*). Let a be a point in the $x = 0$ plane (where $V = 0$) and let b be an arbitrary positioned point. Express both $\vec{E}$ and $d\vec{\ell}$ in terms of their Cartesian components and then compute the integral.

SOLVE

1. The difference in potential is related to the electric field by Equation 23-2*b*:
$$V_b - V_a = -\int_a^b \vec{E}\cdot d\vec{\ell}$$

2. Sketch points a and b and coordinate axes x, y, and z. In addition, sketch an integration path from a to b (Figure 23-3):

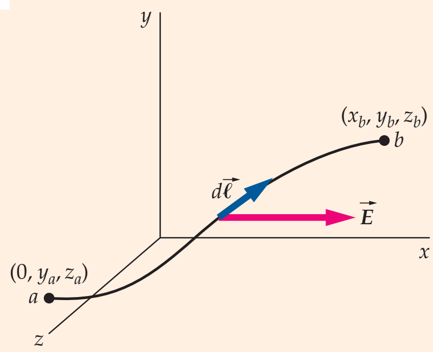

FIGURE 23-3

3. Express both $\vec{E}$ and $d\vec{\ell}$ in terms of their Cartesian components and simplify the expression for $\vec{E}\cdot d\vec{\ell}$:
$$\vec{E}\cdot d\vec{\ell} = E\hat{i}\cdot(dx\,\hat{i} + dy\,\hat{j} + dz\,\hat{k}) = E\,dx$$

4. Substitute the step 3 result into the step 1 result. Let point a be a point in the $x = 0$ plane (that way, $V_a = 0$):
$$V_b - V_a = -\int_{x_a}^{x_b} E\,dx$$

5. Because point a is any point in the $x = 0$ plane, $V_a = 0$ and $x_a = 0$. In addition, E is uniform so it can be factored from the integrand:
$$V_b - 0 = -E\int_0^{x_b} dx \quad \text{so} \quad V_b = -Ex_b$$

6. Replace x_b with x, replace V_b with $V(x)$, and substitute 10 V/m for E:
$$V(x) = -Ex = \boxed{-(10\text{ V/m})x}$$

CHECK The step 6 result is equal to zero if $x = 0$, which is in agreement with the assumption that $V = 0$ at $x = 0$ in the problem statement.

PRACTICE PROBLEM 23-2 Repeat this example for the electric field $\vec{E} = (10\text{ V/m}^2)x\hat{i}$.

In Example 23-1, point a—the point where the value of the potential is specified—is called the **reference point** for the potential function V. The potential at a field point b is obtained by calculating $V - 0 = -\int_a^b \vec{E}\cdot d\vec{\ell}$, where the potential at a is taken to be zero. The integral is to be evaluated along any path from a to b.

We now show how to calculate the potential for a number of different charge distributions.

23-2 POTENTIAL DUE TO A SYSTEM OF POINT CHARGES

The electric potential a distance r from a point charge q at the origin can be calculated using $V_P - V_{\text{ref}} = -\int_{\text{ref}}^{P} \vec{E}\cdot d\vec{\ell}$ (Equation 23-2b), where at the reference point the potential equals V_{ref}, and P is an arbitrary field point (Figure 23-4). The electric field due to the point charge is given by

$$\vec{E} = \frac{kq}{r^2}\hat{r}$$

Substituting for $\vec{E}$ in the integral gives

$$V_P - V_{\text{ref}} = -\int_{\text{ref}}^{P} \vec{E}\cdot d\vec{\ell} = -\int_{\text{ref}}^{P} \frac{kq}{r^2}\hat{r}\cdot d\vec{\ell} = -\int_{r_{\text{ref}}}^{r_P} \frac{kq}{r^2}\,dr$$

where $dr = \hat{r}\cdot d\vec{\ell}$ (see Figure 23-4) is the change in the distance r associated with the displacement $d\vec{\ell}$. Setting V_{ref} equal to zero and integrating along a path from an arbitrary reference point to an arbitrary field point gives

$$V_P - 0 = -\int_{\text{ref}}^{P} \vec{E}\cdot d\vec{\ell} = -kq\int_{r_{\text{ref}}}^{r_P} \frac{1}{r^2}\,dr = \frac{kq}{r_P} - \frac{kq}{r_{\text{ref}}}$$

or

$$V = \frac{kq}{r} - \frac{kq}{r_{\text{ref}}} \qquad 23\text{-}7$$

POTENTIAL DUE TO A POINT CHARGE

where we have replaced r_P (the distance to the field point P) with r and replaced V_P with V. We are free to choose the location of the reference point, so we choose it to give the potential the simplest algebraic form. Choosing the reference point infinitely far from the point charge (so $r_{\text{ref}} \to \infty$) accomplishes this. Thus,

$$V = \frac{kq}{r} \qquad 23\text{-}8$$

COULOMB POTENTIAL

The potential given by Equation 23-8 is called the **Coulomb potential.** It is positive or negative depending on whether q is positive or negative.

The potential energy U of a point charge q' placed a distance r from the point charge q is

$$U = q'V = q'\frac{kq}{r} = \frac{kq'q}{r} \qquad 23\text{-}9$$

ELECTROSTATIC POTENTIAL ENERGY OF A TWO-CHARGE SYSTEM

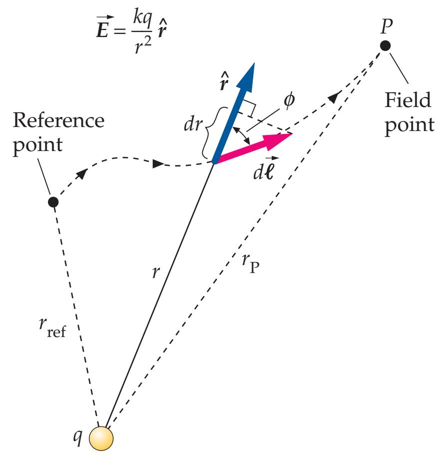

FIGURE 23-4 The change in r is dr. It is the component of $d\vec{\ell}$ in the direction of $\hat{r}$. It can be seen from the figure that $|d\vec{\ell}|\cos\phi = dr$. Because $\hat{r}\cdot d\vec{\ell} = |d\vec{\ell}|\cos\phi$, it follows that $dr = \hat{r}\cdot d\vec{\ell}$.

See **Math Tutorial** *for more information on*

Integrals

This is the electric potential energy of the two-charge system relative to $U = 0$ at infinite separation. If we release a point particle that has charge q' from rest at a distance r_0 from q (and hold q fixed), the point particle that has charge q' will be accelerated away from q (assuming that q has the same sign as q'). At a very great distance from q, the potential energy of the particle that has charge q' approaches zero so its kinetic energy approaches kqq'/r_0.

The work an external agent must do to move a test charge q_0 from rest at infinity to rest at point P, a distance r from q, is kq_0q/r (Figure 23-5). The work per unit charge is kq/r, which is the electric potential V at point P relative to the potential an infinite distance from P.

Choosing the electrostatic potential energy of two point charges to be zero at an infinite separation is analogous to the choice we made in Chapter 11 when we chose the gravitational potential energy of two point masses to be zero at an infinite separation. If two charges (or two masses) are at infinite separation, we think of them as not interacting. That the potential energy is zero if the particles are not interacting has a certain aesthetic appeal.

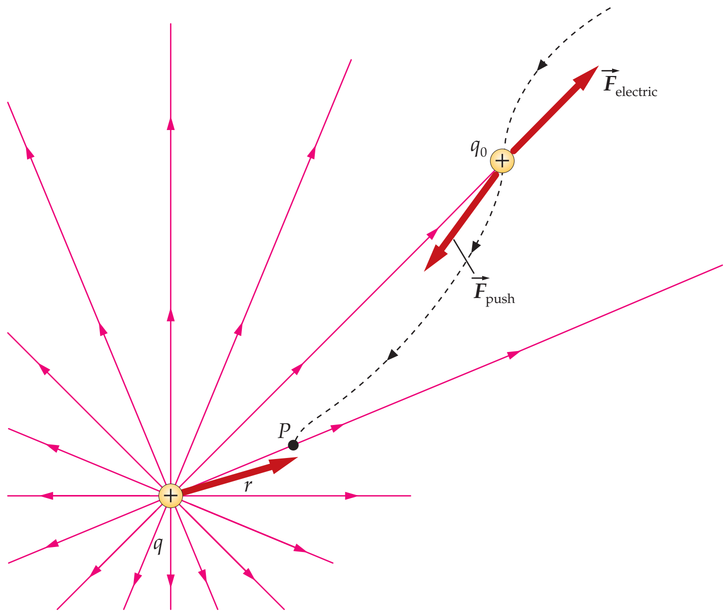

FIGURE 23-5 The work required to bring a test charge q_0 from rest at infinity to rest at point P is kq_0q/r, where r is the distance from P to the positive point charge q. The work per unit charge is thus kq/r, which is the electric potential at point P relative to zero potential at infinity. If the test charge is released from point P, the electric field does work kq_0q/r on the charge as the charge accelerates to infinity.

Example 23-2 Potential Energy of a Hydrogen Atom

(*a*) What is the electric potential at a distance $r_0 = 0.529 \times 10^{-10}$ m from a proton? This is the average distance between the proton and the electron in a hydrogen atom. (*b*) What is the electric potential energy of the electron and the proton at this separation?

PICTURE The electric potential due to the charge of the proton and the potential energy of two point charges are given by Equations 23-8 and 23-9.

SOLVE

(*a*) Use $V = kq/r$ to calculate the potential V due to the charge on the proton at $r = r_0$. For a proton, $q = e$:

$$V = \frac{kq}{r_0} = \frac{ke}{r_0} = \frac{(8.99 \times 10^9\ \mathrm{N\cdot m^2/C^2})(1.6 \times 10^{-19}\ \mathrm{C})}{0.529 \times 10^{-10}\ \mathrm{m}}$$

$$= 27.2\ \mathrm{N\cdot m/C} = \boxed{27.2\ \mathrm{V}}$$

(*b*) Use $U = q'V$, with $q' = -e$ to calculate the potential energy:

$$U = q'V = (-e)(27.2\ \mathrm{V}) = \boxed{-27.2\ \mathrm{eV}}$$

CHECK By examining the units in the equation $V = kq/r$, we can see that the units work out to $\mathrm{N\cdot m/C}$. Because $1\ \mathrm{N\cdot m} = 1\ \mathrm{J}$ and $1\ \mathrm{J/C} = 1\ \mathrm{V}$, we have $1\ \mathrm{N\cdot m/C} = 1\ \mathrm{J/C} = 1\ \mathrm{V}$.

TAKING IT FURTHER If the electron were at rest at this distance from the proton, it would take a minimum of 27.2 eV to remove it from the atom. However, the electron has kinetic energy equal to 13.6 eV, so its total energy in the atom is 13.6 eV − 27.2 eV = −13.6 eV. The minimum energy needed to remove the electron from a hydrogen atom is thus 13.6 eV. This energy is called the *ionization energy.*

PRACTICE PROBLEM 23-3 What is the potential energy of the two point charges in Example 23-2 in SI units?

Example 23-3 Potential Energy of Nuclear-Fission Products

During nuclear fission, a uranium-235 nucleus captures a neutron to form an unstable uranium-236 nucleus. The unstable nucleus then splits apart into two lighter nuclei (Figure 23-6). In addition, two or three neutrons are released. Sometimes the two fission products are a barium nucleus (charge $56e$) and a krypton nucleus (charge $36e$). Assume that immediately after the split these nuclei are positive point charges separated by $r = 14.6 \times 10^{-15}$ m (14.6×10^{-15} m is the sum of the radii of the barium and krypton nuclei). Calculate the potential energy of this two-charge system in electron volts.

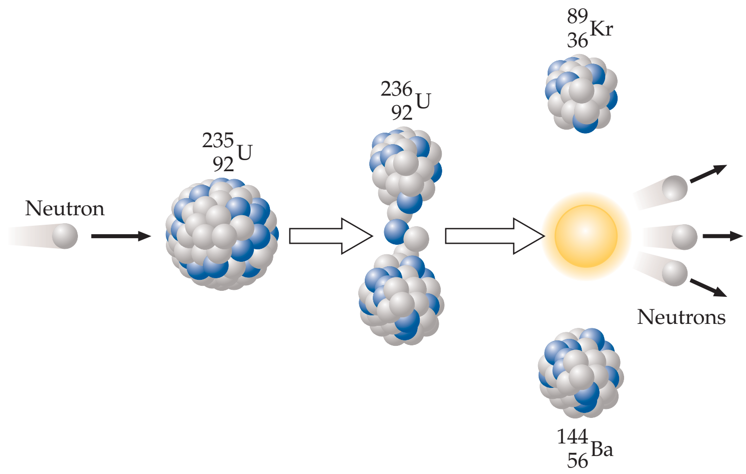

FIGURE 23-6 A uranium-235 nucleus absorbs a neutron and fissions into a barium nucleus and a krypton nucleus.

PICTURE The potential energy for two point charges separated by a distance r is $U = kq_1q_2/r$. To find this energy in electron volts, we calculate the potential due to one of the charges kq_1/r, in volts, and multiply this quantity by the other charge expressed as a multiple of e.

SOLVE

1. Equation 23-9 gives the potential energy of the two charges:

$$U = q_2\frac{kq_1}{r}$$

2. Substitute the given values and factor out e:

$$U = e\frac{36 \cdot 56ke}{r}$$

$$= e\frac{36 \cdot 56 \cdot (8.99 \times 10^9\,\text{N} \cdot \text{m}^2/\text{C}^2)(1.60 \times 10^{-19}\,\text{C})}{14.6 \times 10^{-15}\,\text{m}}$$

$$= e(199 \times 10^6\,\text{V}) = \boxed{199\text{ MeV}}$$

CHECK The potential energy of a proton and an electron in a hydrogen atom, calculated in Example 23-2, is seven orders of magnitude smaller than the potential energy calculated in this example. Because we expect energies for nuclear processes to be much larger than energies for atomic processes, this result is as expected.

TAKING IT FURTHER After the fission, the two nuclei fly apart because of their electrostatic repulsion. Their potential energy of 199 MeV is converted into kinetic energy. Upon colliding with surrounding atoms, this kinetic energy is distributed as thermal energy. During a chain reaction, one or more of the released neutrons produces a fission of another uranium nucleus. The average energy released during chain reactions of this type is about 200 MeV per nucleus, as calculated in this example.

The potential at a field point due to the presence of several point charges is the sum of the potentials due to each of these charges separately. (This result follows from the superposition principle for the electric field.) The potential due to a system of point charges q_i is thus given by

$$V = \sum_i \frac{kq_i}{r_i} \qquad 23\text{-}10$$

POTENTIAL DUE TO A SYSTEM OF POINT CHARGES

where the sum is over all the charges, and r_i is the distance from the ith charge to the field point at which the potential is to be found. Using this formula, the reference point (where $V = 0$) is at infinity and the distance between any two point charges in the system is finite.

PROBLEM-SOLVING STRATEGY

Calculating V Using Equation 23-10

PICTURE We can use Equation 23-10 to calculate the potential at a field point due to any collection of point charges if each point charge is a finite distance from every other point charge.

SOLVE

1. Sketch the charge configuration and include suitable coordinate axes. Label each point charge with a distinct symbol, such as q_1. Draw a straight line from each point charge q_i to the field point P and label it with a suitable symbol, such as r_{iP}. A careful drawing can be very helpful in relating the distances of interest to the distances given in the problem statement.
2. Use the formula $V = \Sigma\, kq_i/r_{iP}$ (Equation 23-10) to calculate the potential at P due to the presence of the point charges.

CHECK If the field point is arbitrarily chosen, take the limit as the field point goes to infinity. In that limit, the potential must approach zero.

Example 23-4 Potential Due to Two Point Charges

Two +5.0-nC point charges are on the x axis, one at the origin and the other at $x = 8.0$ cm. Find the potential at (a) point P_1 on the x axis at $x = 4.0$ cm and (b) point P_2 on the y axis at $y = 6.0$ cm. The reference point (where $V = 0$) is at infinity.

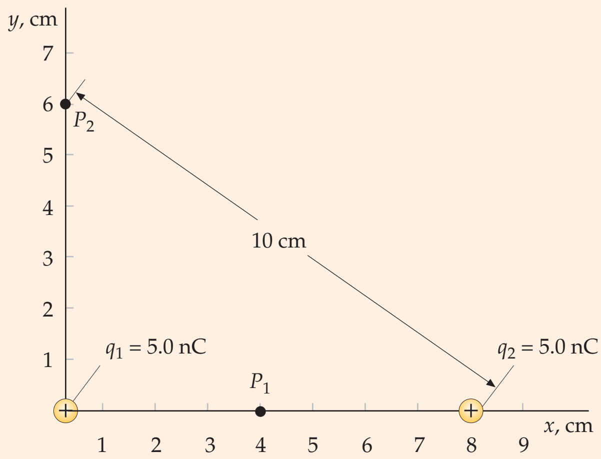

FIGURE 23-7

PICTURE The two positive point charges on the x axis are shown in Figure 23-7, and the potential is to be found at points P_1 and P_2.

SOLVE

(a) 1. Use Equation 23-10 to write V as a function of the distances r_1 and r_2 to the charges:

$$V = \sum_i \frac{kq_i}{r_i} = \frac{kq_1}{r_1} + \frac{kq_2}{r_2}$$

2. Point P_1 is 4.0 cm from each charge, and the charges are equal:

$$r_1 = r_2 = r = 0.040 \text{ m}$$

$$q_1 = q_2 = q = 5.0 \times 10^{-9}\text{ C}$$

3. Use these to find the potential at point P_1:

$$V = \frac{kq}{r} + \frac{kq}{r} = \frac{2kq}{r}$$

$$= \frac{2 \times (8.99 \times 10^9 \text{ N}\cdot\text{m}^2/\text{C}^2)(5.0 \times 10^{-9}\text{ C})}{0.040 \text{ m}} = 2247 \text{ V} = \boxed{2.2 \text{ kV}}$$

(b) Point P_2 is 6.0 cm from one charge and 10 cm from the other. Use these to find the potential at point P_2:

$$V = \frac{(8.99 \times 10^9 \text{ N}\cdot\text{m}^2/\text{C}^2)(5.0 \times 10^{-9}\text{ C})}{0.060 \text{ m}} + \frac{(8.99 \times 10^9 \text{ N}\cdot\text{m}^2/\text{C}^2)(5.0 \times 10^{-9}\text{ C})}{0.10 \text{ m}}$$

$$= 749 \text{ V} + 450 \text{ V} = \boxed{1.2 \text{ kV}}$$

CHECK The calculated potentials are both positive. The potential at a field point is the work per unit charge to bring a test charge from a reference point (where the potential is zero) to the field point. For the potential function used here, the reference point is at infinity. A positive test charge at any location would be repelled by both q_1 and q_2. Thus, an external agent would have to do work on the test charge to bring the test charge from rest at the reference point at infinity to rest at any field point. Thus, we expect the potential at any field point to be positive.

TAKING IT FURTHER Note that in Part (a), the electric field is zero at the point midway between the charges but the potential is not. An external agent must do positive work to bring a test charge to this point from a long distance away, because the electric field is zero only at the final position.

Example 23-5 Potential throughout the *x* Axis

A point charge q_1 is at the origin, and a second point charge q_2 is on the x axis at $x = a$. Using Equation 23-10, find an expression for the potential everywhere on the x axis as a function of x.

PICTURE The total potential at a field point is the sum of the potentials due to each charge separately.

SOLVE

1. Sketch the x axis and place the two charges on it. Let r_1 be the distance from q_1 to an arbitrary field point P at position x on the x axis, that is, $r_1 = |x|$. Let r_2 be the distance r_2 from q_2 to P, that is, $r_2 = |x - a|$ (Figure 23-8):

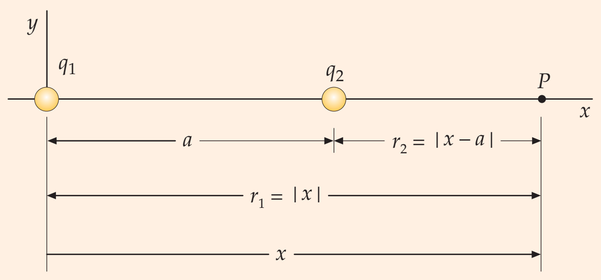

FIGURE 23-8

2. Write the potential as a function of the distances to the two charges:

$$V = \frac{kq_1}{r_1} + \frac{kq_2}{r_2}$$

$$= \boxed{\frac{kq_1}{|x|} + \frac{kq_2}{|x - a|} \qquad x \neq 0, \quad x \neq a}$$

CHECK Note that $V \to \infty$ both as $x \to 0$ and as $x \to a$, and $V \to 0$ both as $x \to -\infty$ and as $x \to +\infty$, as one would expect.

TAKING IT FURTHER Figure 23-9 shows V versus x on the x axis for $q_1 = q_2 > 0$.

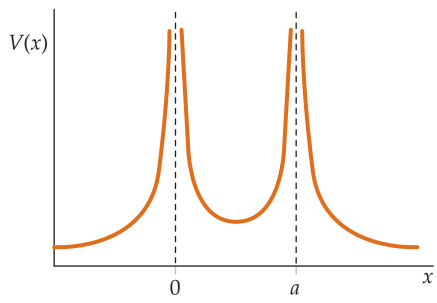

FIGURE 23-9

Example 23-6 Potential Due to an Electric Dipole

An electric dipole consists of a positive point charge $+q$ on the x axis at $x = +\ell/2$ and a negative point charge $-q$ on the x axis at $x = -\ell/2$. Find the potential on the x axis for $x \gg +\ell/2$ in terms of the dipole moment $\vec{p} = q\ell\hat{i}$.

PICTURE The potential at a field point is the sum of the potentials for each charge.

SOLVE

1. Sketch the x axis and place the two charges on it. For $x > \ell/2$, the distance from the field point P to the positive charge is $x - \frac{1}{2}\ell$ and the distance from the field point to the negative charge is $x + \frac{1}{2}\ell$ (Figure 23-10).

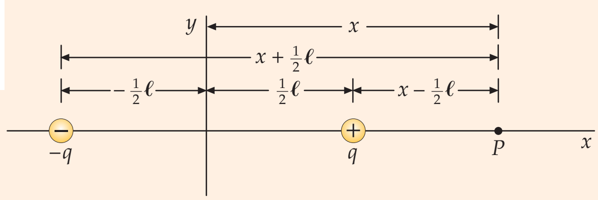

FIGURE 23-10

2. For $x > \ell/2$, the potential due to the two charges is

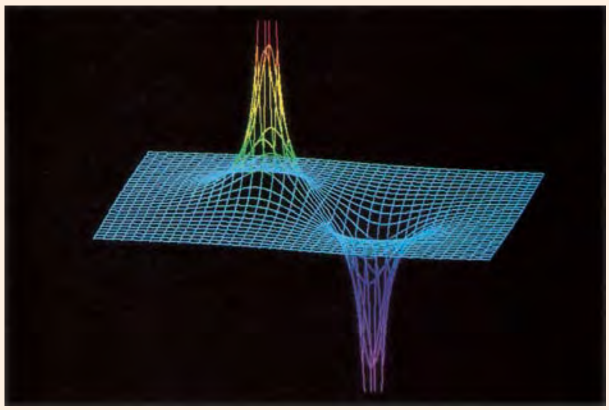
$$V = \frac{kq}{x - (\ell/2)} + \frac{k(-q)}{x + (\ell/2)}$$

$$= \frac{kq\ell}{x^2 - (\ell^2/4)} \qquad x > \frac{\ell}{2}$$

3. The magnitude of $\vec{p}$ is $p = q\ell$. For $x \gg \ell/2$, we can neglect $\ell^2/4$ compared with x^2 in the denominator.

$$V \approx \boxed{\frac{kq\ell}{x^2} = \frac{kp}{x^2} \qquad x \gg \ell}$$

CHECK A dipole has a total charge of zero, so we expect that far from the dipole, the potential would decrease with increasing distance from the dipole more rapidly than it would for a configuration that has a nonzero net charge. The step 3 result is that the potential decreases inversely with the square of the distance. Far from a configuration with a net charge the potential decreases inversely with distance from the configuration, which is less rapidly than inversely with the square of the distance.



The electrostatic potential in a plane containing both point charges of an electric dipole. The potential due to each point charge is proportional to the charge and inversely proportional to the distance from the charge. *(© 1990 Richard Menga/Fundamental Photographs.)*

23-3 COMPUTING THE ELECTRIC FIELD FROM THE POTENTIAL

In Section 23-2, we used knowledge of the electric field to calculate the potential function. To accomplish this calculation, we integrated both sides of the equation $dV = -\vec{E} \cdot d\vec{\ell}$. In this section, we will use knowledge of the potential function and the same equation ($dV = -\vec{E} \cdot d\vec{\ell}$) to calculate the electric field.

Consider a small displacement $d\vec{\ell}$ in an arbitrary electrostatic field $\vec{E}$. The associated change in potential is given by $dV = -\vec{E} \cdot d\vec{\ell}$. If the displacement $d\vec{\ell}$ is perpendicular to $\vec{E}$, then $dV = 0$ (the potential does not change). For a given $|d\vec{\ell}|$, the maximum increase in V occurs when the displacement $d\vec{\ell}$ is in the opposite direction as $\vec{E}$. To solve for $\vec{E}$, we first solve for the component of $\vec{E}$ in the direction of $d\vec{\ell}$. That is,

$$dV = -\vec{E} \cdot d\vec{\ell} = -E \cos\theta \, d\ell = E_{\tan} d\ell \qquad 23\text{-}11$$

where $E_{\tan} = E \cos\theta$ (the tangential component of $\vec{E}$) is the component of $\vec{E}$ in the direction of $d\vec{\ell}$. Then

$$E_{\tan} = -\frac{dV}{d\ell} \qquad 23\text{-}12$$

If the displacement $d\vec{\ell}$ is perpendicular to the electric field, then $dV = 0$ (the potential does not change). For a given $d\vec{\ell}$, the maximum increase in V occurs when the displacement $d\vec{\ell}$ is in the same direction as $-\vec{E}$. A vector that points in the direction of the greatest change in a scalar function and that has a magnitude equal to the derivative of that function with respect to the distance in that direction is called the **gradient** of the function. Thus, the electric field $\vec{E}$ is the negative gradient of the potential V. That is, the direction of the electric field is the same as the direction of the greatest rate of decrease of the potential function with respect to distance.

If the potential V depends only on x, there will be no change in V for displacements in the y or z direction; it follows that E_y and E_z equal zero. For a displacement in the x direction, $d\vec{\ell} = dx\hat{i}$, and Equation 23-11 becomes

$$dV(x) = -\vec{E} \cdot d\vec{\ell} = -\vec{E} \cdot dx\hat{i} = -(\vec{E} \cdot \hat{i})\, dx = -E_x \, dx$$

Then

$$E_x = -\frac{dV(x)}{dx} \qquad 23\text{-}13$$

For a spherically symmetric charge distribution centered at the origin, the potential can be a function only of the radial coordinate r. Displacements perpendicular to the radial direction give no change in $V(r)$, so the electric field must be radial. A displacement in the radial direction is written $d\vec{\ell} = dr\hat{r}$. Equation 23-11 is then

$$dV\,(r) = -\vec{E} \cdot d\vec{\ell} = -\vec{E} \cdot dr\hat{r} = -E_r \, dr$$

and

$$E_r = -\frac{dV\,(r)}{dr} \qquad 23\text{-}14$$

If we know either the potential or the electric field throughout some region of space, we can use one to calculate the other. The potential is often easier to calculate because it is a scalar function, whereas the electric field is a vector function. Note that we cannot calculate $\vec{E}$ if we know the potential V at just a single point—we must know V over a region of space to compute the derivative necessary to obtain $\vec{E}$ throughout that region. If we only know V along a curve or on a surface, then we can only calculate the component of $\vec{E}$ tangent to the curve or surface.

CONCEPT CHECK 23-1

In what direction can you move relative to an electric field so that the electric potential does not change?

CONCEPT CHECK 23-2

In what direction can you move relative to an electric field so that the electric potential increases at the greatest rate?

Example 23-7 $\vec{E}$ for a Potential that Varies with x

Find the electric field for the electric potential function V given by $V = 100\text{ V} - (25\text{ V/m})x$.

PICTURE This potential function depends only on x. Use $E_x = -dV/dx$ (Equation 23-13) and solve for E_x. Because the potential does not vary with y or z, $E_y = E_z = 0$.

SOLVE

The electric field is found from $E_x = -dV/dx$ (Equation 23-13) using $V = 100\text{ V} - (25\text{ V/m})x$:

$$E_x = -\frac{dV}{dx} \text{ and } E_y = E_z = 0 \quad \text{so} \quad \vec{E} = \boxed{+(25\text{ V/m})\hat{i}}$$

CHECK The potential decreases as x increases. Note that the electric field is in the $+x$ direction, the direction of decreasing potential, as expected.

TAKING IT FURTHER This electric field is uniform and in the $+x$ direction. Note that the constant 100 V in the expression for $V(x)$ has no effect on the electric field. The electric field does not depend on the choice of zero for the potential function.

PRACTICE PROBLEM 23-4 (*a*) At what points does V equal zero in this example? (*b*) Write the potential function corresponding to the same electric field with $V = 0$ everywhere on the $x = 0$ plane.

GENERAL RELATION BETWEEN $\vec{E}$ AND V

In vector notation, the gradient of V is written as either $\overrightarrow{grad}V$ or $\vec{\nabla}V$. Then

$$\vec{E} = -\vec{\nabla}V \qquad 23\text{-}15$$

In general, the potential function can depend on x, y, and z. The Cartesian components of the electric field are related to the partial derivatives of the potential with respect to x, y, or z. For example, the x component of the electric field is given by

$$E_x = -\frac{\partial V}{\partial x} \qquad 23\text{-}16a$$

Similarly, the y and z components of the electric field are related to the potential by

$$E_y = -\frac{\partial V}{\partial y} \qquad 23\text{-}16b$$

and

$$E_z = -\frac{\partial V}{\partial z} \qquad 23\text{-}16c$$

Thus, Equation 23-15 in Cartesian coordinates is written

$$\vec{E} = -\vec{\nabla}V = -\left(\frac{\partial V}{\partial x}\hat{i} + \frac{\partial V}{\partial y}\hat{j} + \frac{\partial V}{\partial z}\hat{k}\right) \qquad 23\text{-}17$$

23-4 CALCULATIONS OF V FOR CONTINUOUS CHARGE DISTRIBUTIONS

The potential due to a continuous distribution of charge can be calculated by choosing an element of charge dq, which we treat as a point charge, and invoking superposition, changing the sum in $V = \Sigma kq_i/r_i$ (Equation 23-10) to an integral:

$$V = \int \frac{k\,dq}{r} \qquad 23\text{-}18$$

POTENTIAL DUE TO A CONTINUOUS CHARGE DISTRIBUTION

This equation assumes that $V = 0$ at an infinite distance from the charges, so we cannot use it for any charge distributions of infinite extent, as is the case for artificial charge distributions like an infinite line charge or an infinite plane charge.

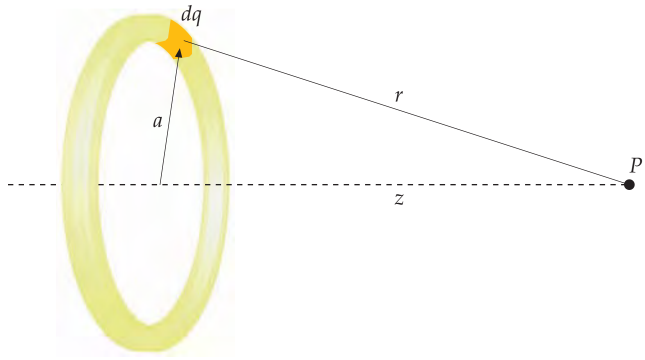


FIGURE 23-11 Geometry for the calculation of the electric potential at a point on the axis of a charged ring of radius a.

V ON THE AXIS OF A CHARGED RING

Figure 23-11 shows a uniformly charged ring of radius a and charge Q in the $z = 0$ plane and centered at the origin. The distance from an element of charge dq to the field point P on the axis of the ring is $r = \sqrt{z^2 + a^2}$. Because this distance is the same for all elements of charge on the ring, we can remove this term from the integral in Equation 23-18. The potential at point P due to the ring is thus

$$V = \int \frac{k\,dq}{r} = \frac{k}{r}\int dq = \frac{kQ}{r}$$

or

$$V = \frac{kQ}{\sqrt{z^2 + a^2}} \qquad \text{23-19}$$

POTENTIAL ON THE AXIS OF A CHARGED RING

Note that when $|z|$ is much greater than a, the potential approaches $kQ/|z|$, the same as the potential due to a point charge Q at the origin.

Example 23-8 A Ring and a Particle — *Try It Yourself*

A ring of radius 4.0 cm is in the $z = 0$ plane and has its center at the origin. The ring has a uniform charge of 8.0 nC. A small particle that has a mass equal to 6.0 mg (6.0×10^{-6} kg) and a charge equal to 5.0 nC is placed on the z axis at $z = 3.0$ cm and released. Find the speed of the particle when it is a great distance from the ring. Assume effects due to gravity are negligible.

PICTURE The particle is repelled by the ring. As the particle moves along the z axis, its potential energy decreases and its kinetic energy increases. Use conservation of mechanical energy to find the kinetic energy of the particle when it is far from the ring. The final speed is found from the final kinetic energy.

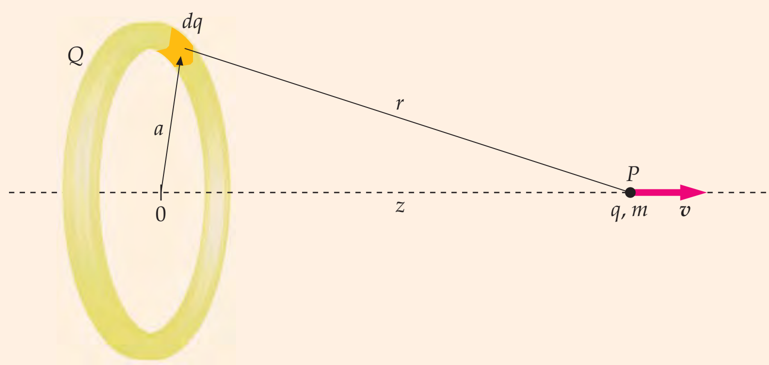

FIGURE 23-12

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. Sketch the ring, the particle, and the z axis. Label the sketch appropriately (Figure 23-12).	
2. Write down the relation between the kinetic energy and the speed.	$K = \frac{1}{2}mv^2$
3. Use $U = qV$, with V given by $V = kQ/\sqrt{z^2 + a^2}$ (Equation 23-19), to obtain an expression for the potential energy V as a function of the distance z of the point charge from the center of the ring.	$U = qV = \dfrac{kqQ}{\sqrt{z^2 + a^2}}$

4. Use conservation of mechanical energy to relate the energy at $z_i = 0.030$ m to the energy as $z_f \to \infty$. Solve for the speed as z_f approaches infinity.

$$U_f + K_f = U_i + K_i$$

$$\frac{kqQ}{\sqrt{z_f^2 + a^2}} + \frac{1}{2}mv_f^2 = \frac{kqQ}{\sqrt{z_i^2 + a^2}} + \frac{1}{2}mv_i^2$$

so $$v_f^2 = \frac{2kqQ}{m\sqrt{z_i^2 + a^2}} = 2.40\ \text{m}^2/\text{s}^2$$

$$v_f = \boxed{1.6\ \text{m/s}}$$

CHECK In step 3, we found that $v_f^2 = 2.40\ \text{m}^2/\text{s}^2$, a positive number. If our result was that v_f^2 had equaled a negative number it would be a clear indication that a mistake had been made.

PRACTICE PROBLEM 23-5 What is the potential energy of the particle when it is at $z = 9.0$ cm?

V ON THE AXIS OF A UNIFORMLY CHARGED DISK

We can use our result for the potential on the axis of a ring charge to calculate the potential on the axis of a uniformly charged disk.

Example 23-9 Find V for a Charged Disk

Find the potential on the axis of a disk of radius R that carries a total charge Q distributed uniformly on its surface.

PICTURE We take the axis of the disk to be the z axis, and we treat the disk as a set of ring charges. The ring of radius a and thickness da in Figure 23-13 has an area of $2\pi a\,da$. The charge of the ring is $dq = \sigma\,dA = \sigma 2\pi a\,da$, where $\sigma = Q/(\pi R^2)$ is the surface charge density. The potential at point P due to the charge on this ring is given by $k\,dq/(z^2 + a^2)^{1/2}$ (Equation 23-19). We then integrate from $a = 0$ to $a = R$ to find the total potential due to the charge on the disk.

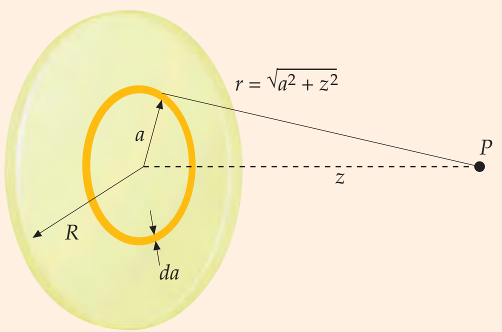

FIGURE 23-13

SOLVE

1. Write the potential dV at point P due to the charged ring of radius a:

$$dV = \frac{k\,dq}{(z^2 + a^2)^{1/2}} = \frac{k\sigma 2\pi a\,da}{(z^2 + a^2)^{1/2}}$$

2. Integrate from $a = 0$ to $a = R$:

$$V = \int_0^R \frac{k\sigma 2\pi a\,da}{(z^2 + a^2)^{1/2}} = k\sigma\pi \int_0^R (z^2 + a^2)^{-1/2} 2a\,da$$

3. The integral is of the form $\int u^n\,du$, with $u = z^2 + a^2$, $du = 2z\,dz$, and $n = -\frac{1}{2}$. When $a = 0$, $u = z^2 + 0^2$ and when $a = R$, $u = z^2 + R^2$:

$$V = k\sigma\pi \int_{z^2+0^2}^{z^2+R^2} u^{-1/2}\,du = k\sigma\pi \left.\frac{u^{1/2}}{\frac{1}{2}}\right|_{z^2}^{z^2+R^2}$$

$$= 2k\sigma\pi\left(\sqrt{z^2 + R^2} - \sqrt{z^2}\right)$$

4. Rearranging this result to find V gives

$$V = \boxed{2\pi k\sigma|z|\left(\sqrt{1 + \frac{R^2}{z^2}} - 1\right)}$$

CHECK For $|z| \gg R$, the potential function V should approach the potential function of a point charge Q at the origin. That is, we expect that for large $|z|$, $V \approx kQ/|z|$. To approximate our result for $|z| \gg R$, we use the binomial expansion:

$$\left(1 - \frac{R^2}{z^2}\right)^{1/2} = 1 + \frac{1}{2}\frac{R^2}{z^2} + \cdots$$

Then

$$V = 2\pi k\sigma|z|\left[\left(1 + \frac{1}{2}\frac{R^2}{z^2} + \cdots\right) - 1\right] \approx \frac{k(\sigma\pi R^2)}{|z|} = \frac{kQ}{|z|}$$

From Example 23-9, we see that the potential on the axis of a uniformly charged disk in the $z = 0$ plane is

$$V = 2\pi k\sigma|z|\left(\sqrt{1 + \frac{R^2}{z^2}} - 1\right) \qquad \text{23-20}$$

POTENTIAL ON THE AXIS OF A UNIFORMLY CHARGED DISK

Example 23-10 Find $\vec{E}$ Given V

Calculate the electric field on the axis of a uniformly charged disk that has a charge q and a radius R using the potential function given in Equation 23-20.

PICTURE Using $E_z = -dV/dz$, we can evaluate E_z by direct differentiation. We cannot evaluate either E_x or E_y by direct differentiation because we do not know how V varies in those directions. However, the symmetry of the charge distribution dictates that *on* the x axis, $E_x = E_y = 0$.

SOLVE

1. Write Equation 23-20 for the potential on the axis of a uniformly charged disk:

$$V = 2\pi k\sigma|z|\left(\sqrt{1 + \frac{R^2}{z^2}} - 1\right) = 2\pi k\sigma[(z^2 + R^2)^{1/2} - |z|]$$

2. Compute $-dV/dz$ to find E_z:

$$E_z = -\frac{dV}{dz} = -2\pi k\sigma\left[\frac{1}{2}(z^2 + R^2)^{-1/2}2z - \frac{d|z|}{dz}\right]$$

3. Evaluate $d|z|/dz$. It is the slope of a graph of $|z|$ versus z (Figure 23-14):*

$$\frac{d|z|}{dz} = \text{sign}(z) = \begin{cases} +1 & z > 0 \\ 0 & z = 0 \\ -1 & z < 0 \end{cases}$$

4. Substituting for $d|z|/dz$ in the step 2 result gives:

$$E_z = -2\pi k\sigma\left(\frac{z}{\sqrt{z^2 + R^2}} - \text{sign}(z)\right)$$

$$= \boxed{2\pi k\sigma\left(\text{sign}(z) - \frac{z}{\sqrt{z^2 + R^2}}\right)}$$

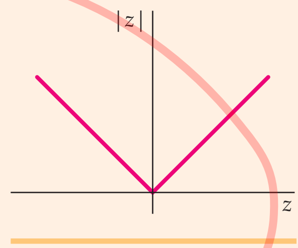

FIGURE 23-14 A plot of $|z|$ versus z.

CHECK By factoring $|z|$ from the radical in the step 4 result, we obtain

$$E_z = -2\pi k\sigma\left(\frac{z}{|z|\sqrt{1 + (a^2/z^2)}} - \text{sign}(z)\right) = \text{sign}(z) \cdot 2\pi k\sigma\left(1 - \frac{1}{\sqrt{1 + (a^2/z^2)}}\right)$$

where we have used $z/|z| = \text{sign}(z)$. This expression for E_z has the same form as the expression for E_z found in Equation 22-9.

TAKING IT FURTHER The step 3 result ($d|z|/dz = \text{sign}\, z$) defines $d|z|/dz$ to equal zero at $z = 0$. In like manner, using $d|z|/dz = \text{sign}\, z$ in the Check defines $z/|z|$ to equal zero at $z = 0$. It is common practice to define the value of a function at a point where it is not continuous to equal the average of the values of the function on either side of the discontinuity. That is what we have done here with $d|z|/dz$ and with $z/|z|$.

PRACTICE PROBLEM 23-6 Using the expression for the potential V on the axis of a uniformly charged ring of radius R (Equation 23-20), compute $-dV/dz$ on the axis and obtain an expression for E_z on the axis. Show that this expression has the same form as that shown in Equation 22-8.

V DUE TO AN INFINITE PLANE OF CHARGE

If we let R become very large, our uniformly charged disk approaches an infinite plane. As R approaches infinity, the potential function $V = 2\pi k\sigma|z|$ $(\sqrt{1 + (R^2/z^2)} - 1)$ (Equation 23-20) approaches infinity. However, we obtained

* See Taking It Further at the end of this example.

Equation 23-20 from Equation 23-18, which assumes that $V = 0$ at infinity. We have a contradiction—Equation 23-20 is not a valid potential function for a uniformly charge disk of infinite radius. For charge distributions that extend to infinity, we cannot choose $V = 0$ at a point at an infinite distance from the charges. Instead, we first find the electric field $\vec{E}$ (by direct integration or from Gauss's law) and then calculate the potential function V from its defining relation $dV = -\vec{E}\cdot d\vec{\ell}$. For an infinite plane of uniform charge of density σ in the $x = 0$ plane, the electric field in the region $x > 0$ is given by Equation 22-10:

$$\vec{E} = \frac{\sigma}{2\epsilon_0}\hat{\imath} = 2\pi k\sigma\hat{\imath} \qquad x > 0$$

The potential increment dV for an arbitrary displacement increment $d\vec{\ell} = dx\hat{\imath} + dy\hat{\jmath} + dy\hat{k}$ is then

$$dV = -\vec{E}\cdot d\vec{\ell} = -(2\pi k\sigma\hat{\imath})\cdot(dx\hat{\imath} + dy\hat{\jmath} + dz\hat{k}) = -2\pi k\sigma\, dx \qquad x > 0$$

Integrating both sides of this equation, we obtain

$$V = -2\pi k\sigma x + V_0 \qquad x > 0$$

where the arbitrary integration constant V_0 is the potential at $x = 0$. Note that the value of this potential function decreases with distance from the plane and approaches $-\infty$ as x approaches $+\infty$.

For negative x, the electric field is

$$\vec{E} = -2\pi k\sigma\hat{\imath} \qquad x > 0$$

so

$$dV = -\vec{E}\cdot d\vec{\ell} = +2\pi k\sigma\, dx \qquad x > 0$$

and the potential is

$$V = V_0 + 2\pi k\sigma x = V_0 - 2\pi k\sigma|x| \qquad x > 0$$

Figure 23-15 is a plot of this potential function. The potential again decreases with distance from the charged plane and approaches $-\infty$ as x approaches $-\infty$. For either positive or negative x, the potential V can be written

$$V = V_0 - 2\pi k\sigma|x| \qquad 23\text{-}21$$

POTENTIAL NEAR AN INFINITE PLANE OF CHARGE

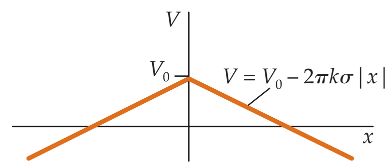

FIGURE 23-15 Plot of V versus x for an infinite plane of charge in the $x = 0$ plane. Note that the potential is continuous at $x = 0$ even though $E_x = -dV/dx$ is not continuous there. The reference point where $V = V_0$ is at the origin.

Example 23-11 A Sheet of Charge and a Point Charge

An infinite flat sheet that has a uniform charge density σ lies in the $x = 0$ plane, and a point charge q is on the x axis at $x = a$ (Figure 23-16). Find the potential at some point P a distance r from the point charge.

PICTURE We can use the principle of superposition. The total potential V is the sum of the individual potentials due to the plane and the point charge. We must add an arbitrary constant in our expression for V, which is determined by our choice of the reference point, where $V = 0$. We are free to choose the location of the reference point to be anywhere but at $x = \pm\infty$ or at $x = a$ on the x axis. For this calculation, we choose $V = 0$ at the origin.

SOLVE

1. Sketch the charge configuration. Include the coordinate axes and a field point at (x, y, z):

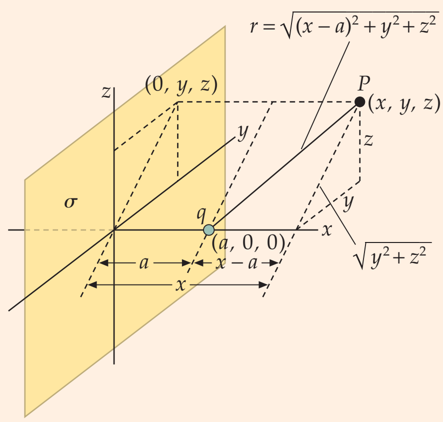

FIGURE 23-16

2. The potential due to the charged plane is given by $V_{\text{plane}} = V_0 - 2\pi k\sigma|x|$ (Equation 23-21) and the potential due to a point charge is given by $V_{\text{point}} = kq/r - kq/r_{\text{ref}}$ (Equation 23-7) where r is the distance from the point charge to the field point. The total potential is the sum of the two potentials:

$$V = V_{\text{plane}} + V_{\text{point}} = -2\pi k\sigma|x| + \frac{kq}{r} + C$$

where the constant $C\ (= V_0 - kq/r_{\text{ref}})$ is chosen to set the potential at the reference point to zero.

3. The distance r from the point charge at $(a, 0, 0)$ to the field point at (x, y, z) is $\sqrt{(x-a)^2 + y^2 + z^2}$:

$$V = -2\pi k\sigma|x| + \frac{kq}{\sqrt{(x-a)^2 + y^2 + z^2}} + C$$

4. We choose to let $V = 0$ at the origin. To do that, set $V = 0$ at $x = y = z = 0$ and solve for the constant C:

$$0 = 0 + \frac{kq}{a} + C \quad \text{so} \quad C = -\frac{kq}{a}$$

5. Substitute $-kq/a$ for C in the step 3 result:

$$V = -2\pi k\sigma|x| + \frac{kq}{\sqrt{(x-a)^2 + y^2 + z^2}} - \frac{kq}{a}$$

$$= \boxed{-2\pi k\sigma|x| + kq\left(\frac{1}{r} - \frac{1}{a}\right)}$$

CHECK The step 5 result is what you would expect by superposing the potential for a uniformly charged plane and a point charge.

TAKING IT FURTHER The answer is not unique. We could have specified the potential at any point, other than at $x = a$ or at $x = \pm\infty$.

V INSIDE AND OUTSIDE A SPHERICAL SHELL OF CHARGE

Here, we find the potential due to a thin spherical shell that has a radius R and a charge Q uniformly distributed on its surface. We are interested in the potential at all points inside, outside, and on the shell. Unlike the infinite plane of charge, this charge distribution is confined to a finite region of space, so, in principle, we could calculate the potential by direct integration of Equation 23-18. However, there is a simpler way. Because the electric field for this charge distribution is easily obtained from Gauss's law, we will calculate the potential from the known electric field using $dV = -\vec{E}\cdot d\vec{\ell}$.

Outside the spherical shell, the electric field is radial and is the same as if all the charge Q were a point charge at the origin:

$$\vec{E} = \frac{kQ}{r^2}\hat{r}$$

where $\hat{r}$ is a unit vector directed away from the center of the sphere. The change in the potential for some displacement $d\vec{\ell}$ outside the shell is then

$$dV = -\vec{E}\cdot d\vec{\ell} = -\frac{kQ}{r^2}\hat{r}\cdot d\vec{\ell} = -\frac{kQ}{r^2}\,dr$$

where the product $\hat{r}\cdot d\vec{\ell}$ is equal to dr (the component of $d\vec{\ell}$ in the direction of $\hat{r}$). Integrating along a path from the reference point at infinity, we obtain

$$V_p = -\int_{\infty}^{\vec{r}_P} \vec{E}\cdot d\vec{\ell} = -\int_{\infty}^{r_P} \frac{kQ}{r^2}\,dr = -kQ\int_{\infty}^{r_P} r^{-2}\,dr = \frac{kQ}{r_P}$$

where P is an arbitrary field point in the region $r \geq R$, and r_p is the distance from the center of the shell to the field point P. The potential is chosen to be zero at infinity. Because P is arbitrary, we replace r_p with r to obtain

$$V = \frac{kQ}{r} \qquad r \geq R$$

Inside the spherical shell, the electric field is zero everywhere. Again integrating from the reference point at infinity, we obtain

$$V_p = -\int_{\infty}^{\vec{r}_P} \vec{E}\cdot d\vec{r} = -\int_{\infty}^{R} \frac{kQ}{r^2}\,dr - \int_{R}^{r_P} (0)\,dr = \frac{kQ}{R}$$

where P is an arbitrary field point in the region $r < R$, and r_P is the distance from the center of the shell to the field point P. The potential at all points inside the shell is kQ/R, where R is the radius of the shell. Inside the shell V is the same everywhere. The potential at any point inside the shell is the work per unit charge to bring a test charge from infinity to the shell. No additional work is required to bring it from the shell to any point inside the shell. Thus,

$$V = \begin{cases} \dfrac{kQ}{r} & (r \geq R) \\ \dfrac{kQ}{R} & (r \leq R) \end{cases} \qquad 23\text{-}22$$

POTENTIAL DUE TO A THIN SPHERICAL SHELL

This potential function is plotted in Figure 23-17.

A region of zero electric field merely implies that the potential field is uniform throughout the region. Consider a spherical shell that has a small hole through it so that we can move a test charge in and out of the shell. If we move the test charge from an infinite distance to the shell, the work per charge we must do is kQ/R. Inside the shell there is no electric field, so it takes no work to move the test charge around inside the shell. The total amount of work per unit charge it takes to bring the test charge from infinity to any point inside the shell is just the work per charge it takes to bring the test charge up to the shell radius R, which is kQ/R. The potential is therefore kQ/R everywhere inside the shell.

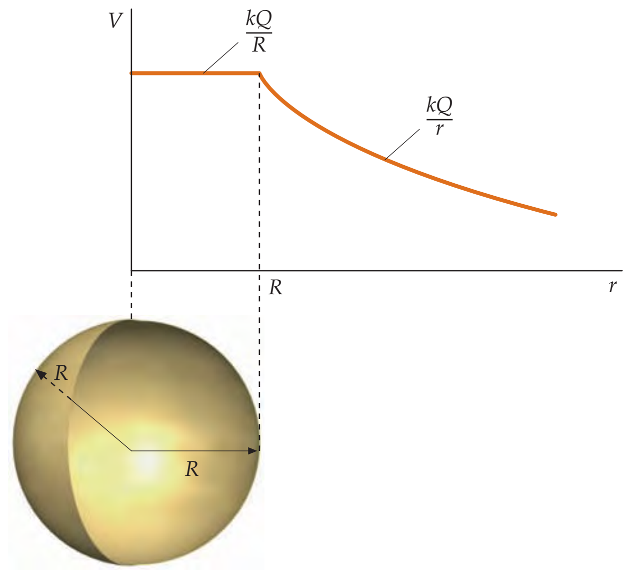

FIGURE 23-17 Electric potential of a uniformly charged thin spherical shell that has a radius R as a function of the distance r from the center of the shell. Inside the shell, the potential has the constant value kQ/R. Outside the shell, the potential is the same as that due to a point charge Q at the center of the sphere.

! A common mistake is to think that the potential must be zero inside a spherical shell because the electric field is zero throughout that region.

PRACTICE PROBLEM 23-7

What is the potential of a spherical shell of radius 10.0 cm carrying a charge of 6.00 μC?

Example 23-12 Find *V* for a Uniformly Charged Sphere *Try It Yourself*

In one model, a proton is considered to be a uniformly charged solid sphere that has a radius R and a charge Q. The electric field inside the sphere is given by $E_r = k\dfrac{Q}{R^3}r$ (Equation 22-18*b*). Find the potential V both inside and outside the sphere.

PICTURE Outside the sphere, the charge looks like a point charge, so the potential is given by $V = kQ/r$. Inside the sphere, V can be found by integrating $dV = -\vec{E}\cdot d\vec{\ell}$, where the electric field inside the sphere given by $\vec{E} = (kQr/R^3)\hat{r}$ (Equation 22-18*b*).

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. Outside the sphere, the electric field is the same as that of a point charge. If we set the potential equal to zero at infinity, the potential there is also the same as that of a point charge.	$V(r) = \boxed{\dfrac{kQ}{r} \quad r \geq R}$
2. For $r \leq R$, find dV from $dV = -\vec{E}\cdot d\vec{\ell}$, where the electric field inside the sphere given by $\vec{E} = (kQr/R^3)\hat{r}$ (Equation 22-18*b*).	$dV = -\vec{E}\cdot d\vec{\ell} = -\dfrac{kQr}{R^3}\hat{r}\cdot d\vec{\ell} = -\dfrac{kQr}{R^3}dr$

3. Find the definite integral using the expression in step 2. Find the change in potential from infinity to an arbitrary field point P in the region $r_P < R$, where r_P is the distance of point P from the center of the sphere.

$$V_P = -\int_{\infty}^{r_P} E_r\,dr = -\int_{\infty}^{R} \frac{kQ}{r^2}\,dr - \int_{R}^{r_P} \frac{kQ}{R^3}\,r\,dr$$
$$= \frac{kQ}{R} - \frac{kQ}{2R^3}(r_P^2 - R^2) = \frac{kQ}{2R}\left(3 - \frac{r_P^2}{R^2}\right)$$

4. Express the result in terms of $r = r_P$:

$$V(r) = \boxed{\frac{kQ}{2R}\left(3 - \frac{r^2}{R^2}\right) \qquad r \le R}$$

CHECK Substituting $r = R$ in the step 4 result gives $V = kQ/R$ as required by the step-1 result. At $r = 0$, $V = 3kQ/2R = 1.5\,kQ/R$, which is greater than kQ/R, as it should be, because the electric field is in the positive radial direction for $r < R$. (An electrostatic field always points in the direction of decreasing potential.)

TAKING IT FURTHER Figure 23-18 shows $V(r)$ as a function of r. Note that both $V(r)$ and $E_r = -dV/dr$ are continuous everywhere.

PRACTICE PROBLEM 23-8 Find the potential function if the reference point where $V = 0$ is at $r = R$ (instead of at $r = \infty$).

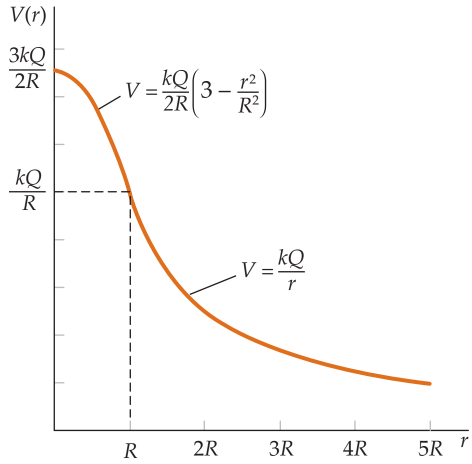

FIGURE 23-18

V DUE TO AN INFINITE LINE CHARGE

We will now calculate the potential due to a uniformly charged infinite line. Let the charge per unit length be λ. Like the infinite plane of charge, this charge distribution is not confined to a finite region of space, so, in principle, we cannot calculate the potential by direct integration of $dV = k\,dq/r$ (Equation 23-18). Instead, we find the potential by integrating the electric field directly. The electric field of a uniformly charged infinite line is given by $\vec{E} = (2k\lambda/R)\,\hat{R}$ (Equation 22-3), where λ is the linear charge density and R is the radial distance from the line. The change in potential for an arbitrary displacement $d\vec{\ell}$ is given by

$$dV = -\vec{E}\cdot d\vec{\ell} = -\frac{2k\lambda}{R}\hat{R}\cdot d\vec{\ell}$$

where $\hat{R}$ is in the radial direction. The product $\hat{R}\cdot d\vec{\ell} = dR$ (the component of $d\vec{\ell}$ in the direction of $\hat{R}$), so $dV = -(2k\lambda/R)\,dR$. Integrating from an arbitrary reference point to an arbitrary field point P (Figure 23-19) gives

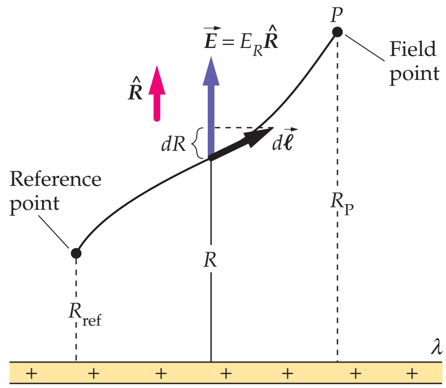

FIGURE 23-19

$$V_P - V_{\text{ref}} = -2k\lambda\int_{R_{\text{ref}}}^{R_P} \frac{dR}{R} = -2k\lambda \ln\frac{R_P}{R_{\text{ref}}}$$

where R_P and R_{ref} are the radial distances of the field and reference points, respectively, from the line charge. For convenience, we choose the potential to equal zero at the reference point ($V_{\text{ref}} = 0$). We cannot choose R_{ref} to be zero because $\ln(0) = -\infty$, and we cannot choose R_{ref} to be infinity because $\ln(\infty) = +\infty$. However, any other choice in the interval $0 < R_{\text{ref}} < \infty$ is acceptable, and the potential function is given by

$$V = 2k\lambda \ln\frac{R_{\text{ref}}}{R} \qquad 23\text{-}23$$

POTENTIAL DUE TO A UNIFORM LINE CHARGE OF INFINITE LENGTH

We do not encounter charge distributions in nature that actually extend to infinity. However, such distributions make excellent models for some real-world situations. An example is the potential of a 500-m-long, nearly straight, high-voltage transmission power line (but not close to either end).

23-5 EQUIPOTENTIAL SURFACES

Because there is no electric field inside the material of a conductor that is in static equilibrium, the value of the potential is the same throughout the region occupied by the conducting material. That is, the conductor is a three-dimensional **equipotential region** and the surface of a conductor is an **equipotential surface.**

The potential V has the same value everywhere on an equipotential surface. If a test charge on an equipotential surface is given a small displacement $d\vec{\ell}$ parallel to the surface, $dV = -\vec{E}\cdot d\vec{\ell} = 0$. Because $\vec{E}\cdot d\vec{\ell}$ is zero for any $d\vec{\ell}$ parallel to the surface, $\vec{E}$ must either be zero or be perpendicular to any and every $d\vec{\ell}$ that is parallel to the surface. The only way $\vec{E}$ can be perpendicular to every $d\vec{\ell}$ parallel to the surface is for $\vec{E}$ to be normal to the surface. Therefore, we conclude that electric field lines are normal to any equipotential surfaces they intersect. Figures 23-20 and 23-21 show equipotential surfaces near a spherical conductor and a nonspherical conductor. Note that anywhere a field line meets or penetrates an equipotential surface, shown in gray, the field line is normal to the equipotential surface. If we go from one equipotential surface to a neighboring equipotential surface by undergoing a displacement $d\vec{\ell}$ along a field line in the direction of the field, the potential changes by $dV = -\vec{E}\cdot d\vec{\ell} = -Ed\ell$. It follows that equipotential surfaces that have a fixed potential difference between them are more closely spaced where the electric field strength E is greater.

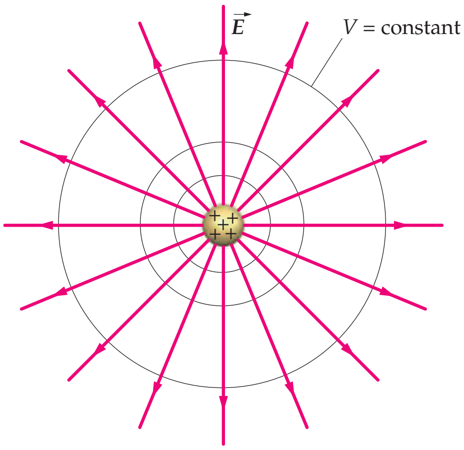

FIGURE 23-20 Equipotential surfaces and electric field lines outside a uniformly charged spherical conductor. The equipotential surfaces are spherical and the field lines are radial. The field lines are normal to the equipotential surfaces.

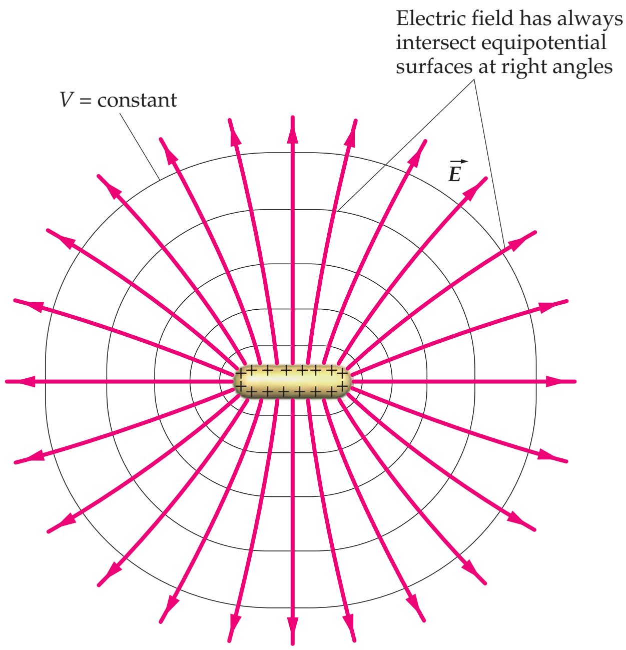

FIGURE 23-21 Equipotential surfaces and electric field lines outside a nonspherical conductor.

Example 23-13 A Hollow Spherical Shell

A hollow, uncharged spherical conducting shell has an inner radius a and an outer radius b. A positive point charge $+q$ is located at the center of the shell. (*a*) Find the charge on each surface of the conductor. (*b*) Find the potential $V(r)$ everywhere, assuming that $V = 0$ at $r = \infty$.

PICTURE (*a*) The charge distribution is spherical, so applying Gauss's law should be a good method for finding the charges on the inner and outer surfaces of the shell. (*b*) Sum the individual potentials for the individual charges to obtain the resultant potential. The potential for a point charge and for a uniform thin spherical shell of charge have already been established (Equations 23-8 and 23-22).

SOLVE

(*a*) 1. The charge inside a closed surface is proportional to the outward flux of $\vec{E}$ through the surface:

$$\phi_{\text{net}} = 4\pi k Q_{\text{inside}}$$

where $\phi_{\text{net}} = \oint_S E_n\, dA$

2. Sketch the point charge and the spherical shell. On a conducting object, charge can reside on its surfaces but not within the conducting material. Label the charge on each surface of the shell. Include a Gaussian surface completely inside the conducting material and enclosing the inner surface (Figure 23-22):

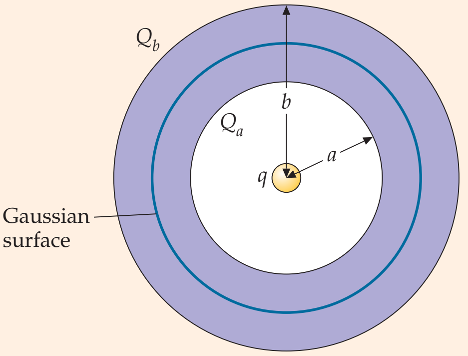

FIGURE 23-22

3. Apply Gauss's law (the step 1 result) to the Gaussian surface and solve for the charge on the inner surface of the shell:

$$E_n = 0 \Rightarrow Q_{\text{inside}} = q + Q_a = 0$$

so $Q_a = \boxed{-q}$

4. The shell is neutral, so solve for the charge on its outer surface:

$$Q_a + Q_b = 0$$

so $Q_b = -Q_a = \boxed{+q}$

(*b*) 1. The potential at any point is the sum of the potentials due to the individual charges:

$$V = V_q + V_{Q_a} + V_{Q_b}$$

2. The potential due to a uniformly charged thin spherical shell of radius R is given by Equation 23-22:

$$V = \begin{cases} \dfrac{kQ}{r} & (r \geq R) \\[2ex] \dfrac{kQ}{R} & (r \leq R) \end{cases}$$

3. Add the potentials in the region $r \geq b$:

$$V = \frac{kq}{r} + \frac{kQ_a}{r} + \frac{kQ_b}{r} = \frac{kq}{r} - \frac{kq}{r} + \frac{kq}{r} = \boxed{\frac{kq}{r} \quad r \geq b}$$

4. Add the potentials in the region $a \leq r \leq b$:

$$V = \frac{kq}{r} - \frac{kq}{r} + \frac{kq}{b} = \boxed{\frac{kq}{b} \quad a \leq r \leq b}$$

5. Add the potentials in the region $0 < r \leq a$:

$$V = \boxed{\frac{kq}{r} - \frac{kq}{a} + \frac{kq}{b} \quad 0 < r \leq a}$$

CHECK All potential functions must be continuous. Thus, we expect the Part (*b*) step-3 and step-4 results to be equal at $r = b$, and the Part (*b*) step 4 and step 5 results to be equal at $r = a$. This expectation is realized by the results obtained. At $r = b$ the step-3 and 4 results both equal kq/b. The same is true of the step 4 and 5 results at $r = a$.

TAKING IT FURTHER Each of the individual potential functions in step 1 of Part (*b*) has its zero-potential reference point at $r = \infty$. Thus, the sum of these functions also has its zero-potential reference point at $r = \infty$. The potential arrived at in the example can be obtained by directly evaluating $-\int_{\infty}^{P} \vec{E} \cdot d\vec{\ell} = -\int_{\infty}^{r_P} E_r \, dr$. Yet a third way to obtain the potential is by evaluating the indefinite integral $-\int E_r \, dr$ in each region to find the integration constants by matching the potential functions at the boundaries. Matching the potential functions at the boundaries is valid because the potential must be a continuous function.

Figure 23-23 shows the electric potential as a function of the distance from the center of the cavity. Inside the conducting material, where $a \le r \le b$, the potential has the constant value kq/b. Outside the shell, the potential is the same as that of a point charge q at the center of the shell. Note that $V(r)$ is continuous everywhere. The electric field is discontinuous at the conductor surfaces, as reflected in the discontinuous slope of $V(r)$ at $r = a$ and $r = b$.

Two conductors that are separated in space will typically not be at the same potential. The potential difference between such conductors depends on their geometrical shapes, their separation in space, and the net charge on each. When two conductors touch, the charge on the conductors redistributes itself so that electrostatic equilibrium is established and the electric field is zero inside both conductors. While touching, the two conductors can be considered to be a single conductor with a single potential. If we put a spherical charged conductor in contact with a second spherical conductor that is uncharged, charge will flow between them until both conductors are at the same potential. If the spherical conductors are identical, after touching they share the original charge equally. If the identical spherical conductors are now separated, each has half the original charge.

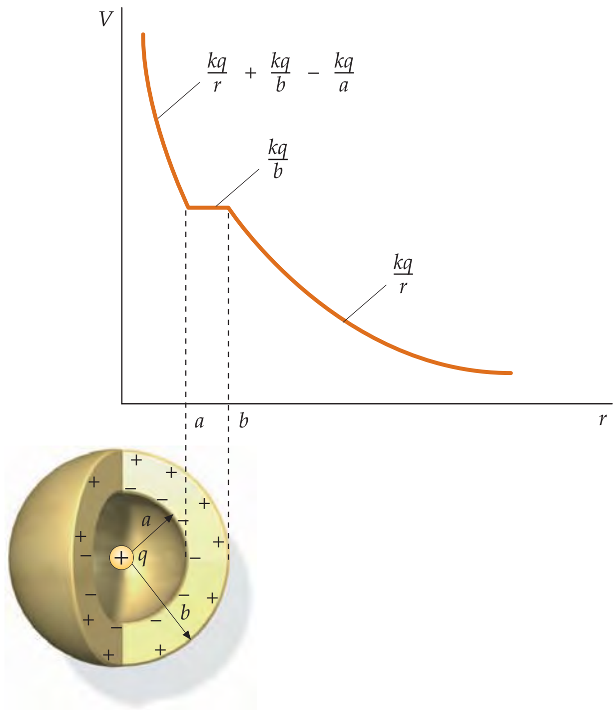

FIGURE 23-23

THE VAN DE GRAAFF GENERATOR

In Figure 23-24, a small conductor carrying a positive charge q is inside the cavity of a larger conductor. In equilibrium, the electric field is zero inside the conducting material of both conductors. The electric field lines that begin on the positive charge q must terminate on the inner surface of the large conductor. This must occur no matter what the charge may be on the outside surface of the large conductor. Regardless of the charge on the large conductor, the small conductor in the cavity is at a greater potential because the electric field lines go from this conductor to the larger conductor. If the conductors are now connected, say, with a fine conducting wire, *all* the charge originally on the smaller conductor will flow to the larger conductor. When the connection is broken, there is no charge on the small conductor in the cavity, and there are no field lines between the conductors. The positive charge transferred from the smaller conductor resides completely on the outside surface of the larger conductor. If we put more positive charge on the small conductor in the cavity and again connect the conductors with a fine wire, all of the charge on the inner conductor will again flow to the outer conductor. The procedure can be repeated indefinitely. This method is used to produce large potentials in a

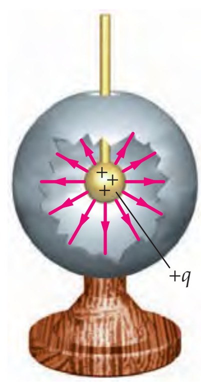

FIGURE 23-24 Small conductor that has a positive charge q inside a larger hollow conductor.

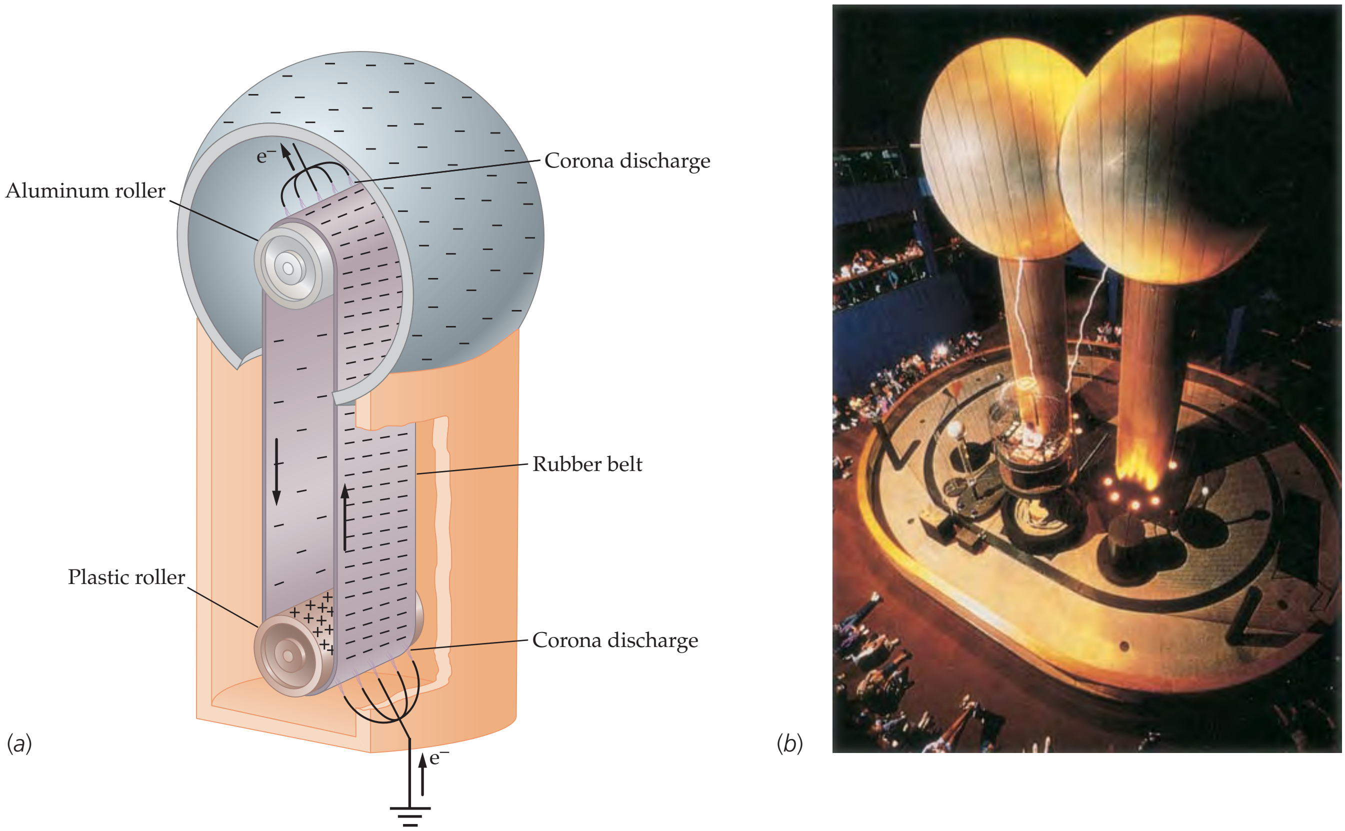

FIGURE 23-25 (*a*) Schematic diagram of a Van de Graaff generator. The lower roller becomes positively charged due to contact with the moving belt. (The inner surface of the belt acquires an equal amount of negative charge that is distributed over a larger area.) The dense positive charge on the roller attracts electrons to the tips of the lower comb where dielectric breakdown takes place and negative charge is transported to the belt via corona discharge. At the top roller the negatively charged belt repels electrons from the tips of the comb and negative charge is transferred from the belt to the comb. The charge is then transferred to the outer surface of the dome. (*b*) These large demonstration Van de Graaff generators in the Boston Science Museum are discharging to the grounded wire cage housing the operator. *((b) © Karen R. Preuss.)*

device called the *Van de Graaff generator*, in which the charge is brought to the inner surface of a larger spherical conductor by a continuous charged belt (Figure 23-25). Work must be done by the motor driving the belt to bring the charge from the bottom to the top of the belt, where the potential is very high. One can often hear the motor speed decrease as the sphere accumulates charge. The greater the charge on the outer conductor, the greater the potential of the outer conductor and the greater the electric field just outside its outer surface. A Van de Graaff accelerator is a device that uses the intense electric field produced by a Van de Graaff generator to accelerate ions and charged subatomic particles such as protons.

DIELECTRIC BREAKDOWN

Many nonconducting materials become ionized in very high electric fields and become conductors. This phenomenon, called **dielectric breakdown,** occurs in air at an electric field strength of $E_{max} \approx 3 \times 10^6$ V/m = 3 MN/C. In air, some of the existing ions are accelerated to greater kinetic energies before they collide with neighboring molecules. Dielectric breakdown occurs when these ions are accelerated to kinetic energies sufficient to result in a growth in ion concentration due to the collisions with neighboring molecules. The maximum potential that can be obtained in a Van de Graaff generator is limited by the dielectric breakdown of the air. Van de Graaff generators can achieve much higher potentials in a controlled atmosphere than they can in air at atmospheric pressure. Sulfur hexafluoride gas at several atmospheres of pressure is used when optimal performance is desired. The magnitude of the electric field for which dielectric breakdown occurs in a material is called the **dielectric strength** of that material. The dielectric strength of air is about 3 MV/m. The discharge through the conducting air resulting from dielectric breakdown is called **arc discharge.** The electric shock you receive when you touch a metal doorknob after walking across a rug on a dry day is a familiar example of arc discharge. These breakdowns occur more often on dry days because moist air can conduct the charge away before the breakdown condition is reached. Lightning is an example of arc discharge on a large scale.

Example 23-14 Dielectric Breakdown for a Charged Sphere

A spherical conductor has a radius of 30 cm (~1.0 ft). (*a*) What is the maximum charge that can be placed on the sphere before dielectric breakdown of the surrounding air occurs? (*b*) What is the maximum potential of the sphere?

PICTURE (*a*) We find the maximum charge by relating the charge to the electric field and setting the field equal to the dielectric strength of air, E_{max}. (*b*) The maximum potential is then found from the maximum charge calculated in Part (*a*).

SOLVE

(*a*) 1. The electric field at the surface of a conductor is proportional to the charge density σ on the surface of the conductor (Equation 22-21):

$$E = \frac{\sigma}{\epsilon_0} = 4\pi k\sigma$$

2. Set this field equal to E_{max}:

$$E_{max} = 4\pi k\sigma_{max}$$

3. The maximum charge Q_{max} is found from σ_{max}:

$$\sigma_{max} = \frac{\text{charge}}{\text{area}} = \frac{Q_{max}}{4\pi R^2}$$

4. Solving for Q_{max} gives:

$$Q_{max} = 4\pi R^2\sigma_{max} = 4\pi R^2\frac{E_{max}}{4\pi k} = \frac{R^2E_{max}}{k}$$

$$= \frac{(0.30\text{ m})^2(3\times10^6\text{ N/C})}{(8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)} = \boxed{3\times10^{-5}\text{ C}}$$

(*b*) Use the expression for the maximum charge to calculate the maximum potential of the sphere:

$$V_{max} = \frac{kQ_{max}}{R} = \frac{k}{R}\left(\frac{R^2E_{max}}{k}\right) = RE_{max}$$

$$= (0.30\text{ m})(3\times10^6\text{ N/C}) = \boxed{9\times10^5\text{ V}}$$

CHECK Small van de Graaff generators are commonly used in hair-raising demonstrations that must achieve a high potential. Our Part (*b*) result is certainly a high potential.

TAKING IT FURTHER The values calculated are for a Van de Graaff generator that has a 2.0-ft-diameter dome. For safety reasons, most classroom Van de Graaff generator domes have a diameter of 1.0 ft or less.

PRACTICE PROBLEM 23-9 Calculate the maximum charge and maximum potential of a Van de Graaff generator that has a 1.0-ft-diameter dome.

Example 23-15 Two Charged Spherical Conductors

Two uncharged spherical conductors of radius $R_1 = 6.0$ cm and $R_2 = 2.0$ cm (Figure 23-26) and separated by a distance much greater than 6.0 cm are connected by a long, very thin conducting wire. A total charge $Q = +80$ nC is placed on one of the spheres and the system is allowed to reach electrostatic equilibrium. (*a*) What is the charge on each sphere? (*b*) What is the electric field strength at the surface of each sphere? (*c*) What is the electric potential of each sphere? (Assume that the charge on the connecting wire is negligible.)

FIGURE 23-26

PICTURE The total charge will be distributed with Q_1 on sphere 1 and Q_2 on sphere 2 so that the spheres will be at the same potential. We can use $V = kQ/R$ for the potential of each sphere.

SOLVE

(*a*) 1. Conservation of charge gives us one relation between the charges Q_1 and Q_2:

$$Q_1 + Q_2 = Q$$

2. Equating the potential of the spheres gives us a second relation for the charges Q_1 and Q_2:

$$\frac{kQ_1}{R_1} = \frac{kQ_2}{R_2} \quad \Rightarrow \quad Q_2 = \frac{R_2}{R_1}Q_1$$

3. Combine the results from steps 1 and 2 and solve for Q_1 and Q_2:

$$Q_1 + \frac{R_1}{R_2}Q_1 = Q \qquad \text{so}$$

$$Q_1 = \frac{R_1}{R_1 + R_2}Q = \frac{6.0\text{ cm}}{8.0\text{ cm}}(80\text{ nC}) = \boxed{60\text{ nC}}$$

$$Q_2 = Q - Q_1 = \boxed{20\text{ nC}}$$

(*b*) Use these results to calculate the electric field strengths at the surface of the spheres:

$$E_1 = \frac{kQ_1}{R_1^2} = \frac{(8.99 \times 10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(60 \times 10^{-9}\text{ C})}{(0.060\text{ m})^2}$$

$$= \boxed{150\text{ kN/C}}$$

$$E_2 = \frac{kQ_2}{R_2^2} = \frac{(8.99 \times 10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(20 \times 10^{-9}\text{ C})}{(0.020\text{ m})^2}$$

$$= \boxed{450\text{ kN/C}}$$

(*c*) Calculate the common potential from kQ/R for either sphere:

$$V_1 = \frac{kQ_1}{R_1} = \frac{(8.99 \times 10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(60 \times 10^{-9}\text{ C})}{0.060\text{ m}}$$

$$= \boxed{9.0\text{ kV}}$$

CHECK If we use sphere 2 to calculate V, we obtain $V_2 = kQ_2/R_2 = (8.99 \times 10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(20 \times 10^{-9}\text{ C})/0.020\text{ m} = 9.0 \times 10^3$ V. An additional check is available, because the electric field strength at the surface of each sphere is proportional to its charge density. The radius of sphere 1 is three times the radius of sphere 2, so its surface area is nine times the surface area of sphere 2. And because sphere 1 has three times the charge, its charge density is one-third the charge density of sphere 2. Therefore, the electric field strength at the surface of sphere 1 should be one-third of the electric field strength at the surface of sphere 2, which is what we found in Part (*b*).

TAKING IT FURTHER The presence of the long, very thin wire connecting the spheres makes the result of this example only approximate because the potential function $V = kQ/r$ is valid for the region outside an isolated conducting sphere. With the wire in place the spheres cannot accurately be modeled as isolated spheres.

When a charge is placed on a conductor of nonspherical shape, like that in Figure 23-27*a*, the surface of the conductor will be an equipotential surface, but the surface charge density and the electric field just outside the conductor will vary from point to point. Near a point where the radius of curvature is small, such as point A in the figure, the surface charge density and electric field will be large, whereas near a point where the radius of curvature is large, such as point B in the figure, the field and surface charge density will be small. We can understand this qualitatively by considering the ends of the conductor to be spheres of different radii. Let σ be the surface charge density.

The potential of a sphere of radius R is

$$V = \frac{kq}{R} = \frac{1}{4\pi\epsilon_0}\frac{Q}{R} \qquad \text{23-24}$$

Because the area of a sphere is $4\pi R^2$, the charge on a sphere is related to the charge density by $Q = 4\pi R^2\sigma$. Substituting this expression for Q into Equation 23-24 we have

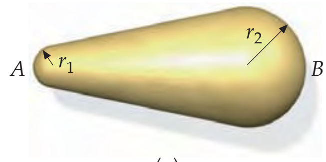
$$V = \frac{1}{4\pi\epsilon_0}\frac{4\pi R^2\sigma}{R} = \frac{R\sigma}{\epsilon_0}$$

Solving for σ, we obtain

$$\sigma = \frac{\epsilon_0 V}{R} \qquad \text{23-25}$$

Because both *spheres* are at the same potential, the sphere that has the smaller radius must have the greater surface charge density. And because $E = \sigma/\epsilon_0$ at the surface of a conductor, the electric field strength is greatest at points on the conductor where the radius of curvature is least.

For an arbitrarily shaped conductor, the potential at which dielectric breakdown occurs depends on the smallest radius of curvature of any part of the conductor. If the conductor has sharp points of very small radius of curvature, dielectric breakdown will occur at relatively low potentials. In the Van de Graaff generator (see Figure 23-25*a*), the charge is transferred onto the belt by sharp-edged conductors near the bottom of the belt. The charge is removed from the belt by sharp-edged conductors near the top of the belt.



(*a*)

(*b*)

FIGURE 23-27 (*a*) A nonspherical conductor. If a charge is placed on such a conductor, it will produce an electric field that is stronger near point A, where the radius of curvature is small, than near point B, where the radius of curvature is large. (*b*) Electric field lines near a nonspherical conductor and plate that have equal and opposite charges. The lines are shown by small bits of thread suspended in oil. Note that the electric field is strongest near points of small radius of curvature, such as at the ends of the plate and at the pointed left side of the conductor. The equipotential surfaces are more closely spaced where the field strength is greater. *((b) Harold M. Waage.)*

23-6 ELECTROSTATIC POTENTIAL ENERGY

Objects that repel each other have more potential energy if they are close together, and objects that attract each other have more potential energy if they are far apart. Suppose there is a point charge q_1 at point 1. To bring a second point charge q_2 from rest at infinity to rest at point 2, a distance r_{12} from point 1, requires that we do work:

$$W_2 = q_2V_2 = q_2\frac{kq_1}{r_{12}} = \frac{kq_2q_1}{r_{12}}$$

where V_2 is the potential at point 2 due to the presence of charge q_1. (It follows that the potential energy of these two point charges is the negative of this work value.)

$$V_2 = \frac{kq_1}{r_{12}}$$

The potential at point 3, a distance r_{13} from q_1 and a distance r_{23} from q_2, is given by

$$V_3 = \frac{kq_1}{r_{13}} + \frac{kq_2}{r_{23}}$$

so to bring in an additional point charge q_3 from rest at infinity to rest at point 3 requires that we do the additional work:

$$W_3 = q_3V_3 = \frac{kq_3q_1}{r_{13}} + \frac{kq_3q_2}{r_{23}}$$

The total work required to assemble the three charges is the **electrostatic potential energy** U of the system of three point charges:

$$U = \frac{kq_2q_1}{r_{12}} + \frac{kq_3q_1}{r_{13}} + \frac{kq_3q_2}{r_{23}} \qquad 23\text{-}26$$

This quantity of work is independent of the order in which the charges are brought to their final positions. In general,

> The electrostatic potential energy of a system of point charges is the work needed to bring the charges from an infinite separation to their final positions.
>
> ELECTROSTATIC POTENTIAL ENERGY OF A SYSTEM

The first two terms on the right-hand side of Equation 23-26 can be written

$$\frac{kq_2q_1}{r_{12}} + \frac{kq_3q_1}{r_{13}} = q_1\left(\frac{kq_2}{r_{12}} + \frac{kq_3}{r_{13}}\right) = q_1V_1$$

where V_1 is the potential at the location of q_1 due to charges q_2 and q_3. Similarly, the second and third terms represent the charge q_3 multiplied by the potential due to charges q_1 and q_2, and the first and third terms equal the charge q_2 multiplied by the potential due to charges q_1 and q_2. We can thus rewrite Equation 23-26 as

$$\begin{aligned}
U &= \frac{1}{2}U + \frac{1}{2}U \\
&= \frac{1}{2}\left(\frac{kq_2q_1}{r_{12}} + \frac{kq_3q_1}{r_{13}} + \frac{kq_3q_2}{r_{23}}\right) + \frac{1}{2}\left(\frac{kq_2q_1}{r_{12}} + \frac{kq_3q_1}{r_{13}} + \frac{kq_3q_2}{r_{23}}\right) \\
&= \frac{1}{2}q_1\left(\frac{kq_2}{r_{12}} + \frac{kq_3}{r_{13}}\right) + \frac{1}{2}q_2\left(\frac{kq_3}{r_{23}} + \frac{kq_1}{r_{12}}\right) + \frac{1}{2}q_3\left(\frac{kq_1}{r_{13}} + \frac{kq_2}{r_{23}}\right) \\
&= \frac{1}{2}(q_1V_1 + q_2V_2 + q_3V_3)
\end{aligned}$$

The electrostatic potential energy U of a system of n point charges is thus

$$U = \frac{1}{2}\sum_{i=1}^{n} q_iV_i \qquad 23\text{-}27$$

ELECTROSTATIC POTENTIAL ENERGY OF A SYSTEM OF POINT CHARGES where V_i is the potential at the location of the ith charge due to the presence of all the other charges in the system.

Equation 23-27 can also describe the electrostatic potential energy of a continuous charge distribution. Consider a spherical conductor of radius R. When the sphere carries a charge q, its potential relative to $V = 0$ at infinity is

$$V = \frac{kq}{R}$$

The work we must do to bring an additional amount of charge dq from infinity to the conductor is $V\,dq$. This work equals the increase in the potential energy of the conductor:

$$dU = V\,dq = \frac{kq}{R}\,dq$$

The total potential energy U is the integral of dU as q increases from zero to its final value Q. Integrating, we obtain

Hearts reach a state called ventricular fibrillation in about two-thirds of people that experience cardiac arrest. In this state, a heart quivers, spasms chaotically, and does not pump. To take a heart out of this state, a significant current is passed through the heart. Then the pacemaker cells in the heart can again establish a regular heartbeat. An external defibrillator applies a large voltage across the chest. *(© Steve Allen/The Image Bank/Getty Images.)*

$$U = \frac{k}{R}\int_0^Q q\,dq = \frac{kQ^2}{2R} = \frac{1}{2}QV \qquad \text{23-28}$$

where $V = kQ/R$ is the potential on the surface of the fully charged sphere. We can interpret Equation 23-28 as $U = Q \times \frac{1}{2}V$ where $\frac{1}{2}V$ is the average potential of the spherical conductor during the charging process. During the charging process, bringing the first element of charge in from infinity to the uncharged sphere requires no work because the charge being brought in is not being repelled by the charge already on the sphere. As the charge on the sphere accumulates, bringing in each additional element of charge to the sphere requires additional work; when the sphere is almost fully charged, bringing the last element of charge in against the repulsive force of the charge on the sphere requires the most work.* The average potential of the sphere during the charging process is one-half its final potential V, so the total work required to bring in the entire charge Q equals $\frac{1}{2}QV$.

Alternatively, if we set $V_i = V$ and $Q = \sum_i q_i$, Equation 23-27 becomes Equation 23-28. We can think of the charge on the uniformly charged spherical shell as a collection of infinitesimal point charges—all at the same potential V. Thus, Equation 23-27 leads directly Equation 23-28.

Although we derived Equation 23-28 for a spherical conductor, it holds for any conductor. The potential of any conductor is proportional to its charge q, so we can write $V = \alpha q$, where α is a proportionality constant. The work needed to bring an additional charge dq from infinity to the conductor is $V\,dq = \alpha q\,dq$, so the total work needed to put a charge Q on the conductor is $\frac{1}{2}\alpha Q^2 = \frac{1}{2}QV$. If we have a set of n conductors with the ith conductor at potential V_i and carrying a charge Q_i, the electrostatic potential energy is

$$U = \frac{1}{2}\sum_{i=1}^{n} Q_i V_i \qquad \text{23-29}$$

ELECTROSTATIC POTENTIAL ENERGY OF A SYSTEM OF CONDUCTORS

* We are assuming that each element of charge is the same size.

Example 23-16 Work Required to Move Point Charges

Four identical positive point charges, each having charge q, are initially at rest at infinite separation. (*a*) Calculate the total work required to move the point charges to the four corners of the square of edge length a by separately calculating the work required to sequentially move each charge to its final position. (*b*) Show that Equation 23-27 gives the total work.

PICTURE Move the charges to the corners of the square sequentially. No work is needed to move the first charge to a corner because the potential at the corner is zero when the other three charges are at infinity. As each additional charge is moved to a corner, work must be done because of the repulsive forces of the previous placed charges.

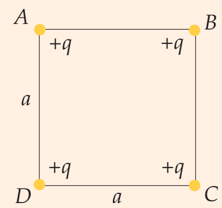


FIGURE 23-28

SOLVE

(*a*) 1. Sketch the square and label the corners A, B, C, and D (Figure 23-28):

2. Place the first charge at point A. To accomplish this step, the work W_A that is needed is zero:

$$W_A = 0 \qquad x > 0$$

3. Bring the second charge to point B. The work required is $W_B = qV_A$, where V_A is the potential at point B due to the first charge at point A a distance a from it:

$$W_B = qV_A = q\left(\frac{kq}{a}\right) = \frac{kq^2}{a}$$

4. $W_C = qV_C$, where V_C is the potential at point C due to q at point A, a distance $\sqrt{2}a$ away, and q at point B, a distance a from it:

$$W_C = qV_C = q\left(\frac{kq}{a} + \frac{kq}{\sqrt{2}a}\right) = \left(1 + \frac{1}{\sqrt{2}}\right)\frac{kq^2}{a}$$

5. Similar considerations give W_D, the work needed to bring the fourth charge to point D:

$$W_D = qV_D = q\left(\frac{kq}{a} + \frac{kq}{\sqrt{2}a} + \frac{kq}{a}\right) = \left(2 + \frac{1}{\sqrt{2}}\right)\frac{kq^2}{a}$$

6. Summing the individual contributions gives the total work required to assemble the four charges:

$$W_{\text{total}} = W_A + W_B + W_C + W_D = \boxed{(4 + \sqrt{2})\frac{kq^2}{a}}$$

(*b*) 1. Calculate W_{total} from Equation 23-27. Use V_D from step 5 of Part (*a*) for the potential V_i at the location of each charge:

$$W_{\text{total}} = U = \frac{1}{2}\sum_{i=1}^{4} q_i V_i$$

where $V_1 = V_2 = V_3 = V_4 = V_D$ and $q_1 = q_2 = q_3 = q_4 = q$

2. The potential at the location of each charge is V_D. Substitute V_D and q for V_i and q_i, respectively, and solve for W_{total}:

$$W_{\text{total}} = \frac{1}{2}\sum_{i=1}^{4} q_i V_i = \frac{1}{2}\sum_{i=1}^{4} qV_D = \frac{1}{2}qV_D\sum_{i=1}^{4} 1$$

$$= \frac{1}{2}qV_D 4 = 2q\left(2 + \frac{1}{\sqrt{2}}\right)\frac{kq}{a}$$

$$= \boxed{(4 + \sqrt{2})\frac{kq^2}{a}}$$

CHECK Parts (*a*) and (*b*) have identical results.

TAKING IT FURTHER W_{total} equals the total electrostatic energy of the charge distribution. It is the work an external agent must do to assemble the configuration, beginning with the four charges at infinite separation.

PRACTICE PROBLEM 23-10 (*a*) How much additional work is required to bring a fifth positive charge q from infinity to the center of the square? (*b*) What is the total work required to assemble the five-charge system?

Physics Spotlight

Lightning—Fields of Attraction

A bolt of lightning strikes near an airport terminal. *(Tom Fox/Dallas Morning News/Corbis.)*

Scientists have observed and analyzed lightning for more than 100 years. In recent years, high-speed digital recording,[*] low-light television cameras,[†] and satellites that have synchronized clocks[‡] have given atmospheric scientists new information about the events that occur with a bolt of cloud-to-ground, or CG, lightning.

Thunderstorm clouds have layers of positive and negative charges and act like enormous, very powerful dipoles. CG lightning is usually negative charge from the lower part of a cloud that travels to the ground by ionization of the air. This charge is often "stepped" through the air with several pauses on the order of milliseconds. The visible bolt is a return positive *stroke* following the ionized path back up from the ground. Most flashes are 3 to 10 strokes back and forth between cloud and ground, several milliseconds apart. The strokes follow the initial path, as it already consists of ionized and heated air, and usually transfer a total negative charge of 20-35 C.[#] CG lightning strikes carrying negative charge to ground have been recorded with more than 1 million volts of potential difference.[°]

Some extremely powerful CG lightning strokes that carry positive charge to ground have transferred total positive charges of up to 400 C,[§] and have been recorded with over 10 million volts of potential. In large supercell thunderstorms that have hail and tornadoes,[¶,**] a majority of CG lightning strokes carry positive charge from the tops of the clouds to the ground rather than carry negative charge from the lower middle of the clouds to the ground. This lightning is associated with strong bursts of energy radiated near the start of the lightning and with brief bursts of light many kilometers above the cloud tops shortly after the strokes.[††]

But very strong bursts of radiated energy have been observed microseconds before less powerful negative lightning.[‡‡,##,°°,§§] Some bursts of energy repeat, detectable by satellite for up to nearly an hour after a lightning strike. Although the bursts last less than a millisecond, they are so energetic that they are associated with radio noise detected as far away as the opposite hemisphere of the planet.[¶¶]

Because high-energy electromagnetic radiation has repeatedly been measured in association with lightning, scientists are coming up with new models about how lightning is formed. One possible model involves "runaway breakdown." Because electric fields associated with thunderstorms are very large, it might be possible for a stray electron or ion to be accelerated by the electric field of a thunderstorm to approach the speed of light.[***] At that speed, the electron would be so energetic that colliding with molecules in the cloud would not halt it, even as it ionized those molecules. The ions could then be further accelerated by the electric field within the storm to produce a shower, or burst, of energy. Many scientists feel that runaway breakdown explains the formation of CG lightning in clouds that have measured electric fields ten times lower than the required potential needed to overcome air's insulating ability.[†††]

Because the technology to detect and to time the energy bursts in relation to lightning flashes is recent, scientists are now developing ways to confirm or refute these new models. The study of lightning is a very attractive field with great potential.

Summary

1. Electric potential at a location, which is defined as the electric potential energy per unit charge that a test charge would have at that location, is an important derived physical concept that is related to the electric field.
2. Because potential is a scalar quantity, it is often easier to calculate than the electric field. Once V is known, $\vec{E}$ can be calculated from V.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Potential Difference	The potential difference $V_b - V_a$ is defined as the negative of the work per unit charge done by the electric field on a test charge as it moves from point a to point b: $$\Delta V = V_b - V_a = \frac{\Delta U}{q_0} = -\int_a^b \vec{E} \cdot d\vec{\ell}$$	23-2*b*
Potential difference for infinitesimal displacements	$$dV = -\vec{E} \cdot d\vec{\ell}$$	23-2*a*
2. Electric Potential		
Potential due to a point charge	$$V = \frac{kq}{r} - \frac{kq}{r_{ref}} \qquad (V = 0 \text{ if } r = r_{ref})$$	23-7
Coulomb potential	$$V = \frac{kq}{r} \qquad (V = 0 \text{ if } r = \infty)$$	23-8
Potential due to a system of point charges	$$V = \sum_i \frac{kq_i}{r_i} \qquad (V = 0 \text{ if } r_i = \infty, i = 1, 2, \ldots)$$	23-10
Potential due to a continuous charge distribution	$$V = \int \frac{k\,dq}{r} \qquad (V = 0 \text{ if } r = \infty)$$ where dq is an increment of charge and r is the distance from the increment to the field point. This expression can be used only if the charge distribution is contained in a finite volume so that the potential can be chosen to be zero at infinity.	23-18
Continuity of electric potential	The potential function V is continuous everywhere in space.	
3. Computing the Electric Field from the Potential	The electric field points in the direction of the most rapid decrease in the potential.	
	The change in potential when a test charge undergoes a displacement $d\vec{\ell}$ is given by $$E_{tan} = -\frac{dV}{d\ell}$$	23-12
Gradient	A vector that points in the direction of the greatest rate of change in a scalar function and that has a magnitude equal to the derivative of that function, with respect to the distance in that direction, is called the gradient of the function. $\vec{E}$ is the negative gradient of V.	
Potential a function of x alone	$$E_x = -\frac{dV(x)}{dx}$$	23-13
Potential a function of r alone	$$E_r = -\frac{dV(r)}{dr}$$	23-14
4. *General Relation between $\vec{E}$ and V	$$\vec{E} = -\vec{\nabla}V = -\left(\frac{\partial V}{\partial x}\hat{i} + \frac{\partial V}{\partial y}\hat{j} + \frac{\partial V}{\partial z}\hat{k}\right)$$ or $$V_b - V_a = -\int_a^b \vec{E} \cdot d\vec{\ell}$$	23-17

TOPIC	RELEVANT EQUATIONS AND REMARKS	
5. Units		
V and ΔV	The SI unit of potential and potential difference is the volt (V): $$1\text{ V} = 1\text{ J/C}$$	23-4
Electric field	$$1\text{ N/C} = 1\text{ V/m}$$	23-5
Electron volt	The electron volt (eV) is the change in potential energy of a particle of charge e as it moves from a to b, where $V_b - V_a = 1$ volt: $$1\text{ eV} = 1.60 \times 10^{-19}\text{ C}\cdot\text{V} = 1.60 \times 10^{-19}\text{ J}$$	23-6
6. Potential Energy of Two Point Charges	$$U = q_0 V = \frac{kq_0 q}{r} \qquad (U = 0 \text{ if } r = \infty)$$	23-9
7. Potential Functions		
On the axis of a uniformly charged ring	$$V = \frac{kQ}{\sqrt{z^2 + a^2}} \qquad (V = 0 \text{ if } \lvert z\rvert = \infty)$$	23-19
On the axis of a uniformly charged disk	$$V = 2\pi k\sigma\lvert z\rvert\left(\sqrt{1 + \frac{R^2}{z^2}} - 1\right) \qquad (V = 0 \text{ if } \lvert z\rvert = \infty)$$	23-20
For an infinite plane of charge	$$V = V_0 - 2\pi k\sigma\lvert x\rvert \qquad (V = V_0 \text{ if } x = 0)$$	23-21
For a spherical shell of charge	$$V = \begin{cases} \dfrac{kQ}{r} & r \geq R \\ \dfrac{kQ}{R} & r \leq R \end{cases} \qquad (V = 0 \text{ if } r = \infty)$$	23-22
For an infinite line charge	$$V = 2k\lambda \ln\frac{R_{\text{ref}}}{R} \qquad (V = 0 \text{ if } r = R_{\text{ref}})$$	23-23
8. Charge on a Nonspherical Conductor	On a conductor of arbitrary shape, the surface charge density σ is greatest at points where the radius of curvature is smallest.	
9. Dielectric Breakdown	The amount of charge that can be placed on a conductor is limited by the fact that molecules of the surrounding medium undergo dielectric breakdown at very high electric fields, causing the medium to become a conductor.	
Dielectric strength	The dielectric strength is the magnitude of the electric field at which dielectric breakdown occurs. The dielectric strength of dry air is $$E_{\text{max}} \approx 3 \times 10^6\text{ V/m} = 3\text{ MV/m}$$	
10. Electrostatic Potential Energy	The electrostatic potential energy of a system of point charges is the work needed to bring the charges from an infinite separation to their final positions.	
Of point charges	$$U = \frac{1}{2}\sum_{i=1}^{n} q_i V_i$$	23-27
Of a conductor with charge Q at potential V	$$U = \tfrac{1}{2}QV$$	23-28
Of a system of conductors	$$U = \frac{1}{2}\sum_{i=1}^{n} Q_i V_i$$	23-29

Answers to Concept Checks

23-1 The change in potential is zero if you move in a direction perpendicular to the direction of $\vec{E}$.

23-2 The potential increases at the greatest rate with respect to distance if you move in the direction opposite to the direction of $\vec{E}$.

Answers to Practice Problems

23-1 Increasing potential

23-2 $V(x) = -(5\ \mathrm{V/m^2})x^2$

23-3 -4.35×10^{-18} J

23-4 (*a*) the $x = 4.0$ m plane, (*b*) $V = -(25\ \mathrm{V/m})x$

23-5 3.7×10^{-6} J

23-6 $V = \operatorname{sign}(z) \cdot 2\pi k\sigma\left(1 - \dfrac{1}{\sqrt{1 + (R^2/z^2)}}\right)$

23-7 $5.39 \times 10^5\ V = 539$ kV

23-8 $V(r) = kQ/r - kQ/R$ for $r \geq R$;

$V(r) = \frac{1}{2}(kQ/R)(1 - r^2/R^2)$ for $r \leq R$

23-9 7.5×10^{-6} C, 4.4×10^5 V

23-10 (*a*) $4\sqrt{2}kq^2/a$, (*b*) $(4 + 5\sqrt{2})kq^2/a$

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • A proton is moved to the left in a uniform electric field that points to the right. Is the proton moving in the direction of increasing or decreasing electric potential? Is the electrostatic potential energy of the proton increasing or decreasing? SSM

2 • An electron is moved to the left in a uniform electric field that points to the right. Is the electron moving in the direction of increasing or decreasing electric potential? Is the electrostatic potential energy of the electron increasing or decreasing?

3 • If the electric potential is uniform throughout a region of space, what can be said about the electric field in that region?

4 • If V is known at only a single point in space, can $\vec{E}$ be found at that point? Explain your answer.

5 •• Figure 23-29 shows a point particle that has a positive charge $+Q$ and a metal sphere that has a charge $-Q$. Sketch the electric field lines and equipotential surfaces for this system of charges. SSM

FIGURE 23-29
Problem 5

6 •• Figure 23-30 shows a point particle that has a negative charge $-Q$ and a metal sphere that has a charge $+Q$. Sketch the electric field lines and equipotential surfaces for this system of charges.

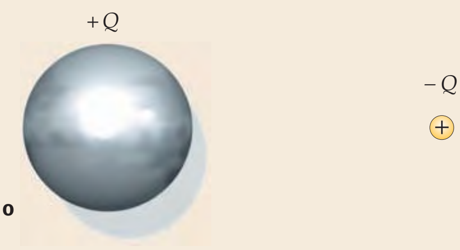

FIGURE 23-30
Problem 6

7 •• Sketch the electric field lines and equipotential surfaces for the region surrounding the charged conductor shown in Figure 23-31, assuming that the conductor has a net positive charge.

FIGURE 23-31
Problem 7

8 •• Two equal positive point charges are separated by a finite distance. Sketch the electric field lines and the equipotential surfaces for this system.

9 •• Two point charges are fixed on the x axis. (*a*) Each has a positive charge q. One is at $x = -a$ and the other is at $x = +a$. At the origin, which of the following is true?
(1) $\vec{E} = 0$ and $V = 0$
(2) $\vec{E} = 0$ and $V = 2kq/a$
(3) $\vec{E} = (2kq/a^2)\hat{i}$ and $V = 0$
(4) $\vec{E} = (2kq/a^2)\hat{i}$ and $V = 2kq/a$
(5) None of the above

(*b*) One point charge has a positive charge $+q$ and the other has a negative charge $-q$. The positive point charge is at $x = -a$ and the negative point charge is at $x = +a$. At the origin, which of the following is true?
(1) $\vec{E} = 0$ and $V = 0$
(2) $\vec{E} = 0$ and $V = 2kq/a$
(3) $\vec{E} = (2kq/a^2)\hat{i}$ and $V = 0$
(4) $\vec{E} = (2kq/a^2)\hat{i}$ and $V = 2kq/a$
(5) None of the above

10 •• The electrostatic potential (in volts) is given by $V(x, y, z) = 4.00|x| + V_0$, where V_0 is a constant, and x is in meters. (*a*) Sketch the electric field for this potential. (*b*) Which of the following charge distributions is most likely responsible for this potential: (1) A negatively charged flat sheet in the $x = 0$ plane, (2) a point charge at the origin, (3) a positively charged flat sheet in the $x = 0$ plane, or (4) a uniformly charged sphere centered at the origin? Explain your answer.

11 •• The electric potential is the same everywhere on the surface of a conductor. Does this mean that the surface charge density is also the same everywhere on the surface? Explain your answer. SSM

12 •• Three identical positive point charges are located at the vertices of an equilateral triangle. If the length of each side of the triangle shrinks to one-fourth of its original length, by what factor does the electrostatic potential energy of this system change? (The electrostatic potential energy approaches zero if the length of each side of the triangle approaches infinity.)

ESTIMATION AND APPROXIMATION

13 • Estimate the maximum potential difference between a thundercloud and Earth, given that the electrical breakdown of air occurs at fields of roughly 3.0×10^6 V/m. SSM

14 • The specifications for the gap width of typical automotive spark plugs is approximately equal to the thickness of the cardboard used for matchbook covers. Because of the high compression of the air–gas mixture in the cylinder, the dielectric strength of the mixture is roughly 2.0×10^7 V/m. Estimate the maximum potential difference across the spark gap during operating conditions.

15 • The radius of a proton is approximately 1.0×10^{-15} m. Suppose two protons having equal and opposite momenta undergo a head-on collision. Estimate the minimum kinetic energy (in MeV) required by each proton to allow the protons to overcome electrostatic repulsion and collide. *Hint: The rest energy of a proton is 938 MeV. If the kinetic energies of the protons are much less than this rest energy, then a nonrelativistic calculation is justified.*

16 • When you touch a friend after walking across a rug on a dry day, you typically draw a spark of about 2.0 mm. Estimate the potential difference between you and your friend just before the spark.

17 • Estimate the maximum surface charge density that can exist at the end of a sharp lightning rod so that no dielectric breakdown of air occurs.

18 •• The electric field strength near the surface of Earth is about 300 V/m. (*a*) Estimate the magnitude of the charge density on the surface of Earth. (*b*) Estimate the total charge on Earth. (*c*) What is value of the electric potential at Earth's surface? (Assume the potential is zero at infinity.) (*d*) If all Earth's electrostatic potential energy could be harnessed and converted to electric energy at reasonable efficiency, how long could it be used to run the consumer households in the United States? Assume the average American household consumes about 500 kW·h of electric energy per month.

ELECTROSTATIC POTENTIAL DIFFERENCE, ELECTROSTATIC ENERGY, AND ELECTRIC FIELD

19 • A point particle has a charge equal to $+2.00$ μC and is fixed at the origin. (*a*) What is the electric potential V at a point 4.00 m from the origin assuming that $V = 0$ at infinity? (*b*) How much work must be done to bring a second point particle that has a charge of $+3.00$ μC from infinity to a distance of 4.00 m from the $+2.00$-μC charge?

20 •• The facing surfaces of two large parallel conducting plates separated by 10.0 cm have uniform surface charge densities that are equal in magnitude but opposite in sign. The difference in potential between the plates is 500 V. (*a*) Is the positive plate or the negative plate at the higher potential? (*b*) What is the magnitude of the electric field between the plates? (*c*) An electron is released from rest next to the negatively charged surface. Find the work done by the electric field on the electron as the electron moves from the release point to the positive plate. Express your answer in both electron volts and joules. (*d*) What is the change in potential energy of the electron when it moves from the release point to the positive plate? (*e*) What is its kinetic energy when it reaches the positive plate?

21 •• A uniform electric field has a magnitude 2.00 kV/m and points in the $+x$ direction. (*a*) What is the electric potential difference between the $x = 0.00$ m plane and the $x = 4.00$ m plane? A point particle that has a charge of $+3.00$ μC is released from rest at the origin. (*b*) What is the change in the electric potential energy of the particle as it travels from the $x = 0.00$ m plane to the $x = 4.00$ m plane? (*c*) What is the kinetic energy of the particle when it arrives at the $x = 4.00$ m plane? (*d*) Find the expression for the electric potential $V(x)$ if its value is chosen to be zero at $x = 0$.

22 •• In a potassium chloride unit, the distance between the potassium ion (K^+) and the chloride ion (Cl^-) is 2.80×10^{-10} m. (*a*) Calculate the energy (in eV) required to separate the two ions to an infinite distance apart. (Model the two ions as two point particles initially at rest.) (*b*) If twice the energy determined in Part (*a*) is actually supplied, what is the total amount of kinetic energy that the two ions have when they were an infinite distance apart?

23 •• Protons are released from rest in a Van de Graaff accelerator system. The protons initially are located where the electric potential has a value of 5.00 MV and then they travel through a vacuum to a region where the potential is zero. (*a*) Find the final speed of these protons. (*b*) Find the accelerating electric field strength if the potential changed *uniformly* over a distance of 2.00 m. SSM

24 •• The picture tube of a television set was, until recently, invariably a cathode-ray tube. In a typical cathode-ray tube, an electron "gun" arrangement is used to accelerate electrons from rest to the screen. The electrons are accelerated through a potential difference of 30.0 kV. (*a*) Which region is at a higher electric potential, the screen or the electron's starting location? Explain your answer. (*b*) What is the kinetic energy (in both eV and J) of an electron as it reaches the screen?

25 ••• (*a*) A positively charged particle is on a trajectory to collide head-on with a massive positively charged nucleus that is initially at rest. The particle initially has kinetic energy K_i. In addition, the particle is initially far from the nucleus. Derive an expression for the distance of closest approach. Your expression should be in terms of the initial kinetic energy K_i of the particle, the charge ze on the particle, and the charge Ze on the nucleus, where both z and Z are integers. (*b*) Find the numerical value for the distance of closest approach between a 5.00-MeV α particle and a stationary gold nucleus and between a 9.00-MeV α particle and a stationary gold nucleus. (The values 5.00 MeV and 9.00 MeV are the initial kinetic energies of the alpha particles. Neglect the motion of the gold nucleus following the collisions.) (*c*) The radius of the gold nucleus is about 7×10^{-15} m. If α particles approach the nucleus closer than 7×10^{-15} m, they experience the strong nuclear force in addition to the electric force of repulsion. In the early twentieth century, before the strong nuclear force was known, Ernest Rutherford bombarded gold nuclei with α particles that had kinetic energies of about 5 MeV. Would you expect this experiment to reveal the existence of this strong nuclear force? Explain your answer.

POTENTIAL DUE TO A SYSTEM OF POINT CHARGES

***Note:* In all the problems in this section, assume that the electric potential is zero at distances far from all charges unless otherwise stated.**

26 • Four point charges, each having a magnitude of 2.00 μC, are fixed at the corners of a square whose edges are 4.00 m long. Find the electric potential at the center of the square if (*a*) all the charges are positive, (*b*) three of the charges are positive and one charge is negative, and (*c*) two charges are positive and two charges are negative. (Assume the potential is zero very far from all charges.)

27 • Three point charges are fixed at locations on the x axis: q_1 is at $x = 0.00$ m, q_2 is at $x = 3.00$ m, and q_3 is at $x = 6.00$ m. Find the electric potential at the point on the y axis at $y = 3.00$ m if (a) $q_1 = q_2 = q_3 = +2.00\ \mu$C, (b) $q_1 = q_2 = +2.00\ \mu$C and $q_3 = -2.00\ \mu$C, and (c) $q_1 = q_3 = +2.00\ \mu$C and $q_2 = -2.00\ \mu$C. (Assume the potential is zero very far from all charges.) SSM

28 • Points A, B, and C are fixed at the vertices of an equilateral triangle whose edges are 3.00 m long. A point particle that has a charge of +2.00 μC is fixed at each of vertices A and B. (a) What is the electric potential at point C? (Assume the potential is zero very far from all charges.) (b) How much work is required to move a point particle having a charge of +5.00 μC from a distance of infinity to point C? (c) How much additional work is required to move the +5.00-μC point particle from point C to the midpoint of side AB?

29 •• Three identical point particles that have charge q are at the vertices of an equilateral triangle that is circumscribed by a circle of radius a that lies in the $z = 0$ plane and is centered at the origin. The values of q and a are +3.00 μC and 60.0 cm, respectively. (Assume the potential is zero very far from all charges.) (*a*) What is the electric potential at the origin? (*b*) What is the electric potential at the point on the z axis at $z = a$? (*c*) How would your answers to Parts (*a*) and (*b*) change if the charges were still on the circle but one is no longer at a vertex of the triangle? Explain your answer.

30 •• Two point charges q and q' are separated by a distance a. At a point $a/3$ from q and along the line joining the two charges the potential is zero. (Assume the potential is zero very far from all charges.) (*a*) Which of the following statements is true?
(1) The charges have the same sign.
(2) The charges have opposite signs.
(3) The relative signs of the charges cannot be determined by using the data given.

(*b*) Which of the following statements is true?
(1) $|q| > |q'|$.
(2) $|q| < |q'|$.
(3) $|q| = |q'|$.
(4) The relative magnitudes of the charges cannot be determined by using the data given.

(*c*) Find the ratio q/q'.

31 •• Two identical positively charged point particles are fixed on the x axis at $x = +a$ and $x = -a$. (*a*) Write an expression for the electric potential $V(x)$ as a function of x for all points on the x axis. (*b*) Sketch $V(x)$ versus x for all points on the x axis. SSM

32 •• A point charge of $+3e$ is at the origin and a second point charge of $-2e$ is on the x axis at $x = a$. (*a*) Sketch the potential function $V(x)$ versus x for all points on the x axis. (*b*) At what point or points, if any, is $V = 0$ on the x axis? (*c*) At what point or points, if any, on the x axis is the electric field zero? Are these locations the same locations found in Part (*b*) ? Explain your answer. (*d*) How much work is needed to bring a third charge $+e$ to the point $x = \frac{1}{2}a$ on the x axis?

33 ••• A dipole consists of equal but opposite point charges $+q$ and $-q$. It is located so that its center is at the origin, and its axis is aligned with the z axis (Figure 23-32). The distance between the charges is L. Let $\vec{r}$ be the vector from the origin to an arbitrary field point and θ be the angle that $\vec{r}$ makes with the $+z$ direction. (*a*) Show that at large distances from the dipole (i.e., for $r \gg L$), the dipole's electric potential is given by $V(r, \theta) \approx k\vec{p} \cdot \hat{r}/r^2 = kp\cos\theta/r^2$, where $\vec{p}$ is the dipole moment of the dipole and θ is the angle between $\vec{r}$ and $\vec{p}$. (*b*) At what points in the region $r \gg L$, other than at infinity, is the electric potential zero? SSM

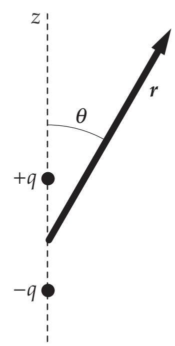

FIGURE 23-32 Problem 33

34 ••• A charge configuration consists of three point charges located on the z axis (Figure 23-33). One has a charge equal to $-2q$, and is located at the origin. The other two each have a charge equal to $+q$, one is located at $z = +L$ and the other is located at $z = -L$. This charge configuration can be modeled as two dipoles: one centered at $z = +L/2$ and with a dipole moment in the $+z$ direction, the other centered at $z = -L/2$ and with a dipole moment in the $-z$ direction. Each of these dipoles has a dipole moment that has a magnitude equal to qL. Two dipoles arranged in this fashion form a *linear electric quadrupole*. (There are other geometrical arrangements of dipoles that create quadrupoles but they are not linear.) (*a*) Using the result from Problem 33, show that at large distances from the quadrupole (i.e., for $r \gg L$), the electric potential is given by $V_{quad}(r, \theta) = 2kB\cos^2\theta/r^3$, where $B = qL^2$. (B is the magnitude of the quadrupole moment of the charge configuration.) (*b*) Show that on the positive z axis, this potential gives an electric field (for $z \gg L$) of $\vec{E} = (6kB/z^4)\hat{k}$. (*c*) Show you get the result of Part (*b*) by adding the electric fields from the three point charges.

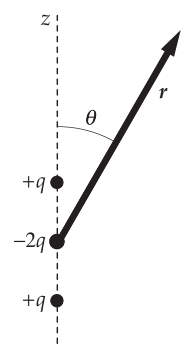

FIGURE 23-33 Problem 34

COMPUTING THE ELECTRIC FIELD FROM THE POTENTIAL

35 • A uniform electric field is in the $-x$ direction. Points a and b are on the x axis, with a at $x = 2.00$ m and b at $x = 6.00$ m. (*a*) Is the potential difference $V_b - V_a$ positive or negative? (*b*) If $|V_b - V_a|$ is 100 kV, what is the magnitude of the electric field?

36 • An electric field is given by the expression $\vec{E} = bx^3\hat{i}$, where $b = 2.00\ \text{kV/m}^4$. Find the potential difference between the point at $x = 1.00$ m and the point $x = 2.00$ m. Which of these points is at the higher potential?

37 •• The electric field on the x axis due to a point charge fixed at the origin is given by $\vec{E} = (b/x^2)\hat{i}$, where $b = 6.00\ \text{kV}\cdot\text{m}$ and $x \neq 0$. (*a*) Find the magnitude and sign of the point charge. (*b*) Find the potential difference between the points on the x axis at $x = 1.00$ m and $x = 2.00$ m. Which of these points is at the higher potential?

38 •• The electric potential due to a particular charge distribution is measured at many points along the x axis. A plot of the data is shown in Figure 23-34. At what location (or locations) is the x component of the electric field equal to zero? At this location (or these locations) is the potential also equal to zero? Explain your answer.

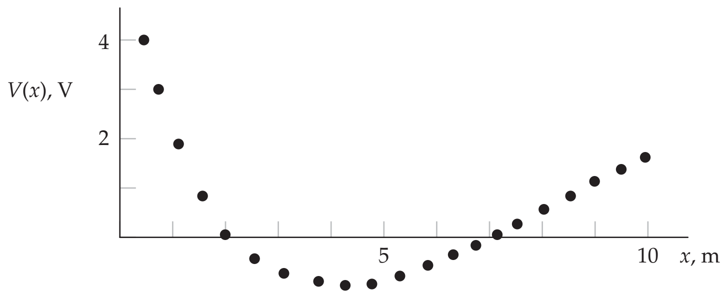

FIGURE 23-34 Problem 38

39 •• Three identical point charges, each with a charge equal to q, lie in the xy plane. Two of the charges are on the y axis at $y = -a$ and $y = +a$, and the third charge is on the x axis at $x = a$. (*a*) Find the potential as a function of position along the x axis. (*b*) Use the Part (*a*) result to obtain an expression for $E_x(x)$, the x component of the electric field as a function of x. Check your answers to Parts (*a*) and (*b*) at the origin and as x approaches ∞ to see if they yield the expected results.

CALCULATIONS OF *V* FOR CONTINUOUS CHARGE DISTRIBUTIONS

40 • A charge of $+10.0\ \mu$C is uniformly distributed on a thin spherical shell of radius 12.0 cm. (Assume the potential is zero very far from all charges.) (*a*) What is the magnitude of the electric field just outside and just inside the shell? (*b*) What is the magnitude of the electric potential just outside and just inside the shell? (*c*) What is the electric potential at the center of the shell? (*d*) What is the magnitude of the electric field at the center of the shell?

41 • An infinite line charge of linear charge density $+1.50\ \mu$C/m lies on the z axis. Find the electric potential at distances from the line charge of (*a*) 2.00 m, (*b*) 4.00 m, and (*c*) 12.0 m. Assume that we choose $V = 0$ at a distance of 2.50 m from the line of charge. SSM

42 • (*a*) Find the maximum net charge that can be placed on a spherical conductor of radius 16 cm before dielectric breakdown of the air occurs. (*b*) What is the electric potential of the sphere when it has this maximum charge? (Assume the potential is zero very far from all charges.)

43 • Find the maximum surface charge density σ_{max} that can exist on the surface of any conductor before dielectric breakdown of the air occurs.

44 •• A conducting spherical shell of inner radius b and outer radius c is concentric with a small metal sphere of radius $a < b$. The metal sphere has a positive charge Q. The total charge on the conducting spherical shell is $-Q$. (Assume the potential is zero very far from all charges.) (*a*) What is the electric potential of the spherical shell? (*b*) What is the electric potential of the metal sphere?

45 •• Two coaxial conducting cylindrical shells have equal and opposite charges. The inner shell has charge $+q$ and an outer radius a, and the outer shell has charge $-q$ and an inner radius b. The length of each cylindrical shell is L, and L is very long compared with b. Find the potential difference $V_a - V_b$ between the shells. SSM

46 •• Positive charge is placed on two conducting spheres that are very far apart and connected by a long, very thin conducting wire. The radius of the smaller sphere is 5.00 cm and the radius of the larger sphere is 12.0 cm. The electric field strength at the surface of the larger sphere is 200 kV/m. Estimate the surface charge density on each sphere.

47 •• Two concentric conducting spherical shells have equal and opposite charges. The inner shell has outer radius a and charge $+q$; the outer shell has inner radius b and charge $-q$. Find the potential difference $V_a - V_b$ between the shells.

48 •• The electric potential at the surface of a uniformly charged sphere is 450 V. At a point outside the sphere at a (radial) distance of 20.0 cm from its surface, the electric potential is 150 V. (The potential is zero very far from the sphere.) What is the radius of the sphere, and what is the charge of the sphere?

49 •• Consider two infinite parallel thin sheets of charge, one in the $x = 0$ plane and the other in the $x = a$ plane. The potential is zero at the origin. (*a*) Find the electric potential everywhere in space if the planes have equal positive charge densities $+\sigma$. (*b*) Find the electric potential everywhere in space if the sheet in the $x = 0$ plane has a charge density $+\sigma$ and the sheet in the $x = a$ plane has a charge density $-\sigma$.

50 ••• The expression for the potential along the axis of a thin uniformly charged disk is given by $V = 2\pi k\sigma|z|\left(\sqrt{1 + \frac{R^2}{z^2}} - 1\right)$ (Equation 23-20), where R and σ are the radius and the charge per unit area of the disk, respectively. Show that this expression reduces to $V = kQ/|z|$ for $|z| \gg R$, where $Q = \sigma\pi R^2$ is the total charge on the disk. Explain why this result is expected. *Hint: Use the binomial theorem to expand the radical.*

51 •• A rod of length L has a total charge Q uniformly distributed along its length. The rod lies along the y axis with its center at the origin. (*a*) Find an expression for the electric potential as a function of position along the x axis. (*b*) Show that the result obtained in Part (*a*) reduces to $V = kQ/|x|$ for $|x| \gg L$. Explain why this result is expected. SSM

52 •• A rod of length L has a charge Q uniformly distributed along its length. The rod lies along the y axis with one end at the origin. (*a*) Find an expression for the electric potential as a function of position along the x axis. (*b*) Show that the result obtained in Part (*a*) reduces to $V = kQ/|x|$ for $|x| \gg L$. Explain why this result is expected.

53 •• A disk of radius R has a surface charge distribution given by $\sigma = \sigma_0 r^2/R^2$ where σ_0 is a constant and r is the distance from the center of the disk. (*a*) Find the total charge on the disk. (*b*) Find an expression for the electric potential at a distance z from the center of the disk on the axis that passes through the disk's center and is perpendicular to its plane. SSM

54 ••• A disk of radius R has a surface charge distribution given by $\sigma = \sigma_0 R/r$ where σ_0 is a constant and r is the distance from the center of the disk. (*a*) Find the total charge on the disk. (*b*) Find an expression for the electric potential at a distance x from the center of the disk on the axis that passes through the disk's center and is perpendicular to its plane.

55 •• A rod of length L has a total charge Q uniformly distributed along its length. The rod lies along the x axis with its center at the origin. (*a*) What is the electric potential as a function of position along the x axis for $x > L/2$? (*b*) Show that for $x \gg L/2$, your result reduces to that due to a point charge Q.

56 ••• A circle of radius a is removed from the center of a uniformly charged thin circular disk of radius b and charge per unit area σ. (*a*) Find an expression for the potential on the x axis a distance x from the center of the disk. (*b*) Show that for $x \gg b$ the electric potential on the axis of the uniformly charged disk with cutout approaches kQ/x, where $Q = \sigma\pi(b^2 - a^2)$ is the total charge on the disk.

57 ••• The expression for the electric potential inside a uniformly charged solid sphere is given by $V(r) = \frac{kQ}{2R}\left(3 - \frac{r^2}{R^2}\right)$, where R is the radius of the sphere and r is the distance from the center. This expression was obtained in Example 23-12 by first finding the electric field. In this problem, you derive the same expression by modeling the sphere as a nested collection of thin spherical shells, and then adding the potentials of these shells at a field point inside the sphere. The potential dV that is a distance r from the center of a uniformly charged thin spherical shell that has a radius r' and a charge dQ is given by $dV = k\,dQ/r$ for $r \geq r'$ and $dV = k\,dQ/r'$ for $r \leq r'$ (Equation 23-22). Consider a sphere of radius R containing a charge Q that is uniformly distributed and you want to find V at some point inside the sphere (i.e., for $r < R$). (*a*) Find an expression for the charge dQ on a spherical shell of radius r' and thickness dr'. (*b*) Find an expression for the potential dV at r due to the charge on a shell of radius r' and thickness dr', where $r \leq r' \leq R$. (*c*) Integrate your expression in Part (*b*) from $r' = r$ to $r' = R$ to find the potential at r due to all the charge in the region farther than r from the center of the sphere. (*d*) Find an expression for the potential dV at r due to the charge in a shell of radius r' and thickness dr', where $r' \leq r$. (*e*) Integrate your expression in Part (*d*) from $r' = 0$ to $r' = r$ to find the potential at r due to all the charge in the region closer than r to the center of the sphere. (*f*) Find the total potential V at r by adding your Part (*c*) and Part (*e*) results.

58 •• Calculate the electric potential at the point a distance $R/2$ from the center of a uniformly charged thin spherical shell of radius R and charge Q. (Assume the potential is zero far from the shell.)

59 •• A circle of radius a is removed from the center of a uniformly charged thin circular disk of radius b. Show that the potential at a point on the central axis of the disk a distance z from its geometrical center is given by $V(z) = 2\pi k\sigma(\sqrt{z^2 + b^2} + \sqrt{z^2 + a^2})$, where σ is the charge density of the disk. SSM

EQUIPOTENTIAL SURFACES

60 • An infinite flat sheet of charge has a uniform surface charge density equal to 3.50 $\mu C/m^2$. How far apart are the equipotential surfaces whose potentials differ by 100 V?

61 •• Consider two parallel uniformly charged infinite planes that are equal but oppositely charged. (*a*) What is (are) the shape(s) of the equipotential surfaces in the region between them? Explain your answer. (*b*) What is (are) the shape(s) of the equipotential surfaces in the regions not between them? Explain your answer. SSM

62 •• A Geiger tube consists of two elements, a long metal cylindrical shell and a long straight metal wire running down its central axis. Model the tube as if both the wire and cylinder are infinitely long. The central wire is positively charged and the outer cylinder is negatively charged. The potential difference between the wire and the cylinder is 1.00 kV. (*a*) What is the direction of the electric field inside the tube? (*b*) Which element is at a higher electric potential? (*c*) What is (are) the shape(s) of the equipotential surfaces inside the tube? (*d*) Consider two equipotential surfaces described in Part (*c*). Suppose they differ in electric potential by 10 V. Do two such equipotential surfaces near the central wire have the same spacing as they would near the outer cylinder? If not, where in the tube are the equipotential surfaces that are more widely spaced? Explain your answer.

63 •• Suppose the cylinder in the Geiger tube in Problem 62 has an inside diameter of 4.00 cm and the wire has a diameter of 0.500 mm. The cylinder is grounded so its potential is equal to zero. (*a*) What is the radius of the equipotential surface that has a potential equal to 500 V? Is this surface closer to the wire or to the cylinder? (*b*) How far apart are the equipotential surfaces that have potentials of 200 and 225 V? (*c*) Compare your result in Part (*b*) to the distance between the two surfaces that have potentials of 700 and 725 V, respectively. What does this comparison tell you about the electric field strength as a function of the distance from the central wire? SSM

64 •• A point particle that has a charge of +11.1 nC is at the origin. (*a*) What is (are) the shapes of the equipotential surfaces in the region around this charge? (*b*) Assuming the potential to be zero at $r = \infty$, calculate the radii of the five surfaces that have potentials equal to 20.0 V, 40.0 V, 60.0 V, 80.0 V, and 100.0 V, and sketch them to scale centered on the charge. (*c*) Are these surfaces equally spaced? Explain your answer. (*d*) Estimate the electric field strength between the 40.0-V and 60.0-V equipotential surfaces by dividing the difference between the two potentials by the difference between the two radii. Compare this estimate to the exact value at the location midway between these two surfaces.

ELECTROSTATIC POTENTIAL ENERGY

65 • Three point charges are on the x axis: q_1 is at the origin, q_2 is at $x = +3.00$ m, and q_3 is at $x = +6.00$ m. Find the electrostatic potential energy of this system of charges for the following charge values: (*a*) $q_1 = q_2 = q_3 = +2.00\ \mu C$; (*b*) $q_1 = q_2 = +2.00\ \mu C$ and $q_3 = -2.00\ \mu C$; and (*c*) $q_1 = q_3 = +2.00\ \mu C$ and $q_2 = -2.00\ \mu C$. (Assume the potential energy is zero when the charges are very far from each other.)

66 • Point charges q_1, q_2, and q_3 are fixed at the vertices of an equilateral triangle whose sides are 2.50 m long. Find the electrostatic potential energy of this system of charges for the following charge values: (*a*) $q_1 = q_2 = q_3 = +4.20\ \mu C$, (*b*) $q_1 = q_2 = +4.20\ \mu C$ and $q_3 = -4.20\ \mu C$; and (*c*) $q_1 = q_2 = -4.20\ \mu C$ and $q_3 = +4.20\ \mu C$. (Assume the potential energy is zero when the charges are very far from each other.)

67 •• (*a*) How much charge is on the surface of an isolated spherical conductor that has a 10.0-cm radius and is charged to 2.00 kV? (*b*) What is the electrostatic potential energy of this conductor? (Assume the potential is zero far from the sphere.) SSM

68 ••• Four point charges, each having a charge with a magnitude of 2.00 μC, are at the corners of a square whose sides are 4.00 m long. Find the electrostatic potential energy of this system under the following conditions: (*a*) all of the charges are negative, (*b*) three of the charges are positive and one of the charges is negative, (*c*) the charges at two adjacent corners are positive and the other two charges are negative, and (*d*) the charges at two opposite corners are positive and the other two charges are negative. (Assume the potential energy is zero when the point charges are very far from each other.)

69 •• Four point charges are fixed at the corners of a square centered at the origin. The length of each side of the square is $2a$. The charges are located as follows: $+q$ is at $(-a, +a)$, $+2q$ is at $(+a, +a)$, $-3q$ is at $(+a, -a)$, and $+6q$ is at $(-a, -a)$. A fifth particle that has a mass m and a charge $+q$ is placed at the origin and released from rest. Find its speed when it is a very far from the origin. SSM

70 •• Consider two point particles that have charge $+e$, are at rest, and are separated by 1.50×10^{-15} m. (*a*) How much work was required to bring them together from a very large separation distance? (*b*) If they are released, how much kinetic energy will each have when they are separated by twice their separation at release? (*c*) The mass of each particle is 1.00 u (1.00 amu). What speed will each have when they are very far from each other?

71 ••• Consider an electron and a proton that are initially at rest and are separated by 2.00 nm. Neglecting any motion of the much more massive proton, what is the minimum (*a*) kinetic energy and (*b*) speed with which the electron must be projected at so it reaches a point a distance of 12.0 nm from the proton? Assume the electron's velocity is directed radially away from the proton. (*c*) How far will the electron travel away from the proton if it has twice that initial kinetic energy?

GENERAL PROBLEMS

72 • A positive point charge equal to 4.80×10^{-19} C is separated from a negative point charge of the same magnitude by 6.40×10^{-10} m. What is the electric potential at a point 9.20×10^{-10} m from each of the two charges?

73 • Two positive point charges each have a charge of $+q$ and are fixed on the y axis at $y = +a$ and $y = -a$. (*a*) Find the electric potential at any point on the x axis. (*b*) Use your result in Part (*a*) to find the electric field at any point on the x axis. SSM

74 • If a conducting sphere is to be charged to a potential of 10.0 kV, what is the smallest possible radius of the sphere so that the electric field near the surface of the sphere will not exceed the dielectric strength of air?

75 •• **SPREADSHEET** Two infinitely long parallel wires have a uniform charge per unit length λ and $-\lambda$, respectively. The wires are parallel with the z axis. The positively charged wire intersects the x axis at $x = -a$, and the negatively charged wire intersects the x axis at $x = +a$. (*a*) Choose the origin as the reference point where the potential is zero, and express the potential at an arbitrary point (x, y) in the xy plane in terms of x, y, λ, and a. Use this expression to solve for the potential everywhere on the y axis. (*b*) Using $a = 5.00$ cm and $\lambda = 5.00$ nC/m, obtain the equation for the equipotential surface in the xy plane that passes through the point $x = \frac{1}{4}a$, $y = 0$. (*c*) Use a spreadsheet program to plot the equipotential surface found in Part (*b*). SSM

76 •• The equipotential curve graphed in Problem 75 should be a circle. (*a*) Show mathematically that it is a circle. (*b*) The equipotential circle in the xy plane is the intersection of a three-dimensional equipotential surface and the xy plane. Describe the three-dimensional surface using one or two sentences.

77 ••• The hydrogen atom in its ground state can be modeled as a positive point charge of magnitude $+e$ (the proton) surrounded by a negative charge distribution that has a charge density (the electron) that varies with the distance from the center of the proton r as $\rho(r) = -\rho_0 e^{-2r/a}$ (a result obtained from quantum mechanics), where $a = 0.523$ nm is the most probable distance of the electron from the proton. (*a*) Calculate the value of ρ_0 needed for the hydrogen atom to be neutral. (*b*) Calculate the electrostatic potential (relative to infinity) of this system as a function of the distance r from the proton.

78 •• Charge is supplied to the metal dome of a Van de Graaff generator by the belt at the rate of 200 μC/s when the potential difference between the belt and the dome is 1.25 MV. The dome transfers charge to the atmosphere at the same rate, so the 1.25 MV potential difference is maintained. What minimum power is needed to drive the moving belt and maintain the 1.25 MV potential difference?

79 •• A positive point charge $+Q$ is located on the x axis at $x = -a$. (*a*) How much work is required to bring an identical point charge from infinity to the point on the x axis at $x = +a$? (*b*) With the two identical point charges in place at $x = -a$ and $x = +a$, how much work is required to bring a third point charge $-Q$ from infinity to the origin? (*c*) How much work is required to move the charge $-Q$ from the origin to the point on the x axis at $x = 2a$ along the semicircular path shown (Figure 23-35)?

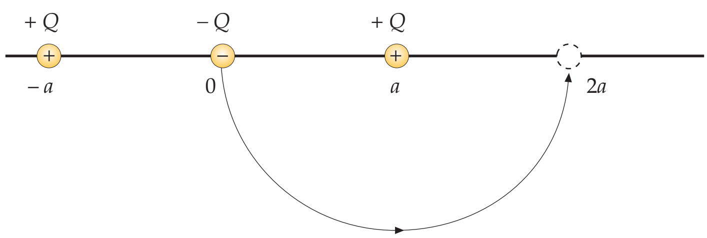

FIGURE 23-35 Problem 79

80 •• A charge of +2.00 nC is uniformly distributed on a ring of radius 10.0 cm that lies in the $x = 0$ plane and is centered at the origin. A point charge of +1.00 nC is initially located on the x axis at $x = 50.0$ cm. Find the work required to move the point charge to the origin.

81 •• Two metal spheres each have a radius of 10.0 cm. The centers of the two spheres are 50.0 cm apart. The spheres are initially neutral, but a charge Q is transferred from one sphere to the other, creating a potential difference between the spheres of 100 V. A proton is released from rest at the surface of the positively charged sphere and travels to the negatively charged sphere. (*a*) What is the proton's kinetic energy just as it strikes the negatively charged sphere? (*b*) At what speed does it strike the sphere?

82 • **SPREADSHEET** (*a*) Using a spreadsheet program, graph $V(z)$ versus z for a uniformly charged ring in the $z = 0$ plane and centered at the origin. The potential on the z axis is given by $V(z) = kQ/\sqrt{a^2 + z^2}$ (Equation 23-19). (*b*) Use your graph to estimate the points on the z axis where the electric field strength is greatest.

83 •• A spherical conductor of radius R_1 is charged to 20 kV. When it is connected by a long, very thin conducting wire to a second conducting sphere far away, its potential drops to 12 kV. What is the radius of the second sphere?

84 •• A metal sphere centered at the origin has a surface charge density that has a magnitude of 24.6 nC/m^2 and a radius less than 2.00 m. A distance of 2.00 m from the origin, the electric potential is 500 V and the electric field strength is 250 V/m. (Assume the potential is zero very far from the sphere.) (*a*) What is the radius of the metal sphere? (*b*) What is the sign of the charge on the sphere? Explain your answer.

85 •• Along the central axis of a uniformly charged disk, at a point 0.60 m from the center of the disk, the potential is 80 V and the magnitude of the electric field is 80 V/m. At a distance of 1.5 m, the potential is 40 V and the magnitude of the electric field is 23.5 V/m. (Assume the potential is zero very far from the sphere.) Find the total charge on the disk.

86 •• A radioactive ^{210}Po nucleus emits an α particle that has a charge $+2e$. When the α particle is a large distance from the nucleus, it has a kinetic energy of 5.30 MeV. Assume that the α particle had negligible kinetic energy as it left the surface of the nucleus. The "daughter" (or residual) nucleus ^{206}Pb has a charge $+82e$. Determine the radius of the ^{206}Pb nucleus. (Neglect the radius of the α particle and assume the ^{206}Pb nucleus remains at rest.)

87 ••• (*a*) Configuration *A* consists of two point particles; one particle has a charge of $+q$ and is on the x axis at $x = +d$ and the other particle has a charge of $-q$ and is at $x = -d$ (Figure 23-36*a*). Assuming the potential is zero at large distances from these charged particles, show that the potential is also zero everywhere on the $x = 0$ plane. (*b*) Configuration *B* consists of a flat metal plate of infinite extent and a point particle located a distance d from the plate (Figure 23-36*b*). The point particle has a charge equal to $+q$ and the plate is grounded. (Grounding the plate forces its potential to equal zero.) Choose the line perpendicular to the plate and through the point charge as the x axis, and choose the origin at the surface of the plate nearest the particle. (These choices put the particle on the x axis at $x = +d$.) For configuration *B*, the electric potential is zero both at all points in the half-space $x \geq 0$ that are very far from the particle and at all points on the $x = 0$ plane—just as was the case for configuration *A*. A theorem, called the *uniqueness theorem*, implies that throughout the half-space $x \geq 0$ the potential function V—and thus the electric field $\vec{E}$—for the two configurations are identical. Using this result, obtain the electric field $\vec{E}$ at every point in the $x = 0$ plane in configuration *B*. (The uniqueness theorem tells us that in configuration *B* the electric field at each point in the $x = 0$ plane is the same as it is in configuration *A*.) Use this result to find the surface charge density σ at each point in the conducting plane (in configuration *B*). SSM

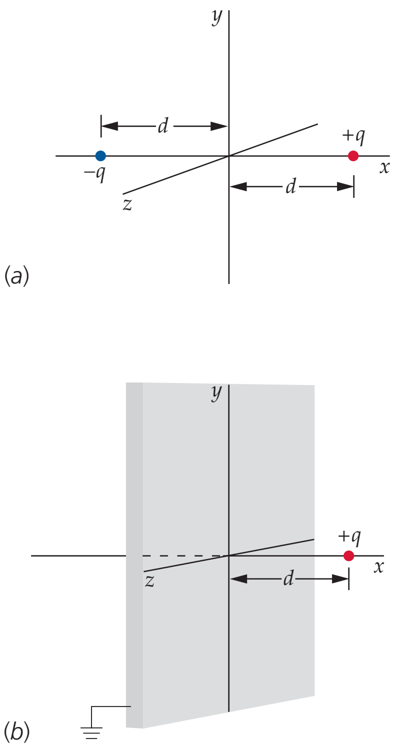

FIGURE 23-36 Problem 87

88 ••• A particle that has a mass m and a positive charge q is constrained to move along the x axis. At $x = -L$ and $x = L$ are two ring charges of radius L (Figure 23-37). Each ring is centered on the x axis and lies in a plane perpendicular to it. Each ring has a total positive charge Q uniformly distributed on it. (*a*) Obtain an expression for the potential $V(x)$ on the x axis due to the charge on the rings. (*b*) Show that $V(x)$ has a minimum at $x = 0$. (*c*) Show that for $|x| \ll L$, the potential approaches the form $V(x) = V(0) + \alpha x^2$. (*d*) Use the result of Part (*c*) to derive an expression for the angular frequency of oscillation of the mass m if it is displaced slightly from the origin and released. (Assume the potential equals zero at points far from the rings.)

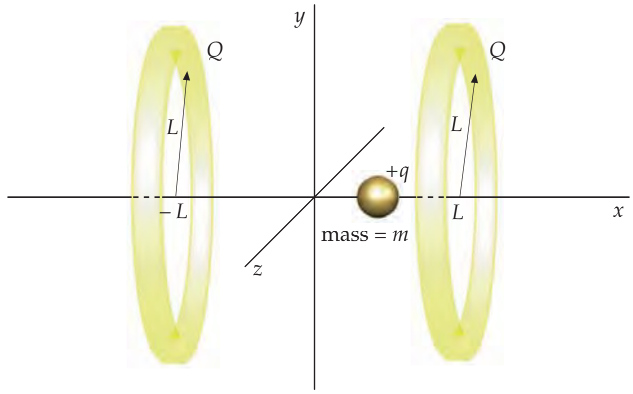

FIGURE 23-37 Problem 88

89 ••• Three concentric conducting thin spherical shells have radii a, b, and c so that $a < b < c$. Initially, the inner shell is uncharged, the middle shell has a positive charge $+Q$, and the outer shell has a charge $-Q$. (Assume the potential equals zero at points far from the shells.) (*a*) Find the electric potential of each of the three shells. (*b*) If the inner and outer shells are now connected by a conducting wire that is insulated as it passes through a small hole in the middle shell, what is the electric potential of each of the three shells, and what is the final charge on each shell?

90 ••• Consider two concentric spherical thin metal shells of radii a and b, where $b \geq a$. The outer shell has a charge Q, but the inner shell is grounded. This means that the potential on the inner shell is the same as the potential at points far from the shells. Find the charge on the inner shell.

91 ••• Show that the total work needed to assemble a uniformly charged sphere that has a total charge of Q and radius R is given by $3Q^2/(20\pi\epsilon_0 R)$. Energy conservation tells us that this result is the same as the resulting electrostatic potential energy of the sphere. *Hint: Let ρ be the charge density of the sphere that has charge Q and radius R. Calculate the work dW to bring in charge dq from infinity to the surface of a uniformly charged sphere of radius r ($r < R$) and charge density ρ. (No additional work is required to smear dq throughout a spherical shell of radius r, thickness dr, and charge density ρ. Why?)* SSM

92 ••• (*a*) Use the result of Problem 91 to calculate the *classical electron radius*, the radius of a uniform sphere that has a charge $-e$ and an electrostatic potential energy equal to the rest energy of the electron (5.11×10^5 eV). Comment on the shortcomings of this model for the electron. (*b*) Repeat the calculation in Part (*a*) for a proton using its rest energy of 938 MeV. Experiments indicate the proton has an approximate radius of about 1.2×10^{-15} m. Is your result close to this value?

93 ••• (*a*) Consider a uniformly charged sphere that has radius R and charge Q and is composed of an incompressible fluid, such as water. If the sphere fissions (splits) into two halves of equal volume and equal charge, and if these halves stabilize into uniformly charged spheres, what is the radius R' of each? (*b*) Using the expression for potential energy shown in Problem 91, calculate the change in the total electrostatic potential energy of the charged fluid. Assume that the spheres are separated by a large distance. SSM

94 ••• Problem 93 can be modified to be used as a very simple model for nuclear fission. When a ^{235}U nucleus absorbs a neutron, it can fission into the fragments ^{140}Xe, ^{94}Sr, and 2 neutrons. The ^{235}U has 92 protons, while ^{140}Xe has 54 protons and ^{94}Sr has 38 protons. Estimate the energy released during this fission process (in MeV), assuming that the mass density of the nucleus is constant and has a value of 4×10^{17} kg/m^3.

CHAPTER 24

THE ENERGY FOR THE ELECTRONIC FLASH OF THIS CAMERA HAS BEEN TRANSFERRED FROM A BATTERY TO A CAPACITOR. *(PhotoDisc/Getty Images.)*

Capacitance

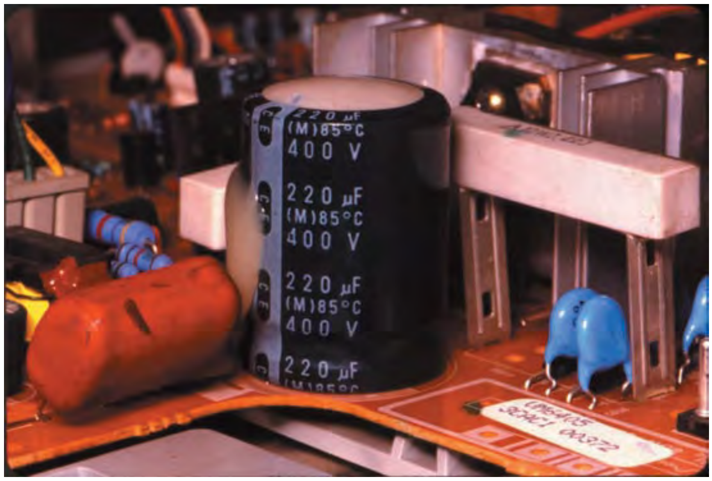
? How do you determine how much energy can be stored in a capacitor? (See Example 24-3.)

How many people do you know that *don't* have a digital camera, a cell phone, a cell-phone/digital-camera combination, or any of a myriad of additional portable electronic devices? Virtually all portable electronic devices contain one or more capacitors, and life without portable electronic devices seems unthinkable today. We live in an on-the-run age yet still manage to stay in communication with people important to us using cell phones, to enjoy music using mp3 players, and even to check and send email using PDA (personal digital assistant) devices.

In the previous chapters, we discussed the relation of electric fields to charges and how the relation of charges translates into electric potential energy. Here we show that potential energy can be stored and released using the concept of capacitance.

In this chapter, we will discuss circuits containing batteries and capacitors. In the next few chapters, the concepts of electric potential and capacitance will be further developed as they relate to circuits containing resistors, inductors, and other devices.

24-1 CAPACITANCE



Capacitors are used in large numbers in common electronic devices such as television sets. Some capacitors are used to store energy, but most are used to filter unwanted electrical frequencies. *(© Tom Pantages Images.)*

The potential V of a single isolated conductor due to the charge Q on it is proportional to Q and depends on the size and shape of the conductor. Typically, the larger the surface area of a conductor, the more charge it can carry for a given potential. For example, if the potential is chosen to be zero at infinity, the potential of a spherical conductor having a radius R and a charge Q is

$$V = \frac{kQ}{R}$$

(The equation for an isolated sphere $V = kQ/R$ (Equation 23-22) is established in Chapter 23.) The ratio Q/V of the charge to the potential of an isolated conductor is called its **self-capacitance *C*.** A **capacitor** is a device consisting of two conductors, one that has a charge Q and the other that has a charge $-Q$. The ratio of charge Q to the potential difference V between the two conductors is called the **capacitance** of the capacitor.

$$C = \frac{Q}{V} \tag{24-1}$$

DEFINITION—CAPACITANCE

Capacitance is a measure of the capacity to store charge for a given potential difference. Because the potential difference is proportional to the charge, this ratio does not depend on either Q or V, but only on the sizes, shapes, and relative positions of the conductors. The self-capacitance of an isolated spherical conductor is

$$C = \frac{Q}{V} = \frac{Q}{kQ/R} = \frac{R}{k} = 4\pi\epsilon_0 R \tag{24-2}$$

The SI unit of capacitance is the coulomb per volt, which is called a **farad** (F) after the great English experimentalist Michael Faraday:

$$1\ \text{F} = 1\ \text{C/V} \tag{24-3}$$

The farad is a rather large unit, so submultiples such as the microfarad ($1\ \mu\text{F} = 10^{-6}$ F) or the picofarad ($1\ \text{pF} = 10^{-12}$ F) are more commonly used. Because capacitance is in farads and R is in meters, we can see from Equation 24-2 that the SI unit for the electric constant (the permittivity of empty space), ϵ_0, can also be written as a farad per meter:

$$\epsilon_0 = 8.85 \times 10^{-12}\ \text{F/m} = 8.85\ \text{pF/m} \tag{24-4}$$

ELECTRIC CONSTANT

PRACTICE PROBLEM 24-1

Find the radius of a spherical conductor that has a capacitance of 1.0 F.

The farad is indeed a very large unit.

CONCEPT CHECK 24-1

A sphere of capacitance C_1 carries a charge of 20 μC. If the charge is increased to 60 μC, what is the new capacitance C_2?

CAPACITORS

A capacitor is usually charged by transferring a charge Q from one conductor to the other conductor, which leaves one of the conductors having a charge $+Q$ and the other conductor having a charge $-Q$. The capacitance of the device is defined to be Q/V, where Q is the magnitude of the charge on either conductor and V is the magnitude of the potential difference between the conductors. To calculate the capacitance, we place equal and opposite charges on the conductors and then find the potential difference V by first finding the electric field $\vec{E}$ due to the charges and then calculating V from $\vec{E}$.

When we speak of the charge on a capacitor, we mean the magnitude of the charge on either conductor. The use of V rather than ΔV for the magnitude of the potential difference between the plates is standard and simplifies many of the equations relating to capacitance.

The first capacitor was the Leyden jar (Figure 24-1), a glass container lined with metal on its outside and base and either filled with water or lined with foil on its inside. It was invented at the University of Leyden in the Netherlands by eighteenth-century experimenters who, while studying the effects of electric charges on people and animals, got the idea of trying to store a large amount of charge in a bottle of water. An experimenter held up a jar of water in one hand while charge was conducted to the water by a chain from a static electric generator. When the experimenter reached over to lift the chain out of the water with his other hand, he was knocked unconscious. Benjamin Franklin realized that the device for storing charge did not have to be jar shaped and used foil-covered window glass, called Franklin panes. Using several of these panes connected in parallel, Franklin stored a large charge and attempted to kill a turkey with them. Instead, he knocked himself out. Franklin later wrote, “I tried to kill a turkey but nearly succeeded in killing a goose.”

FIGURE 24-1 Leyden jar with bells. The bell on the pole through the stopper is connected to a conductor on the inside surface of the jar. The second bell is connected to the conductor on the outside surface of the jar. The system is energized by connecting a battery between the two bells for a short time. After the battery is removed the conducting ball swings from one bell to the other, transferring charge a little bit at a time. *(Courtesy of Bernhard Thomas.)*

PARALLEL-PLATE CAPACITORS

A common capacitor is the **parallel-plate capacitor,** which uses two parallel conducting plates. In practice, the plates are often thin metallic foils that are separated and insulated from one another by a thin plastic film. This “sandwich” is then rolled up, which allows for a large surface area in a relatively small space. Let A be the area of the surface (the area of that side of each plate that faces the other plate), and let d be the separation distance, which is very small compared to the length and width of the plates. We place a charge $+Q$ on one plate and $-Q$ on the other plate. These charges attract each other and become uniformly distributed on the inside surfaces of the plates. Because the plates are very close together, the electric field between them is uniform and has a magnitude of $E = \sigma/\epsilon_0$. [That the electric field strength just outside the surface of a conductor is given by $E = \sigma/\epsilon_0$ (Equation 22-21) is established in Chapter 22.] Because $\vec{E}$ is uniform between the plates (Figure 24-2), the potential difference between the plates equals the field strength E multiplied by the plate separation d:

$$V = Ed = \frac{\sigma}{\epsilon_0}d = Qd/(\epsilon_0 A) \qquad 24\text{-}5$$

where we have substituted Q/A for σ. The capacitance of the parallel-plate capacitor is thus

$$C = \frac{Q}{V} = \frac{Q}{Qd/(\epsilon_0 A)} = \frac{\epsilon_0 A}{d} \qquad 24\text{-}6$$

CAPACITANCE OF A PARALLEL-PLATE CAPACITOR

Note that because V is proportional to Q, the capacitance does not depend on either Q or V. For a parallel-plate capacitor, the capacitance is proportional to the area of the plates and is inversely proportional to the gap width (separation distance). In general, capacitance depends on the size, shape, and geometrical arrangement of the conductors. Capacitance also depends on the properties of the insulating medium between the conductors as we shall see in Section 24-4.

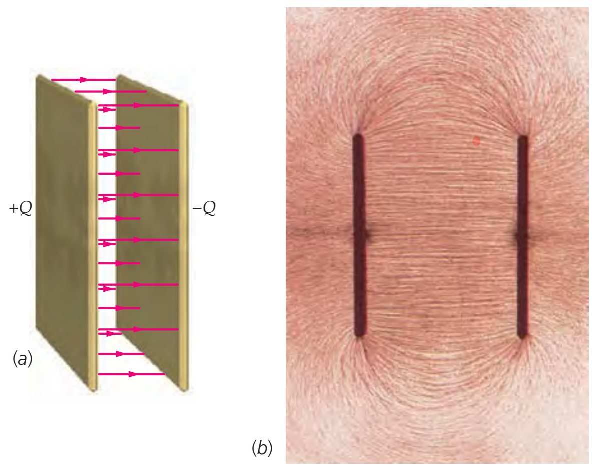


FIGURE 24-2 (*a*) Electric field lines between the plates of a parallel-plate capacitor. The lines are equally spaced between the plates, indicating that the electric field is uniform. (*b*) Electric field lines in a parallel-plate capacitor shown by small bits of thread suspended in oil. *(Harold M. Waage.)*

PROBLEM-SOLVING STRATEGY

Calculating Capacitance

PICTURE Make a sketch of the capacitor that has a charge of $+Q$ on one conductor and a charge of $-Q$ on the other conductor.

SOLVE

1. Determine the electric field $\vec{E}$, usually by using Gauss's law.
2. Determine the magnitude of the potential difference V between the two conductors by integrating $dV = -\vec{E} \cdot d\vec{\ell}$ (Equation 23-2*a*).
3. The capacitance is equal to $C = Q/V$.

CHECK Check that the result depends only on the electric constant* and on geometrical factors such as lengths and areas.

Example 24-1 The Capacitance of a Parallel-Plate Capacitor

A parallel-plate capacitor has square metallic plates of edge length 10 cm separated by 1.0 mm. (*a*) Calculate the capacitance of this device. (*b*) As this capacitor is charged to 12 V, how much charge is transferred from one plate to another?

PICTURE The capacitance C is determined by the area and the separation of the plates. Once C is found, the charge for a given voltage V is found from the definition of capacitance $C = Q/V$.

SOLVE

(*a*) We find the capacitance using $C = \epsilon_0 A/d$ (Equation 24-6):

$$C = \frac{\epsilon_0 A}{d} = \frac{(8.85\text{ pF/m})(0.10\text{ m})^2}{0.0010\text{ m}} = 88.5\text{ pF} = \boxed{89\text{ pF}}$$

(*b*) The charge transferred is found from $Q = CV$ (the definition of capacitance):

$$Q = CV = (88.5\text{ pF})(12\text{ V}) = 1.06 \times 10^{-9}\text{ C} = \boxed{1.1\text{ nC}}$$

CHECK The Part (*b*) expression has units of farads multiplied by volts. Because 1 F = 1 C/V (Equation 24-3), the product of farads and volts equals coulombs, which is the appropriate unit for charge.

TAKING IT FURTHER Q is the magnitude of the charge on each plate of the capacitor. A charge of 1.1 nC corresponds to a transfer of 6.6×10^9 electrons from one plate to the other.

PRACTICE PROBLEM 24-2 How large would the plate area have to be for the capacitance to equal 1.0 F?

CYLINDRICAL CAPACITORS

A cylindrical capacitor consists of a long conducting cylinder of radius R_1 and a larger, concentric cylindrical conducting shell of radius R_2. The cylinders have the same length. A coaxial cable, such as that used for cable television, can be thought of as a cylindrical capacitor. The capacitance per unit length of a coaxial cable is important in determining the transmission characteristics of the cable.

* Capacitance also depends on a property of any nonconducting material placed between the conductors. This dependence is introduced in Section 24-4.

Example 24-2 An Expression for the Capacitance of a Cylindrical Capacitor

Find an expression for the capacitance of a cylindrical capacitor consisting of two conductors, each of length L. One conductor is a cylinder of radius R_1 and the second conductor is a coaxial cylindrical shell of inner radius R_2, where $R_1 < R_2 \ll L$ as shown in Figure 24-3.

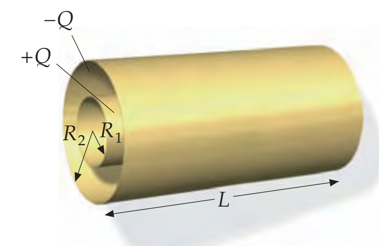

FIGURE 24-3

PICTURE We place charge $+Q$ on the inner conductor and charge $-Q$ on the outer conductor and calculate the potential difference $V = V_{R_2} - V_{R_1}$ from the electric field between the conductors, which is found from Gauss's law. Because the electric field is not uniform (it depends on the distance R from the axis) we must integrate $\vec{E}$ to find the potential difference.

SOLVE

1. The capacitance is defined as the ratio Q/V:

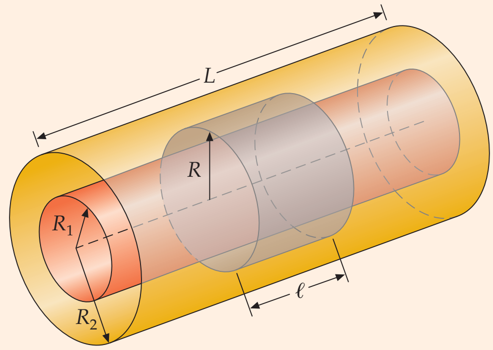
$$C = Q/V$$

2. V is related to the electric field:

$$dV = -\vec{E} \cdot d\vec{\ell}$$

3. To find E_R we choose a soup-can-shaped Gaussian surface of radius R and length ℓ, where $R_1 < R < R_2$ and $\ell \ll L$. The entire Gaussian surface is located far from the ends of the coaxial conductors (Figure 24-4):

FIGURE 24-4



4. On the Gaussian surface, $\vec{E}$ is either zero or is in the radial direction. Thus, there is no flux of $\vec{E}$ through either of the two flat ends of the can. The area of the curved side of the can is $2\pi R\ell$, and on this side $E_n = E_R$, so Gauss's law gives:

$$\phi_{\text{net}} = \oint_S E_n\, dA = \frac{Q_{\text{inside}}}{\epsilon_0}$$

where
$$\oint_S E_n\, dA = \int_{\text{left end}} E_n\, dA + \int_{\text{curved side}} E_n\, dA + \int_{\text{right end}} E_n\, dA$$
$$= 0 + \int_{\text{curved side}} E_R\, dA + 0 = E_R \int_{\text{curved side}} dA = E_R 2\pi R\ell$$

5. Substituting for $\oint_S E_n\, dA$ in the previous step gives:

$$E_R 2\pi R\ell = \frac{Q_{\text{inside}}}{\epsilon_0}$$

6. Assuming the charge per unit length on the inner shell is uniformly distributed, find Q_{inside}:

$$\frac{Q_{\text{inside}}}{Q} = \frac{\ell}{L} \quad \text{so} \quad Q_{\text{inside}} = \frac{\ell}{L}Q$$

7. Substitute for Q_{inside} in the step 5 result and solve for E_R:

$$E_R 2\pi R\ell = \frac{1}{\epsilon_0}\frac{\ell}{L}Q \quad \text{so} \quad E_R = \frac{Q}{2\pi L\epsilon_0 R}$$

8. Integrate to find $V = |V_{R_2} - V_{R_1}|$:

$$V_{R_2} - V_{R_1} = \int_{V_{R_1}}^{V_{R_2}} dV = -\int_{R_1}^{R_2} E_R\, dR = -\frac{Q}{2\pi L\epsilon_0}\int_{R_1}^{R_2}\frac{dR}{R} = -\frac{Q}{2\pi L\epsilon_0}\ln\frac{R_2}{R_1}$$

$$\text{so} \quad V = |V_{R_2} - V_{R_1}| = \frac{Q}{2\pi L\epsilon_0}\ln\frac{R_2}{R_1}$$

9. Rearrange this result to find $C = Q/V$:

$$C = \frac{Q}{V} = \boxed{\frac{2\pi\epsilon_0 L}{\ln(R_2/R_1)}}$$

CHECK The step 9 result is dimensionally correct. Capacitances always have the dimension of ϵ_0 multiplied by length.

TAKING IT FURTHER The capacitance of a cylindrical capacitor is proportional to the length of the cylinders. In addition, we were able to factor E_R from the integrand in step 4 because the symmetry reveals that E_R is the same everywhere on the curved side of the can.

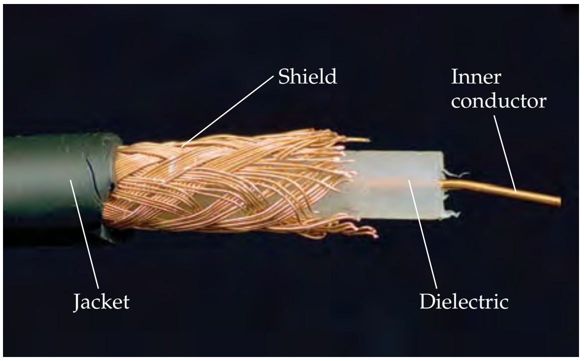
CONCEPT CHECK 24-2

How is the capacitance affected if the potential across a cylindrical capacitor is increased from 20 V to 80 V?

From Example 24-2, we see that the capacitance of a cylindrical capacitor is given by

$$C = \frac{2\pi\epsilon_0 L}{\ln(R_2/R_1)} \qquad 24\text{-}7$$

CAPACITANCE OF A CYLINDRICAL CAPACITOR



A coaxial cable is a long cylindrical capacitor that has a solid wire for the inner conductor and a braided-wire shield for the outer conductor. The outer rubber coating has been peeled back from the cable to show the conductors and the white plastic insulator that separates the conductors. The braided-wire shield blocks ambient electric fields from reaching the inner conductor, which carries the information of interest (such as the video and audio signal for a television show). *(John Perry Fish.)*

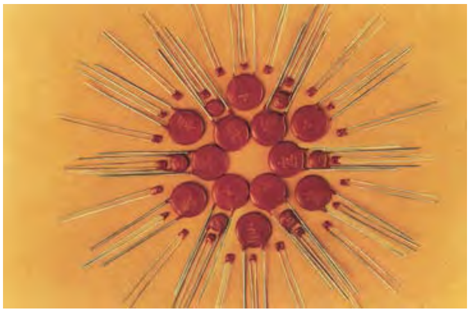
A variable air-gap capacitor such as those used in the tuning circuits of old radios. The semicircular plates rotate through the fixed plates, which changes the amount of surface area between the plates, and hence the capacitance. *(Loren Winters/Visuals Unlimited.)*



Ceramic capacitors for use in electronic circuits. *(Courtesy Tusonix, Tucson, AZ.)*

24-2 THE STORAGE OF ELECTRICAL ENERGY

When a capacitor is being charged, electrons are transferred from the positively charged conductor to the negatively charged conductor. This leaves the positively charged conductor with an electron deficit and the negatively charged conductor with an electron surplus. Alternatively, transferring positive charges from the negatively charged conductor to the positively charged conductor could also charge a capacitor. Either way, work must be done to charge a capacitor, and at least some of this work is stored as electrostatic potential energy.

We start with two uncharged conductors that do not touch each other. Let q be the positive charge that has been transferred during the initial stages of the charging process. The potential difference then is $V = q/C$. If a small amount of additional positive charge dq is now transferred from the negative conductor to the positive conductor through a potential increase of V (Figure 24-5), the electrical potential energy of the charge, and thus the capacitor, is increased by

$$dU = V\,dq = \frac{q}{C}\,dq$$

The total increase in potential energy U is the integral of dU as q increases from zero to its final value Q (Figure 24-6):

$$U = \int dU = \int_0^Q \frac{q}{C}\,dq = \frac{1}{C}\int_0^Q q\,dq = \frac{1}{2}\frac{Q^2}{C}$$

This potential energy is the energy stored in the capacitor. Using the definition of capacitance ($C = Q/V$), we can express this energy in terms of either Q and V, C and V, or Q and C:

$$U = \frac{1}{2}\frac{Q^2}{C} = \frac{1}{2}QV = \frac{1}{2}CV^2 \qquad 24\text{-}8$$

ENERGY STORED IN A CAPACITOR

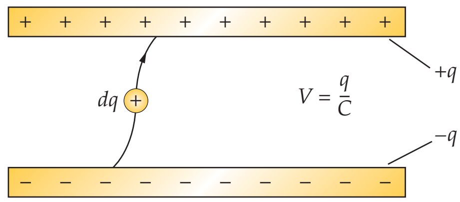


FIGURE 24-5 When a small amount of positive charge dq is moved from the negative conductor to the positive conductor, its potential energy is increased by $dU = V\,dq$, where V is the potential difference between the conductors.

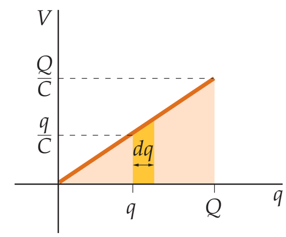

FIGURE 24-6 The work needed to charge a capacitor is the integral of $V\,dq$ from the original charge of $q = 0$ to the final charge of $q = Q$. This work is equal to area under the curve. That is, the work equals the area of the triangle of height Q/C and width Q.

PRACTICE PROBLEM 24-3

A 185-μF capacitor is charged to 200 V. How much energy is stored in the capacitor?

PRACTICE PROBLEM 24-4

Obtain the expression for the electrostatic energy stored in a capacitor (Equation 24-8) from $U = \frac{1}{2}\sum_{i=1}^{n} Q_i V_i$ (Equation 23-29), using $Q_1 = -Q$, $Q_2 = +Q$, $n = 2$, and $V_2 = V_1 + V$.

Suppose we charge a capacitor by connecting it to a battery. The potential difference V when the capacitor is fully energized with charge $+Q$ on one conductor and charge $-Q$ on the other is just the potential difference between the terminals of the battery before they were connected to the capacitor. The total work done *by the battery* in charging the capacitor is QV, which is twice the amount of energy stored in the capacitor. The additional work done by the battery is either dissipated as thermal energy in the battery and in the connecting wires* or radiated as electromagnetic waves.†

Example 24-3 Charging a Parallel-Plate Capacitor with a Battery

A parallel-plate capacitor that has square plates which are 14 cm on a side and are separated by 2.0 mm is connected to a battery and charged to 12 V. (*a*) What is the charge on the capacitor? (*b*) How much energy is stored in the capacitor? (*c*) The battery is then disconnected from the capacitor and the plates are pulled apart until the plate separation is increased to 3.5 mm. How much does the stored energy change as the plate separation is increased from 2.0 mm to 3.5 mm?

PICTURE (*a*) The charge on the capacitor can be calculated from the capacitance. (*b*) The energy stored in the capacitor can be calculated if we know both the charge and the capacitance. (*c*) The charge remains constant as the plates are separated because the capacitor is not connected to the battery during separation. The energy change is found by using the charge and new potential difference to calculate the new energy, from which we subtract the original energy.

* We show in Section 25-6 that if the capacitor is connected to an ideal battery by wires of some resistance R, half the energy supplied by the battery in charging the capacitor is dissipated as thermal energy in the wires.

† We show in Section 30-3 that under certain circumstances the circuit will act as a broadcast antenna and a significant portion of the work will be broadcast as electromagnetic radiation.

SOLVE

(*a*) 1. The charge Q on the capacitor equals the product of C_0 and V_0, where C_0 is the capacitance and $V_0 = 12$ V is the battery voltage:

$$Q = C_0 V_0$$

2. The capacitance of the parallel-plate capacitor is given by Equation 24-6:

$$C_0 = \frac{\epsilon_0 A}{d_0}$$

3. Substitute for C_0 and calculate Q:

$$Q = C_0 V_0 = \frac{\epsilon_0 A}{d_0} V_0 = \frac{(8.85 \text{ pF/m})(0.14 \text{ m})^2}{0.0020 \text{ m}}(12 \text{ V}) = 1.04 \text{ nC}$$

$$= \boxed{1.0 \text{ nC}}$$

(*b*) Calculate the energy stored:

$$U_0 = \tfrac{1}{2} Q V_0 = \tfrac{1}{2}(1.04 \text{ nC})(12 \text{ V}) = 6.24 \text{ nJ} = \boxed{6.2 \text{ nJ}}$$

(*c*) 1. The battery is disconnected and the plate separation is increased to 3.5 mm. The change in energy is proportional to the change in the voltage:

$$\Delta U = U - U_0 = \tfrac{1}{2} Q V - \tfrac{1}{2} Q V_0 = \tfrac{1}{2} Q (V - V_0)$$

2. The voltage is the field strength E multiplied by the separation distance d:

$$V = Ed \quad \text{and} \quad V_0 = E_0 d_0:$$

3. At the surface of a conductor, $E = \sigma/\epsilon_0$ (Equation 22-21). While the capacitor is disconnected, σ remains constant. Thus, E remains constant:

$$E = E_0$$

4. Combining the last two steps establishes that V is proportional to d:

$$E = \frac{V}{d} = \frac{V_0}{d_0} \quad \text{so} \quad V = \frac{d}{d_0} V_0$$

5. Substitute for V in the equation of Part (*c*), step 1 by using the result from Part (*c*), step 4. Solve for ΔU, by using the value for U_0 from Part (*b*):

$$\Delta U = \frac{1}{2} Q \left(\frac{d}{d_0} V_0 - V_0 \right) = \left(\frac{d}{d_0} - 1 \right) \left(\frac{1}{2} Q V_0 \right) = \left(\frac{d}{d_0} - 1 \right) U_0$$

$$= \left(\frac{3.5 \text{ mm}}{2.0 \text{ mm}} - 1 \right)(6.24 \text{ nJ}) = \boxed{4.7 \text{ nJ}}$$

CHECK An increase in potential energy with an increase in plate separation is expected. The plates are oppositely charged, so they attract each other. Thus, it takes work to separate them farther. This work done on the plates results in an increase in the potential energy of the system.

TAKING IT FURTHER An application of the dependence of capacitance on separation distance is shown in Figure 24-7.

PRACTICE PROBLEM 24-5 Find the final voltage V between the capacitor plates.

PRACTICE PROBLEM 24-6 (*a*) Find the initial capacitance C_0 in this example when separation of the plates is 2.0 mm. (*b*) Find the final capacitance C when separation of the plates is 3.5 mm.

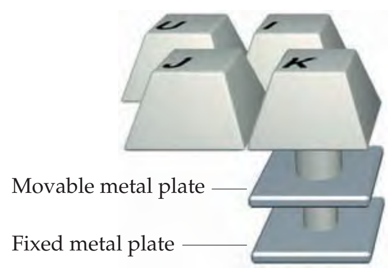

FIGURE 24-7 Capacitance switching in computer keyboards. A metal plate attached to each key acts as the top plate of a capacitor. Depressing the key decreases the separation between the top and bottom plates and increases the capacitance, which triggers the electronic circuitry of the computer to acknowledge the keystroke.

It is instructive to work Part (*c*) of Example 24-3 in another way. The oppositely charged plates of a capacitor exert attractive forces on one another. Work must be done on the plates to overcome the forces to increase the plate separation. Assume that the lower plate is held fixed and the upper plate is moved. The force on the upper plate is the charge $+Q$ on the plate multiplied by the electric field $\vec{E}'$ *due to the charge* $-Q$ *on the lower plate*. This field is half the total field $\vec{E}$ between the plates because the charge on the upper plate and the charge on the lower plate contribute equally to the electric field in the region between the plates. When the potential difference is 12 V and the separation is 2.0 mm, the total field strength between the plates is

$$E = \frac{V}{d} = \frac{12\text{ V}}{2.0\text{ mm}} = 6.0\text{ V/mm} = 6.0\text{ kV/m}$$

The magnitude of the force exerted on the upper plate by the bottom plate is thus

$$F = QE' = Q(\tfrac{1}{2}E) = (1.04\text{ nC})(3.0\text{ kV/m}) = 3.1\ \mu\text{N}$$

The work that must be done to move the upper plate a distance of $\Delta d = 1.5$ mm is then

$$W = F\,\Delta d = (3.1\ \mu\text{N})(1.5\text{ mm}) = 4.7\text{ nJ}$$

This value is the same as the number of joules calculated in Part (*c*) of Example 24-3. This work is equal to the increase in the potential energy.

ELECTROSTATIC FIELD ENERGY

During the process of charging a capacitor, an electric field is produced between the plates. The work required to charge the capacitor can be thought of as the work required to establish the electric field. That is, we can think of the energy stored in a capacitor as energy stored in the electric field, called **electrostatic field energy.**

Consider a parallel-plate capacitor. We can relate the energy stored in the capacitor to the electric field strength E between the plates. The potential difference between the plates is related to the electric field by $V = Ed$, where d is the plate separation distance. The capacitance is given by $C = \epsilon_0 A/d$ (Equation 24-6). The energy stored (Equation 24-8) is

$$U = \frac{1}{2}CV^2 = \frac{1}{2}\left(\frac{\epsilon_0 A}{d}\right)(Ed)^2 = \frac{1}{2}\epsilon_0 E^2(Ad)$$

The quantity Ad is the volume of the space between the plates of the capacitor. This volume is the volume of the region containing the electric field. The energy per unit volume is called the **energy density** u_e. The energy density in an electric field of strength E is thus

$$u_e = \frac{\text{energy}}{\text{volume}} = \frac{1}{2}\epsilon_0 E^2 \qquad 24\text{-}9$$

ENERGY DENSITY OF AN ELECTROSTATIC FIELD

Thus, the energy per unit volume of the electrostatic field is proportional to the square of the electric field strength. *Although we obtained Equation 24-9 by considering the electric field between the plates of a parallel-plate capacitor, the result applies to any electric field*. Whenever there is an electric field in space, the electrostatic energy per unit volume is given by Equation 24-9.

PRACTICE PROBLEM 24-7

(*a*) Calculate the energy density u_e for Example 24-3 when the plate separation is 2.0 mm.
(*b*) Show that the increase in energy in Example 24-3 equal to u_e multiplied by the increase in volume ($A\,\Delta d$) of the region between the plates.

We can illustrate the generality of Equation 24-9 by calculating the electrostatic field energy of a spherical conductor that has a radius R and a charge Q. The self-capacitance of a spherical conductor is given by $C = R/k$ (Equation 24-2) and the electrostatic potential energy is given by $U = \frac{1}{2}Q^2/C$ (Equation 24-8). Thus, for a spherical conductor:

$$U = \frac{1}{2}\frac{Q^2}{C} = \frac{1}{2}\frac{Q^2}{R/k} = \frac{kQ^2}{2R} \qquad \text{24-10}$$

We now obtain the same result by considering the energy density of an electric field given by Equation 24-9. When the conductor has a charge Q, the electric field is radial and is given by

$$E_r = 0 \qquad r < R \text{ (inside the conductor)}$$

$$E_r = \frac{kQ}{r^2} \qquad r > R \text{ (outside the conductor)}$$

Because the electric field is spherically symmetric, we choose a spherical shell for our volume element. If the radius of the shell is r and its thickness is dr, the volume is $d\mathcal{V} = 4\pi r^2\,dr$ (Figure 24-8). The energy dU in this volume element is

$$dU = u_e\,d\mathcal{V} = \frac{1}{2}\epsilon_0 E^2 4\pi r^2\,dr$$

$$= \frac{1}{2}\epsilon_0\left(\frac{kQ}{r^2}\right)^2(4\pi r^2\,dr) = \frac{1}{2}(4\pi\epsilon_0 k^2)Q^2\frac{dr}{r^2} = \frac{1}{2}kQ^2\frac{dr}{r^2}$$

where we have used $4\pi\epsilon_0 = 1/k$. Because the electric field is zero for $r < R$, we obtain the total energy in the electric field by integrating from $r = R$ to $r = \infty$:

$$U = \int u_e\,d\mathcal{V} = \frac{1}{2}kQ^2\int_R^\infty r^{-2}\,dr = \frac{1}{2}k\frac{Q^2}{R} = \frac{1}{2}\frac{Q^2}{C} \qquad \text{24-11}$$

which is the same as Equation 24-8.

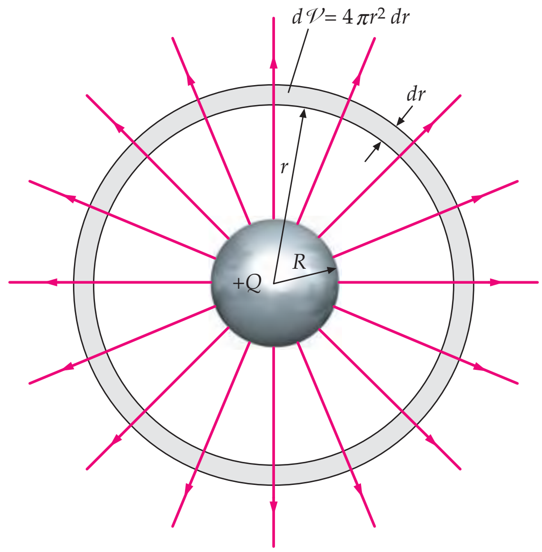

FIGURE 24-8 Geometry for the calculation of the electrostatic energy of a spherical conductor that has a charge Q. The volume of the space between r and $r + dr$ is $d\mathcal{V} = 4\pi r^2\,dr$. The electrostatic field energy in this volume element is $u_e\,d\mathcal{V}$, where $u_e = \frac{1}{2}\epsilon_0 E^2$ is the energy density.

24-3 CAPACITORS, BATTERIES, AND CIRCUITS

Next, we examine what happens when an initially uncharged capacitor is connected to the terminals of a battery. The potential difference between the two terminals of a battery is called its **terminal voltage.** The terminals of a battery (Figure 24-9) are connected to dissimilar conductors called *electrodes*, and within the battery the electrodes are separated by a conducting liquid or paste called an *electrolyte*. Because of chemical reactions in the battery, charge is transferred from one electrode to the other. This leaves one electrode of the battery (the anode) positively charged and the other electrode (the cathode) negatively charged; this charge separation is maintained by chemical reactions within the battery. Within the battery, there is an electric field directed away from the positive electrode and toward the negative electrode.* When the plates of an uncharged capacitor are connected to the terminals of the battery, the negative electrode shares its negative charge with the plate connected to it and the positive battery terminal shares its positive charge with the plate connected to it. This charge sharing momentarily reduces the amount of charge on each of the battery electrodes, and thus decreases the potential difference between the electrodes. This decrease in terminal voltage triggers the chemical reactions within the battery, and charge is transferred from one electrode to the other electrode in an effort to maintain the terminal voltage at its initial level, which is called the **open-circuit terminal voltage.** These chemical reactions cease when the battery has transferred sufficient charge from one capacitor plate to the other capacitor plate to increase the potential difference between the capacitor plates to the open-circuit terminal voltage of the battery.

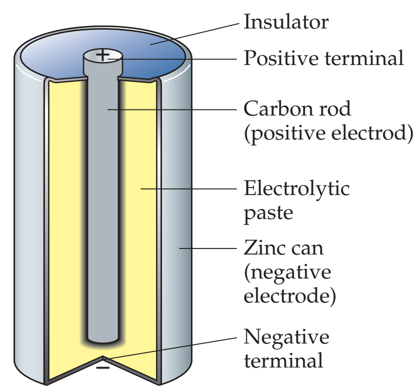

FIGURE 24-9 A carbon-zinc cell.

* This electric field from the positive to the negative terminal exists outside as well as within the battery.

A battery is a "charge pump." When we connect the plates of an uncharged capacitor to the terminals of a battery (Figure 24-10), the terminal voltage of the battery drops. This results in the battery pumping charge from one plate to the other plate until the open-circuit terminal voltage is again reached.

In electric circuit diagrams, the symbol representing a battery is ⊣|⊢ +, where the longer vertical line represents the positive terminal and the shorter vertical line represents the negative terminal. The symbol representing a capacitor is ⊣⊢.

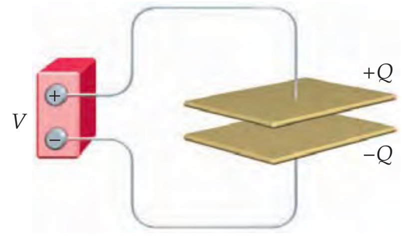

FIGURE 24-10 When the conductors of an uncharged capacitor are connected to the terminals of a battery, the battery "pumps" charge from one conductor to the other until the potential difference between the conductors equals the open circuit potential difference between the battery terminals.* The amount of charge transferred through the battery is $Q = CV$.

> **PRACTICE PROBLEM 24-8**
> A 6.0-μF capacitor, initially uncharged, is connected to the terminals of a 9.0-V battery. What total amount of charge then flows through the battery as the capacitor is charged to the open-circuit terminal voltage of the battery?

COMBINATIONS OF CAPACITORS

Example 24-4 Capacitors Connected in Parallel

A circuit consists of a 6.0-μF capacitor, a 12.0-μF capacitor, a 12.0-V battery, and a switch, connected as shown in Figure 24-11. The switch is initially open and the capacitors are initially uncharged. The switch is then closed and the capacitors charge. When the capacitors are fully charged and the open-circuit terminal voltage of the battery is restored, (*a*) what is the potential of each conductor in the circuit? (Choose the negative battery terminal to be the zero-potential reference point.) (*b*) What is the charge on each capacitor plate? (*c*) What total charge passed through the battery?

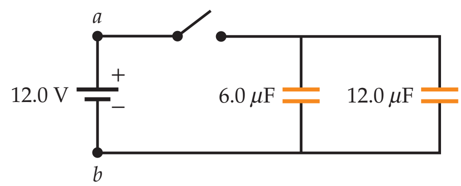

FIGURE 24-11

PICTURE The potential is the same throughout a conductor in electrostatic equilibrium. Thus, after the charges stop flowing, all of the conductors connected to each other by a conducting wire are at the same potential. The charge Q on a capacitor is related to the potential difference V across the capacitor by $Q = CV$. In addition, the charges on the plates of a single capacitor are equal in magnitude but opposite in sign.

SOLVE

(*a*) Use a red marker to color the positive (+) battery terminal and all the conductors connected to it (Figure 24-12), and use a blue marker to color the negative (−) battery terminal and all the conductors connected to it:

All points colored red are at potential
$\boxed{V_a = 12\text{ V}}$
All points colored blue are at potential
$\boxed{V_b = 0}$

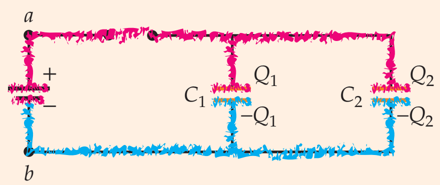

FIGURE 24-12

(*b*) Use $Q = CV$ to find the magnitude of the charge on the plates. (The plate of a capacitor at the higher potential has a positive charge):

$$Q_1 = C_1V = (6.0\ \mu\text{F})(12.0\text{ V}) = \boxed{72\ \mu\text{C}}$$

$$Q_2 = C_2V = (12.0\ \mu\text{F})(12.0\text{ V}) = \boxed{144\ \mu\text{C}}$$

(*c*) The plates become charged because the battery acts as a charge pump:

$$Q = Q_1 + Q_2 = \boxed{216\ \mu\text{C}}$$

CHECK The charge on the 12.0-μF capacitor is two times the charge on the 6.0-μF capacitor when the voltage across each is 12.0 V. This result is as expected. The capacitance of a capacitor is a measure of its capacity to store charge for a given voltage.

TAKING IT FURTHER The equivalent capacitance of the two-capacitor combination is Q/V, where Q is the charge passing through the battery and V is the open-circuit terminal voltage of the battery. For this example $C_{eq} = (216\ \mu\text{C})/(12.0\text{ V}) = 18.0\ \mu\text{F}$.

* We will discuss batteries more fully in Chapter 25. Here, all we need to know is that a battery is a device that stores energy, supplies electrical energy, and pumps charge in an effort to restore the potential difference between its terminals to the open circuit terminal voltage V.

When two capacitors are connected, as shown in Figure 24-13, so that the upper plates of the two capacitors are connected by a conducting wire and are therefore at a common potential, and the lower plates are also connected together and are at a common potential, just like the capacitors in Example 24-4, the capacitors are said to be **connected in parallel.** Devices connected in parallel share a common potential difference across each device *due solely to the way they are connected*.

In Figure 24-13, assume that points a and b are connected to a battery or some other device that maintains a potential difference $V = V_a - V_b$ between the plates of each capacitor. If the capacitances are C_1 and C_2, the charges Q_1 and Q_2 stored on the plates are given by

$$Q_1 = C_1V$$

and

$$Q_2 = C_2V$$

The total charge stored is

$$Q = Q_1 + Q_2 = C_1V + C_2V = (C_1 + C_2)V$$

A combination of capacitors in a circuit can sometimes be substituted with a single capacitor that is operationally equivalent to the combination. The substitute capacitor is said to have an **equivalent capacitance.** That is, if a combination of initially uncharged capacitors is connected to a battery, the charge Q that flows through the battery as the capacitor combination becomes charged is the same as the charge that flows through the same battery if connected to a single uncharged capacitor of equivalent capacitance. Therefore, the equivalent capacitance of two capacitors in parallel is the ratio of the charge $Q_1 + Q_2$ to the potential difference:

$$C_{eq} = \frac{Q}{V} = \frac{Q_1 + Q_2}{V} = \frac{Q_1}{V} + \frac{Q_2}{V} = C_1 + C_2 \qquad 24\text{-}12$$

Thus, for two capacitors in parallel, C_{eq} is the sum of the individual capacitances. When we add a second capacitor in parallel with the first capacitor, the area that the charge is distributed on is increased, allowing more charge to be stored for the same potential difference.

The same reasoning can be extended to three or more capacitors connected in parallel, as in Figure 24-14:

$$C_{eq} = C_1 + C_2 + C_3 + \ldots \qquad 24\text{-}13$$

EQUIVALENT CAPACITANCE FOR CAPACITORS IN PARALLEL

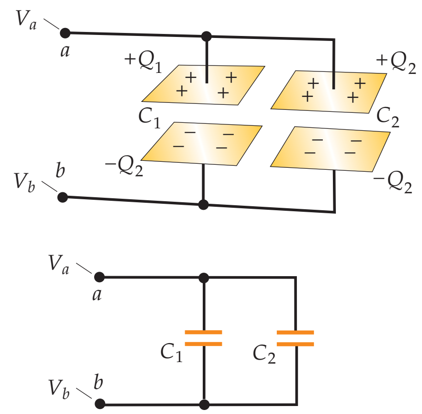

FIGURE 24-13 Two capacitors in parallel. The upper plates are connected to each other by a conductor and are therefore at a common potential V_a; the lower plates are similarly connected together and therefore at a common potential V_b.

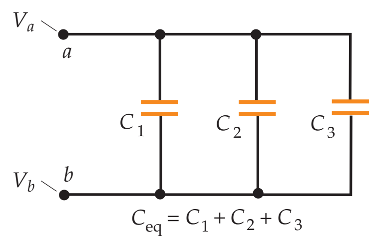

FIGURE 24-14 Three capacitors in parallel. The effect of adding an additional capacitor in parallel with a combination of capacitors is to increase the equivalent capacitance.

Example 24-5 Capacitors Connected in Series

A circuit consists of a 6.0-μF capacitor, a 12-μF capacitor, a 12-V battery, and a switch, connected as shown in Figure 24-15. Initially, the switch is open and the capacitors are uncharged. The switch is then closed and the capacitors charge. When the open-circuit terminal voltage is restored to the battery, the capacitors are fully charged. (*a*) What is the potential of each conductor in the circuit? (Choose the negative battery terminal to be the zero-potential reference point.) If the potential of a conductor is not known, represent its potential symbolically. (*b*) What is the charge on each capacitor plate? (*c*) What total charge passed through the battery?

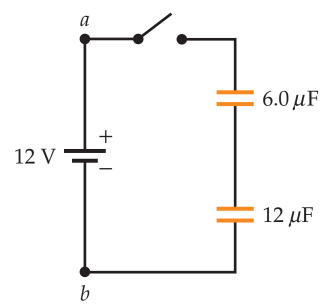

FIGURE 24-15

PICTURE The potential is the same throughout a conductor in electrostatic equilibrium. After the charges stop moving, all of the conductors connected by a conducting wire are at the same potential. The charge on a capacitor is related to the potential difference across the capacitor by $Q = CV$. Charge does not travel across the gap between the plates of a capacitor.

SOLVE

(*a*) Use a red marker to color the positive (+) battery terminal and all conductors connected to it, use a blue marker to color the negative (−) battery terminal and all the conductors connected to it, and use a green marker to color all other mutually connected conductors (Figure 24-16):

All points colored red are at potential $\boxed{V_a = 12\text{ V}}$

All points colored blue are at potential $\boxed{V_b = 0}$

All points colored green are at the yet unknown potential $\boxed{V_m}$

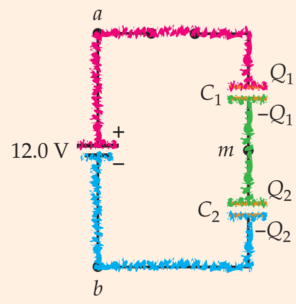

FIGURE 24-16

(*b*) 1. Express the potential difference across each capacitor in terms of the Part(*a*) results:

$$V_1 = V_a - V_m \quad \text{and} \quad V_2 = V_m - V_b$$

2. Use $Q = CV$ to relate the charge on each capacitor to the potential difference:

$$Q_1 = C_1V_1 = C_1(V_a - V_m)$$

and

$$Q_2 = C_2V_2 = C_2(V_m - V_b)$$

3. Eliminating V_m gives:

$$\left.\begin{aligned} V_a - V_m &= \frac{Q_1}{C_1} \\ V_m - V_b &= \frac{Q_2}{C_2} \end{aligned}\right\} \Rightarrow \quad V_a - V_b = \frac{Q_1}{C_1} + \frac{Q_2}{C_2}$$

4. During charging, there is no charge transferred either to or from the green region in Figure 24-16, so its net charge remains zero:

$$(-Q_1) + Q_2 = 0 \quad \text{so} \quad Q_1 = Q_2$$

5. Let $Q = Q_1 = Q_2$. Substitute Q for both Q_1 and Q_2 and solve for Q:

$$V_a - V_b = \frac{Q}{C_1} + \frac{Q}{C_2} \quad \text{so} \quad Q = \frac{V_a - V_b}{\dfrac{1}{C_1} + \dfrac{1}{C_2}} = \frac{12\text{ V} - 0}{\dfrac{1}{6.0\ \mu\text{F}} + \dfrac{1}{12\ \mu\text{F}}} = 48\ \mu\text{C}$$

$$Q_1 = Q_2 = \boxed{48\ \mu\text{C}}$$

(*c*) All the charge passing through the battery ends up on the upper plate of C_1:

$$Q_1 = Q = \boxed{48\ \mu\text{C}}$$

CHECK The potential difference across a capacitor is equal to Q/C. Thus the potential difference across the 6.0-μF and 12-μF capacitors are $(48\ \mu\text{C})/(6.0\ \mu\text{F}) = 8.0\text{ V}$ and $(48\ \mu\text{C})/(12\ \mu\text{F}) = 4.0\text{ V}$, respectively. The sum of these potential differences is $8.0\text{ V} + 4.0\text{ V} = 12.0\text{ V}$, which is as expected because the battery is a 12-V battery.

TAKING IT FURTHER The equivalent capacitance of the two-capacitor combination is Q/V, where Q is the charge passing through the battery and V is the open-circuit terminal voltage of the battery. For this example $C_{eq} = (48\ \mu\text{C})/(12\text{ V}) = 4.0\ \mu\text{F}$.

PRACTICE PROBLEM 24-9 Find the potential V_m on the conductors colored green in Figure 24-16.

CONCEPT CHECK 24-3

During the charging of the capacitors in Example 24-5, did the net charge within the battery increase, decrease, or remain the same?

Consider the circuit shown in Figure 24-15. If we start at point b and follow a path that goes once around the circuit in the clockwise direction, the potential goes up by 12 V as we step across the battery, drops by 4 V as we step across the 6-μF capacitor, drops by an additional 8 V as we step across the 12-μF capacitor, and remains the same on the path back to point b (thus completing the trip around the circuit). The changes in potential (+12 V, −4 V, and −8 V) add to zero, which is not a special circumstance. The changes in potential around any closed path always sum to zero. Adding the changes in potential around a circuit loop and setting the sum equal to zero is a very useful tool for analyzing electric circuits. Known as **Kirchhoff's loop rule,** it is a consequence of the fact that the potential difference between any two points does not depend on the path taken from one of the points to the other.

> The changes in potential around any closed path always sum to zero.
>
> KIRCHHOFF'S LOOP RULE

A **junction** is a point in a wire where the wire divides into two or more wires. In Figure 24-17, two capacitors are connected so that a plate of one capacitor is connected to a plate of a second capacitor by a wire containing no junctions, just like the wire connecting the capacitors in Example 24-5. Devices connected in this manner are connected in **series.**

Capacitors C_1 and C_2 in Figure 24-17 are connected in series and initially they are without charge. If points a and b are then connected to the terminals of a battery, electrons will be pumped through the battery from the upper plate of C_1 to the lower plate of C_2. This leaves the upper plate of C_1 with a charge $+Q$ and the lower plate of C_2 with a charge $-Q$. When a charge $+Q$ appears on the upper plate of C_1, the electric field produced by that charge induces an equal negative charge, $-Q$, on the lower plate of C_1. The charge on the lower plate of C_1 comes from electrons drawn from the upper plate of C_2. Thus, there will be a charge equal to $+Q$ on the upper plate of C_2. The potential difference across C_1 is

$$V_1 = \frac{Q}{C_1}$$

Similarly, the potential difference across the second capacitor is

$$V_2 = \frac{Q}{C_2}$$

The potential difference across the two capacitors in series is the sum of these potential differences:

$$V = V_a - V_b = V_1 + V_2 = \frac{Q}{C_1} + \frac{Q}{C_2} = Q\left(\frac{1}{C_1} + \frac{1}{C_2}\right) \qquad \text{24-14}$$

The equivalent capacitance of the two capacitors is

$$C_{\text{eq}} = \frac{Q}{V} \qquad \text{24-15}$$

where Q is the charge that passes through the battery during the charging process. Substituting Q/C_{eq} for V in Equation 24-14, and then dividing both sides by Q, gives

$$\frac{1}{C_{\text{eq}}} = \frac{1}{C_1} + \frac{1}{C_2} \qquad \text{24-16}$$

Equation 24-16 can be generalized to three or more capacitors connected in series:

$$\frac{1}{C_{\text{eq}}} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} + \cdots \qquad \text{24-17}$$

EQUIVALENT CAPACITANCE FOR EQUALLY CHARGED CAPACITORS IN SERIES

PRACTICE PROBLEM 24-10

Two capacitors have capacitances of 20 μF and 30 μF. Find the equivalent capacitance if the capacitors are connected (*a*) in parallel and (*b*) in series.

Note that in Practice Problem 24-10, the equivalent capacitance of the two capacitors in series is less than the capacitance of either capacitor. Adding a capacitor in series increases $1/C_{\text{eq}}$, which means the equivalent capacitance C_{eq} decreases. When we add a second capacitor in series, we decrease the equivalent capacitance of the combination. The plate separation is, in effect, increased, so it requires a greater potential difference to store the same charge.

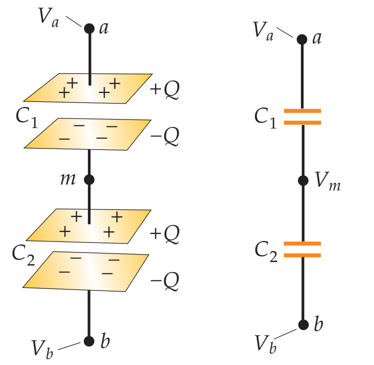

FIGURE 24-17 The total charge on the two interconnected capacitor plates equals zero. The potential difference across the pair equals the sum of the potential differences across the individual capacitors. The two capacitors are connected in series.

A capacitor bank for storing energy to be used by the pulsed Nova laser at Lawrence Livermore Laboratories. The laser is used in fusion studies. *(Lawrence Livermore National Laboratory.)*

! Equation 24-10 is valid if the capacitors are connected in series AND if the total charge on each pair of capacitor plates connected by an otherwise isolated conductor is zero.

Example 24-6 Using the Equivalence Formula

A 6.0-μF capacitor and a 12-μF capacitor, each initially uncharged, are connected in series across a 12-V battery. Using the equivalence formula for capacitors in series, find the charge on each capacitor and the potential difference across each.

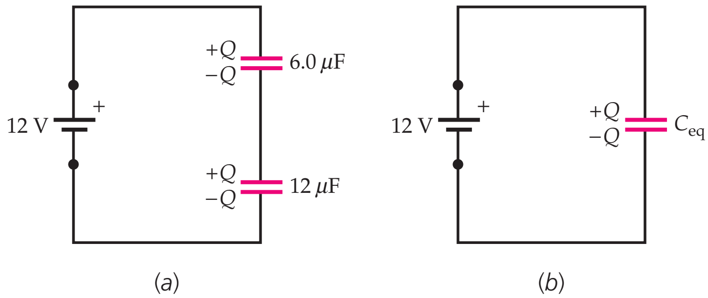

FIGURE 24-18

PICTURE Figure 24-18*a* shows the circuit in this example and Figure 24-18*b* shows an equivalent capacitor that has the same charge $Q = C_{eq}V$. After finding the charge, we can find the potential drop across each capacitor.

SOLVE

1. The charge on each capacitor equals the charge on the equivalent capacitor:

$$Q = C_{eq}V$$

2. The equivalent capacitance of the series combination is found from:

$$\frac{1}{C_{eq}} = \frac{1}{C_1} + \frac{1}{C_2} = \frac{1}{6.0\ \mu\text{F}} + \frac{1}{12\ \mu\text{F}} = \frac{3}{12\ \mu\text{F}}$$

$$C_{eq} = 4.0\ \mu\text{F}$$

3. Use this value to find the charge Q. This is the charge that passed through the battery. It is also the charge on each capacitor:

$$Q = C_{eq}V = (4.0\ \mu\text{F})(12\ \text{V}) = \boxed{48\ \mu\text{C}}$$

4. Use the result for Q to find the potential across the 6.0-μF capacitor:

$$V_1 = \frac{Q}{C_1} = \frac{48\ \mu\text{C}}{6.0\ \mu\text{F}} = \boxed{8.0\ \text{V}}$$

5. Again, use the result for Q to find the potential across the 12-μF capacitor:

$$V_2 = \frac{Q}{C_2} = \frac{48\ \mu\text{C}}{12\ \mu\text{F}} = \boxed{4.0\ \text{V}}$$

CHECK The sum of these potential differences is 12 V, as required.

TAKING IT FURTHER The results are the same as those obtained in Example 24-5.

Example 24-7 Series, Parallel, or Neither *Conceptual*

Consider the capacitors shown in Figure 24-19*a*. (*a*) Identify all parallel combinations of capacitors. (*b*) Identify all series combinations of capacitors.

PICTURE Capacitors connected in parallel share a common potential difference across each capacitor due solely to the way they are connected. The potential along a conducing path remains constant. Use markers to color each conducting path a unique color. Two capacitors are connected in series if a plate of one capacitor is connected to a plate of a second capacitor by a conducting wire that contains no junctions.

SOLVE

(*a*) 1. Use markers to give each electric potential unique color (Figure 24-19*b*). The potential can change only at a circuit device such as a capacitor or a battery.

2. Capacitors connected in parallel share a common potential difference across each capacitor due solely to the way they are connected.

Capacitors 4 and 7 are the only two capacitors that are connected in parallel with each other.

(*b*) If two capacitors are connected so that a plate of one capacitor is connected to a plate of a second capacitor by a conducting wire containing no junctions then the capacitors are connected in series.

Capacitors 8 and 9 are the only two capacitors that are connected in series with each other.

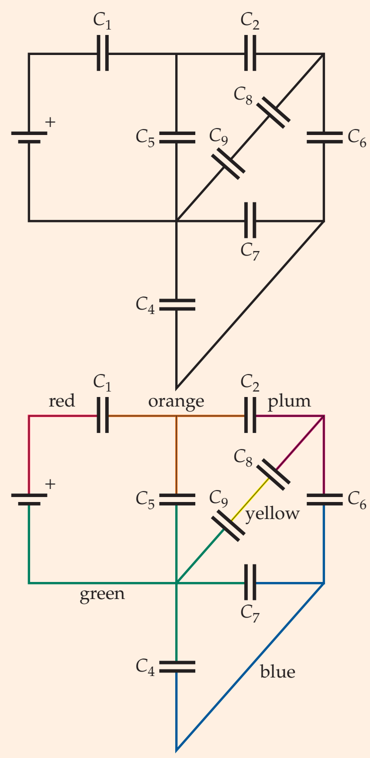

FIGURE 24-19

TAKING IT FURTHER Capacitors 1 and 2 are not in series. We make this conclusion because there is a junction connecting the wire that connects capacitors 1 and 2. Capacitors 2 and 5 are not in parallel even though one plate of each capacitor has an orange-colored wire attached to it. However, there is plum-colored wire connected to one of the plates of capacitor 2 and there is not a plum-colored wire connected to a plate of capacitor 5. Thus, we know the two capacitors do not share the same potential difference due to the way they are wired.

Example 24-8 Capacitors Reconnected

The two capacitors in Example 24-6 are removed from the battery and carefully disconnected from each other so that the charge on each of the plates is not changed (Figure 24-20*a*). They are then reconnected, positive plate to positive plate and negative plate to negative plate (Figure 24-20*b*), in a circuit containing open switches S_1 and S_2. Find the potential difference across the capacitors and the charge on each capacitor after the switches are closed and the charges have stopped flowing.

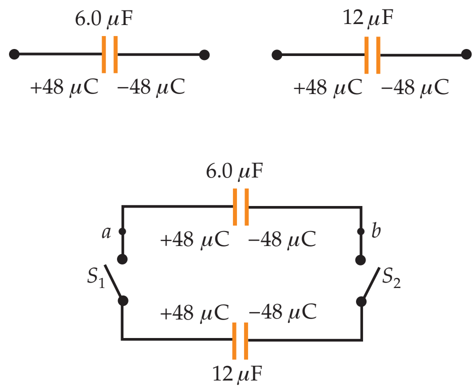

FIGURE 24-20

PICTURE Just after the two capacitors are disconnected from the battery, they have equal charges of 48 μC. After switches S_1 and S_2 in the new circuit are closed the voltages across the capacitors are the same. Use the definition of capacitance and conservation of charge to solve for the charge on each capacitor. Once these charges are known, use them to solve for the voltage.

SOLVE

1. Draw and label the circuit after both switches have been closed. Let C_1 and C_2 be 6.0 μF and 12 μF, respectively (Figure 24-21).

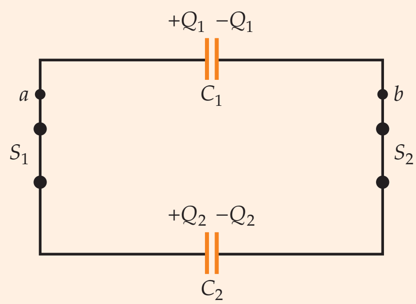

FIGURE 24-21

2. The wiring is such that after the switches are closed the voltage is the same across each capacitor. $\quad V = V_1 = V_2$

3. For each capacitor, $V = Q/C$. Substitute this into the step 2 result. $\quad \dfrac{Q_1}{C_1} = \dfrac{Q_2}{C_2}$

4. The sum of the charges on the two capacitor plates on the left remains 96 μC. $\quad Q_1 + Q_2 = 96\ \mu\text{C}$

5. Simultaneously solve the equations in steps 3 and 4 for the charge on each capacitor. $\quad Q_1 = \boxed{32\ \mu\text{C}}$

$$Q_2 = \boxed{64\ \mu\text{C}}$$

6. Calculate the potential difference. $\quad V = \dfrac{Q_1}{C_1} = \boxed{5.3\ \text{V}}$

CHECK Note that $Q = Q_1 + Q_2 = 96\ \mu$C and that $Q_2/C_2 = 5.33$ V, as required for consistency.

TAKING IT FURTHER After the switches are closed, the two capacitors are connected in parallel with the potential difference between point *a* and point *b* being the potential difference across the pair. Thus, $C_{eq} = C_1 + C_2 = 18\ \mu$F, $Q = Q_1 + Q_2 = 96\ \mu$C, and $V = Q/C_{eq} =$ 5.33 V. In addition, after the switches are closed, the two capacitors are connected in series. However, the series equivalence formula (Equation 24-17) is NOT valid because the sum of the charges on each pair of capacitor plates connected by a single, otherwise isolated, wire does NOT equal zero.

PRACTICE PROBLEM 24-11 Find the potential energy stored in the capacitors before and after they are reconnected.

There is decrease in the potential energy stored in the capacitors when they are reconnected. This "missing" potential energy is either dissipated as thermal energy in the wires or radiated away.

! Charge IS conserved when capacitors are reconnected, but while energy IS conserved, electrical potential energy is NOT conserved.

Example 24-9 Capacitors in Series and in Parallel

Three capacitors are connected as shown in Figure 24-22. (*a*) Find the equivalent capacitance of the three-capacitor combination. (*b*) The capacitors are initially uncharged. The combination is then connected to a 6.0-V battery. Find the potential difference across each capacitor and the charge on each capacitor after the battery is connected and the charges have stopped flowing.

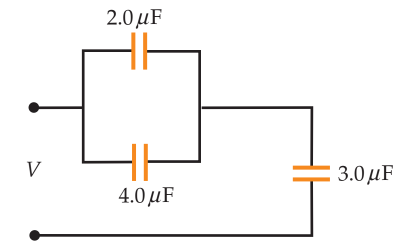

FIGURE 24-22

PICTURE The 2.0-μF capacitor and the 4.0-μF capacitor are connected in parallel, and the parallel combination is connected in series with the 3.0-μF capacitor. We first find the equivalent capacitance of the parallel combination (Figure 24-23*a*), then we combine this equivalent capacitance with the 3.0-μF capacitor to reach a final equivalent capacitance (Figure 24-23*b*). The charge on the positive plate of the 3.0-μF capacitor is the charge passing through the battery $Q = C_{eq}V$ as shown in Figure 24-23*a*.

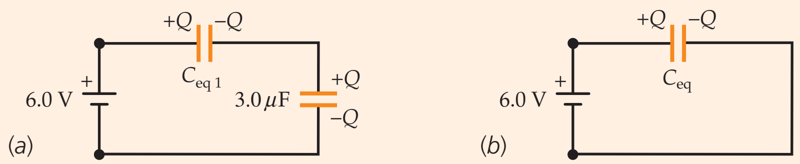

FIGURE 24-23

SOLVE

(*a*) 1. The equivalent capacitance of the two capacitors in parallel is the sum of the capacitances:

$$C_{eq\,1} = C_1 + C_2 = 2.0\ \mu\text{F} + 4.0\ \mu\text{F} = 6.0\ \mu\text{F}$$

2. Find the equivalent capacitance of the 6.0-μF capacitor in series with the 3.0-μF capacitor:

$$\frac{1}{C_{eq}} = \frac{1}{C_{eq\,1}} + \frac{1}{C_3} = \frac{1}{6.0\ \mu\text{F}} + \frac{1}{3.0\ \mu\text{F}} = \frac{1}{2.0\ \mu\text{F}}$$

$$C_{eq} = \boxed{2.0\ \mu\text{F}}$$

(*b*) 1. Calculate the charge Q that passed through the battery during charging. This is the charge on the 3.0-μF capacitor:

$$Q = C_{eq}V = (2.0\ \mu\text{F})(6.0\ \text{V}) = \boxed{12\ \mu\text{C}}$$

2. The potential drop across the 3.0-μF capacitor is Q/C_3:

$$V_3 = \frac{Q_3}{C_3} = \frac{Q}{C_3} = \frac{12\ \mu\text{C}}{3.0\ \mu\text{F}} = \boxed{4.0\ \text{V}}$$

3. The potential drop across the parallel combination V_{24} is $Q/C_{eq\,1}$:

$$V_{24} = \frac{Q}{C_{eq\,1}} = \frac{12\ \mu\text{C}}{6.0\ \mu\text{F}} = \boxed{2.0\ \text{V}}$$

4. The charge on each of the parallel capacitors is found from $Q_i = C_iV_{24}$, where $V_{24} = 2.0$ V:

$$Q_2 = C_2V_{24} = (2.0\ \mu\text{F})(2.0\ \text{V}) = \boxed{4.0\ \mu\text{C}}$$

$$Q_4 = C_4V_{24} = (4.0\ \mu\text{F})(2.0\ \text{V}) = \boxed{8.0\ \mu\text{C}}$$

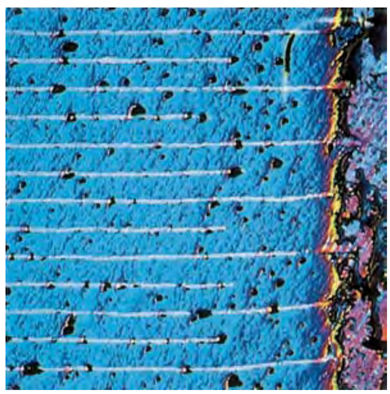
CHECK The voltage drop across the parallel combination (2.0 V) plus the voltage drop across the 3.0-μF capacitor (4.0 V) equals the voltage of the battery. Also, the sum of the charges on the parallel capacitors (4.0 μC + 8.0 μC) equals the total charge (12 μC) on the 3.0-μF capacitor.

PRACTICE PROBLEM 24-12 Find the energy stored in each capacitor.

24-4 DIELECTRICS

A nonconducting material (for example, air, glass, paper, or wood) is called a **dielectric.** When the space between the two conductors of a capacitor is occupied by a dielectric, the capacitance is increased by a factor that is characteristic of the dielectric, a fact discovered experimentally by Michael Faraday. The reason for this increase is that the electric field between the plates of a capacitor is weakened by the dielectric. Thus, for a given charge on the plates, the potential difference V is reduced and the capacitance (Q/V) is increased.

Consider an isolated charged capacitor without a dielectric between its plates. A dielectric slab is then inserted between the plates, completely filling the space between



A cut section of a multilayer capacitor that has a blue ceramic dielectric. The white lines are the edges of the conducting plates.(*© Manfred Kage/Peter Arnold, Inc.)*

the plates. If the electric field strength is E_0 before the dielectric slab is inserted, after the dielectric slab is inserted between the plates the electric field strength is

$$E = \frac{E_0}{\kappa} \qquad 24\text{-}18$$

ELECTRIC FIELD INSIDE A DIELECTRIC

where κ (kappa) is called the **dielectric constant** of the inserted material. For a parallel-plate capacitor of separation d, the potential difference V between the plates is

$$V = Ed = \frac{E_0 d}{\kappa} = \frac{V_0}{\kappa}$$

where V is the potential difference with the dielectric and $V_0 = E_0 d$ is the original potential difference without the dielectric. The new capacitance is

$$C = \frac{Q}{V} = \frac{Q}{V_0/\kappa} = \kappa \frac{Q}{V_0}$$

or

$$C = \kappa C_0 \qquad 24\text{-}19$$

EFFECT OF A DIELECTRIC ON CAPACITANCE

where $C_0 = Q/V_0$ is the capacitance without the dielectric. The capacitance of a parallel-plate capacitor filled with a dielectric of constant κ is thus

$$C = \frac{\kappa \epsilon_0 A}{d} = \frac{\epsilon A}{d} \qquad 24\text{-}20$$

where

$$\epsilon = \kappa \epsilon_0 \qquad 24\text{-}21$$

The parameter ϵ is called the **permittivity** of the dielectric.

In the preceding discussion, the capacitor was electrically isolated (not part of a circuit), so we assumed that the charge on its plates did not change as the dielectric was inserted. This is the case if the capacitor is charged and then removed from the charging source (the battery) before the insertion of the dielectric. If the dielectric is inserted while the battery remains connected, the battery pumps additional charge to maintain the original potential difference. The total charge on the plates is then $Q = \kappa Q_0$. In either case, the capacitance (Q/V) is increased by the factor κ.

PRACTICE PROBLEM 24-13

The 89-pF capacitor of Example 24-1 is filled with a dielectric of constant $\kappa = 2.0$.(*a*) Find the new capacitance. (*b*) Find the charge on the capacitor when the dielectric is in place and the capacitor is attached to a 12-V battery.

PRACTICE PROBLEM 24-14

The capacitor in the previous problem is charged to 12 V without the dielectric and is then disconnected from the battery. The dielectric of constant $\kappa = 2.0$ is then inserted. Find the new values for (*a*) the charge Q, (*b*) the voltage V, and (*c*) the capacitance C.

Dielectrics not only increase the capacitance of a capacitor, they also provide a means for keeping parallel conducting plates apart and they increase the potential difference at which dielectric breakdown occurs.* Consider a parallel-plate capacitor made from two sheets of metal foil that are separated by a thin plastic sheet.

* Recall from Chapter 23 that for electric fields greater than about 3×10^6 V/m, air breaks down; that is, it becomes ionized and begins to conduct.

The plastic sheet allows the metal sheets to be very close together without actually being in electrical contact, and because the dielectric strength of plastic is greater than that of air, a greater potential difference can be attained before dielectric breakdown occurs. Table 24-1 lists the dielectric constants and dielectric strengths of some dielectrics. Note that for air $\kappa \approx 1$; so, for most situations we do not need to distinguish between air and a vacuum.

Table 24-1 Dielectric Constants and Dielectric Strengths of Various Materials

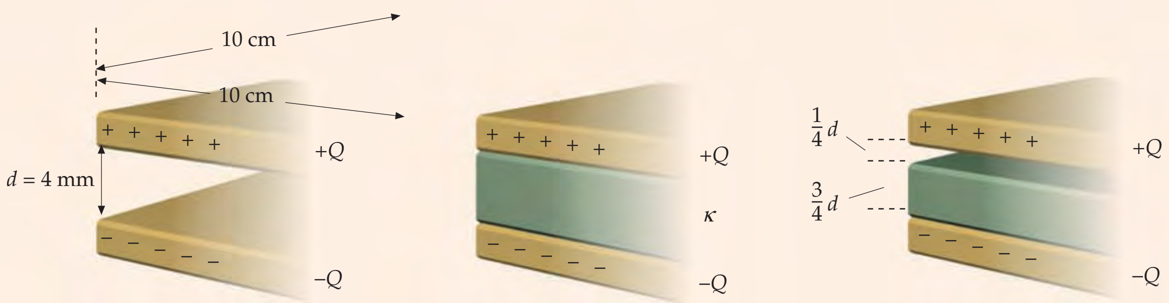
Material	Dielectric Constant κ	Dielectric Strength, kV/mm
Air	1.00059	3
Bakelite	4.9	24
Gasoline	2.0 (70°F)	
Glass (Pyrex)	5.6	14
Mica	5.4	10–100
Neoprene	6.9	12
Paper	3.7	16
Paraffin	2.1–2.5	10
Plexiglas	3.4	40
Polystyrene	2.55	24
Porcelain	7	5.7
Strontium titanate	240	8
Transformer oil	2.24	12

Example 24-10 Using a Dielectric in a Parallel-Plate Capacitor

A parallel-plate capacitor has square plates of edge length 10 cm and a separation of $d = 4.0$ mm. A dielectric slab of constant $\kappa = 2.0$ has dimensions 10 cm × 10 cm × 4.0 mm. (*a*) What is the capacitance without the dielectric? (*b*) What is the capacitance if the dielectric slab fills the space between the plates? (*c*) What is the capacitance if a dielectric slab that has dimensions 10 cm × 10 cm × 3.0 mm is inserted into the 4.0-mm gap?

PICTURE The capacitance without the dielectric, C_0, is found from the area and spacing of the plates (Figure 24-24*a*). When the capacitor is filled with a slab of dielectric constant κ (Figure 24-24*b*), the capacitance is $C = \kappa C_0$ (Equation 24-19). If the dielectric only partially fills the capacitor (Figure 24-24*c*), we isolate the capacitor and calculate the potential difference V with a given charge Q_0, then apply the definition of capacitance, $C = Q/V$.

FIGURE 24-24



SOLVE

(*a*) If there is no dielectric, the capacitance C_0 is given by Equation 24-6:

$$C_0 = \frac{\epsilon_0 A}{d} = \frac{(8.85\text{ pF/m})(0.10\text{ m})^2}{0.0040\text{ m}} = 22.1\text{ pF} = \boxed{22\text{ pF}}$$

(*b*) When the capacitor is filled with a material that has dielectric constant κ, its capacitance C is increased by the factor κ:

$$C = \kappa C_0 = (2.0)(22.1\text{ pF}) = 44.2\text{ pF} = \boxed{44\text{ pF}}$$

(*c*) 1. We keep the capacitor electrically isolated, so the charge remains constant when dielectric slabs are inserted or removed. The capacitance is related to the charge Q_0 and the new potential difference V:

$$C = \frac{Q_0}{V}$$

2. When the 3.0-mm-thick slab is in place, the potential difference V across the entire gap is the potential difference across the empty portion of the gap plus the potential difference across dielectric slab:

$$V = V_{\text{gap}} + V_{\text{slab}} = E_{\text{gap}}(\tfrac{1}{4}d) + E_{\text{slab}}(\tfrac{3}{4}d)$$

3. The field strength E_{gap} in the empty gap is σ_0/ϵ_0, where $\sigma_0 = Q_0/A$. This is the same as the field strength E_0 when no dielectric is between the plates:

$$E_{\text{gap}} = E_0 = \frac{\sigma_0}{\epsilon_0} = \frac{Q_0}{\epsilon_0 A}$$

4. The field in the dielectric slab is reduced by the factor κ^{-1}:

$$E_{\text{slab}} = \frac{E_0}{\kappa}$$

5. Substituting the results of the previous two steps into the step 2 result yields V in terms of κ. Note that the potential difference when no dielectric is between the plates is $V_0 = E_0 d$:

$$V = E_0 d_{\text{gap}} + E_{\text{slab}} d_{\text{slab}} = E_0\left(\frac{1}{4}d\right) + \frac{E_0}{\kappa}\left(\frac{3}{4}d\right)$$

$$= E_0 d\left(\frac{1}{4} + \frac{3}{4\kappa}\right) = V_0\left(\frac{\kappa + 3}{4\kappa}\right)$$

6. Using $C = Q_0/V$, we find the new capacitance in terms of the original capacitance, $C_0 = Q_0/V_0$:

$$C = \frac{Q_0}{V} = \frac{Q_0}{V_0\dfrac{\kappa + 3}{4\kappa}} = \frac{Q_0}{V_0}\left(\frac{4\kappa}{\kappa + 3}\right) = C_0\left(\frac{4\kappa}{\kappa + 3}\right)$$

$$= (22.1\text{ pF})\left(\frac{4 \cdot 2.0}{2.0 + 3}\right) = \boxed{35\text{ pF}}$$

CHECK The absence of a dielectric corresponds to $\kappa = 1$. Substituting 1 for κ in the final step in Part (*c*) would result $C = C_0$, as expected. Suppose that the dielectric slab were a conducting slab instead of a dielectric. In a conductor, $E = 0$; so, according to $E = E_0/\kappa$ (Equation 24-18), κ for a conductor would equal infinity. As κ approaches infinity, the quantity $4\kappa/(\kappa + 3)$ approaches 4, so the result for the final step in Part (*c*) approaches $4C_0$. A conducting slab simply reduces the plate separation by the thickness of the slab. The plate separation when the conducting slab is in place would be $\frac{1}{4}d$. According to Equation 24-20 ($C = \kappa\epsilon_0 A/d$), C should be $4C_0$, as it is for very large values of κ.

TAKING IT FURTHER The results of this example are independent of the vertical position of the dielectric (or conducting) slab in the space between the plates.

PROBLEM-SOLVING STRATEGY

Calculating Capacitance II

PICTURE To calculate the capacitance of a capacitor that has a gap containing two or more dielectric slabs, first calculate the electric field strength E_0 using charge Q and with no dielectrics in the gap.

SOLVE

1. When the dielectric is in the gap, the electric field strength within a dielectric slab is $E = E_0/\kappa$, where κ is the dielectric constant.

2. Use $\vec{E}$ within a dielectric slab to calculate the voltage V_{slab} across the slab. The voltage V across the entire gap is the sum of the voltages across the individual slabs in the gap plus the sum of the voltages across any empty regions of the gap.
3. Then, calculate C using $C = Q/V$.

CHECK Evaluate your expression for C by setting κ equal to 1. Then compare your result with the expression for C_0 (the capacitance without a dielectric present).

Example 24-11 A Homemade Capacitor *Context-Rich*

When studying capacitors in physics class, your professor claims that you could build a parallel-plate capacitor from waxed paper and aluminum foil. You decide to build one about the size of a piece of notebook paper. Before testing its charge-storing power on your gullible roommate, you decide to calculate the amount of charge the capacitor will store when connected to a 9.0-V battery.

PICTURE We want charge, which we can get from the definition $C = Q/V$ if we know the capacitance. We can get the capacitance from the parallel-plate capacitor formula $C = \epsilon_0 A/d$. We will need to either measure or estimate the thickness of the waxed paper.

SOLVE

1. The charge on a capacitor is related to the voltage and the capacitance by the definition of capacitance: $Q = CV$
2. The capacitance is obtained from the parallel-plate capacitance formula: $C = \dfrac{\kappa\epsilon_0 A}{d}$
3. Substituting for C and solving for Q give: $Q = CV = \dfrac{\kappa\epsilon_0 VA}{d}$
4. A sheet of notebook paper is approximately 8.5 by 11 in: $A = 8.5\text{ in} \times 11\text{ in} = 93.5\text{ in}^2 = 0.0603\text{ m}^2$
5. We assume a sheet of wax paper is the same thickness as a sheet of the paper your physics textbook is made of. Measure the thickness of 300 sheets of paper in a book (from page 1 through page 600): The 300 sheets of paper are 2.0 cm (0.020 m) thick. So, the thickness of a single sheet of paper is $0.020\text{ m}/300 = 66.7\ \mu\text{m}$.
6. Using the step 3 result, solve for the charge. Assume the dielectric constant of wax paper is 2.3 (the same as that of paraffin):

$$Q = \frac{\kappa\epsilon_0 AV}{d} = \frac{2.3\,(8.85\text{ pF/m})(0.0603\text{ m}^2)(9.0\text{ V})}{66.7 \times 10^{-6}\text{ m}}$$
$$= 1.66 \times 10^5\text{ pC} = \boxed{0.17\,\mu\text{C}}$$

CHECK A farad is a coulomb per volt, so the units do reduce to coulombs.

ENERGY STORED IN THE PRESENCE OF A DIELECTRIC

The energy stored in a parallel-plate capacitor that has a dielectric is

$$U = \tfrac{1}{2}QV = \tfrac{1}{2}CV^2$$

We can express the capacitance C in terms of the area and separation of the plates, and the voltage difference V in terms of the electric field and plate separation, to obtain

$$U = \frac{1}{2}CV^2 = \frac{1}{2}\left(\frac{\epsilon A}{d}\right)(Ed)^2 = \frac{1}{2}\epsilon E^2(Ad)$$

The quantity Ad is the volume of the region where there is an electric field. (This is the region between the two plates.) The energy per unit volume is thus

$$u_e = \tfrac{1}{2}\epsilon E^2 = \tfrac{1}{2}\kappa\epsilon_0 E^2 \qquad 24\text{-}22$$

Part of this energy is the energy associated with the electric field (Equation 24-9) and the rest is the energy associated with mechanical stress associated with the polarization of the dielectric (discussed in Section 24-5).

Example 24-12 Inserting the Dielectric—Battery Disconnected

A parallel combination of two parallel-plate air-gap capacitors, each having a capacitance of 2.00 μF, are connected in parallel across a 12.0-V battery. The battery is disconnected from the parallel combination, and then a slab that has a dielectric constant $\kappa = 2.50$ is inserted between the plates of one of the capacitors, completely filling the gap. Before the dielectric slab is inserted, find (*a*) the charge on and energy stored in each capacitor, and (*b*) the total energy stored in the capacitors. After the dielectric is inserted, find (*c*) the potential difference across each capacitor, (*d*) the charge on each capacitor, and (*e*) the total energy stored in the capacitors.

PICTURE The capacitors are connected in parallel, so the voltage across each is the same. The charge Q and total energy U can be found for each capacitor from its capacitance C and voltage V. After the capacitors are removed from the battery, the total charge on the pair remains the same. When the dielectric is inserted into one of the capacitors, its capacitance changes. The potential across the parallel combination can be found from the total charge and the equivalent capacitance.

SOLVE

(*a*) The charge on each capacitor is found from its capacitance C and voltage $V = 12.0$ V:

$$Q = CV = (2.00\ \mu\text{F})(12.0\ \text{V}) = \boxed{24.0\ \mu\text{C}}$$

(*b*) 1. The energy stored in each capacitor is found from its charge Q and its voltage V:

$$U = \tfrac{1}{2}QV = \tfrac{1}{2}(24.0\ \mu\text{C})(12.0\ \text{V}) = 144\ \mu\text{J}$$

2. The total potential energy is twice that stored in each capacitor:

$$U_{\text{total}} = 2U = \boxed{288\ \mu\text{J}}$$

(*c*) 1. The potential across the parallel combination is related to the total charge Q_{total} and the equivalent capacitance C_{eq}:

$$V = \frac{Q_{\text{total}}}{C_{\text{eq}}}$$

2. The capacitance of the capacitor that has the dielectric is increased by the factor κ. The equivalent capacitance is the sum of the capacitances:

$$C_{\text{eq}} = C_1 + C_2 = C_1 + \kappa C_2 = (2.00\ \mu\text{F}) + 2.50(2.00\ \mu\text{F})$$
$$= 2.00\ \mu\text{F} + 5.00\ \mu\text{F} = 7.00\ \mu\text{F}$$

3. The total charge remains 48.0 μC. Substitute for Q_{total} and C_{eq} to calculate V:

$$V = \frac{Q_{\text{total}}}{C_{\text{eq}}} = \frac{48.0\ \mu\text{C}}{7.00\ \mu\text{F}} = \boxed{6.86\ \text{V}}$$

(*d*) The charge on each capacitor is again obtained from $Q = CV$:

$$Q_1 = (2.00\ \mu\text{F})(6.86\ \text{V}) = \boxed{13.7\ \mu\text{C}}$$

$$Q_2 = (5.00\ \mu\text{F})(6.86\ \text{V}) = \boxed{34.3\ \mu\text{C}}$$

(*e*) The potential energy stored in each capacitor is found from its new charge and new voltage:

$$U = U_1 + U_2 = \tfrac{1}{2}Q_1V + \tfrac{1}{2}Q_2V = \tfrac{1}{2}(Q_1 + Q_2)V$$
$$= \tfrac{1}{2}(13.7\ \mu\text{C} + 34.3\ \mu\text{C})(6.86\ \text{V}) = \boxed{165\ \mu\text{J}}$$

CHECK When the dielectric is inserted into one of the capacitors, the electric field is weakened so the potential difference across it is lowered. Because the two capacitors are connected in parallel, charge must flow from the other capacitor so that the potential difference is the same across both capacitors. Note that the capacitor that has the dielectric has the greater charge, and that when the charges calculated for each capacitor in Part (*d*) are added, $Q_1 + Q_2 = 13.7\ \mu\text{C} + 34.3\ \mu\text{C} = 48.0\ \mu\text{C}$, the result is the same as the original net charge.

TAKING IT FURTHER The total energy of 165 μJ is 123 μJ less than the original energy of 288 μJ. When the dielectric is inserted, it is attracted by the charges on the plates, so it must be restrained from accelerating into the gap. During this process $-123\ \mu$J of work ($165\ \mu\text{J} + 123\ \mu\text{J} = 288\ \mu\text{J}$) is done on the dielectric by the forces of restraint. To remove the dielectric from the gap, $+123\ \mu$J must be done on it, and this work is stored as potential energy in the capacitors.

Example 24-13 Running Out of Fuel *Context-Rich*

You are flying from New Zealand to Hawaii when the electronic components of the fuel gauge on the instrument panel of the small plane you are in start to combust. Your companion becomes very concerned and asks you to try to find a solution for the problem. The gauge consists of an air-gap cylindrical capacitor in the fuel tank (Figure 24-25). The axis of this capacitor is vertical, and fuel fills the gap up to the level of the fuel in the tank. Can you find a way make the gauge work? You had noticed the tank was half full when the gauge broke. In addition, a handheld multimeter capable of measuring capacitance (Figure 24-26) is on board.

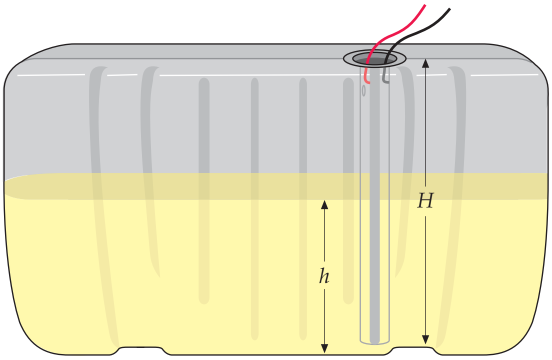


FIGURE 24-25 The cylinder is one of the plates of the capacitor. A coaxial rod is the other plate. The top of the cylinder is to be capped with the two wires feeding through the cap. This way no fuel can exit the tank through the top of the cylinder. One of the wires is attached to the cylinder and the second wire is attached to the rod. There needs to be a small hole though the side of the cylinder—near the top. This hole prevents pressure from building up as the tank is filled.

FIGURE 24-26 *(Paul Silverman/ Fundamental Photographs.)*

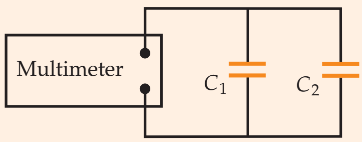
PICTURE The cylindrical capacitor can be modeled as a parallel combination of two capacitors, with the submerged portion as one of the capacitors and the portion above the fuel as the other. The ratio of the length of the submerged portion to the entire length is the desired reading.

SOLVE

1. Disconnect the two wires from the fuel tank at the instrument panel, connect them to the multimeter, and measure the capacitance so you know the reading $C_{1/2}$ when the tank is half full:

$$C = C_{1/2}$$

2. Model the capacitor as a parallel combination of two capacitors, one submerged and one not, and make a schematic diagram of the combination. Label the capacitances C_1 and C_2, where C_2 is the capacitance of the submerged portion.



3. The capacitance of a cylindrical capacitor is proportional to its length. Let H be the height of the tank (and the length of the capacitor) and let h be the height of the fuel. The capacitance of the capacitor is C_0 when the tank is empty:

$$C_1 = \frac{H-h}{H}C_0 \quad \text{and} \quad C_2 = \frac{h}{H}\kappa C_0$$

4. The equivalent capacitance C is the sum of the capacitances:

$$C = C_1 + C_2 = \frac{H-h}{H}C_0 + \frac{h}{H}\kappa C_0 = \left[1 + (\kappa - 1)\frac{h}{H}\right]C_0$$

5. Look up the dielectric constant of gasoline in Table 24-1. (Lucky you had your physics book with you):

$$\kappa = 2.0$$

$$C = \left[1 + (2.0 - 1)\frac{h}{H}\right]C_0 = \left[1 + 1.0\frac{h}{H}\right]C_0$$

6. Just before the gauge burned the tank was half full. Set $C = C_{1/2}$ and $h = h/H$ and solve for C_0:

$$C_{1/2} = \left[1 + 1.0\frac{1}{2}\right]C_0 \Rightarrow C_0 = \frac{2}{3}C_{1/2}$$

7. Substitute for C_0 in the step 4 result, and then solve for h/H. You now have a formula to convert the readings of the meter C into the fraction of the fuel remaining:

$$C = \left[1 + 1.0\frac{h}{H}\right]\frac{2}{3}C_{1/2} \quad \text{so} \quad \boxed{\frac{h}{H} = \frac{3}{2}\frac{C}{C_{1/2}} - 1}$$

CHECK Substituting $C_{1/2}$ for C in our step 7 result gives $h/H = \frac{1}{2}$, as expected. In addition, substituting zero for h, C_0 for C, and solving for C_0 gives $C_0 = \frac{2}{3}C_{1/2}$, which is the expression obtained for C_0 in step 6.

TAKING IT FURTHER Because fuel tanks are not of uniform height, this fuel gauge will not be very accurate. This is the case with many automotive fuel gauges.

Example 24-14 Inserting the Dielectric—Battery Connected

Try It Yourself

For the circuit of Example 24-12, the dielectric is slowly inserted into one of the capacitors while the battery remains connected. Find (*a*) the charge on each capacitor, (*b*) the total energy stored in the capacitors, and (*c*) the work done by the battery during the insertion process.

PICTURE Because the battery is still connected, the potential difference across the capacitors remains 12.0 V. This condition determines the charge and energy stored in each capacitor. Let subscript 1 refer to the capacitor without the dielectric and subscript 2 refer to the capacitor with the dielectric.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
(*a*) Calculate the charge on each capacitor from $Q = CV$ using the result that $C_1 = 2.00\ \mu\text{F}$ and $C_2 = 5.00\ \mu\text{F}$ as found in Example 24-12.	$Q_1 = C_1V = \boxed{24.0\ \mu\text{C}}$ $Q_2 = C_2V = \boxed{60.0\ \mu\text{C}}$
(*b*) 1. Calculate the energy stored in each capacitor from $U = \frac{1}{2}CV^2$. (Check your results by using $U = \frac{1}{2}QV$.)	$U_1 = 144\ \mu\text{J}$ $\quad U_2 = 360\ \mu\text{J}$
2. Add your results for U_1 and U_2 to obtain the final energy.	$U_{\text{total}} = \boxed{504\ \mu\text{J}}$
(*c*) The work done by the battery during the insertion process is the battery voltage multiplied by the charge passing through the battery. This charge is the increase of the charge on C_2.	$W = V\Delta Q = (12.0\ \text{V})(60.0\ \mu\text{C} - 24.0\ \mu\text{C}) = \boxed{432\ \mu\text{J}}$

CHECK The total energy of the two capacitors is larger when the dielectric is in place by $504\ \mu\text{J} - 288\ \mu\text{J} = 216\ \mu\text{J}$ than when the dielectric is not in place. This result is expected because during the insertion the battery delivers $432\ \mu\text{J}$, which is more than enough to account for the increase in the energy stored in the capacitors as the dielectric is inserted. (The dielectric is pulled in by forces of electrical attraction, so work must be done on the dielectric by the restraining forces to prevent the dielectric from gaining speed during the insertion.)

CONCEPT CHECK 24-4

Does the work done by the restraining forces to prevent the dielectric from gaining speed during insertion have a positive value or a negative value?

24-5 MOLECULAR VIEW OF A DIELECTRIC

A dielectric weakens the electric field between the plates of a capacitor. This happens because the polarized molecules of the dielectric produce an electric field within the dielectric in a direction opposite to the field produced by the charges on the plates. The electric field produced by the dielectric is due to the electric dipole moments of the molecules of the dielectric.

Although atoms and molecules are neutral, they are affected by electric fields because they contain positive and negative charges that can individually respond to external fields. We can think of an atom as a very small, positively charged nucleus surrounded by a negatively charged electron cloud. In some atoms and molecules, the charge configuration is sufficiently symmetric so that the "center of negative charge" coincides with the center of positive charge. An atom or molecule that has this symmetry has zero dipole moment and is said to be nonpolar. In the presence of an external electric field, however, the positive and negative charges experience forces in opposite directions, so the positive and negative charges then separate until the attractive force they exert on each other balances the forces due to the external electric field (Figure 24-27). The molecule is then said to be polarized and it behaves like the electric dipole it is.

In some molecules (for example, HCl and H_2O), the centers of positive and negative charge do not coincide, even in the absence of an external electric field. As we noted in Chapter 21, these polar molecules have a permanent electric dipole moment.

When a dielectric is placed in the field of a charged capacitor, its molecules are polarized in such a way that there is a net dipole moment parallel to the field. If the molecules are polar, their dipole moments, originally oriented at random, tend to become aligned due to the torque exerted by the field.* If the molecules are nonpolar, the field induces dipole moments that are parallel to the field. In either case, the molecules in the dielectric are polarized in the direction of the external field (Figure 24-28).

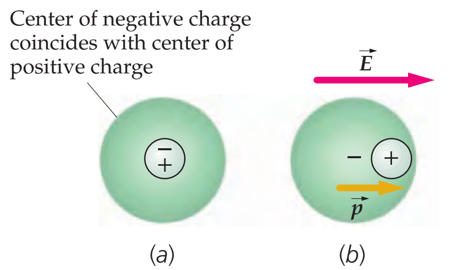


FIGURE 24-27 Schematic diagrams of the charge distributions of an atom or nonpolar molecule. (*a*) In the absence of an external electric field, the center of positive charge coincides with the center of negative charge. (*b*) In the presence of an external electric field, the centers of positive and negative charge are displaced, producing an induced dipole moment in the direction of the external field.

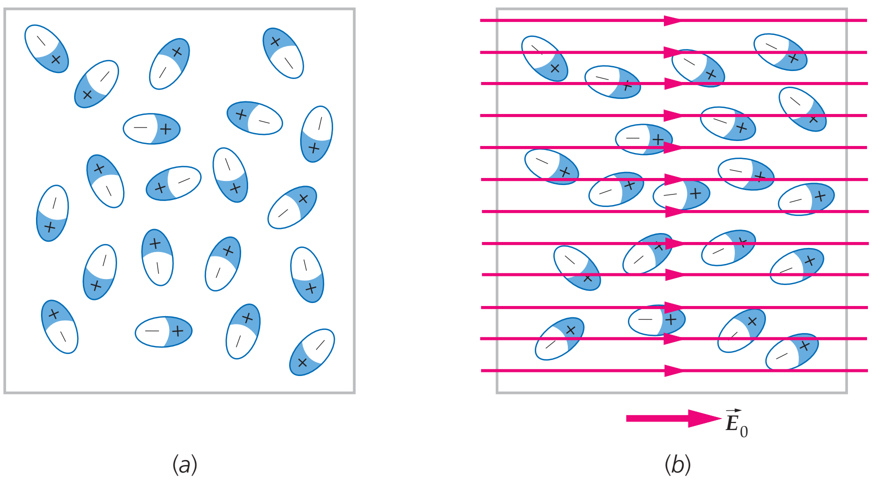

FIGURE 24-28 (*a*) The randomly oriented electric dipoles of a polar dielectric in the absence of an external electric field. (*b*) In the presence of an external electric field, the dipoles are partially aligned parallel to the field.

The net effect of the polarization of a homogeneous dielectric in a parallel-plate capacitor is the creation of surface charges on the dielectric faces near the plates, as shown in Figure 24-29. The surface charge on the dielectric is called a **bound charge,** because the surface charge is bound to the surface molecules of the dielectric and cannot move about like the free charge on the conducting capacitor plates. This bound charge produces an electric field opposite in direction to the electric field produced by the free charge on the conductors. Thus, the net electric field between the plates is reduced, as illustrated in Figure 24-30.

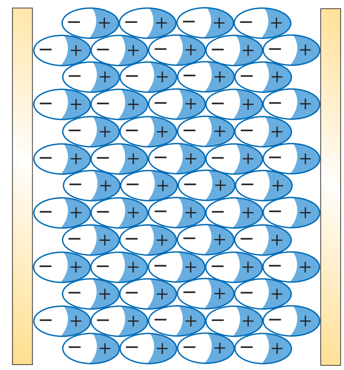

FIGURE 24-29 When a dielectric is placed between the plates of a capacitor, the electric field of the capacitor polarizes the molecules of the dielectric. The result is a bound charge on the surface of the dielectric that produces its own electric field; this field opposes the external field. The field of the bound surface charges thus weakens the electric field within the dielectric.

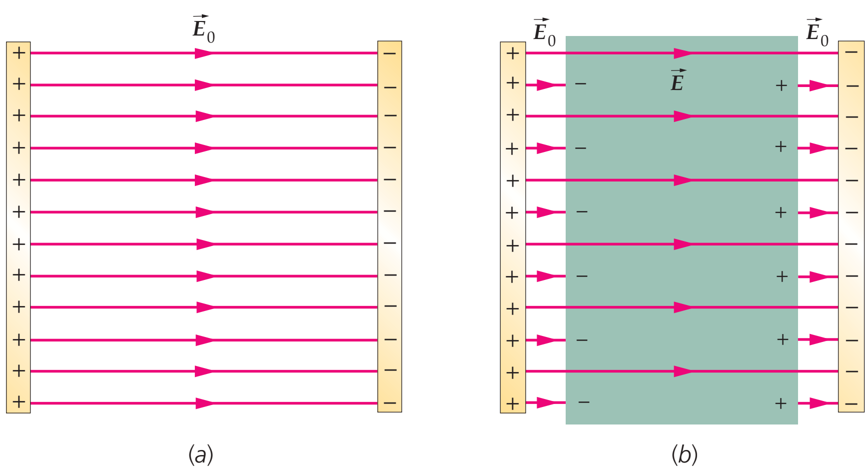

FIGURE 24-30 The electric field between the plates of a capacitor that has (*a*) no dielectric and (*b*) a dielectric. The surface charge on the dielectric weakens the original field between the plates.

* The degree of alignment depends on the external field and on the temperature. It is approximately proportional to $pE/(kT)$, where pE is the maximum energy of a dipole in a field E, and kT is the characteristic thermal energy.

Example 24-15 Induced Dipole Moment—Hydrogen Atom

A hydrogen atom consists of a proton of charge $+e$ and an electron of charge $-e$. The charge distribution of the atom is spherically symmetric, so the atom is nonpolar. Consider a model in which the hydrogen atom consists of a positive point charge $+e$ at the center of a uniformly charged spherical cloud of radius R and total charge $-e$. Show that when such an atom is placed in a uniform external electric field $\vec{E}$, the induced dipole moment is proportional to $\vec{E}$; that is, $\vec{p} = \alpha\vec{E}$, where α is called the *polarizability*.

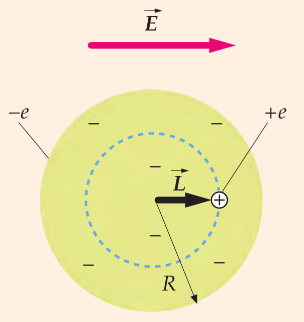

FIGURE 24-31

PICTURE In the external field, the center of the uniform negative cloud is displaced from the positive charge by an amount L so that the force exerted by the field $e\vec{E}$ on the positive point charge is balanced by the force on it exerted by the negative cloud $e\vec{E}'$, where $\vec{E}'$ is the field due to the cloud at the location of the point charge (Figure 24-31). We use Gauss's law to find E', and then we calculate the induced dipole moment $\vec{p} = q\vec{L}$, where $q = e$ and $\vec{L}$ is the position of the positive charge relative to the center of the cloud. The dipole moment, defined as $q\vec{L}$, is discussed in Section 21-4.

SOLVE

1. Write the magnitude of the induced dipole moment in terms of e and L:

$$p = eL$$

2. We can find L by calculating the field E'_n due to the negatively charged cloud at a distance L from the center. We use Gauss's law to compute E'_n. Choose a spherical Gaussian surface of radius L concentric with the cloud. Then E'_n is the same everywhere on this surface:

$$\phi_{\text{net}} = \oint E_n\, dA = \frac{Q_{\text{inside}}}{\epsilon_0}$$

$$E'_n = \frac{Q_{\text{inside}}}{4\pi\epsilon_0 L^2}$$

3. The charge inside the sphere of radius L equals the charge density multiplied by the volume:

$$Q_{\text{inside}} = \rho\tfrac{4}{3}\pi L^3 = \frac{-e}{\tfrac{4}{3}\pi R^3}\tfrac{4}{3}\pi L^3 = -e\frac{L^3}{R^3}$$

4. Substitute this value of Q_{inside} to calculate E'_n:

$$E'_n = \frac{Q_{\text{inside}}}{4\pi\epsilon_0 L^2} = \frac{-eL^3/R^3}{4\pi\epsilon_0 L^2} = -\frac{e}{4\pi\epsilon_0 R^3}L$$

5. Solve for L:

$$L = -\frac{4\pi\epsilon_0 R^3}{e}E'_n$$

6. E'_n is negative because $\vec{E}'$ points inward on the Gaussian surface. At the positive charge, $\vec{E}'$ points to the left. Because E' is equal to E, we conclude that $E'_n = -E$:

$$E'_n = -E \quad \text{so} \quad L = \frac{4\pi\epsilon_0 R^3}{e}E$$

7. Substitute these results for L and E'_n to express p in terms of the external field strength E:

$$p = eL = 4\pi\epsilon_0 R^3 E$$

so $\boxed{\vec{p} = \alpha\vec{E}}$

where $\alpha = 4\pi\epsilon_0 R^3$

CHECK We expected α to be positive because we expected $\vec{p}$ and $\vec{E}$ to be in the same direction. Our step 7 result met this expectation.

TAKING IT FURTHER The charge distribution of the negative charge in a hydrogen atom, obtained from quantum theory, is spherically symmetric, but the charge density decreases exponentially with distance rather than being uniform. Nevertheless, the above calculation shows that the dipole moment is proportional to the external field $p = \alpha E$, and the polarizability α is of the order of $4\pi\epsilon_0 R^3$, where R is the radius of the atom or molecule. The dielectric constant κ can be related to the polarizability α and to the number of molecules per unit volume.

MAGNITUDE OF THE BOUND CHARGE

The bound charge density σ_b on the surfaces of the dielectric is related to the dielectric constant κ and to the free charge density σ_f on the surfaces of the plates. Consider a dielectric slab between the plates of a parallel-plate capacitor, as shown in Figure 24-32. If the dielectric is a thin slab between plates that are close together, the electric field inside the dielectric slab due to the bound charge densities, $+\sigma_b$ on the right and $-\sigma_b$ on the left, is just the field due to two infinite-plane charge densities. Thus, the field E_b has the magnitude

$$E_b = \frac{\sigma_b}{\epsilon_0}$$

This field is directed to the left and subtracts from the electric field E_0 due to the free charge density on the capacitor plates, which has the magnitude

$$E_0 = \frac{\sigma_f}{\epsilon_0}$$

The strength of the net field $E = E_0/\kappa$ is the difference between these magnitudes:

$$E = E_0 - E_b = \frac{E_0}{\kappa}$$

or

$$E_b = \left(1 - \frac{1}{\kappa}\right)E_0$$

Writing σ_b/ϵ_0 for E_b and σ_f/ϵ_0 for E_0, we obtain

$$\sigma_b = \left(1 - \frac{1}{\kappa}\right)\sigma_f \qquad \text{24-23}$$

The bound charge density σ_b is always less than or equal to the free charge density σ_f on the capacitor plates, and it is zero if $\kappa = 1$, which is the case when there is no dielectric. For a conducting slab, $\kappa = \infty$ and $\sigma_b = \sigma_f$.

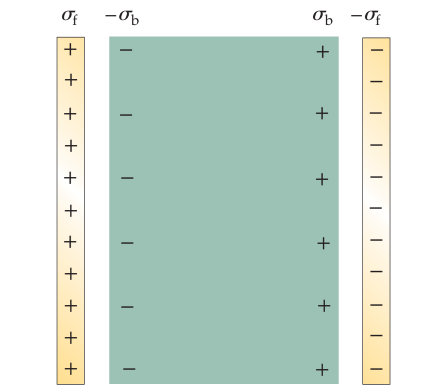

FIGURE 24-32 A parallel-plate capacitor with a dielectric slab between the plates. If the plates are closely spaced, each of the surface charges can be considered as an infinite plane charge. The electric field due to the free charge on the plates is directed to the right and has a magnitude $E_0 = \sigma_f/\epsilon_0$. That due to the bound charge is directed to the left and has a magnitude $E_b = \sigma_b/\epsilon_0$.

CONCEPT CHECK 24-5

Does the capacitance always increase when a dielectric is inserted into the gap of a capacitor? Explain your answer.

*THE PIEZOELECTRIC AND PYROELECTRIC EFFECTS

In certain crystals that have polar molecules (for example, quartz, tourmaline, and topaz), a mechanical stress applied to the crystal produces polarization of the molecules. This is known as the **piezoelectric effect.** The polarization of the stressed crystal causes a potential difference across the crystal, which can be used to produce an electric current. Piezoelectric crystals are used in transducers (for example, microphones, phonograph pickups, and vibration-sensing devices) to convert mechanical strain into electrical signals. The converse piezoelectric effect, in which a voltage applied to such a crystal induces mechanical strain (deformation), is used in headphones and many other devices. Because the natural frequency of vibration of quartz is in the range of radio frequencies, and because its resonance curve is very sharp,* quartz is used extensively to stabilize radio-frequency oscillators and to make accurate clocks.

Many crystals that exhibit the piezoelectric effect also exhibit the **pyroelectric effect,** which is the generation of a large electric field within the crystal when the temperature of the crystal is increased. Pyroelectric crystals are sometimes used to accelerate charged particles to such high speeds that X rays, and even nuclear fusion, result when the charged particles impact a target material.

* Resonance in AC circuits, which will be discussed in Chapter 29, is analogous to mechanical resonance, which was discussed in Chapter 14.

Physics Spotlight

Changes in Capacitors—Charging Ahead

In 1746, shortly after the Leyden jar was publicized, 180 soldiers demonstrated the power of a large Leyden jar to the French court. They joined hands in a circle and waited to be connected to the Leyden jar. When a single shock from the jar passed through the circle, all the soldiers simultaneously jumped and shouted.[*,†] Some Leyden jars have since been measured with a capacitance of 2.5 nF at 10 kV.

Capacitor come in many different sizes and shapes as well as several different types. Circuit designers choose the size, shape and type to suit the requirements for specific circumstances. *(Maynard & Bouchard/Scientifica/Visuals Unlimited.)*

Capacitors have come a long way since then. One change (of many) that was made during the nineteenth century was the addition of mineral oil to capacitors as a dielectric. However, oil-filled condensers, as they were known, are fire hazards when heated. In 1929, the Swann chemical company produced polychlorinated biphenyls, or PCBs, for use as dielectrics in industrial capacitors.[‡] PCBs are resistant to burning and do not easily react with other substances. They also have dielectric constants slightly larger than mineral oil's. Unfortunately, PCBs proved to be carcinogenic, and they are extremely toxic when partially burned.[#] In 1979, PCB manufacture was banned in the United States, and the use of PCBs as dielectrics for capacitors[°] was discontinued. (Numerous older capacitors using PCBs are still in service as of 2006.[§]) The ban on PCBs in new capacitors caused researchers to try to develop more efficient capacitors. (In this context, efficient usually means with greater capacitance per unit mass.)

Several types of very efficient capacitors are available. Many capacitors now take advantage of the large dielectric coefficients of specialized ceramics,[¶] plastic films, and polymer gels. But the most efficient capacitors are electrical double-layer capacitors (EDLCs). EDLCs are composed of electrodes that are made of porous carbon deposited on either side of an *electrolyte separator*. The layers are tightly wound and placed into a container. The carbon and the electrolyte separator are so thin that the distance between the layers of carbon is molecules thick.[**] The capacitors are called double layered because each layer of electrolyte has two layers of charge.

Owing to the porous nature of the carbon, each layer has a very large surface area for the carbon to be in contact with the electrolyte—from 400 up to 2000 m^2/g. This large surface area combined with the very thin electrolyte layer yields a large capacitance. Because the electrolyte layers are very thin, most electrical double-layer capacitors have low breakdown voltages. An EDLC the size of a D-cell battery weighs 60 grams, has a capacitance of 350 farads, and is rated at 2.5 volts.[††] Because of the low breakdown voltage, EDLCs are rarely used individually. A package of six of the D-cell–sized capacitors in series has an equivalent capacitance of 58 farads with a rating of 15 volts.[‡‡]

EDLCs are already incorporated into cell phones, cameras, and automobiles. For frequently used rechargeable items, EDLCs may soon be inexpensive and powerful enough to be used instead of batteries.

Summary

1. Capacitance is an important defined quantity that relates charge to potential difference.
2. Two devices connected in *parallel* share a common potential difference across each device *due solely to the way they are connected*.
3. Two devices connected in *series* are connected by a conducting path *that contains no junctions*.
4. The changes in potential around any closed path *always* sum to zero. This is known as Kirchhoff's loop rule

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Capacitor	A capacitor is a device for storing charge and energy. It consists of two conductors that are insulated from each other and carry equal and opposite charges.	
2. Capacitance	Definition of capacitance $$C = \frac{Q}{V}$$	24-1
Single conductor	Q is the conductor's total charge, V is the conductor's potential relative to its surroundings.	
Capacitor	Q is the magnitude of the charge on either conductor, V is the magnitude of the potential difference between the conductors.	
Of an isolated spherical conductor	$$C = 4\pi\epsilon_0 R$$	24-2
Of a parallel-plate capacitor	$$C = \frac{\epsilon_0 A}{d}$$	24-6
Of a cylindrical capacitor	$$C = \frac{2\pi\epsilon_0 L}{\ln(R_2/R_1)}$$	24-7
Energy stored in a capacitor	$$U = \frac{1}{2}QV = \frac{1}{2}\frac{Q^2}{C} = \frac{1}{2}CV^2$$	24-8
Energy density of an electric field	$$u_e = \tfrac{1}{2}\epsilon_0 E^2$$	24-9
3. Equivalent Capacitance		
Parallel capacitors	When devices are connected in parallel, the voltage drop is the same across each. $$C_{eq} = C_1 + C_2 + C_3 + \ldots$$	24-13
Series capacitors	When capacitors are in series, the voltage drops add. If the total charge on each connected pair of plates is zero, then: $$\frac{1}{C_{eq}} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} + \ldots$$	24-17
4. Dielectrics		
Macroscopic behavior	A nonconducting material is called a dielectric. When a dielectric is inserted between the plates of a charged, electrically isolated capacitor, the electric field between the plates is weakened and the capacitance is thereby increased by the factor κ, which is the dielectric constant.	
Microscopic view	The electric field in the dielectric of a capacitor is weakened because the molecular dipole moments (either preexisting or induced) tend to align with the applied field and thereby produce a second electric field inside the dielectric that opposes the applied field. The aligned dipole moment of the dielectric is proportional to the applied field.	

TOPIC	RELEVANT EQUATIONS AND REMARKS	
Electric field inside	$E = \frac{E_0}{\kappa}$	24-18
Effect on capacitance	$C = \kappa C_0$	24-19
Permittivity ϵ	$\epsilon = \kappa\epsilon_0$	24-21
Uses of a dielectric	1. Increases capacitance 2. Increases dielectric strength 3. Physically separates conductors	
***5. Piezoelectric Effect**	In certain crystals a mechanical stress changes the polarization of the material, which results in a voltage across the crystal. Conversely, an applied voltage induces mechanical strain (deformation) in the crystal.	
***Pyroelectric Effect**	In certain crystals an increase in temperature changes the polarization of the material, which results in a voltage across the crystal.	

Answers to Concept Checks

24-1 $C_2 = C_1$. The capacitance does not depend on the charge. If the charge is tripled, the potential of the sphere will be tripled and the ratio Q/V, which depends only on the radius of the sphere, remains unchanged.

24-2 The capacitance of any capacitor does not depend on the potential. To increase V you must increase the charge Q, and vice versa. The ratio Q/V depends only on the geometry of the capacitor and on the nature of any dielectric material separating the plates.

24-3 The net charge remains the same. Like a water pump transfers water, a battery transfers charge. The amount of water in a water pump does not change and the amount of charge in a battery does not change.

24-4 A negative value.

24-5 Yes. Capacitance is defined as $C = Q/V$. So for an isolated charged capacitor, a capacitor for which Q is constant, the capacitance C is inversely proportional to the voltage V. When a dielectric is inserted into an isolated capacitor the bound surface charges induced on the dielectric result in a reduced electric-field strength within the dielectric. The voltage is directly proportional to the electric-field strength, so a reduced electric-field strength means a reduced voltage and an increased capacitance.

Answers to Practice Problems

24-1 9.0×10^9 m, which is about 1400 times the radius of Earth. (The farad is indeed a very large unit.)

24-2 $A = 1.1 \times 10^8\ \text{m}^2$, which corresponds to a square 11 km on a side

24-3 3.7 J

24-4 $U = \frac{1}{2}\sum_{i=1}^{n} Q_i V_i = \frac{1}{2}Q_1V_1 + \frac{1}{2}Q_2V_2$

$$= \tfrac{1}{2}(-Q)V_1 + \tfrac{1}{2}(+Q)(V_1 + V) = \tfrac{1}{2}QV$$

24-5 21 V

24-6 (*a*) $C_0 = 87$ pF, (*b*) $C = 50$ pF

24-7 (*a*) $u_e = \frac{1}{2}\epsilon_0 E^2 = 160\ \mu\text{J/m}^3$,
(*b*) $\Delta\text{vol} = A\,\Delta d = 2.9 \times 10^{-5}\ \text{m}^3$, $u_e\,\Delta\text{vol} = 4.7$ nJ, in agreement with Example 24-3

24-8 54 μC

24-9 4.0 V

24-10 (*a*) 50 μF, (*b*) 12 μF

24-11 $U_i = q_2/(2C_1) + q_2/(2C_2)$, where $q = 48\ \mu\text{C}$. Thus, $U_i = 288\ \mu\text{J}$. $U_f = Q_1^2/(2C_1) + Q_2^2/(2C_2) = 256\ \mu\text{J}$.

24-12 $U_2 = 4.0\ \mu\text{J}$, $U_3 = 24\ \mu\text{J}$, $U_4 = 8.0\ \mu\text{J}$. Note that $U_2 + U_3 + U_4 = 36\ \mu\text{J} = \frac{1}{2}QV = \frac{1}{2}Q^2/C_{eq} = \frac{1}{2}C_{eq}V^2$.

24-13 (*a*) 0.18 nF, (*b*) 2.1 nC

24-14 (*a*) $Q = 1.1$ nC (which is unchanged), (*b*) $V = 6.0$ V, (*c*) $C = 180$ pF

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • If the voltage across a parallel-plate capacitor is doubled, its capacitance (*a*) doubles, (*b*) drops by half, (*c*) remains the same.

2 • If the charge on an isolated spherical conductor is doubled, its self-capacitance (*a*) doubles, (*b*) drops by half, (*c*) remains the same.

3 • True or false: The electrostatic energy density is uniformly distributed in the region between the conductors of a cylindrical capacitor.

4 • If the distance between the plates of a charged and isolated parallel-plate capacitor is doubled, what is the ratio of the final stored energy to the initial stored energy?

5 • A parallel-plate capacitor is connected to a battery. The space between the two plates is empty. If the separation between the capacitor plates is tripled while the capacitor remains connected to the battery, what is the ratio of the final stored energy to the initial stored energy? SSM

6 • If the capacitor of Problem 5 is disconnected from the battery before the separation between the plates is tripled, what is the ratio of the final stored energy to the initial stored energy?

7 • True or false:

(*a*) The equivalent capacitance of two capacitors in parallel is always greater than the larger of the two capacitance values.

(*b*) The equivalent capacitance of two capacitors in series is always less than the least of the two capacitance values if the charges on the two plates that are connected by an otherwise isolated conductor sum to zero.

8 • Two uncharged capacitors have capacitances C_0 and $2C_0$, respectively, and are connected in series. This series combination is then connected across the terminals a battery. Which of the following is true?

(*a*) The capacitor $2C_0$ has twice the charge of the other capacitor.

(*b*) The voltage across each capacitor is the same.

(*c*) The energy stored by each capacitor is the same.

(*d*) The equivalent capacitance is $3C_0$.

(*e*) The equivalent capacitance is $2C_0/3$.

9 • A dielectric is inserted between the plates of a parallel-plate capacitor, completely filling the region between the plates. Air initially filled the region between the two plates. The capacitor was connected to a battery during the entire process. True or false:

(*a*) The capacitance value of the capacitor increases as the dielectric is inserted between the plates.

(*b*) The charge on the capacitor plates decreases as the dielectric is inserted between the plates.

(*c*) The electric field between the plates does not change as the dielectric is inserted between the plates.

(*d*) The energy storage of the capacitor decreases as the dielectric is inserted between the plates. SSM

10 •• Capacitors A and B (Figure 24-33) have identical plate areas and gap separations. The space between the plates of each capacitor is half-filled with a dielectric as shown. Which has the larger capacitance, capacitor A or capacitor B? Explain your answer.

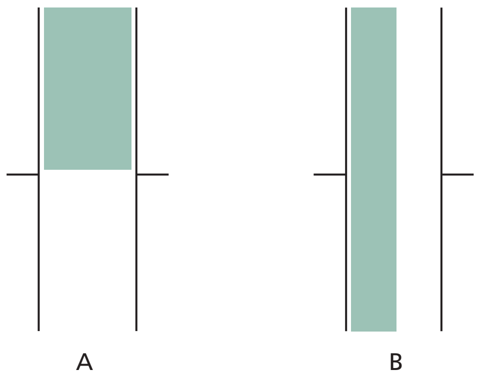

FIGURE 24-33 Problem 10

11 •• (*a*) Two identical capacitors are connected in parallel. This combination is then connected across the terminals of a battery. How does the total energy stored in the parallel combination of the two capacitors compare to the total energy stored if just one of the capacitors were connected across the terminals of the same battery? (*b*) Two identical capacitors that have been discharged are connected in series. This combination is then connected across the terminals of a battery. How does the total energy stored in the series combination of the two capacitors compare to the total energy stored if just one of the capacitors were connected across the terminals of the same battery? SSM

12 •• Two identical capacitors that have been discharged are connected in series across the terminals of a 100-V battery. When only one of the capacitors is connected across the terminals of the battery, the energy stored is U_0. What is the total energy stored in the two capacitors when the series combination is connected to the battery? (*a*) $4U_0$, (*b*) $2U_0$, (*c*) U_0, (*d*) $U_0/2$, (*e*) $U_0/4$

ESTIMATION AND APPROXIMATION

13 •• Disconnect the coaxial cable from a television or other device and estimate the diameter of the inner conductor and the diameter of the shield. Assume a plausible value (see Table 24-1) for the dielectric constant of the dielectric separating the two conductors and estimate the capacitance per unit length of the cable. SSM

14 •• ENGINEERING APPLICATION, CONTEXT-RICH You are part of an engineering research team that is designing a pulsed nitrogen laser. To create the high energy densities needed to operate such a laser, the electrical discharge from a high-voltage capacitor is used. Typically, the energy requirement per pulse (i.e., per discharge) is 100 J. Estimate the capacitance required if the discharge is to create a spark across a gap of about 1.0 cm. Assume that the dielectric breakdown of nitrogen is the same as the value for normal air.

15 •• Estimate the capacitance of the Leyden jar shown in Figure 24-34. The figure of a man is one-tenth the height of an average man. SSM

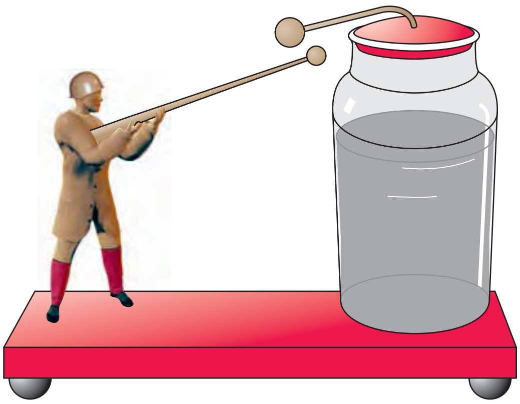

FIGURE 24-34 Problem 15

CAPACITANCE

16 • An isolated conducting sphere that has a 10.0-cm radius has an electric potential of 2.00 kV (the potential far from the sphere is zero). (*a*) How much charge is on the sphere? (*b*) What is the self-capacitance of the sphere? (*c*) By how much does the self-capacitance change if the sphere's electric potential is increased to 6.00 kV?

17 • The charge on one plate of a capacitor is $+30.0\ \mu$C and the charge on the other plate is $-30.0\ \mu$C. The potential difference between the plates is 400 V. What is the capacitance of the capacitor?

18 •• Two isolated conducting spheres of equal radius R have charges $+Q$ and $-Q$, respectively. Their centers are separated by a distance d that is large compared to their radius. Estimate the capacitance of this unusual capacitor.

THE STORAGE OF ELECTRICAL ENERGY

19 • (*a*) The potential difference between the plates of a 3.00-μF capacitor is 100 V. How much energy is stored in the capacitor? (*b*) How much additional energy is required to increase the potential difference between the plates from 100 V to 200 V? SSM

20 • The charges on the plates of a 10-μF capacitor are $\pm 4.0\ \mu$C. (*a*) How much energy is stored in the capacitor? (*b*) If charge is transferred until the charges on the plates are equal to $\pm 2.0\ \mu$C, how much stored energy remains?

21 • (*a*) Find the energy stored in a 20.0-nF capacitor when the charges on the plates are $\pm 5.00\ \mu$C. (*b*) How much additional energy is stored if charges are increased from $\pm 5.00\ \mu$C to $\pm 10.0\ \mu$C?

22 • What is the maximum electric energy density in a region containing dry air at standard conditions?

23 •• An air-gap parallel-plate capacitor that has a plate area of 2.00 m^2 and a separation of 1.00 mm is charged to 100 V. (*a*) What is the electric field between the plates? (*b*) What is the electric energy density between the plates? (*c*) Find the total energy by multiplying your answer from Part (*b*) by the volume between the plates. (*d*) Determine the capacitance of this arrangement. (*e*) Calculate the total energy from $U = \frac{1}{2}CV^2$, and compare your answer with your result from Part (*c*). SSM

24 •• A solid metal sphere has radius of 10.0 cm and a concentric metal spherical shell has an inside radius of 10.5 cm. The solid sphere has a charge 5.00 nC. (*a*) Estimate the energy stored in the electric field in the region between the spheres. *Hint: You can treat the spheres essentially as parallel flat slabs separated by 0.5 cm.* (*b*) Estimate the capacitance of this two-sphere system. (*c*) Estimate the total energy stored in the electric field from $\frac{1}{2}Q^2/C$ and compare it to your answer in Part (*a*).

25 •• A parallel-plate capacitor has plates of area 500 cm^2 and is connected across the terminals of a battery. After some time has passed, the capacitor is disconnected from the battery. When the plates are then moved 0.40 cm farther apart, the charge on each plate remains constant but the potential difference between the plates increases by 100 V. (*a*) What is the magnitude of the charge on each plate? (*b*) Do you expect the energy stored in the capacitor to increase, decrease, or remain constant as the plates are moved this way? Explain your answer. (*c*) Support your answer to Part (*b*) by determining the change in stored energy in the capacitor due to the movement of the plates.

COMBINATIONS OF CAPACITORS

26 • (*a*) How many 1.00-μF capacitors connected in parallel would it take to store a total charge of 1.00 mC if the potential difference across each capacitor is 10.0 V? Diagram the parallel combination. (*b*) What would be the potential difference across this parallel combination? (*c*) If the capacitors in Part (*a*) are discharged, connected in series, and then energized until the potential difference across each is equal to 10.0 V, find the charge on each capacitor and the potential difference across the connection.

27 • A 3.00-μF capacitor and a 6.00-μF capacitor are discharged and then connected in series, and the series combination is then connected in parallel with an 8.00-μF capacitor. Diagram this combination. What is the equivalent capacitance of this combination?

28 • Three capacitors are connected in a triangle as shown in Figure 24-35. Find an expression for the equivalent capacitance between points a and c in terms of the three capacitance values.

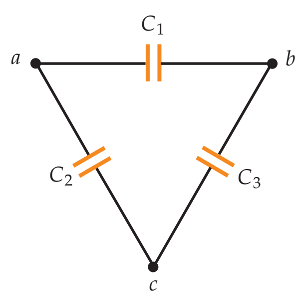

FIGURE 24-35 Problem 28

29 •• A 10.0-μF capacitor and a 20.0-μF capacitor are connected in parallel across the terminals of a 6.00-V battery. (*a*) What is the equivalent capacitance of this combination? (*b*) What is the potential difference across each capacitor? (*c*) Find the charge on each capacitor. (*d*) Find the energy stored in each capacitor.

30 •• A 10.0-μF capacitor and a 20.0-μF capacitor are discharged and then connected in series. The series combination is then connected across the terminals of a 6.00-V battery. (*a*) What is the equivalence capacitance of this combination? (*b*) Find the charge on each capacitor. (*c*) Find the potential difference across each capacitor. (*d*) Find the energy stored in each capacitor.

31 •• Three identical capacitors are connected so that their maximum equivalent capacitance, which is 15.0 μF, is obtained. (*a*) Determine how the capacitors are connected and diagram the combination. (*b*) There are three additional ways to connect all three capacitors. Diagram these three ways and determine the equivalent capacitances for each arrangement.

32 •• For the circuit shown in Figure 24-36, the capacitors were each discharged before being connected to the voltage source. Find (*a*) the equivalent capacitance of the combination, (*b*) the charge stored on the positively charged plate of each capacitor, (*c*) the voltage across each capacitor, and (*d*) the energy stored in each capacitor.

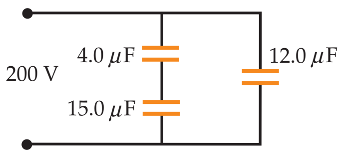

FIGURE 24-36 Problem 32

33 •• (*a*) Show that the equivalent capacitance of two capacitors in series can be written

$$C_{eq} = \frac{C_1 C_2}{C_1 + C_2}$$

(*b*) Using only this formula and some algebra, show that C_{eq} must always be less than C_1 and C_2, and hence must be less than the smaller of the two values. (*c*) Show that the equivalent capacitance of three capacitors in series can be written

$$C_{eq} = \frac{C_1 C_2 C_3}{C_1 C_2 + C_2 C_3 + C_1 C_3}$$

(*d*) Using only this formula and some algebra, show that C_{eq} must always be less than each of C_1, C_2, and C_3, and hence must be less than the least of the three values.

34 •• For the circuit shown in Figure 24-37 find (*a*) the equivalent capacitance between the terminals, (*b*) the charge stored on the positively charged plate of each capacitor, (*c*) the voltage across each capacitor, and (*d*) the total stored energy.

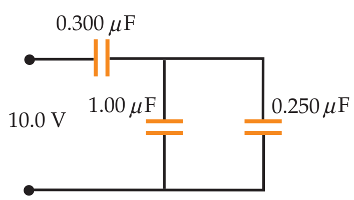

FIGURE 24-37 Problem 34

35 •• Five identical capacitors of capacitance C_0 are connected in a so-called bridge network, as shown in Figure 24-38. (*a*) What is the equivalent capacitance between points *a* and *b*? (*b*) Find the equivalent capacitance between points *a* and *b* if the capacitor at the center is replaced by a capacitor that has a capacitance of $10C_0$.

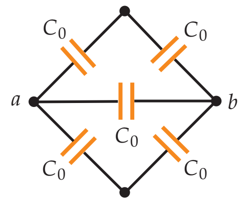

FIGURE 24-38 Problem 35

36 •• You and your laboratory team have been given a project by your electrical engineering professor. Your team must design a network of capacitors that has an equivalent capacitance of 2.00 μF and breakdown voltage of 400 V. The restriction is that your team must use only 2.00-μF capacitors that have individual breakdown voltages of 100 V. Diagram the combination.

37 •• Find the different equivalent capacitances that can be obtained by using two or three of the following capacitors: a 1.00-μF capacitor, a 2.00-μF capacitor, and a 4.00-μF capacitor.

38 ••• What is the equivalent capacitance (in terms of C, which is the capacitance of one of the capacitors) of the infinite ladder of capacitors shown in Figure 24-39?

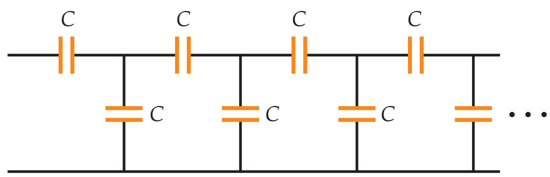

FIGURE 24-39 Problem 38

PARALLEL-PLATE CAPACITORS

39 • A parallel-plate capacitor has a capacitance of 2.00 μF and a plate separation of 1.60 mm. (*a*) What is the maximum potential difference between the plates, so that dielectric breakdown of the air between the plates does not occur? (*b*) How much charge is stored at this potential difference?

40 • An electric field of 2.00×10^4 V/m exists between the circular plates of a parallel-plate capacitor that has a plate separation of 2.00 mm. (*a*) What is the potential difference across the capacitor plates? (*b*) What plate radius is required if the positively charged plate is to have a charge of 10.0 μC?

41 •• A parallel-plate, air-gap capacitor has a capacitance of 0.14 μF. The plates are 0.50 mm apart. (*a*) What is the area of each plate? (*b*) What is the potential difference between the plates if the positively charged plate has a charge of 3.2 μC? (*c*) What is the stored energy? (*d*) What is the maximum energy this capacitor can store before dielectric breakdown of the air between the plates occurs?

42 •• Design a 0.100-μF parallel-plate capacitor that has air between its plates and that can be charged to a maximum potential difference of 1000 V before dielectric breakdown occurs. (*a*) What is the minimum possible separation between the plates? (*b*) What minimum area must each plate of the capacitor have?

CYLINDRICAL CAPACITORS

43 • In preparation for an experiment that you will do in your introductory nuclear physics lab, you are shown the inside of a Geiger tube. You measure the radius and the length of the central wire of the Geiger tube to be 0.200 mm and 12.0 cm, respectively. The outer surface of the tube is a conducing cylindrical shell that has an inner radius of 1.50 cm. The shell is coaxial with the wire and has the same length (12.0 cm). Calculate (*a*) the capacitance of your tube, assuming that the gas in the tube has a dielectric constant of 1.00, and (*b*) the value of the linear charge density on the wire when the potential difference between the wire and shell is of 1.20 kV.

44 •• A cylindrical capacitor consists of a long wire that has a radius R_1, a length L, and a charge $+Q$. The wire is enclosed by a coaxial outer cylindrical shell that has an inner radius R_2, length L, and charge $-Q$. (*a*) Find expressions for the electric field and energy density as a function of the distance R from the axis. (*b*) How much energy resides in a region between the conductors that has a radius R, a thickness dR, and a volume $2\pi rL\,dR$? (*c*) Integrate your expression from Part (*b*) to find the total energy stored in the capacitor. Compare your result with that obtained by using the formula $U = Q^2/(2C)$ in conjunction with the known expression for the capacitance of a cylindrical capacitor.

45 ••• Three concentric, thin, long conducting cylindrical shells have radii of 2.00 mm, 5.00 mm, and 8.00 mm. The space between the shells is filled with air. The innermost and outermost shells are connected at one end by a conducting wire. Find the capacitance per unit length of this configuration.

46 ••• **Engineering Application** A *goniometer* is a precise instrument for measuring angles. A *capacitive goniometer* is shown in Figure 24-40*a*. Each plate of the variable capacitor (Figure 24-40*b*) consists of a flat metal semicircle that has an inner radius R_1 and an outer radius R_2. The plates share a common rotation axis, and the width of the air gap separating the plates is d. Calculate the capacitance as a function of the angle θ and the parameters given.

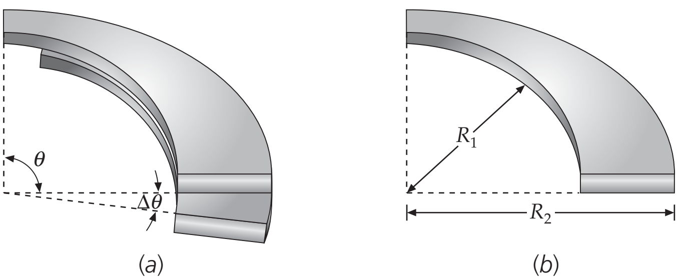

FIGURE 24-40 Problem 46

47 ••• **Engineering Application** A *capacitive pressure gauge* is shown in Figure 24-41. Each plate has an area A. The plates are separated by a material that has a dielectric constant κ, a thickness d, and a Young's modulus Y. If a pressure increase of ΔP is applied to the plates, derive an expression for the change in capacitance.

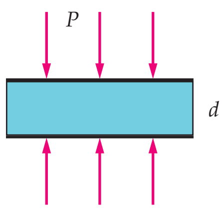

FIGURE 24-41 Problem 47

SPHERICAL CAPACITORS

48 •• Model Earth as a conducting sphere. (*a*) What is its self-capacitance? (*b*) Assume the magnitude of the electric field at Earth's surface is 150 V/m. What charge density does this correspond to? Express this value in fundamental charge units e per square centimeter.

49 •• A spherical capacitor consists of a thin spherical shell that has a radius R_1 and a thin, concentric spherical shell that has a radius R_2, where $R_2 > R_1$. (*a*) Show that the capacitance is given by $C = 4\pi\epsilon_0 R_1R_2/(R_2 - R_1)$. (*b*) Show that when the radii of the shells are nearly equal, the capacitance is approximately given by the expression for the capacitance of a parallel-plate capacitor, $C = \epsilon_0 A/d$, where A is the area of the sphere and $d = R_2 - R_1$. SSM

50 •• A spherical capacitor is composed of an inner sphere which has a radius R_1 and a charge $+Q$ and an outer concentric spherical thin shell which has a radius R_2 and a charge $-Q$. (*a*) Find the electric field and the energy density as a function of r, where r is the distance from the center of the sphere, for $0 \le r < \infty$. (*b*) Calculate the energy associated with the electrostatic field in a spherical shell between the conductors that has a radius r, a thickness dr, and a volume $4\pi r^2\,dr$. (*c*) Integrate your expression from Part (*b*) to find the total energy and compare your result with the result obtained using $U = \frac{1}{2}QV$.

51 ••• An isolated conducting sphere of radius R has a charge Q distributed uniformly over its surface. Find the distance R' from the center of the sphere such that half the total electrostatic energy of the system is associated with the electric field beyond that distance.

DISCONNECTED AND RECONNECTED CAPACITORS

52 •• A 2.00-μF capacitor is energized to a potential difference of 12.0 V. The wires connecting the capacitor to the battery are then disconnected from the battery and connected across a second, initially uncharged capacitor. The potential difference across the 2.00-μF capacitor then drops to 4.00 V. What is the capacitance of the second capacitor?

53 •• A 100-pF capacitor and a 400-pF capacitor are both charged to 2.00 kV. They are then disconnected from the voltage source and are connected together, positive plate to negative plate and negative plate to positive plate. (*a*) Find the resulting potential difference across each capacitor. (*b*) Find the energy dissipated when the connections are made. SSM

54 •• Two capacitors, one that has a capacitance of 4.00 μF and one that has a capacitance of 12.0 μF, are first discharged and then are connected in series. The series combination is then connected across the terminals of a 12.0-V battery. Next, they are carefully disconnected so that they are not discharged and they are then reconnected to each other—positive plate to positive plate and negative plate to negative plate. (*a*) Find the potential difference across each capacitor after they are reconnected. (*b*) Find the energy stored in the capacitors before they are disconnected from the battery, and find the energy stored after they are reconnected.

55 •• A 1.2-μF capacitor is charged to 30 V. After charging, the capacitor is disconnected from the voltage source and is connected across the terminals of a second capacitor that had previously been discharged. The final voltage across the 1.2-μF capacitor is 10 V. (*a*) What is the capacitance of the second capacitor? (*b*) How much energy was dissipated when the connection was made?

56 •• A 12-μF capacitor and a capacitor of unknown capacitance are both charged to 2.00 kV. After charging, the two capacitors are disconnected from the voltage source. The capacitors are then connected to each other—positive plate to negative plate and negative plate to positive plate. The final voltage across the terminals of the 12-μF capacitor is 1.00 kV. (*a*) What is the capacitance of the second capacitor? (*b*) How much energy was dissipated when the connection was made?

57 •• Two capacitors, one that has a capacitance of 4.00 μF and one that has a capacitance of 12.0 μF, are connected in parallel. The parallel combination is then connected across the terminals of a 12.0-V battery. Next, they are carefully disconnected so that they are not discharged. They are then reconnected to each other— the positive plate of each capacitor connected to the negative plate of the other. (*a*) Find the potential difference across each capacitor after they are reconnected. (*b*) Find the energy stored in the capacitors before they are disconnected from the battery, and find the energy stored after they are reconnected.

58 •• A 20-pF capacitor is charged to 3.0 kV and then removed from the battery and connected to an uncharged 50-pF capacitor. (*a*) What is the new charge on each capacitor? (*b*) Find the energy stored in the 20-pF capacitor before it is disconnected from the battery, and the energy stored in the two capacitors after they are connected to each other. Does the stored energy increase or decrease when the two capacitors are connected to each other?

59 •• Capacitors 1, 2, and 3 have capacitances equal to 2.00 μF, 4.00 μF, and 6.00 μF, respectively. The capacitors are connected in parallel, and the parallel combination is connected across the terminals of a 200-V source. The capacitors are then disconnected from both the voltage source and each other, and are connected to three switches as shown in Figure 24-42. (*a*) What is the potential difference across each capacitor when switches S_1 and S_2 are closed but switch S_3 remains open? (*b*) After switch S_3 is closed, what is the final charge on the leftmost plate of each capacitor? (*c*) Give the final potential difference across each capacitor after switch S_3 is closed. SSM

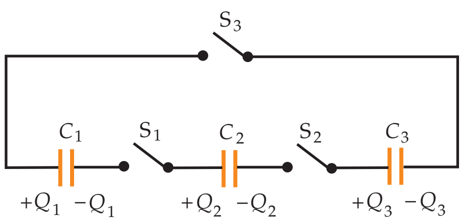

FIGURE 24-42 Problem 59

60 •• A capacitor has a capacitance C and a charge Q on its positively charged plate. A student connects one terminal of the capacitor to a terminal of an identical capacitor whose plates are electrically neutral. When the remaining two terminals are connected, charge flows until electrostatic equilibrium is reestablished and both capacitors have charge $Q/2$ on them. Compare the total energy initially stored in the one capacitor to the total energy stored in the two capacitors in which electrostatic equilibrium is reestablished. If there is less energy afterward, where do you think the missing energy went? *Hint: Wires that transport charge can heat up, which is called Joule heating and is discussed in detail in Chapter 25.*

DIELECTRICS

61 • **Engineering Application, Context-Rich** You are a laboratory assistant in a physics department that has budget problems. Your supervisor wants to construct inexpensive parallel-plate capacitors for use in introductory laboratory experiments. The design uses polyethylene, which has a dielectric constant of 2.30, between two sheets of aluminum foil. The area of each sheet of foil is 400 cm^2 and the thickness of the polyethylene is 0.300 mm. Find the capacitance of this arrangement.

62 •• The radius and the length of the central wire in a Geiger tube are 0.200 mm and 12.0 cm, respectively. The outer surface of the tube is a conducing cylindrical shell that has an inner radius of 1.50 cm. The shell is coaxial with the wire and has the same length (12.0 cm). The tube is filled with a gas that has a dielectric constant of 1.08 and a dielectric strength of 2.00×10^6 V/m. (*a*) What is the maximum potential difference that can be maintained between the wire and shell? (*b*) What is the maximum charge per unit length on the wire?

63 •• **Engineering Application, Context-Rich** You are a materials science engineer and your group has fabricated a new dielectric, that has a dielectric constant of 24 and a dielectric strength of 4.0×10^7 V/m. Suppose you want to use this material to construct a 0.10-μF parallel plate capacitor that can withstand a potential difference of 2.0 kV. (*a*) What is the minimum plate separation required to do this? (*b*) What is the area of each plate at this separation?

64 •• A parallel-plate capacitor has plates separated by a distance d. The capacitance of this capacitor is C_0 when no dielectric is in the space between the plates. However, the space between the plates is completely filled by two different dielectrics. One dielectric has a thickness $\frac{1}{4}d$ and a dielectric constant κ_1, and the other dielectric has a thickness $\frac{3}{4}d$ and a dielectric constant κ_2. Find the capacitance of this capacitor.

65 •• Two capacitors each have two conducting plates of surface area A and an air gap of width d. They are connected in parallel, as shown in Figure 24-43, and each has a charge Q on the positively charged plate. A slab that has a width d, an area A, and a dielectric constant κ is inserted between the plates of *one* of the capacitors. Calculate the new charge Q' on the positively charged plate of that capacitor after electrostatic equilibrium is reestablished.

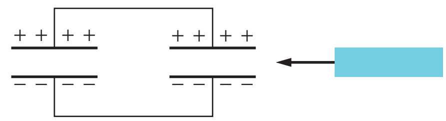

FIGURE 24-43 Problem 65

66 •• A parallel-plate capacitor has a plate separation d and has a capacitance equal to C_0 when there is only empty space in the space between the plates. A slab of thickness t, where $t < d$, that has a dielectric constant κ is placed in the space between the plates—completely covering one of the plates. What is the capacitance with the slab inserted?

67 •• **Biological Application** The membrane of the axon of a nerve cell can be modeled as a thin cylindrical shell of radius 1.00×10^{-5} m, having a length of 10.0 cm and a thickness of 10.0 nm. The membrane has a positive charge on one side and a negative charge on the other, and the membrane acts as a parallel-plate capacitor of area $2\pi rL$ and separation d. Assume the membrane is filled with a material whose dielectric constant is 3.00. (*a*) Find the capacitance of the membrane. If the potential difference across the membrane is 70.0 mV, find (*b*) the charge on the positively charged side of the membrane, and (*c*) the electric field strength in the membrane.

68 •• The space between the plates of a capacitor that is connected across the terminals of a battery is filled with a dielectric material. Determine the dielectric constant of the material if the induced bound charge per unit area on it is (*a*) 80 percent of the free charge per unit area on the plates, (*b*) 20 percent of the free charge per unit area on the plates, and (*c*) 98 percent of the free charge per unit area on the plates.

69 •• The positively charged plate of a parallel-plate capacitor has a charge equal to Q. When the space between the plates is evacuated of air, the electric field strength between the plates is 2.5×10^5 V/m. When the space is filled with a certain dielectric material, the field strength between the plates is reduced to 1.2×10^5 V/m.(*a*) What is the dielectric constant of the material? (*b*) If $Q = 10$ nC, what is the area of the plates? (*c*) What is the total induced bound charge on either face of the dielectric material?

70 •• Find the capacitance of the parallel-plate capacitor shown in Figure 24-44.

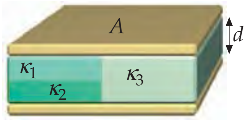

FIGURE 24-44 Problem 70

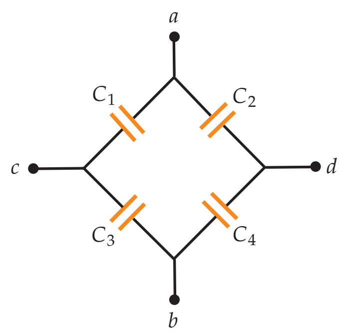

FIGURE 24-46 Problem 76

GENERAL PROBLEMS

71 • You are given four identical capacitors and a 100-V battery. When only one of the capacitors is connected to the battery the energy stored is U_0. Combine the four capacitors in such a way that the total energy stored in all four capacitors is U_0. Describe the combination and explain your answer.

72 • Three capacitors have capacitances of 2.00 μF, 4.00 μF, and 8.00 μF. Find the equivalent capacitance if (*a*) the capacitors are connected in parallel and (*b*) the capacitors are connected in series.

73 • A 1.00-μF capacitor is connected in parallel with a 2.00-μF capacitor, and this combination is connected in series with a 6.00-μF capacitor. What is the equivalent capacitance of this combination?

74 • The voltage across a parallel-plate capacitor that has a plate separation equal to 0.500 mm is 1.20 kV. The capacitor is disconnected from the voltage source and the separation between the plates is increased until the energy stored in the capacitor has been doubled. Determine the final separation between the plates.

75 •• Determine the equivalent capacitance, in terms of C_0, of each of the combinations of capacitors shown in Figure 24-45.

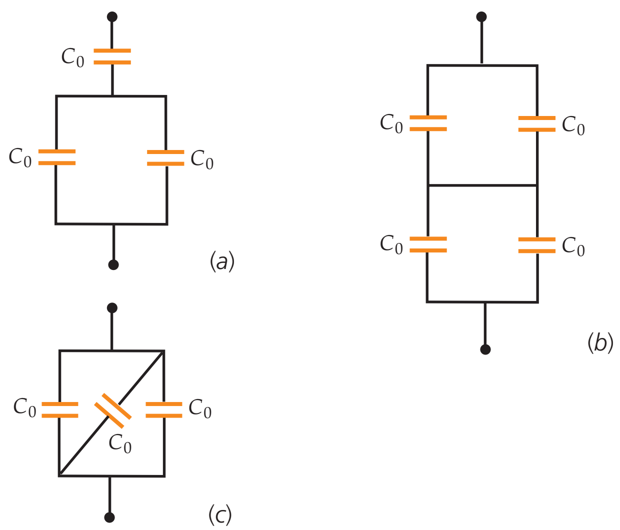

FIGURE 24-45 Problem 75

76 •• Figure 24-46 shows four capacitors connected in the arrangement known as a capacitance bridge. The capacitors are initially uncharged. What must the relation between the four capacitances be so that the potential difference between points c and d remains zero when a voltage V is applied between points a and b?

77 •• The plates of a parallel-plate capacitor are separated by distance d, and each plate has area A. The capacitor is charged to a potential difference V and then disconnected from the voltage source. The plates are then pulled apart until the separation is $3d$. Find (*a*) the new capacitance, (*b*) the new potential difference, and (*c*) the new stored energy. (*d*) How much work was required to change the plate separation from d to $3d$?

78 •• A parallel-plate capacitor has capacitance C_0 when there is no dielectric in the space between the plates. The space between the plates is then filled with a material that has a dielectric constant of κ. When a second capacitor of capacitance C' is connected in series with the first, the capacitance of the series combination is C_0. Find C' in terms of C_0.

79 •• A parallel combination of two identical 2.00-μF parallel-plate capacitors (no dielectric is in the space between the plates) is connected to a 100-V battery. The battery is then removed and the separation between the plates of one of the capacitors is doubled. Find the charge on the positively charged plate of each of the capacitors. SSM

80 •• A parallel-plate capacitor that has no dielectric in the space between the plates has a capacitance C_0 and a plate separation d. Two dielectric slabs that have dielectric constants of κ_1 and κ_2, respectively, are then inserted between the plates as shown in Figure 24-47. Each slab has a thickness $\frac{1}{2}d$ and has area A, the same area as each capacitor plate. When the charge on the positively charged capacitor plate is Q, find (*a*) the electric field in each dielectric and (*b*) the potential difference between the plates. (*c*) Show that the capacitance of the system after the slabs are inserted is given by $[2\kappa_1\kappa_2/(\kappa_1 + \kappa_2)]C_0$. (*d*) Show that $[2\kappa_1\kappa_2/(\kappa_1 + \kappa_2)]C_0$ is the equivalent capacitance of a series combination of two capacitors, each having plates of area A and a gap width equal to $d/2$. The space between the plates of one is filled with a material that has a dielectric constant equal to κ_1 and the space between the plates of the other is filled with a material that has a dielectric constant equal to κ_2.

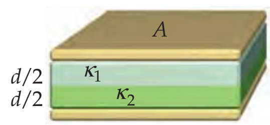

FIGURE 24-47 Problem 80

81 •• The plates of a parallel-plate capacitor are separated by distance d_0, and each plate has area A. A metal slab of thickness d and area A is inserted between the plates in such a way that the slab is parallel with the capacitor plates. (*a*) Show that the new capacitance is given by $\epsilon_0 A/(d_0 - d)$, regardless of the distance between the metal slab and the positively charged plate. (*b*) Show that this arrangement can be modeled as a capacitor that has plate separation a in series with a capacitor of plate separation b, where $a + b + d = d_0$.

82 •• A parallel-plate capacitor that has plate area A is filled with two dielectrics of equal size, as shown in Figure 24-48. (*a*) Show that this system can be modeled as two capacitors that are connected in parallel and each have an area $\frac{1}{2}A$. (*b*) Show that the capacitance is given by $\frac{1}{2}(\kappa_1 + \kappa_2)C_0$, where C_0 is the capacitance if there were no dielectric materials in the space between the plates.

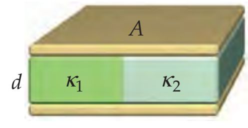

FIGURE 24-48 Problem 82

83 •• A parallel-plate capacitor that has no dielectric in the space between the plates has a plate area A and a gap width x. A charge Q is on the positively charged plate. (*a*) Find the stored electrostatic energy as a function of x. (*b*) Find the increase in energy dU due to an increase in plate separation dx from $dU = (dU/dx)\,dx$. (*c*) If F is the force exerted by one plate on the other, the work needed to move one plate a distance dx is $F\,dx = dU$. Show that $F = Q_2/(2\epsilon_0 A)$. (*d*) Show that the force in Part (*c*) equals $\frac{1}{2}EQ$, where Q is the charge on one plate and E is the electric field between the plates. Give a conceptual explanation for the factor $\frac{1}{2}$ in this result.

84 •• A rectangular parallel-plate capacitor that has a length a and a width b has a dielectric that has a width b partially inserted a distance x between the plates, as shown in Figure 24-49. (*a*) Find the capacitance as a function of x. Neglect edge effects. (*b*) Show that your answer gives the expected results for $x = 0$ and $x = a$.

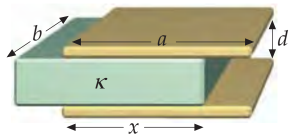

FIGURE 24-49 Problems 84 and 85

85 ••• An electrically isolated capacitor that has a charge Q on its positively charged plate is partly filled with a dielectric substance as shown in Figure 24-49. The capacitor consists of two rectangular plates that have edge lengths a and b and are separated by distance d. The dielectric is inserted into the gap a distance x. (*a*) What is the energy stored in the capacitor? *Hint: The capacitor can be modeled as two capacitors connected in parallel*. (*b*) Because the energy of the capacitor decreases as x increases, the electric field must be doing work on the dielectric, meaning that there must be an electric force pulling it in. Calculate this force by examining how the stored energy varies with x. (*c*) Express the force in terms of the capacitance and potential difference V between the plates. (*d*) From where does this force originate? SSM

86 ••• A spherical capacitor consists of a solid conducting sphere that has a radius a and a charge $+Q$ and a concentric conducting spherical shell that has an inner radius b and a charge $-Q$. The space between the two is filled with two different dielectric materials of dielectric constants κ_1 and κ_2. The boundary between the two dielectrics occurs a distance $\frac{1}{2}(a + b)$ from the center. (*a*) Calculate the electric field in the regions $a < r < \frac{1}{2}(a + b)$ and $\frac{1}{2}(a + b) < r < b$. (*b*) Integrate the expression $dV = -\vec{E}\cdot d\vec{\ell}$ to obtain the potential difference, V, between the two conductors. (*c*) Use $C = Q/V$ to obtain an expression for the capacitance of this system. (*d*) Show that your answer from Part (*c*) simplifies to the expected one if κ_1 equals κ_2.

87 ••• A capacitance balance is shown in Figure 24-50. The balance has a weight attached on one side and a capacitor that has a variable gap width on the other side. Assume the upper plate of the capacitor has negligible mass. When the capacitor potential difference between the plates is V_0, the attractive force between the plates balances the weight of the hanging mass. (*a*) Is the balance stable? That is, if we balance it out, and then move the plates a little closer together, will they snap shut or move back to the equilibrium point? (*b*) Calculate the value of V_0 required to balance an object of mass M, assuming the plates are separated by distance d_0 and have area A. *Hint: A useful relation is that the force between the plates is equal to the derivative of the stored electrostatic energy with respect to the plate separation.*

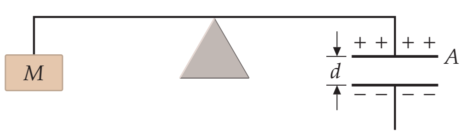

FIGURE 24-50 Problem 87

88 ••• **ENGINEERING APPLICATION, CONTEXT-RICH** You are an intern at an engineering company that makes capacitors used for energy storage in pulsed lasers. Your manager asks your team to construct a parallel-plate, air-gap capacitor that will store 100 kJ of energy. (*a*) What minimum volume is required between the plates of the capacitor? (*b*) Suppose you have developed a dielectric that has a dielectric strength of 3.00×10^8 V/m and a dielectric constant of 5.00. What volume of this dielectric, between the plates of the capacitor, is required for it to be able to store 100 kJ of energy?

89 ••• Consider two parallel-plate capacitors, C_1 and C_2, that are connected in parallel. The capacitors are identical except that C_2 has a dielectric inserted between its plates. A 200 V battery is connected across the combination until electrostatic equilibrium is established, and then the battery is disconnected. (*a*) What is the charge on each capacitor? (*b*) What is the total stored energy of the capacitors? (*c*) The dielectric is removed from C_2. What is the final stored energy of the capacitors? (*d*) What is the final voltage across the two capacitors?

90 ••• A capacitor is constructed of two coaxial conducting thin cylindrical shells of radii a and b ($b > a$), which have a length $L \gg b$. A charge of $+Q$ is on the inner cylinder, and a charge of $-Q$ is on the outer cylinder. The region between the two cylinders is filled with a material that has a dielectric constant κ. (*a*) Find the potential difference between the cylinders. (*b*) Find the density of the free charge σ_f on the inner cylinder and the outer cylinder. (*c*) Find the bound charge density σ_b on the inner cylindrical surface of the dielectric and on the outer cylindrical surface of the dielectric. (*d*) Find the total stored energy. (*e*) If the dielectric will move without friction, how much mechanical work is required to remove the dielectric cylindrical shell?

91 ••• Before switch S is closed, as shown in Figure 24-51, the voltage across the terminals of the switch is 120 V and the voltage across the capacitor labeled C_1 is 40.0 V. The capacitance of C_1 is 0.200 μF. The total energy stored in the two capacitors is 1.44 mJ. After closing the switch, the voltage across each capacitor is 80.0 V, and the energy stored by the two capacitors has dropped to 960 μJ. Determine the capacitance of C_2 and the charge on that capacitor before the switch was closed.

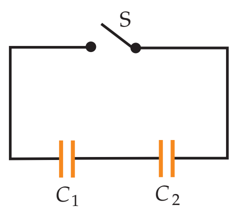

FIGURE 24-51 Problem 91

92 ••• An air-filled parallel-plate capacitor that has gap width d has plates that each have an area A. The capacitor is charged to a potential difference V and is then removed from the voltage source. A dielectric slab that has a dielectric constant of 2.00, a thickness d, and an area $\frac{1}{2}A$ is then inserted, as shown in Figure 24-52. Let σ_1 be the free charge density at the conductor–dielectric surface, and

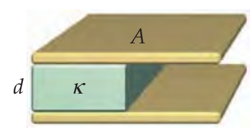

FIGURE 24-52 Problem 92

let σ_2 be the free charge density at the conductor–air surface. (*a*) Explain why the electric field must have the same value inside the dielectric as in the free space between the plates. (*b*) Show that $\sigma_1 = 2\sigma_2$. (*c*) Show that the final capacitance (after the slab is inserted) is 1.50 times the capacitance when the capacitor is filled with air. (*d*) Show that the final potential difference is $\frac{2}{3}V$. (*e*) Show that energy stored after the slab is inserted is only two-thirds of the energy stored before insertion.

93 ••• A capacitor has rectangular plates of length a and width b. The top plate is inclined at a small angle, as shown in Figure 24-53. The plate separation varies from y_0 at the left to $2y_0$ at the right, where y_0 is much less than a or b. Calculate the capacitance of this arrangement. *Hint: Break the problem up into a parallel combination. Choose strips of width dx and length b to approximate small (differential) capacitors (each having a value of dC). Each will have a plate area of b dx and separation distance $y_0 + (y_0/a)x$. Then argue that these differential capacitors are connected in parallel.*

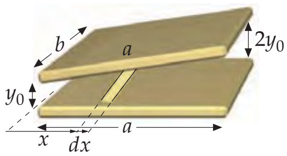

FIGURE 24-53
Problem 93

94 ••• Not all dielectrics that separate the plates of a capacitor are rigid. For example, the membrane of a nerve axon is a lipid bilayer that has a finite compressibility. Consider a parallel-plate capacitor whose plate separation is maintained by a material that has a dielectric constant of 3.00, a dielectric strength of 40.0 kV/mm, and a Young's modulus for compressive stress of $5.00 \times 10^6\ \mathrm{N/m^2}$. When the potential difference between the capacitor plates is zero, the thickness of the dielectric is equal to 0.200 mm and the capacitance of the capacitor is given by C_0. (*a*) Derive an expression for the capacitance as a function of the potential difference between the capacitor plates. (*b*) What is the maximum value of this potential difference? (Assume that the dielectric constant and the dielectric strength do *not* change under compression.)

CHAPTER 25

UNDERSTANDING DIRECT-CURRENT CIRCUITS CAN HELP YOU PERFORM POTENTIALLY DANGEROUS TASKS LIKE JUMP-STARTING A VEHICLE. *(© Tom Stewart/CORBIS.)*

? When jump-starting your car using a second car, which terminal of the battery of your car should be connected to the positive terminal of the battery of the second car? (See Example 25-15.)

Electric Current and Direct-Current Circuits

When we turn on a light, we connect the wire filament in the lightbulb across a potential difference that causes charge to flow through the wire, which is similar to the way a pressure difference in a garden hose causes water to flow through the hose. The flow of charge constitutes an electric current. We usually think of currents as being in conducting wires, but the electron beam in a cathode-ray tube (CRT) video monitor and a beam of charged ions from a particle accelerator also constitute electric currents.

In Chapter 25, we look at direct-current (dc) circuits, which are circuits where the direction of the current in a circuit element does not vary with time. Direct currents can be produced by batteries connected to resistors and capacitors. In Chapter 29, we discuss alternating-current (ac) circuits, in which the direction of the current changes.

25-1 CURRENT AND THE MOTION OF CHARGES

When a switch is thrown to turn on a circuit, a very small amount of charge accumulates along the surfaces of the wires and other conducting elements of the circuit, and these surface charges produce electric fields that drive the motion of charges through the conducting materials of the circuit. In the circuits we consider here, the time required for these small surface charges to be established is very short. The time for steady-state flow to be established depends on the size and the conductivity of the elements in the circuit, but the time is instantaneous as far as our perceptions are concerned. In steady state, charge no longer continues to accumulate at points along the circuit and the current is steady. (For the circuits in this chapter containing capacitors and resistors, the current may increase or decrease slowly, but appreciable changes occur only over a period that is much longer than the time needed to reach the steady state.)

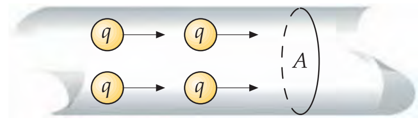

FIGURE 25-1 A segment of a current-carrying wire. If ΔQ is the amount of charge that flows through the cross-sectional area A in time Δt, the current through A is $I = \Delta Q/\Delta t$ in the limit that Δt approaches zero.

Electric current is the rate of flow of charge through a surface—typically a cross-sectional surface of a conducting wire. Figure 25-1 shows a segment of a wire that is carrying a current (charges are moving). If ΔQ is the charge that flows through the cross-sectional area A in time Δt, the current I is

$$I = \frac{\Delta Q}{\Delta t} \qquad 25\text{-}1$$

in the limit that Δt approaches zero. The SI unit of current is the **ampere** (A)*:

$$1\ \text{A} = 1\ \text{C/s} \qquad 25\text{-}2$$

Mobile charges can be negatively charged or positively charged. In addition, a direction along the wire is designated as the positive direction. By convention, the sign of the current is positive if the current is due either to positive charges moving in the positive direction or to negative charges moving in the negative direction. However, the current is negative if it is due either to positive charges moving in the negative direction or to negative charges moving in the positive direction. This convention was established before it was known that the mobile charge carriers in metals were free electrons. Thus, in a current-carrying metallic wire, the free electrons move in the negative direction when the current is positive, and vice versa.

In a metal wire, the motion of negatively charged free electrons is quite complex. When there is no electric field in the wire, the free electrons move in random directions with relatively large speeds of the order of 10^6 m/s.† In addition, the electrons collide repeatedly with the lattice ions in the wire. Because the velocity vectors of the electrons are randomly oriented, the *average* velocity is zero. When an electric field is applied, the field exerts a force $-e\vec{E}$ on each free electron, giving it a change in velocity in the direction opposite the field. However, any additional kinetic energy acquired is quickly dissipated by collisions with the lattice ions in the wire. During the time between collisions with the lattice ions, the free electrons, on average, acquire an additional velocity in the direction opposite to the field. The net result of this repeated acceleration and dissipation of energy is that the electrons drift along the wire with a small average velocity, directed opposite to the electric-field direction, called the **drift velocity.** The **drift speed** is the magnitude of the drift velocity.

* The ampere is operationally defined (see Chapter 26) in terms of the magnetic force that current-carrying wires exert on one another. The coulomb is then defined as the ampere-second.

† The average kinetic energy of the free electrons in a metal is quite large, even at very low temperatures. These electrons do not have the classical Maxwell–Boltzmann energy distribution and do not obey the classical equipartition theorem. We discuss the energy distribution of these electrons and calculate their average speed in Chapter 38.

The motion of the free electrons in a metal is similar to the motion of the molecules of a gas, such as air. In still air at room temperature, the gas molecules move with large speeds (about 500 m/s) due to their thermal energy, but their average velocity is zero. When there is a breeze, the air molecules have a small average velocity or drift velocity in the direction of the breeze superimposed on their random high-speed motions. Similarly, when there is no applied electric field, the average velocity of all the free electrons in a metal is zero, but when there is an applied electric field, the average velocity is not zero due to the small drift velocities of the free electrons.

Let n be the number of mobile charged particles (charge carriers) per unit volume in a conducting wire of cross-sectional area A. We call n the **number density** of the charge carriers. Assume that each particle carries a charge q and moves in the positive direction with a drift speed v_d. During time Δt, all the particles in the volume $Av_d\,\Delta t$, shown in Figure 25-2 as a shaded region, pass through the area element. The number of particles in this volume is $nAv_d\,\Delta t$, and the total free charge in the volume is

$$\Delta Q = qnAv_d\,\Delta t$$

The current is thus

$$I = \frac{\Delta Q}{\Delta t} = qnAv_d \qquad 25\text{-}3$$

RELATION BETWEEN CURRENT AND DRIFT SPEED

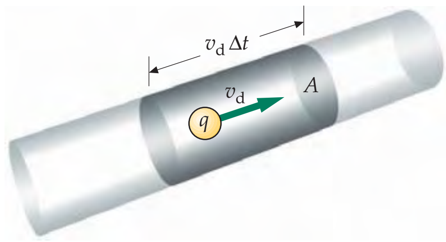

FIGURE 25-2 During time Δt, all the free charges initially in the shaded volume pass through A. If there are n charge carriers per unit volume, each having charge q, the total free charge in this volume is $\Delta Q = qnAv_d\,\Delta t$, where v_d is the drift speed of the charge carriers.

Equation 25-3 can be used to find the current due to the flow of any species of charged particle. If the current is the result of the motion of more than one species of mobile charge, as it sometimes is in ionic solutions such as salt water, then the total current is the sum of the currents for each of the individual species of mobile charges.

The number density of charge carriers in a conductor can be measured by the Hall effect, which is discussed in Chapter 26. The result is that, in most metals, there is approximately one free electron per atom.

The current per unit area is qnv_d, which is gotten by dividing both sides of Equation 25-3 by the area A. The **current density** vector, $\vec{J}$, is specified by

$$\vec{J} = qn\vec{v}_d \qquad 25\text{-}4$$

DEFINITION—CURRENT DENSITY

The **current** through a surface S is defined as the flux of the current density vector $\vec{J}$ through the surface. That is,

$$I = \int_S \vec{J}\cdot d\vec{A} = \int_S \vec{J}\cdot\hat{n}\,dA \qquad 25\text{-}5$$

DEFINITION—CURRENT

where $d\vec{A}$ is an element of area for the surface and $\hat{n}$ is the unit vector normal to the surface S in the direction of $d\vec{A}$ (see Figure 25-3). If $\vec{J}$ is uniform and if the surface is flat, which means that $\hat{n}$ would be uniform, then the flux can be expressed

$$I = \int_S \vec{J}\cdot d\vec{A} = \vec{J}\cdot\vec{A} = \vec{J}\cdot\hat{n}A = JA\cos\theta$$

where $\vec{A}$ is the area of the surface and θ is the angle between $\vec{J}$ and $\hat{n}$. The sign of the current I is the same as the sign of $\cos\theta$. If $\theta < 90°$ I is positive, and if $\theta > 90°$

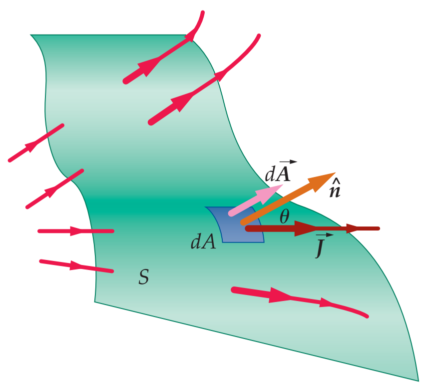

FIGURE 25-3 Current density $\vec{J}$ is a vector field that we can visualize by drawing field lines. The red directed lines are field lines of the current density field. These field lines serve as streamlines for the flow of charge. The current I (through S) is the flux of $\vec{J}$ through surface S.

then I is negative (Figure 25-4). The black arrow with the plus sign next to each wire in the figure indicates the choice for the direction of $\hat{n}$ on the cross-sectional surfaces of the wire.

For a given current density $\vec{J}$ and surface S, the sign of the current I is determined by the choice of the direction of $\hat{n}$.

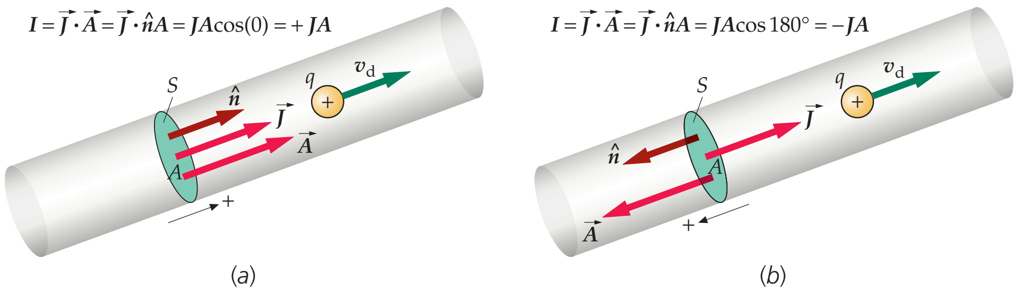

FIGURE 25-4 The flat surface S is perpendicular to the current density vector $\vec{J}$. The area vector $\vec{A}$ for the surface S is defined to be in the same direction as normal $\hat{n}$ for the surface. However, there are two choices for the direction of $\hat{n}$. (*a*) The current I through surface S is positive if the direction of $\hat{n}$ is chosen so that $\hat{n}$ and $\vec{J}$ are in the same direction. (*b*) The current I through surface S is negative if the direction of $\hat{n}$ is chosen so that $\hat{n}$ and $\vec{J}$ are in opposite directions.

Example 25-1 Finding the Drift Speed

The wire used for student laboratory experiments is typically made of copper and has a radius equal to 0.815 mm. (*a*) Estimate the total charge of the free electrons in each meter of such a wire carrying a current that has a magnitude equal to 1.0 A. Assume one free electron per atom. (*b*) Calculate the drift speed of the free electrons.

PICTURE Equation 25-3 relates the drift speed to the number density of charge carriers, which approximately equals the number density n_a of copper atoms. We can find n_a from the mass density and molar mass of copper and Avogadro's number.

SOLVE

(*a*) 1. The drift speed is related to the current and number density of charge carriers:

$$I = nqv_dA$$

2. If there is one free electron per atom, the number density n of free electrons equals the number density n_a of atoms:

$$n = n_a$$

3. The number density of atoms n_a is related to the mass density ρ_m, Avogadro's number N_A, and the molar mass M. For copper, $\rho_m = 8.93\ \text{g/cm}^3$ and $M = 63.5$ g/mol:

$$n_a = \frac{\rho_m N_A}{M} = \frac{(8.93\ \text{g/cm}^3)(6.02 \times 10^{23}\ \text{atoms/mol})}{63.5\ \text{g/mol}}$$
$$= 8.47 \times 10^{22}\ \text{atoms/cm}^3 = 8.47 \times 10^{28}\ \text{atoms/m}^3$$

4. The charge density ρ_{fe} of the free electrons equals the number density multiplied by the charge:

$$\rho_{fe} = -en = -(1.60 \times 10^{-19}\ \text{C})(8.47 \times 10^{28}\ \text{m}^{-3}) = -1.36 \times 10^{10}\ \text{C/m}^3$$

5. The charge is the charge density multiplied by the volume:

$$Q = \rho_{fe}AL = -enAL \quad \text{so}$$
$$Q/L = -enA = (-1.36 \times 10^{10}\ \text{C/m}^3)\,\pi(8.15 \times 10^{-4}\ \text{m})^2$$
$$= -2.83 \times 10^4\ \text{C/m} = \boxed{-2.8 \times 10^4\ \text{C/m}}$$

(*b*) Substituting numerical values in Equation 25-3 yields v_d (The current is negative because Equation 25-3 is valid only for charges moving in the positive direction.):

$$v_d = \frac{I}{nqA} = \frac{I}{-neA} = \frac{I}{Q/L}$$
$$= \frac{-1.0\ \text{C/s}}{(-2.83 \times 10^4\ \text{C/m})} = \boxed{3.5 \times 10^{-2}\ \text{mm/s}}$$

CHECK Because there is 28 000 coulombs of mobile charge per meter of wire [Part (*a*), step 5], only a small drift speed is expected for a current of one coulomb per second. The Part (*b*) result is in agreement with this expectation.

PRACTICE PROBLEM 25-1 How long would it take for an electron to drift from your car battery to the starter motor, a distance of about 1 m, if its drift speed is 3.5×10^{-5} m/s?

The drift speed of the mobile electrons in the wire in Example 25-1 is only a few hundredths of a millimeter per second. If electrons drift along wires at such low speeds, why does an electric light on the ceiling come on instantly when the wall switch is turned on? A comparison with water in a hose may prove useful. If you attach an empty 100-ft-long hose to a water faucet and turn on the water, it typically takes several seconds for the water to travel the length of the hose to the nozzle. However, if the hose is already full of water when the faucet is opened, the water emerges from the nozzle almost instantaneously. Because of the water pressure at the faucet, the segment of water near the faucet pushes on the water immediately next to it, which pushes on the next segment of water, and so on, until the last segment of water is pushed out the nozzle. This pressure wave moves down the hose at the speed of sound in water, and the water quickly reaches a steady flow rate.

Unlike a water hose, a metal wire is never empty. That is, there are always a very large number of conduction electrons throughout the metal wire. Thus, electrons start moving along the entire length of the wire (including the wire inside the lightbulb) almost immediately after the light switch is turned on. The transport of a significant amount of electrons in a wire is accomplished not by a few electrons moving rapidly down the wire, but by a very large number of electrons slowly drifting down the wire. Surface charges are established on the wires, and these surface charges produce an electric field. It is the electric field produced by these surface charges that drives the conduction electrons through the wire.

Example 25-2 Finding the Number Density

In a certain particle accelerator, a current of 0.50 mA is carried by a 5.0-MeV proton beam that has a radius equal to 1.5 mm. (*a*) Find the number density of protons in the beam. (*b*) If the beam hits a target, how many protons hit the target in 1.0 s?

PICTURE To find the number density, we use the relation $I = qnAv$ (Equation 25-3), where v is the drift speed of the charge carriers. (The drift speed is the magnitude of the average velocity.) We can find v from the energy. (In a 5.0-MeV beam, each particle in the beam has a kinetic energy equal to 5.0 MeV.) The amount of charge Q that hits the target in time Δt is $I\,\Delta t$, and the number N of protons that hits the target is Q divided by the charge per proton.

SOLVE

(*a*) 1. The number density is related to the current, the charge, the cross-sectional area, and the speed:

$$I = qnAv$$

2. We find the speed of the protons from their kinetic energy:

$$K = \tfrac{1}{2}mv^2 = 5.0\text{ MeV}$$

3. Use $m = 1.67 \times 10^{-27}$ kg for the mass of a proton, and solve for the speed:

$$v = \sqrt{\frac{2K}{m}} = \sqrt{\frac{(2)(5.0 \times 10^6\text{ eV})}{1.67 \times 10^{-27}\text{ kg}} \times \frac{1.60 \times 10^{-19}\text{ J}}{1\text{ eV}}}$$

$$= 3.09 \times 10^7\text{ m/s} = \boxed{3.1 \times 10^7\text{ m/s}}$$

4. Substitute to calculate n:

$$n = \frac{I}{qAv}$$

$$= \frac{0.50 \times 10^{-3}\ \text{A}}{(1.60 \times 10^{-19}\ \text{C/proton})\ \pi(1.5 \times 10^{-3}\ \text{m})^2\ (3.10 \times 10^7\ \text{m/s})}$$

$$= 1.43 \times 10^{13}\ \text{protons/m}^3 = \boxed{1.4 \times 10^{13}\ \text{protons/m}^3}$$

(*b*) 1. The number of protons N that hit the target in 1.0 s is related to the total charge ΔQ that hits in 1.0 s and the proton charge q:

$$\Delta Q = Nq$$

2. The charge ΔQ that strikes the target in time Δt is the current multiplied by the time:

$$\Delta Q = I\,\Delta t$$

3. The number of protons is then:

$$N = \frac{\Delta Q}{q} = \frac{I\,\Delta t}{q} = \frac{(0.50 \times 10^{-3}\ \text{A})(1.0\ \text{s})}{1.60 \times 10^{-19}\ \text{C/proton}}$$

$$= 3.13 \times 10^{15}\ \text{protons} = \boxed{3.1 \times 10^{15}\ \text{protons}}$$

CHECK The number of protons N hitting the target in time Δt is the number in the volume $Av\,\Delta t$. Thus, $N = nAv\,\Delta t$. Substituting $n = I/(qAv)$ then gives $N = nAv\,\Delta t = [I/(qAv)](Av)\,\Delta t = I\,\Delta t/q = \Delta Q/q$, which is the expression for N that we used in Part (*b*).

TAKING IT FURTHER We were able to use the classical expression for kinetic energy in step 2 of Part (*a*) without taking relativity into consideration, because the proton kinetic energy of 5.0 MeV is much less than the proton rest energy (about 931 MeV). The speed found, 3.1×10^7 m/s, is about one-tenth the speed of light.

PRACTICE PROBLEM 25-2 Using the number density found in Part (*a*), how many protons are there in a volume of 1.0 mm³ of the space containing the beam?

25-2 RESISTANCE AND OHM'S LAW

Current in a conductor is driven by an electric field $\vec{E}$ inside the conductor that exerts a force $q\vec{E}$ on the free charges. (In electrostatic equilibrium, the electric field must be zero inside a conductor, but when there is a current in a conductor, the conductor is no longer in electrostatic equilibrium.) The free charges drifts down the conductor, driven by forces exerted on the charges by the electric field. In a metal, the free charges are negatively charged, so the free charges are driven in a direction opposite to the direction of the electric field $\vec{E}$. If the only forces on the free charges were the electric forces, then the free charges would gain speed indefinitely. However, this does not happen because the free electrons interact with the lattice of ions that make up the metal, and the interaction forces oppose the drifting motion of the free electrons.

Figure 25-5 shows a wire segment that has a length ΔL, a cross-sectional area A, and a current I. Because electric fields point in the direction of decreasing potential, the potential at point a is greater than the potential at point b. If we model the current as the flow of positive charge carriers, these positive charge carriers drift in the direction of decreasing potential. Assuming the electric field $\vec{E}$ to be uniform throughout the segment, the **potential drop** V between points a and b is

$$V = V_a - V_b = E\,\Delta L \qquad 25\text{-}6$$

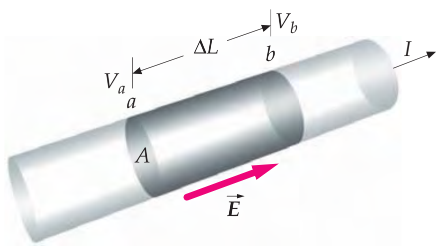

FIGURE 25-5 A segment of wire that has a current I. The potential drop $V_a - V_b$ is related to the electric field by $V_a - V_b = E\,\Delta L$.

The ratio of the potential drop in the direction of the current* to the current is called the **resistance** of the segment,

$$R = \frac{V}{I} \qquad 25\text{-}7$$

DEFINITION—RESISTANCE

where the *direction of the current* refers to the direction of the current density vector. The SI unit of resistance, the volt per ampere, is called an **ohm** (Ω):

$$1\Omega = 1\ \text{V/A} \qquad 25\text{-}8$$

* Because current is a scalar it does not have a direction.

For many materials, the resistance of a sample of the material does not depend on either the potential drop or the current. Such materials, which include most metals, are called **ohmic materials.** For many ohmic materials resistance remains essentially constant over a wide range of conditions. In that case the potential drop across a segment of the material is proportional to the current in the material. Equation 25-7 is typically written:

$$V = IR \tag{25-9}$$

OHM'S LAW

The relation $V = IR$ is commonly referred to as Ohm's law, even when the resistance R varies with the current I.

Figure 25-6 shows the potential difference V versus the current I for two conductors. For one conductor (Figure 25-6*a*), the relation is linear, but for the other conductor (Figure 25-6*b*), the relation is not linear. Ohm's law is not a fundamental law of nature, like Newton's laws or the laws of thermodynamics, but rather is an empirical description of a property shared by many materials under specified conditions. As we shall see, the resistance of a conductor does vary with the temperature of the conductor.

See* Math Tutorial *for more information on

Direct and Inverse Proportions

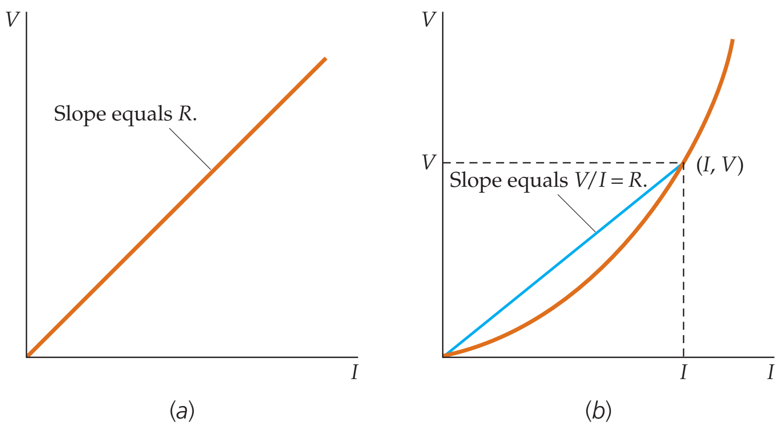

FIGURE 25-6 Plots of V versus I. (*a*) The potential drop is proportional to the current in accord with Ohm's law. The resistance $R = V/I$, equal to the slope of the line, is independent of I as indicated by the constant slope of the line. (*b*) The potential drop is not proportional to the current. The resistance $R = V/I$, equal to the slope of the chord connecting the origin with the point (I, V), increases with increasing I.

PRACTICE PROBLEM 25-3

A wire of resistance 3.0 Ω carries a current of 1.5 A. What is the potential drop across the wire?

The resistance R of a conducting wire is found to be proportional to the length L of the wire and inversely proportional to its cross-sectional area A:

$$R = \rho\frac{L}{A} \tag{25-10}$$

where the proportionality constant ρ is called the **resistivity** of the conducting material.* The unit of resistivity is the ohm-meter ($\Omega \cdot \mathrm{m}$). Note that Equation 25-9 and Equation 25-10 for electrical conduction and electrical resistance are of the same form as Equation 20-9 ($\Delta T = IR$) and Equation 20-10 [$R = \Delta|x|/(kA)$] for thermal conduction and thermal resistance. For the equations that describe current, the potential difference V is substituted for the temperature difference ΔT and $1/\rho$ is substituted for the thermal conductivity k. (In fact, $1/\rho$ is called the *electrical conductivity*.†) Ohm was led to his law by the similarity between the conduction of electricity and the conduction of heat.

* The symbol ρ used here for the resistivity was used in previous chapters for volume charge density. Care must be taken to identify what quantity ρ refers to from context.

† The unit of conductance is the siemens (S), $1\ \mathrm{S} = 1\ \Omega^{-1}$, and the units for conductivity are siemens per meter (S/m).

PRACTICE PROBLEM 25-4

A Nichrome wire ($\rho = 110 \times 10^{-8}\ \Omega \cdot \mathrm{m}$) has a radius of 0.65 mm. What length of wire is needed to obtain a resistance of 2.0 Ω?

For a segment of wire that has a length L, a cross-sectional area A, a current I, and a resistance R, the voltage drop V across the length of the segment is related to the current I in the segment by

$$V = IR = I\rho\frac{L}{A}$$

The voltage drop V and the electric field strength E are related by $V = EL$. Substituting EL for V and J for I/A gives

$$EL = \rho JL$$

Dividing both sides by L and expressing E and J as vectors, we obtain

$$\vec{E} = \rho\vec{J} \qquad \text{25-11}$$

Equation 25-11 is an alternative version of Ohm's law. It states that the current density vector $\vec{J}$ at a point in a current-carrying conductor is equal to the reciprocal of the resistivity multiplied by the electric field vector $\vec{E}$ at the same point.

The resistivity of any given metal depends on the temperature. Figure 25-7 shows the temperature dependence of the resistivity of copper. This graph is nearly a straight line, which means that the resistivity varies nearly linearly with temperature.* In tables, the resistivity is usually given in terms of its value at 20°C, ρ_{20}, along with the **temperature coefficient of resistivity,** α, which is the ratio of the fractional change in resistivity to the change in temperature:

$$\alpha = \frac{(\rho - \rho_0)/\rho_0}{T - T_0} \qquad \text{25-12}$$

where ρ_0 is the resistivity at temperature T_0 and ρ is the resistivity at temperature T.

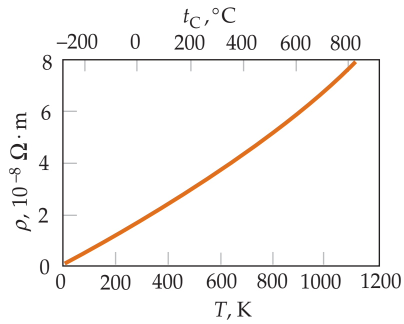

FIGURE 25-7 Plot of resistivity ρ versus temperature for copper. Because the Celsius and absolute temperatures differ only in the choice of zero, the resistivity has the same slope whether it is plotted against t_C or T.

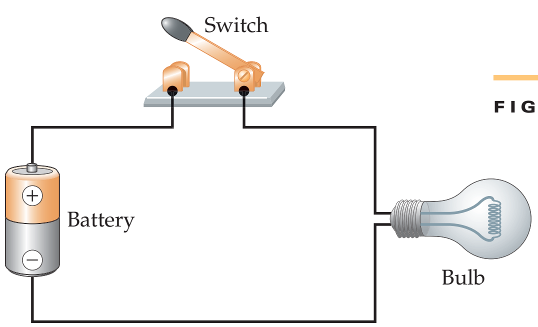

FIGURE 25-8

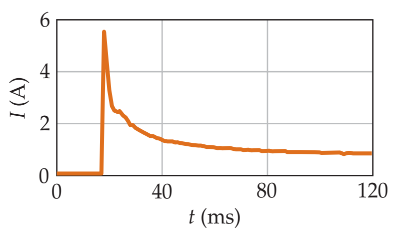

FIGURE 25-9 The current in the tungsten filament of an incandescent light bulb peaks when the bulb is first connected to the battery, but during the next 100 ms or so the current drops to its steady-state value of about 0.75 A. This occurs because the resistance of the filament increases with increasing temperature.

CONCEPT CHECK 25-1

The filament in the lightbulb shown in Figure 25-8 is a thin tungsten wire, and Figure 25-9 is a plot of the current in the filament as a function of time. Note that the current increases rapidly when the switch is closed, and then decreases until the current is maintained at a constant value. (*a*) Why does the current initially get larger than the constant value? (*b*) Why does the current remain constant following the initial surge?

* There is a breakdown in this linearity for all metals at very low temperatures that is not shown in Figure 25-7.

Table 25-1 Resistivities and Temperature Coefficients

Material	Resistivity ρ at 20°C, $\Omega\cdot$m	Temperature Coefficient α at 20°C, K^{-1}
Conducting Elements		
Aluminum	2.8×10^{-8}	3.9×10^{-3}
Copper	1.7×10^{-8}	3.93×10^{-3}
Iron	10×10^{-8}	5.0×10^{-3}
Lead	22×10^{-8}	4.3×10^{-3}
Mercury	96×10^{-8}	0.89×10^{-3}
Platinum	100×10^{-8}	3.927×10^{-3}
Silver	1.6×10^{-8}	3.8×10^{-3}
Tungsten	5.5×10^{-8}	4.5×10^{-3}
Carbon	3500×10^{-8}	-0.5×10^{-3}
Conducting alloys

Table 25-2 Wire Diameters and Cross-Sectional Areas for Commonly Used Copper Wires

AWG* Gauge Number	Diameter† at 20°C, mm	Area, mm^2
4	5.189	21.15
6	4.115	13.30
8	3.264	8.366
10	2.588	5.261
12	2.053	3.309
14	1.628	2.081
16	1.291	1.309
18	1.024	0.8235
20	0.8118	0.5176
22	0.6438	0.3255

* American wire gauge.

† The diameter d is related to the gauge number n by $d = 0.127 \times 92^{[(36-n)/39]}$.

Table 25-1 gives the resistivity and the temperature coefficient at 20°C for various materials. Note the tremendous range of resistivity values for various materials at 20°C. The classical theory of conduction predicts that the resistivities of metals decrease with increases in temperature, which is one of several reasons that the classical theory of conduction has been discredited. However, the increases in resistivities of metals with increases in temperature are consistent with the quantum-mechanical theory of conduction. Both the classical and the quantum-mechanical theories of conduction are presented in Chapter 38.

Electrical wires are manufactured in standard sizes. The diameter of the circular cross section is indicated by a *gauge number*—larger numbers correspond to smaller diameters—as can be seen in Table 25-2.

Example 25-3 Resistance per Unit Length

Calculate the resistance per unit length of a 14-gauge copper wire.

PICTURE To calculate the resistance per unit length of the 14-gauge wire, you will need to find the resistivity of copper from Table 25-1 and the cross-sectional area of the copper wire from Table 25-2.

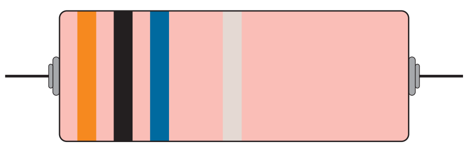
SOLVE

1. From Equation 25-10, the resistance per unit length equals the resistivity divided by unit area:
$$R = \rho\frac{L}{A} \quad \text{so} \quad \frac{R}{L} = \frac{\rho}{A}$$
2. Find the resistivity of copper from Table 25-1 and the cross-sectional area of the copper wire from Table 25-2:
$$\rho = 1.7 \times 10^{-8}\ \Omega\cdot\text{m}$$
$$A = 2.08\ \text{mm}^2$$
3. Use these values to find R/L:
$$\frac{R}{L} = \frac{\rho}{A} = \frac{1.7 \times 10^{-8}\ \Omega\cdot\text{m}}{2.08 \times 10^{-6}\ \text{m}^2} = \boxed{8.2 \times 10^{-3}\ \Omega/\text{m}}$$

CHECK 14-gauge copper wire is commonly used for household lighting circuits. The resistance of a 100-W, 120-V lightbulb filament is 144 Ω and the resistance of 100 m of 14-gauge copper wire is 0.82 Ω, so the resistance of the 14-gauge copper wire is negligible compared to the resistance of the lightbulb filament as expected.

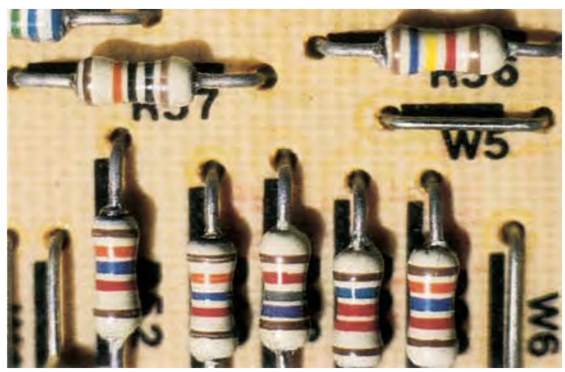
Carbon, which has a relatively high resistivity, is used in resistors found in electronic equipment. Resistors are often marked with colored stripes that indicate their resistance value. The code for interpreting these colors is given in Table 25-3.

Table 25-3 The Color Code for Resistors and Other Devices



Colors		Numeral	Tolerance		
Black	=	0	Brown	=	1%
Brown	=	1	Red	=	2%
Red	=	2	Gold	=	5%
Orange	=	3	Silver	=	10%
Yellow	=	4	None	=	20%
Green	=	5			
Blue	=	6			
Violet	=	7			
Gray	=	8			
White	=	9			

The color bands consist of a group of three or four equally spaced bands that represent the value of the resistance in ohms, plus an additional tolerance band that is separate from the group. The value bands are read starting with the band closest to the end of the resistor. If there are three value bands, the first two bands represent a number between 1 and 99 the third band represents the number of zeros that follow. For the resistor shown, the colors of the first three bands are, respectively, orange, black, and blue. Thus, the number is 30 000 000 and the resistance value is 30 MΩ. (If a green band had been inserted between the black and blue bands, the resistance value would have been 305 MΩ.) The band separated from the others is the tolerance band. If the tolerance band is silver, as shown here, the tolerance is 10 percent. Ten percent of 30 is 3, so the resistance value is (30 ± 3) MΩ.



Color-coded carbon resistors on a circuit board. *(© Chris Rogers/The Stock Market.)*

PRACTICE PROBLEM 25-5

What are the values of the resistance and tolerance of the resistor shown on the lower left in the photo?

Example 25-4 The Electric Field That Drives the Current

Find the electric field strength E in the 14-gauge copper wire of Example 25-3 when the wire has a current equal to 1.3 A.

PICTURE We find the electric field strength as the potential drop for a given length of wire, $E = V/L$. The potential drop is found using Ohm's law, $V = IR$, and the resistance per length is given in Example 25-3.

SOLVE

1. The electric field strength equals the potential drop per unit length: $E = \dfrac{V}{L}$
2. Write Ohm's law for the potential drop: $V = IR$
3. Substitute this expression into the equation for E: $E = \dfrac{V}{L} = \dfrac{IR}{L} = I\dfrac{R}{L}$
4. Substitute the value of R/L found in Example 25-3 to calculate E: $E = I\dfrac{R}{L} = (1.3\text{ A})(8.2 \times 10^{-3}\ \Omega/\text{m}) = \boxed{0.011\text{ V/m}}$

CHECK An electric field of 0.011 V/m means that the potential drop for a 100-m length of the wire is 1.1 V. This result seems acceptable for a 120-V household circuit. However, a 13-A current would mean an 11-V drop, which is much less acceptable. (It is unacceptable because many devices do not function properly if the potential difference applied across their terminals is significantly less than the full 120 volts.)

25-3 ENERGY IN ELECTRIC CIRCUITS

When there is an electric field in a conductor, the free electrons gain kinetic energy due to the work done on the free electrons by the field. However, steady state is soon achieved as the kinetic energy gain is continuously dissipated into the thermal energy of the conductor by interactions between the free electrons and the lattice ions of the conductor. This mechanism for increasing the thermal energy of a conductor is called **Joule heating.**

Consider the segment of wire of length L and cross-sectional area A shown in Figure 25-10*a*. The wire carries a steady current that we will model as positive free charge in the wire that is moving to the right. Consider the free charge Q initially in the segment. During time Δt, this free charge undergoes a small displacement to the right (Figure 25-10*b*). This displacement is equivalent to an amount of charge ΔQ (Figure 25-10*c*) being moved from its left end, where it had potential energy $\Delta Q\, V_a$, to its right end, where it has potential energy $\Delta Q\, V_b$. The net change in the potential energy of Q is thus

$$\Delta U = \Delta Q(V_b - V_a)$$

Because $V_a > V_b$, this represents a net loss in the potential energy. The potential energy lost is then

$$-\Delta U = \Delta Q\, V$$

where $V = V_a - V_b$ is the *potential drop* across the segment in the direction of the current. The rate of potential energy loss is

$$-\frac{\Delta U}{\Delta t} = \frac{\Delta Q}{\Delta t} V$$

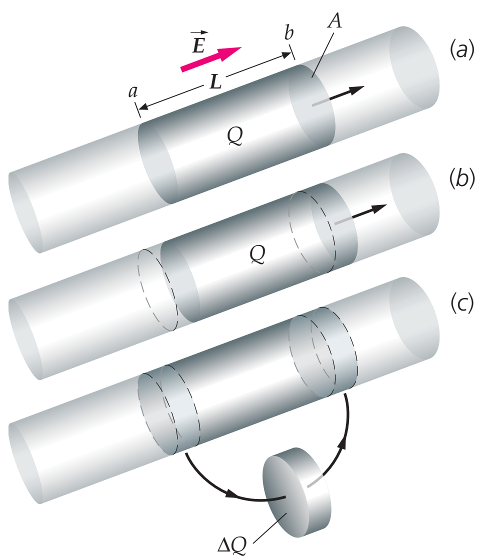


FIGURE 25-10 During a time Δt, an amount of charge ΔQ passes point a, where the potential is V_a. During the same time interval, an equal amount of charge leaves the segment, passing point b, where the potential is V_b. The net effect during time Δt is that the charge Q initially in the segment both loses an amount of potential energy equal to $\Delta Q\, V_a$ and gains an amount equal to $\Delta Q\, V_b$. This change amounts to a net decrease in potential energy because $V_a > V_b$.

Taking the limit as Δt approaches zero gives

$$-\frac{dU}{dt} = \frac{dQ}{dt}V = IV$$

where $I = dQ/dt$ is the current. The rate of potential energy loss is the power P delivered to the conducting segment, and it is equal to the rate of dissipation of electrical potential energy in the segment:

$$P = IV \qquad 25\text{-}13$$

RATE OF POTENTIAL ENERGY LOSS

If V is in volts and I is in amperes, the power is in watts. The power loss is the product IV, where V is the decrease in potential energy per unit charge, and I is the rate at which the charge flows past a cross section of the segment. Equation 25-13 applies to any device in a circuit. The rate at which potential energy is delivered to the device is the product of the potential drop across the device in the direction of the current, and the current through the device. In a conductor (a resistor is a conductor), the potential energy is dissipated as thermal energy. Using $V = IR$, or $I = V/R$, we can write Equation 25-13 in other convenient forms

$$P = IV = I^2R = \frac{V^2}{R} \qquad 25\text{-}14$$

POWER DELIVERED TO A RESISTOR

Example 25-5 Power Delivered to a Resistor

A 12.0-Ω resistor has a current equal to 3.00 A. Find the power delivered to this resistor.

PICTURE Because we are given the current and the resistance, but not the potential drop, $P = I^2R$ (Equation 25-14) is the most convenient equation to use. Alternatively, we could find the potential drop from $V = IR$, then use $P = IV$.

SOLVE

1. Compute I^2R: $P = I^2R = (3.00\text{ A})^2(12.0\ \Omega) = \boxed{108\text{ W}}$

CHECK The potential drop across the resistor is $V = IR = (3.00\text{ A})(12.0\ \Omega) = 36.0\text{ V}$. We can use this value to find the power from $P = IV = (3.00\text{ A})(36.0\text{ V}) = 108\text{ W}$.

PRACTICE PROBLEM 25-6 A wire has a resistance equal to 5.0 Ω and a current equal to 3.0 A for 6.0 s. (*a*) What is the power being delivered to the wire during the 6.0 s? (*b*) How much thermal energy is produced during the 6.0 s?

EMF AND BATTERIES

To maintain a steady current in a conductor, we need a constant supply of electrical energy. A device that supplies electrical energy to a circuit is called a **source of emf.** (The letters *emf* stand for *electromotive force* a term that is now rarely used. The term is something of a misnomer because it is definitely not a force. In addition, a source of emf is sometimes called a seat of emf.) Examples of emf sources are a battery, which converts chemical energy into electrical energy, and a generator, which converts mechanical energy into electrical energy. A source of emf does nonconservative work on the charge passing through it, increasing or decreasing the potential energy of the charge (much the same as your lifting a weight increases the gravitational potential energy of a weight). The work per unit charge is called the **emf** $\mathcal{E}$ of the source. The unit of emf is the volt, the same unit as potential difference. An **ideal battery** is a source of emf that maintains a constant potential difference between its two terminals, independent of the current through the battery. The potential difference between the terminals of an ideal battery is equal in magnitude to the emf of the battery.

Figure 25-11 shows a simple circuit consisting of a resistance R connected to an ideal battery. The resistance is indicated by the symbol -\/\/\/-. The straight lines indicate connecting wires of negligible resistance. The source of emf ideally maintains a constant potential difference equal to emf $\mathcal{E}$ between points a and b, with point a being at the higher potential. There is negligible potential difference between points a and c and between points d and b, because the connecting wire is assumed to have negligible resistance. The potential drop from point c to d is therefore equal in magnitude to the emf $\mathcal{E}$, and the current I through the resistor is given by $I = \mathcal{E}/R$. The direction of the current in this circuit is clockwise, as shown in the figure.

Note that *inside* the source of emf, the charge flows from a region where its potential energy is low to a region where its potential is high, so the charge gains electric potential energy.* When charge ΔQ flows through the ideal source of emf $\mathcal{E}$, its potential energy is increased by the amount $\Delta Q\mathcal{E}$. The charge then flows through the resistor, where this potential energy is dissipated as thermal energy. The rate at which energy is supplied by the source of emf is the power output of the source:

$$P = \frac{(\Delta Q)\mathcal{E}}{\Delta t} = I\mathcal{E} \qquad 25\text{-}15$$

POWER SUPPLIED BY AN IDEAL EMF SOURCE

In the simple circuit of Figure 25-11, the power output by the ideal source of emf equals the power delivered to the resistor.

The battery in Figure 25-11 can be thought of as a charge pump that pumps the charge from a region where its potential energy is low to a region where its potential energy high. Figure 25-12 shows a mechanical analog of the simple electric circuit just discussed.

The electric ray has two large electric organs on each side of its head, where current passes from the lower to the upper surface of the body. These organs are composed of columns, with each column consisting of one hundred forty to half a million gelatinous plates. In saltwater fish, these batteries are connected in parallel, whereas in freshwater fish the batteries are connected in series, transmitting discharges of higher voltage. Fresh water has a higher resistivity than salt water, so to be effective a higher voltage is required. It is with such a battery that an average electric ray can electrocute a fish, delivering 50 A at 50 V. *(Stephen Frink/CORBIS.)*

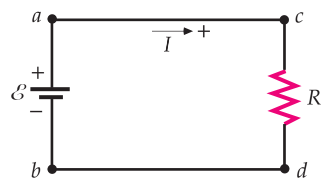

FIGURE 25-11 A simple circuit consisting of an ideal battery of emf $\mathcal{E}$, a resistance R, and connecting wires that are assumed to be of negligible resistance.

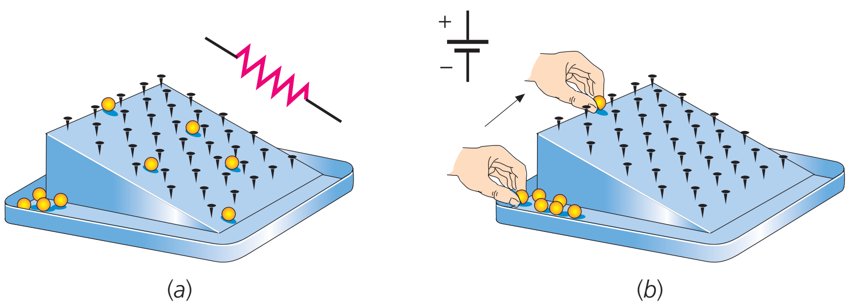

FIGURE 25-12 A mechanical analog of a simple circuit consisting of a resistance and source of emf. (a) The marbles start at some height h above the bottom and are accelerated between collisions with the nails by the gravitational field. The nails are analogous to the lattice ions in the resistor. During the collisions, the marbles transfer the kinetic energy they obtained between collisions to the nails. Because of the many collisions, the marbles have only a small, approximately constant, drift velocity toward the bottom. (b) When the marbles reach the bottom, a child picks them up, lifts them to their original height h, and starts them again. The child, who does work mgh on each marble of mass m, is analogous to the source of emf. The energy source in this case is the internal chemical energy of the child.

* When a battery is being charged (by a generator or by another battery), within the battery the charge flows from a region where its potential energy is high to a region where its potential energy is low, thus losing electric potential energy. The energy lost is converted to chemical energy and stored in the battery being charged.

In a **real battery,** the potential difference across the battery terminals, called the **terminal voltage,** is not simply equal to the emf of the battery. Consider a circuit consisting of a real battery and a variable resistor. If the current is varied by varying the resistance R and the terminal voltage V of the battery is measured, the terminal voltage is found to decrease as the current increases (Figure 25-13), as if there were a resistor internal to the battery.

Thus, we can consider a real battery to consist of an ideal source of emf $\mathcal{E}$ and a resistor with resistance r, called the **internal resistance** of the battery.

The circuit diagram for a nonideal battery and resistor is shown in Figure 25-14. If the current in the circuit is I, the potential at point a is related to the potential at point b by

$$V_a = V_b + \mathcal{E} - Ir$$

The terminal voltage is thus

$$V_a - V_b = \mathcal{E} - Ir \qquad \text{25-16}$$

The terminal voltage of the battery decreases linearly with current, as we saw in Figure 25-13. The potential drop across the resistor R is IR and is equal to the terminal voltage:

$$IR = V_a - V_b = \mathcal{E} - Ir$$

Solving for the current I, we obtain

$$I = \frac{\mathcal{E}}{R + r} \qquad \text{25-17}$$

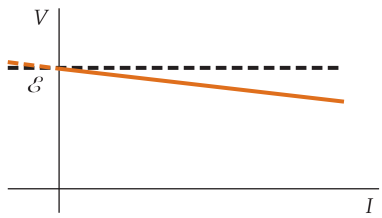

FIGURE 25-13 Terminal voltage V versus I for a real battery. The dashed line shows the terminal voltage of an ideal battery, which has the same magnitude as $\mathcal{E}$.

If a battery is connected as shown in Figure 25-14, the terminal voltage given by Equation 25-16 is less than the emf of the battery because of the decrease in potential due to the internal resistance of the battery. Real batteries, such as a good car battery, usually have an internal resistance of the order of a few hundredths of an ohm, so the terminal voltage is nearly equal to the emf unless the current is very large. One sign of a bad battery is an unusually high internal resistance. If you suspect that your car battery is bad, checking the terminal voltage with a voltmeter, which draws very little current, is not always sufficient. You need to check the terminal voltage while current is being drawn from the battery, such as while you are trying to start your car. Then the terminal voltage may drop considerably, indicating a high internal resistance and a bad battery.

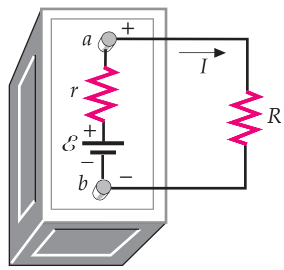

FIGURE 25-14 A real battery can be represented by an ideal battery of emf $\mathcal{E}$ and a small resistance r.

Batteries are often rated in ampere-hours (A·h), which is the maximum charge that batteries can deliver:

$$1\ \text{A}\cdot\text{h} = (1\ \text{C/s})(3600\ \text{s}) = 3600\ \text{C}$$

The energy stored in the battery is the product of the emf and the total charge it can deliver.

$$E_{\text{stored}} = Q\mathcal{E} \qquad \text{25-18}$$

The stored energy is the amount of work that the battery can do.

Example 25-6 Terminal Voltage, Power, and Stored Energy

An 11.0-Ω resistor is connected across a battery of emf 6.00 V and internal resistance 1.00 Ω. Find (*a*) the current, (*b*) the terminal voltage of the battery, (*c*) the power supplied by the chemical reactions within the battery, (*d*) the power delivered to the external resistor, and (*e*) the power delivered to the battery's internal resistance. (*f*) If the battery is rated at 150 A·h, how much energy does the battery store?

PICTURE The circuit diagram is the same as the circuit diagram shown in Figure 25-14. We find the current from $I = \mathcal{E}/(R + r)$ (Equation 25-17) and then use it to find the terminal voltage and power delivered to the resistors.

SOLVE

(*a*) Equation 25-17 gives the current: $I = \dfrac{\mathcal{E}}{R + r} = \dfrac{6.00\text{ V}}{11.0\ \Omega + 1.00\ \Omega} = \boxed{0.500\text{ A}}$

(*b*) Use the current to calculate the terminal voltage of the battery: $V_a - V_b = \mathcal{E} - Ir = 6.00\text{ V} - (0.500\text{ A})(1.00\ \Omega) = \boxed{5.50\text{ V}}$

(*c*) The power supplied by the chemical reactions within the battery equals $\mathcal{E}I$: $P = \mathcal{E}I = (6.00\text{ V})(0.500\text{ A}) = \boxed{3.00\text{ W}}$

(*d*) The power delivered to the external resistance equals I^2R (Equation 25-14): $I^2R = (0.500\text{ A})^2(11.0\ \Omega) = \boxed{2.75\text{ W}}$

(*e*) The power delivered to the internal resistance is I^2r: $I^2r = (0.500\text{ A})^2(1.00\ \Omega) = \boxed{0.250\text{ W}}$

(*f*) The energy stored is the emf of the battery multiplied by the total charge the battery can deliver: $W = Q\mathcal{E} = \left(150\text{ A}\cdot\text{h} \times \dfrac{3600\text{ C}}{\text{A}\cdot\text{h}}\right)(6.00\text{ V}) = \boxed{3.24\text{ MJ}}$

CHECK Of the 3.00 W of power supplied by the chemical reactions of the battery, 2.75 W is delivered to the external resistor and 0.250 W is dissipated in the battery due the internal resistance of the battery.

TAKING IT FURTHER The value of the internal resistance of the battery in this example is larger than that of most batteries. This value was chosen to simplify the calculations. In other examples, we may simply assume that the internal resistance of the battery is negligible.

Example 25-7 Maximum Power Delivered

For a battery that has an emf equal to $\mathcal{E}$ and internal resistance equal to r, what value of external resistance R should be placed across the terminals to obtain the maximum power delivered to the resistor?

PICTURE The circuit diagram is shown in Figure 25-14. The power delivered to the resistor is I^2R (Equation 25-14), where $I = \mathcal{E}/(R + r)$ (Equation 25-17). To find the value of R that results in the maximum power being delivered to the resistor, we set dP/dR equal to zero and solve for R.

SOLVE

1. Use $I = \mathcal{E}/(R + r)$ (Equation 25-17) to eliminate I from $P = I^2R$ so that P is written as a function of R and the constants $\mathcal{E}$ and r: $P = \dfrac{\mathcal{E}^2R}{(R + r)^2}$
2. Calculate the derivative dP/dR (We use the quotient rule.): $\dfrac{dP}{dR} = \dfrac{(R + r)^2\mathcal{E}^2 - 2\mathcal{E}^2R(R + r)}{(R + r)^4} = \dfrac{\mathcal{E}^2(r - R)}{(R + r)^3}$
3. Solve for the value of R for which dP/dR equals zero: $\boxed{R = r}$

CHECK For $R = 0$, the current is maximum but $P = 0$, so no power is delivered to the external resistor when $R = 0$. To take the limit of P as $R \to \infty$ we factor R from the denominator to obtain

$$P = \frac{\mathcal{E}^2R}{(R + r)^2} = \frac{\mathcal{E}^2}{R(1 + r/R)^2}$$

From this result we can see that as $R \to \infty$, $P \to 0$. This means that P must be maximum for R in the range $0 < R < \infty$, so $R = r$ is a plausible result.

TAKING IT FURTHER The maximum value of P occurs when $R = r$, that is, when the load resistance equals the internal resistance. A similar result holds for alternating-current circuits. Choosing $R = r$ to maximize the power delivered to the load is known as *impedance matching*. A graph of P versus R is shown in Figure 25-15.

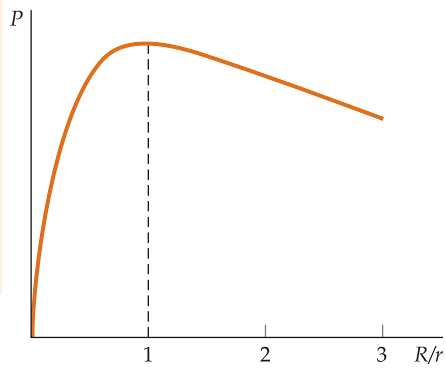

FIGURE 25-15 The power delivered to the external resistor is maximum if $R = r$.

25-4 COMBINATIONS OF RESISTORS

The analysis of a circuit can often be simplified by replacing a combination of two or more resistors with a single equivalent resistor that has the same current and potential drop as the combination of resistors. The replacement of a combination of resistors by an equivalent resistor is similar to the replacement of a combination of capacitors by an equivalent capacitor, discussed in Chapter 24.

RESISTORS IN SERIES

When two or more resistors are connected like R_1 and R_2 in Figure 25-16 so that due to the way they are connected the current in each resistor is the same, the resistors are said to be connected in series. The potential drop across R_1 is IR_1 and the potential drop across R_2 is IR_2, where I is the current in each resistor. The potential drop across the two resistors is the sum of the potential drops across the individual resistors:

$$V = IR_1 + IR_2 = I(R_1 + R_2) \qquad 25\text{-}19$$

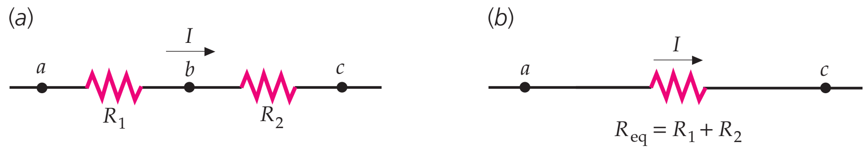

FIGURE 25-16 (*a*) Two resistors connected in series that carry the same current. (*b*) The resistors in Figure 25-16*a* can be replaced by a single equivalent resistance $R_{eq} = R_1 + R_2$ that gives the same total potential drop when carryng the same current as in Figure 25-16*a*.

The single equivalent resistance R_{eq} that yields the same total potential drop V when carrying the same current I is found by setting V equal to IR_{eq} (Figure 25-16*b*). Then R_{eq} is given by

$$R_{eq} = R_1 + R_2$$

When there are more than two resistors connected in series, the equivalent resistance is

$$R_{eq} + R_1 + R_2 + R_3 + \ldots \qquad 25\text{-}20$$

EQUIVALENT RESISTANCE FOR RESISTORS IN SERIES

RESISTORS IN PARALLEL

Two resistors that are connected, as in Figure 25-17*a*, so that due to the way they are wired they have the same potential difference across them, are connected in parallel. Note that due to the way the circuit is wired, one terminal of each resistor is at the potential of point a, and the other terminal of each resistor is at the potential of point b. Let I be the current in the wire leading to point a. At point a, the circuit splits into two branches and the current I divides into two parts—current I_1 in the upper branch containing resistor R_1 and current I_2 in the lower branch containing R_2. The *branch currents* I_1 and I_2 sum to the current I in the wire leading into point a:

$$I = I_1 + I_2 \qquad 25\text{-}21$$

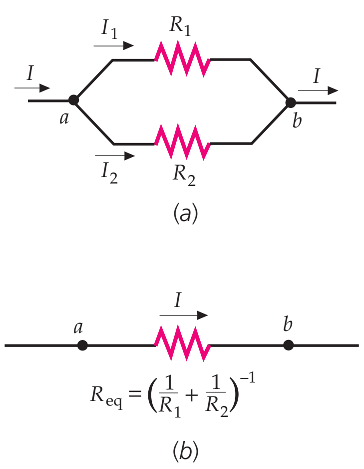

FIGURE 25-17 (*a*) Two resistors are in parallel when they are connected together at both ends so that the potential drop is the same across each. (*b*) The two resistors in Figure 25-17*a* can be replaced by an equivalent resistance R_{eq} that is related to R_1 and R_2 by $1/R_{eq} = 1/R_1 + 1/R_2$.

At point b the branch currents recombine so the current in the wire following point b is also equal to $I = I_1 + I_2$. The potential drop V across either resistor, $V = V_a - V_b$, is related to the branch currents by

$$V = I_1R_1 \text{ and } V = I_2R_2 \qquad \text{25-22}$$

The equivalent resistance for parallel resistors is the resistance R_{eq} for which the same total current I requires the same potential drop V (Figure 25-17*b*):

$$V = IR_{eq} \qquad \text{25-23}$$

Solving Equations 25-22 and 25-23 for I, I_1 and I_2 and substituting into $I = I_1 + I_2$ (Equation 25-21), we have

$$\frac{V}{R_{eq}} = \frac{V}{R_1} + \frac{V}{R_2} = V\left(\frac{1}{R_1} + \frac{1}{R_2}\right) \qquad \text{25-24}$$

Dividing both sides by V gives

$$\frac{1}{R_{eq}} = \frac{1}{R_1} + \frac{1}{R_2}$$

which can be solved for the equivalent resistance, R_{eq}, for two resistors in parallel. This result can be generalized for parallel combinations such as that shown in Figure 25-18, in which three or more resistors are connected in parallel:

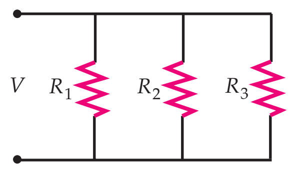

FIGURE 25-18 Three resistors in parallel.

$$\frac{1}{R_{eq}} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} + \ldots \qquad \text{25-25}$$

EQUIVALENT RESISTANCE FOR RESISTORS IN PARALLEL

! The equivalent resistance of a parallel combination of resistors is less than the resistance of any single resistor in the combination.

PRACTICE PROBLEM 25-7

A 2.0-Ω resistor and a 4.0-Ω resistor are connected (*a*) in series and (*b*) in parallel. Find the equivalent resistances for both combinations.

The equivalent resistance of a parallel combination of resistors is less than the resistance of any single resistor in the combination. From Equation 25-25, we see that

$$\frac{1}{R_{eq}} > \frac{1}{R_i}$$

where R_i is the resistance of any single resistor in the combination. Multiplying both sides of this inequality by the product $R_{eq}R_i$, we obtain

$$R_i > R_{eq}$$

Resistors are, in reality, conductors. (They do not conduct as well as the wires connecting them in a circuit, but they are conductors nevertheless.) Adding more resistors in parallel means adding more conducting paths for charges to flow along. The creation of additional parallel paths lowers the equivalent resistance of the combination.

Example 25-8 Identifying Series and Parallel Combinations *Conceptual*

The circuit shown in Figure 25-19 has a battery and six resistors. (*a*) Which resistors, if any, are connected in series? (*b*) Which resistors, if any, are connected in parallel?

PICTURE Resistors are connected in series if the current through each of them is the same due to the way they are connected. Resistors are connected in parallel if the potential difference (voltage) across each of them is the same due to the way they are connected.

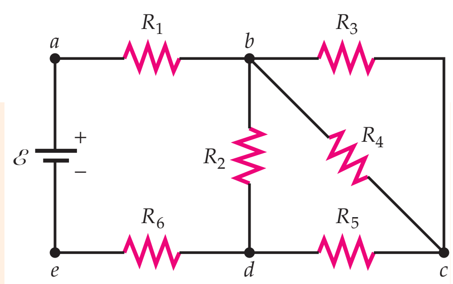

FIGURE 25-19

SOLVE

(a) In a circuit, the current only changes at junctions (points b, c, and d):

Resistors 1 and 6 are connected in series.

(b) 1. The potential along any path does not change except in batteries, resistors, or capacitors. Let V_a, V_b, V_c, V_d, and V_e be the potentials at points a, b, c, d, and e, respectively. Construct a table that lists the potential of both terminals of each resistor:

Resistor	V_a	V_b	V_c	V_d	V_e
1	X	X			
2		X		X	
3		X	X		
4		X	X		
5			X	X	
6				X	X

2. The table reveals that a terminal of resistor 3 and a terminal of resistor 4 are both at potential V_b, and the other terminals of the same resistors are both at potential V_c:

Resistors 3 and 4 are connected in parallel.

TAKING IT FURTHER Resistor 5 is in series with the parallel combination consisting of resistors 3 and 4. Resistor 2 is in parallel with the combination consisting of resistors 3, 4, and 5. In addition, resistor 6, the battery, resistor 1, and the combination of resistors 2, 3, 4, and 5 are in series.

PROBLEM-SOLVING STRATEGY

Problems Involving Series and/or Parallel Combinations of Resistors

PICTURE If no circuit diagram is provided, draw one.

SOLVE

1. Identify each series and/or parallel combination of resistors and calculate its equivalent resistance.
2. Redraw the circuit so that each series or parallel combination of resistors is replaced by a single resistor of equivalent resistance.
3. Repeat steps 2 and 3 until there are no more series or parallel combinations. (At this point the circuit should contain only a single resistor.) Apply $V = IR$ and calculate the current.
4. Return to the previous drawing and calculate the voltage across and/or the current in each resistor in that drawing.
5. Repeat step 4 until you calculate all currents and/or voltages of interest.

CHECK Calculate the power delivered to each resistor (using $P = IV$ or its equivalent) and calculate the power supplied by the chemical reactions in each battery using $P = I\mathcal{E}$. Then check to see that the total power being delivered equals the total power being supplied.

Example 25-9 Resistors in Parallel

An ideal battery applies a potential difference of 12 V across the parallel combination of 4.0-Ω and 6.0-Ω resistors shown in Figure 25-20. Find (a) the equivalent resistance, (b) the total current, (c) the current through each resistor, (d) the power delivered to each resistor, and (e) the power supplied by the battery.

PICTURE Choose symbols and directions for the currents in Figure 25-21.

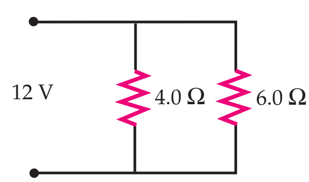

FIGURE 25-20

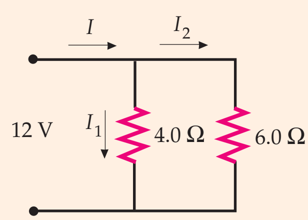

FIGURE 25-21

SOLVE

(*a*) Calculate the equivalent resistance:

$$\frac{1}{R_{eq}} = \frac{1}{4.0\ \Omega} + \frac{1}{6.0\ \Omega} = \frac{3.0}{12.0\ \Omega} + \frac{2.0}{12.0\ \Omega} = \frac{5.0}{12.0\ \Omega}$$

$$R_{eq} = \frac{12.0\ \Omega}{5.0} = \boxed{2.4\ \Omega}$$

(*b*) The total current is the potential drop divided by the equivalent resistance:

$$I = \frac{V}{R_{eq}} = \frac{12\ V}{2.4\ \Omega} = \boxed{5.0\ \text{A}}$$

(*c*) We obtain the current through each resistor using Equation 25-22 and using the potential drop across the parallel combination, 12 V:

$$V = IR$$

$$I_1 = \frac{12\ V}{4.0\ \Omega} = \boxed{3.0\ \text{A}}$$

$$I_2 = \frac{12\ V}{6.0\ \Omega} = \boxed{2.0\ \text{A}}$$

(*d*) Use $P = VI$ together with $V = IR$ to find the power delivered to each resistor:

$$P = VI = (IR)R = I^2R$$

$$P_1 = I_1^2R = (3.0\ \text{A})^2(4.0\ \Omega) = \boxed{36\ \text{W}}$$

$$P_2 = I_2^2R = (2.0\ \text{A})^2(6.0\ \Omega) = \boxed{24\ \text{W}}$$

(*e*) Use $P = \mathcal{E}I$ to find the power supplied by the battery:

$$P = \mathcal{E}I = (12\ \text{V})(5.0\ \text{A}) = \boxed{60\ \text{W}}$$

CHECK The power supplied by the battery equals the total power delivered to the two resistors $P = 60\ \text{W} = 36\ \text{W} + 24\ \text{W}$. In Part (*d*), we could just as well have calculated the power delivered to each resistor from $P_1 = VI_1 = (12\ \text{V})(3.0\ \text{A}) = 36\ \text{W}$ and $P_2 = VI_2 = (12\ \text{V})(2.0\ \text{A}) = 24\ \text{W}$.

TAKING IT FURTHER The ratio of the currents in the two parallel resistors equals the inverse ratio of the resistances. This result follows from $I_1R_1 = I_2R_2$ (Equation 25-22). Rearranging gives

$$\frac{I_1}{I_2} = \frac{R_2}{R_1} \text{ (two parallel resistors)} \qquad 25\text{-}26$$

Example 25-10 Resistors in Series — *Try It Yourself*

A 4.0-Ω resistor and a 6.0-Ω resistor are connected in series to a battery that has an emf equal to 12.0 V and has a negligible internal resistance. Find (*a*) the equivalent resistance of the two resistors, (*b*) the current in the circuit, (*c*) the potential drop across each resistor, (*d*) the power delivered to each resistor, and (*e*) the total power delivered to the resistors.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

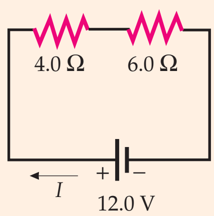

FIGURE 25-22

Steps	Answers
(*a*) 1. Draw a circuit diagram (Figure 25-22):	
2. Calculate R_{eq} for the two series resistors:	$R_{eq} = \boxed{10.0\ \Omega}$
(*b*) Use $V = IR_{eq}$ to find the current through the battery:	$I = \boxed{1.2\ \text{A}}$
(*c*) Use Ohm's law to find the potential drop across each resistor:	$V_4 = \boxed{4.8\ \text{V}}$ $V_6 = \boxed{7.2\ \text{V}}$
(*d*) Find the power delivered to each resistor using $P = I^2R$:	$P_4 = \boxed{5.8\ \text{W}}$ $P_6 = \boxed{8.6\ \text{W}}$
(*e*) Add your results from Part (*d*) to find the total power:	$P = \boxed{14.4\ \text{W}}$

CHECK The current through the battery in this example is 1.2 A, but in the corresponding parallel circuit with the same resistors (Example 25-9) the current in the battery is 5.0 A. The current in a circuit is expected to be less when the resistors are connected in series.

Example 25-11 Series and Parallel Combinations *Try It Yourself*

Consider the circuit in Figure 25-23. When switch S_1 is open and switch S_2 is closed, find (*a*) the equivalent resistance of the circuit, (*b*) the current in the source of emf, (*c*) the potential drop across each resistor, and (*d*) the current in each resistor. (*e*) If switch S_1 is now closed, find the current in the 2.0-Ω resistor. (*f*) If switch S_2 is now opened (while switch S_1 remains closed), find the potential drops across the 6.0-Ω resistor and across switch S_2.

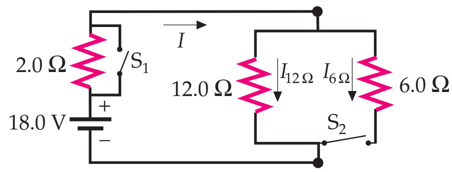

FIGURE 25-23

PICTURE (*a*) To find the equivalent resistance of the circuit, first replace the two parallel resistors by their equivalent resistance. Ohm's law can then be used to find the current and potential drops. For Part (*b*) and Part (*c*), use Ohm's law.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
(*a*) 1. Find the equivalent resistance of the 6.0- and 12.0-Ω parallel combination.	$R_{eq} = 4.0\ \Omega$
2. Combine your result in step 1 with the 2.0-Ω resistor in series to find the total equivalent resistance of the circuit.	$R'_{eq} = \boxed{6.0\ \Omega}$
(*b*) Find the current using Ohm's law. This is the current both in the battery and in the 2-Ω resistor.	$I_{2\Omega} = \boxed{3.0\text{ A}}$
(*c*) 1. Find the potential drop across the 2.0-Ω resistor from $V_{2\Omega} = IR$.	$V_{2\Omega} = \boxed{6.0\text{ V}}$
2. Find the potential drop across each resistor in the parallel combination using $V_p = IR_{eq}$, where V_p is the potential drop across the parallel combination.	$V_{6\Omega} = V_{12\Omega} = \boxed{12.0\text{ V}}$
(*d*) Find the current in the 6.0-Ω and 12.0-Ω resistors from $I = V_p/R$.	$I_{6\Omega} = \boxed{2.0\text{ A}}$ $I_{12\Omega} = \boxed{1.0\text{ A}}$
(*e*) When S_1 is closed, the potential drop across the 2.0-Ω resistor is zero. Using $V_{2\Omega} = IR$, calculate the current through the 2.0-Ω resistor.	$I_{2\Omega} = \boxed{0}$
(*f*) When S_2 is open, the current through the 6.0-Ω resistor is zero. Using $V_{6\Omega} = IR$, calculate the potential drop across the 6.0-Ω resistor. The potential drop across the 6.0-Ω resistor plus the potential drop across switch S_2 equals the potential drop across the 12.0-Ω resistor.	$V_{6\Omega} = \boxed{0}$ $V_{S_2} = V_{12\Omega} = \boxed{18\text{ V}}$

CHECK When S_1 is open and S_2 is closed, the current in the 6.0-Ω resistor is twice that in the 12.0-Ω resistor, as we should expect. In addition, these two currents sum to give the current in the 2.0-Ω resistor, as they must. Finally, note that the potential drops across the 2.0-Ω resistor and the parallel combination sum to the emf of the battery; $V_{2\Omega} + V_p = 6.0\text{ V} + 12.0\text{ V} = 18.0\text{ V}$.

PRACTICE PROBLEM 25-8 Repeat Part (*a*) through Part (*d*) of this example, but with the 6.0-Ω resistor having been replaced by a wire of negligible resistance.

Example 25-12 Combinations of Combinations *Try It Yourself*

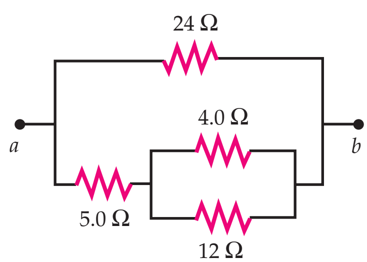

FIGURE 25-24

Find the equivalent resistance of the combination of resistors shown in Figure 25-24.

PICTURE You can analyze this complicated combination step by step. First, find the equivalent resistance R_{eq} of the 4.0-Ω and 12-Ω parallel combination. Next, find the equivalent resistance R'_{eq} of the series combination of the 5.0-Ω resistor and R_{eq}. Finally, find the equivalent resistance R''_{eq} of the parallel combination of the 24-Ω resistor and R'_{eq}.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. Find the equivalent resistance R_{eq} of the 4.0-Ω and 12-Ω resistors in parallel.	$R_{eq} = 3.0\ \Omega$
2. Find the equivalent resistance R'_{eq} of R_{eq} in series with the 5.0-Ω resistor.	$R'_{eq} = 8.0\ \Omega$
3. Find the equivalent resistance of R'_{eq} in parallel with the 24-Ω resistor.	$R''_{eq} = \boxed{6.0\ \Omega}$

CHECK As expected for parallel combinations, the step-1 and step-3 results are less than the resistance of either of the two resistors in parallel. In addition, the step-2 result is greater than either of the two resistors in series, as expected for series combinations.

Example 25-13 Blowing the Fuse *Context-Rich*

You are making a snack for you and some friends to help you get ready for a full night of studying. You decide that coffee, toast, and popcorn would be a good start. You turn on the toaster, place some popcorn in the microwave, and turn on the microwave. Because your apartment is in an older building, you know that the fuse may blow when you turn on too many appliances. Should you start the coffeemaker? You look on the appliances and find that the toaster has a rating of 900 W, the microwave has a rating of 1200 W, and the coffeemaker has a rating of 600 W. You know that your apartment uses 20-A fuses.

PICTURE We can assume that household circuits are wired in parallel, because plugging in one device does not affect others that are in the circuit. Household voltage in the United States is 120 V. (We can neglect the fact that it is not dc.) If we can determine the current through each device, we can add up the total current in the circuit and see how it compares to the fuse current.

SOLVE

1. The power delivered to a device is the current multiplied by the voltage. That is, $P = IV$. Solve for the current for each device:

$$I_{toaster} = \frac{P_{toaster}}{V} = \frac{900\ \text{W}}{120\ \text{V}} = 7.5\ \text{A}$$

$$I_{m\text{-}wave} = \frac{P_{m\text{-}wave}}{V} = \frac{1200\ \text{W}}{120\ \text{V}} = 10.0\ \text{A}$$

$$I_{c\text{-}maker} = \frac{P_{c\text{-}maker}}{V} = \frac{600\ \text{W}}{120\ \text{V}} = 5.0\ \text{A}$$

2. The current through the fuse is the sum of these currents: $I_{fuse} = 22.5\ \text{A}$

3. A current this large is above the 20-A rating of the fuse: $\boxed{\text{Your guests will have to wait on the coffee.}}$

CHECK The maximum possible power that can be delivered by a 120-V circuit that has a 20-A fuse is $P_{max} = I_{max}V = (20\ \text{A})(120\ \text{V}) = 2400\ \text{W}$. The total power needed to run the three appliances simultaneously is $900\ \text{W} + 1200\ \text{W} + 600\ \text{W} = 2700\ \text{W}$, which is 300 W more than the maximum that the circuit can deliver.

TAKING IT FURTHER We have assumed that the apartment has only one circuit, and thus only one fuse. Typically, there are several circuits, each fused separately. The coffeemaker can be plugged into an outlet that is on a different circuit than the outlet for the toaster and microwave without a fuse blowing.

25-5 KIRCHHOFF'S RULES

There are many circuits, such as the circuit shown in Figure 25-25, that cannot be analyzed by merely replacing combinations of resistors by an equivalent resistance. The two resistors R_1 and R_2 in this circuit appear as though they might be in parallel, but they are not. The potential drop is not the same across both resistors because of the presence of the emf source $\mathcal{E}_2$ in series with R_2. Nor are R_1 and R_2 in series, because the wire connecting them has a branch point—they do not have the same current due to the way they are connected.

Two rules, called **Kirchhoff's rules,** apply to this circuit and to any other circuit:

1. When any closed loop is traversed, the algebraic sum of the changes in potential around the loop must equal zero.
2. At any junction (branch point) in a circuit where the current can divide, the sum of the currents into the junction must equal the sum of the currents out of the junction.

KIRCHHOFF'S RULES

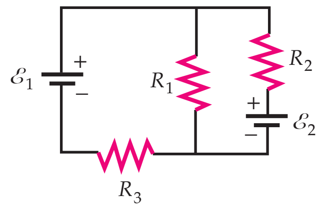

FIGURE 25-25 An example of a circuit that cannot be analyzed by replacing combinations of resistors in series or parallel with their equivalent resistances. The potential drops across R_1 and R_2 are not equal because of the emf source $\mathcal{E}_2$, so these resistors are not in parallel. (Parallel resistors would be connected together at both ends.) The resistors do not have the same current, so they are not in series.

Kirchhoff's first rule, called the **loop rule,** was introduced in Chapter 24. This rule follows directly from the presence of a conservative field $\vec{E}$.* To say $\vec{E}$ is conservative means that

$$\oint_C \vec{E} \cdot d\vec{r} = 0 \qquad 25\text{-}27$$

where the integral is taken around any closed curve C. Changes in potential ΔV and $\vec{E}$ are related by $\Delta V = V_b - V_a = -\int_a^b \vec{E} \cdot d\vec{r}$. Thus, Equation 25-27 implies that the sum of the changes in potential (the sum of the ΔVs) around any closed path equals zero.

Kirchhoff's second rule, called the **junction rule,** follows from the conservation of charge. Figure 25-26 shows the junction of three wires carrying currents I_1, I_2, and I_3. Because charge does not originate or accumulate at this point, the conservation of charge implies the junction rule, which for this case gives

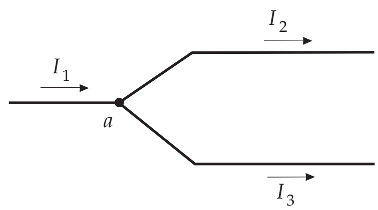

FIGURE 25-26 Illustration of Kirchhoff's junction rule. The current I_1 into point a equals the sum $I_2 + I_3$ of the currents out of point a.

$$I_1 = I_2 + I_3 \qquad 25\text{-}28$$

Charges do accumulate on the surfaces of conductors. However, it would require a very large surface area, such as the surface area of some capacitor plates, to accumulate a significant amount of charge. The surface areas of the conductors that are used in common circuits are much too small to accumulate a significant amount of charge.

SINGLE-LOOP CIRCUITS

As an example of using Kirchhoff's loop rule, consider the circuit shown in Figure 25-27, which contains two batteries that have internal resistances r_1 and r_2 and three external resistors. We wish to find the current in terms of the emfs and resistances.

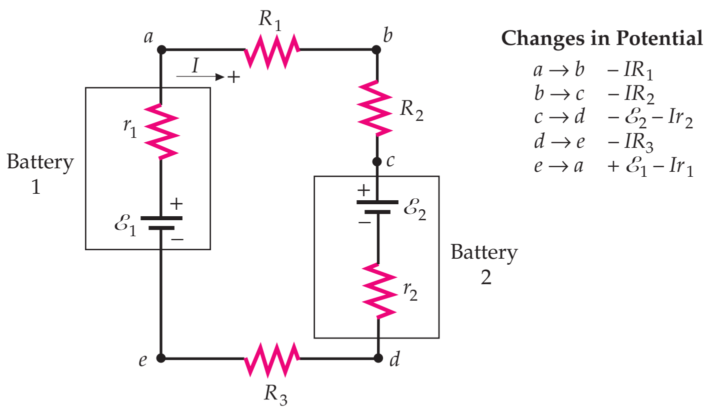

FIGURE 25-27 Circuit containing two batteries and three external resistors.

* There is also such a thing as a nonconservative electric field that is discussed in Chapter 28. The resultant electric field is the superposition of the conservative electric field and the nonconservative electric field. Kirchhoff's loop rule applies only to the conservative part of the electric field.

We choose clockwise as positive, as indicated by the arrow with the plus sign next to it in Figure 25-27. We then apply Kirchhoff's loop rule as we traverse the circuit in the positive direction, beginning at point a. Note that we encounter a potential drop as we traverse the source of emf between points c and d and we encounter a potential rise as we traverse the source of emf between e and a. Assuming that I is positive, we encounter a potential drop as we traverse each resistor. Beginning at point a, we obtain from Kirchhoff's loop rule

$$(V_b - V_a) + (V_c - V_b) + (V_d - V_c) + (V_e - V_d) + (V_a - V_e) = 0$$

Expressing the changes in potential in terms of the current, the emfs, and the resistances gives

$$(-IR_1) + (-IR_2) + (-\mathcal{E}_2 - Ir_2) + (-IR_3) + (\mathcal{E}_1 - Ir_1) = 0$$

Solving for the current I, we obtain

$$I = \frac{\mathcal{E}_1 - \mathcal{E}_2}{R_1 + R_2 + R_3 + r_1 + r_2} \qquad 25\text{-}29$$

If $\mathcal{E}_2$ is greater than $\mathcal{E}_1$, we get a negative value for the current I, indicating that the current is in the negative (counterclockwise) direction.

For this example, we assume that $\mathcal{E}_1$ is greater than $\mathcal{E}_2$, so the current is positive. In addition, we model the current as positive charge carriers that move clockwise around the circuit. (The actual charge carriers are negatively charged electrons traveling counterclockwise.) Then, charge flows through battery 2 from the high-potential end to the low-potential end. Therefore, a positive charge ΔQ moving through battery 2 from point c to point d loses potential energy $\Delta Q\mathcal{E}_2$ (in addition to any energy dissipated within the battery due to the internal resistance r_2). If battery 2 is a rechargeable battery, much of this lost potential energy is stored in the battery as chemical energy, which means that battery 2 is *charging.*

The analysis of a circuit is usually simplified if we define the potential to equal zero at a convenient point in the circuit. Then we calculate the potential at the other points relative to it. Because only potential differences are important, any point in a circuit can be chosen to have zero potential. In many circuits, however, one point is connected to a rod that is driven into the ground. Such a point is said to be grounded or put to earth, and the potential is defined to be zero at that point. However, in an automobile the negative terminal of the battery is connected to the engine block by a heavy cable (called a grounding cable), and the point where the cable is connected to the engine block is referred to as ground. In the following example, we choose point e in the figure to be at zero potential. This is indicated by the ground symbol ⏚ at point e.

Example 25-14 Finding the Potential

Suppose the elements in the circuit in Figure 25-28 have the values $\mathcal{E}_1 = 12.0$ V, $\mathcal{E}_2 = 4.0$ V, $r_1 = r_2 = 1.0\ \Omega$, $R_1 = R_2 = 5.0\ \Omega$, and $R_3 = 4.0\ \Omega$. (*a*) Find the potentials at points a through e in the figure, assuming that the potential at point e is zero. (*b*) Discuss the energy transfers in the circuit.

PICTURE To find the potential differences, we first need to find the current I in the circuit. The potential drop across each resistor is equal to the product IR. To discuss the energy transfers, we calculate the power delivered to or supplied by each element using Equations 25-14 and 25-15.

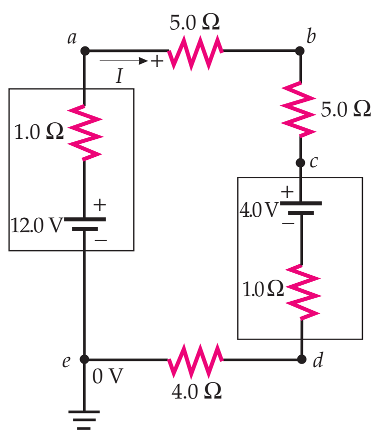

FIGURE 25-28

SOLVE

(*a*) 1. The current I in the circuit is found using Equation 25-29:

$$I = \frac{12.0\text{ V} - 4.0\text{ V}}{5.0\ \Omega + 5.0\ \Omega + 4.0\ \Omega + 1.0\ \Omega + 1.0\ \Omega} = \frac{8.0\text{ V}}{16\ \Omega} = 0.50\text{ A}$$

2. We now find the potential at each labeled point in the circuit:

$$V_a = V_e + \mathcal{E}_1 - Ir_1 = 0 + 12.0\text{ V} - (0.50\text{ A})(1.0\ \Omega) = \boxed{11.5\text{ V}}$$

$$V_b = V_a - IR_1 = 11.5\text{ V} - (0.50\text{ A})(5.0\ \Omega) = \boxed{9.0\text{ V}}$$

$$V_c = V_b - IR_2 = 9.0\text{ V} - (0.50\text{ A})(5.0\ \Omega) = \boxed{6.5\text{ V}}$$

$$V_d = V_c - \mathcal{E}_2 - Ir_2 = 6.5\text{ V} - 4.0\text{ V} - (0.50\text{ A})(1.0\ \Omega) = \boxed{2.0\text{ V}}$$

$$V_e = V_d + IR_3 = 2.0\text{ V} - (0.50\text{ A})(4.0\ \Omega) = \boxed{0.0\text{ V}}$$

(*b*) 1. First, calculate the power supplied by the chemical reactions in the emf source that has emf $\mathcal{E}_1$:

$$P_{\mathcal{E}_1} = \mathcal{E}_1 I = (12.0\text{ V})(0.50\text{ A}) = 6.0\text{ W}$$

2. Part of this power is delivered to the resistors, both inside and outside the batteries:

$$P_R = I^2R_1 + I^2R_2 + I^2R_3 + I^2r_1 + I^2r_2$$
$$= (0.50\text{ A})^2(5.0\ \Omega + 5.0\ \Omega + 4.0\ \Omega + 1.0\ \Omega + 1.0\ \Omega) = 4.0\text{ W}$$

3. The remaining 2.0 W of power goes into charging battery 2:

$$P_{\mathcal{E}_2} = \mathcal{E}_2 I = (4.0\text{ V})(0.50\text{ A}) = 2.0\text{ W}$$

4. The rate at which potential energy is being delivered in the circuit is

$$P = P_R + P_{\mathcal{E}_1} = 6.0\text{ W}$$

CHECK The rate at which the 12-V battery converts chemical energy to electrical potential energy (6.0 W) is equal to the rate at which the 4.0-V battery converts electrical potential energy to chemical energy (2.0 W) plus the rate at which potential energy is dissipated (4.0 W).

Note that the terminal voltage of the battery that is being charged in Example 25-14 is $V_c - V_d = 4.5$ V, which is greater than the emf of the battery. If the same 4.0-V battery were used to deliver 0.50 A to an external circuit, its terminal voltage would be 3.5 V (again assuming that its internal resistance is 1.0 Ω). If the internal resistance is very small, the terminal voltage of a battery is nearly equal to its emf, whether the battery is delivering energy to an external circuit or is being charged. Some real batteries, such as those used in automobiles, are nearly reversible and can easily be recharged. Other types of batteries are not reversible. If you attempt to recharge one of those batteries by driving current through it from its positive to its negative terminal, virtually all of the energy will be dissipated into thermal energy rather than being transformed into the chemical energy of the battery.

Example 25-15 Jump-Starting a Car

A fully charged* car battery is to be connected by jumper cables to a discharged car battery in order to charge it. (*a*) To which terminal of the discharged battery should the positive terminal of the charged battery be connected? (*b*) Assume that the charged battery has an emf of $\mathcal{E}_1 = 12.0$ V, the discharged battery has an emf of $\mathcal{E}_2 = 11.0$ V, the internal resistances of the batteries are $r_1 = r_2 = 0.020\ \Omega$, and the resistance of the jumper cables is $R = 0.010\ \Omega$. What will be the charging current? (*c*) What will be the current if the batteries are connected incorrectly?

PICTURE For Part (*a*) the batteries should be connected so the initially discharged battery is charged. To calculate the current apply Kirchhoff's loop rule.

* Batteries do not store charge. A *fully charged* battery is one with a maximum amount of stored chemical energy.

SOLVE

(*a*) To charge the discharged battery, we connect positive terminal to positive terminal and negative terminal to negative terminal, to drive current through the discharged battery from the positive terminal to the negative terminal (Figure 25-29):

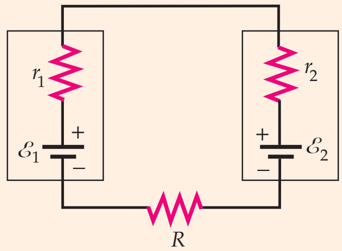

FIGURE 25-29

(*b*) Use Kirchhoff's loop rule to find the charging current:

$$\mathcal{E}_1 - Ir_1 - Ir_2 - \mathcal{E}_2 - IR = 0$$

so

$$I = \frac{\mathcal{E}_1 - \mathcal{E}_2}{R + r_1 + r_2} = \frac{12.0\text{ V} - 11.0\text{ V}}{0.050\ \Omega} = \boxed{20\text{ A}}$$

(*c*) When the batteries are connected incorrectly, positive terminals to negative terminals, the emfs add:

$$\mathcal{E}_1 - Ir_1 + \mathcal{E}_2 - Ir_2 - IR = 0$$

so

$$I = \frac{\mathcal{E}_1 + \mathcal{E}_2}{R + r_1 + r_2} = \frac{12.0\text{ V} + 11.0\text{ V}}{0.050\ \Omega} = \boxed{460\text{ A}}$$

CHECK If the batteries are connected incorrectly, as shown in Figure 25-30, the current is very large and the batteries could explode—producing a shower of boiling battery acid.

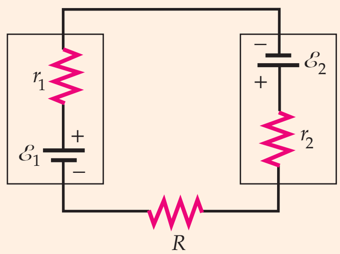

FIGURE 25-30 Two batteries connected incorrectly—dangerous!

MULTILOOP *CIRCUITS*

In multiloop circuits, often the direction of the current in one or more branches of the circuit are not obvious. Fortunately, Kirchhoff's rules do not require that we know these directions initially. In fact, the opposite is true. Kirchhoff's rules enable us to determine the directions of the currents. To accomplish this, for each branch of the circuit we arbitrarily assign a positive direction along the branch, and we indicate this assignment by placing a corresponding arrow on the circuit diagram (Figure 25-31). If the current density in the branch is in this positive direction, then when we solve for this current we will get a positive value. However, if the current density is opposite to the assigned positive direction, when we solve for the current we will get a negative value. In a resistor, an electric field within the resistor causes the current, and the current is in the same direction as the electric field. Because the electric field always points in the direction of decreasing potential, we know that in a resistor the direction of the current is also the direction of decreasing potential. Therefore, any time we traverse a resistor in the direction of the current, the change in potential is negative, and vice versa. Here is the rule:

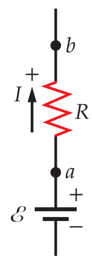

FIGURE 25-31 It is not known whether the current I has a positive or a negative value. Whether it is positive or negative, $V_b - V_a = -IR$. If the current is in the positive direction, then I is positive and $-IR$ is negative. If the current is in the negative direction, however, then I is negative and $-IR$ is positive.

> For each branch of a circuit, we draw an arrow to indicate the positive direction for that branch. Then, if we traverse a resistor in the direction of the arrow, the change in potential ΔV is equal to $-IR$ (and if we traverse a resistor in the direction opposite the direction of the arrow, ΔV is equal to $+IR$).
>
> SIGN RULE FOR THE CHANGE IN POTENTIAL ACROSS A RESISTOR

If we traverse a resistor in the positive direction, and if I is positive, then $-IR$ is negative. This is as expected, because in a resistor, the current is always in the direction of decreasing potential. However, if we traverse a resistor in the positive direction, and if I is negative, then $-IR$ is positive. Similarly, if we traverse a resistor in the negative direction, and if I is positive, then $+IR$ is positive. And if we traverse a resistor in the negative direction and if I is negative, then $+IR$ is negative.

To analyze circuits containing more than one loop, we need to use both of Kirchhoff's rules, with Kirchhoff's junction rule applied to junctions (points where the current splits into two or more parts).

Example 25-16 Applying Kirchhoff's Rules

(*a*) Find the current in each branch of the circuit shown in Figure 25-32. (*b*) Find the energy dissipated in the 4.0-Ω resistor in 3.0 s.

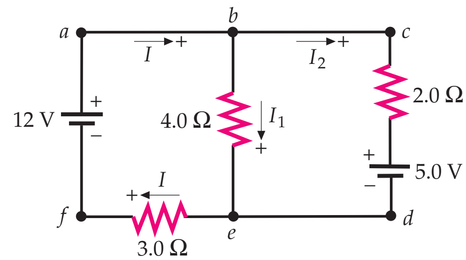

FIGURE 25-32

PICTURE There are three branch currents, I, I_1, and I_2, to be determined, so we need three equations. One equation comes from applying the junction rule to point b. (We can also apply the junction rule to point e, the only other junction in the circuit, but it gives exactly the same information.) The other two relations are obtained by applying the loop rule. There are three loops in the circuit: the two interior loops, *abefa* and *bcdeb*, and the exterior loop, *abcdefa*. We can use any two of these loops—the third will give redundant information. There is at least one direction arrow on each branch in Figure 25-32. Each direction arrow indicates the positive direction for that branch. If our analysis results in a negative value for a branch current, then that current is in the direction opposite to the direction arrow for that branch.

SOLVE

(*a*) 1. Apply the junction rule to point b:

$$I = I_1 + I_2$$

2. Apply the loop rule to the outer loop, *abcdefa*:

$$-(2.0\ \Omega)I_2 - 5.0\ \text{V} - (3.0\ \Omega)(I_1 + I_2) + 12\ \text{V} = 0$$

3. Divide the above equation by 1 Ω, recalling that (1 V)/(1 Ω) = 1 A, then simplify:

$$7.0\ \text{A} - 3.0I_1 - 5.0I_2 = 0$$

4. For the third condition, apply the loop rule to the loop on the right, *bcdeb*:

$$-(2.0\ \Omega)I_2 - 5.0\ \text{V} + (4.0\ \Omega)I_1 \quad \text{so} \quad -5.0\ \text{V} + 4.0I_1 - 2.0I_2 = 0$$

5. The results for steps 3 and 4 can be combined to solve for I_1 and I_2. To do so, first multiply the result for step 3 by 2, and then multiply the result for step 4 by -5:

$$14\ \text{A} - 6.0I_1 - 10I_2 = 0$$
$$25\ \text{A} - 20I_1 + 10I_2 = 0$$

6. Add the equations in step 5 to eliminate I_2, then solve for I_1;

$$39\ \text{A} - 26I_1 = 0$$
$$I_1 = \frac{39\ \text{A}}{26} = \boxed{1.5\ \text{A}}$$

7. Substitute I_1 in the results for step 3 or 4 to solve for I_2:

$$7.0\ \text{A} - 3.0(1.5\ \text{A}) - 5.0I_2 = 0$$
$$I_2 = \frac{2.5\ \text{A}}{5.0} = \boxed{0.50\ \text{A}}$$

8. Finally, I_1 and I_2 determine I using the equation in step 1:

$$I = I_1 + I_2 = 1.5\ \text{A} + 0.50\ \text{A} = \boxed{2.0\ \text{A}}$$

(*b*) 1. The power delivered to the 4.0-Ω resistor is found using $P = I_1^2R$:

$$P = I_1^2R = (1.5\ \text{A})^2(4.0\ \Omega) = 9.0\ \text{W}$$

2. The total energy dissipated in the 4.0-Ω resistor during time Δt is $W = P\,\Delta t$. In this case, $\Delta t = 3.0$ s:

$$W = P\,\Delta t = (9.0\ \text{W})(3.0\ \text{s}) = \boxed{27\ \text{J}}$$

CHECK In Figure 25-33, we have chosen the potential to be zero at point f, and we have labeled the currents and the potentials at the other points. Note that $V_b - V_e = 6.0$ V and $V_e - V_f = 6.0$ V. Applying the loop rule to the loop on the left gives $+12\ \text{V} - 6.0\ \text{V} - 6.0\ \text{V} = 0$.

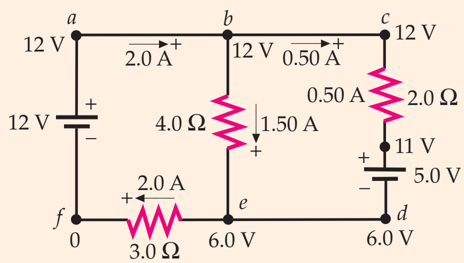

FIGURE 25-33

TAKING IT FURTHER Applying the loop rule to the loop on the left, *abefa,* gives $12\text{ V} - (4.0\ \Omega)I_1 - (3.0\ \Omega)(I_1 + I_2) = 0$, or $12\text{ A} - 7.0I_1 - 3.0I_2 = 0$. Note that this is just the result for step 3 minus the result for step 4 and hence contains no new information, as expected.

PRACTICE PROBLEM 25-9 Find I_1 for the case in which the 3.0-Ω resistor approaches (*a*) zero resistance and (*b*) infinite resistance.

Example 25-16 illustrates the general methods for the analysis of multiloop circuits. These methods are listed in the following problem-solving strategy.

PROBLEM-SOLVING STRATEGY

Method for Analyzing Multiloop Circuits

PICTURE Draw a sketch of the circuit.

SOLVE

1. Replace any series or parallel resistor combinations or capacitor combinations with their equivalent values.
2. Repeat step 1 as many times as possible.
3. Next, assign a positive direction for each branch of the circuit and indicate this direction with an arrow. Label the current in each branch. Add a plus sign and a minus sign to indicate the high-potential terminal and low-potential terminal of each source of emf.
4. Apply the junction rule to all but one of the junctions.
5. Apply the loop rule to the different loops until the total number of independent equations equals the total number of unknowns. When traversing a resistor in the positive direction, the change in potential equals $-IR$. When traversing a battery from the negative terminal to the positive terminal, the change in potential equals $\mathcal{E} \pm Ir$.
6. Solve the equations to obtain the values of the unknowns.

CHECK Check your results by assigning a potential of zero to one point in the circuit and use the values of the currents found to determine the potentials at other points in the circuit.

Example 25-17 A Three-Branch Circuit

(*a*) Find the current in each branch of the circuit shown in Figure 25-34. (*b*) Assign $V = 0$ to point c and then find the potential at each other point a through f.

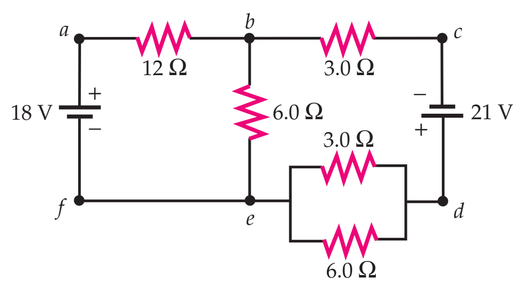

FIGURE 25-34

PICTURE First, replace the two parallel resistors by an equivalent resistance. Second, assign a positive direction to each branch and indicate each choice with an arrow. Third, place a plus sign and a minus sign at the high-potential and low-potential terminals of each battery. Assign a symbol for the current in each branch. These branch currents can then be found by applying the junction rule at either junction b or junction e and by applying the loop rule twice.

SOLVE

(*a*) 1. Find the equivalent resistance of the 3.0-Ω and 6.0-Ω parallel resistors:

$R_{eq} = 2.0\ \Omega$

2. Redraw the circuit (Figure 25-35) with the 2.0-Ω resistor in place of the parallel combination. Place an arrow on each branch indicating your direction-sign assignments. Let I be the current in branch with the 18-V battery, let I_1 be the current in the 6.0-Ω resistor, and let I_2 be the current in branch with the 21-V battery:

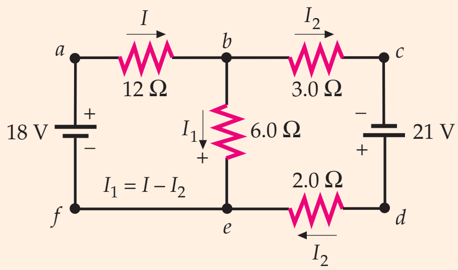

FIGURE 25-35

3. Apply the junction rule at point b:

$I = I_1 + I_2$

4. Apply Kirchhoff's loop rule to loop *abefa* to obtain an equation involving I and I_2:

$18\text{ V} - (12\ \Omega)I - (6.0\ \Omega)I_1 = 0$

5. Simplify the equation from step 4 (dividing both sides by 6.0 Ω):

$3.0\text{ A} - 2.0I - 1.0I_1 = 0$

6. Apply Kirchhoff's loop rule to loop *bcdeb*:

$-(3.0\ \Omega)I_2 + 21\text{ V} - (2.0\ \Omega)I_2 + (6.0\ \Omega)I_1 = 0$

7. Simplify the equation in step 6 (dividing both sides by 1.0 Ω):

$21\text{ A} + 6.0I_1 - 5.0I_2 = 0$

8. Solve the simultaneous equations (from steps 3, 5, and 7) for I, I_1, and I_2. One way to do this calculation is first substitute $I_1 + I_2$ for I in the step 5 equation to obtain $3.0\text{ A} - 3.0I_1 - 2.0I_2 = 0$. This equation and the step 7 equation constitute two equations and two unknowns. Solve for the currents:

$I_1 = \boxed{-1.0\text{ A}}\quad I_2 = \boxed{3.0\text{ A}}\quad I = \boxed{2.0\text{ A}}$

9. Use $V = I_2R_{eq}$ to find the potential drop across the parallel combination consisting of the 3.0-Ω and 6.0-Ω resistors:

$V = 6.0\text{ V}$

10. Use the result of step 9 and Ohm's law to find the current in each of the parallel resistors;

$I_{3\,\Omega} = \boxed{2.0\text{ A}}\quad I_{6\,\Omega} = \boxed{1.0\text{ A}}$

(*b*) Redraw Figure 25-35 showing the direction and value of the current in each branch of the circuit (Figure 25-36). Begin with $V = 0$ at point c and calculate the potential at points d, e, f, a, and b:

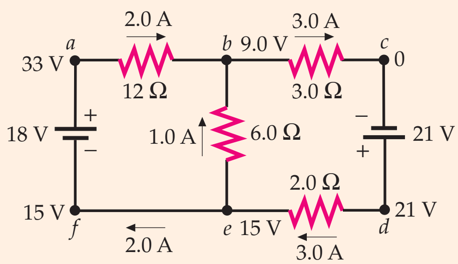

FIGURE 25-36

$V_d = V_c + 21\text{ V} = 0 + 21\text{ V} = \boxed{21\text{ V}}$

$V_e = V_d - (3.0\text{ A})(2.0\ \Omega) = 21\text{ V} - 6.0\text{ V} = \boxed{15\text{ V}}$

$V_f = V_e = \boxed{15\text{ V}}$

$V_a = V_f + 18\text{ V} = 15\text{ V} + 18\text{ V} = \boxed{33\text{ V}}$

$V_b = V_a - (2.0\text{ A})(12.0\ \Omega) = 33\text{ V} - 24\text{ V} = \boxed{9\text{ V}}$

CHECK From point b to point c the potential drops by $(3.0\text{ A})(3.0\ \Omega) = 9.0\text{ V}$, which gives $V_c = 0$, as assumed. From point e to point b the potential drops by $(1.0\text{ A})(6.0\ \Omega) = 6.0\text{ V}$, so $V_b = V_e - 6.0\text{ V} = 15\text{ V} - 6.0\text{ V} = 9\text{ V}$.

AMMETERS, VOLTMETERS, AND OHMMETERS

The devices that measure current, potential difference, and resistance are called **ammeters, voltmeters,** and **ohmmeters,** respectively. Often, all three of these meters are included in a single *multimeter* that can be switched from one use to another. You might use a voltmeter to measure the terminal voltage of your car battery and an ohmmeter to measure the resistance of some electrical device at home (for example, a toaster or lightbulb) when you suspect a short circuit or a broken wire.

To measure the current in a resistor in a simple circuit, we place an ammeter in series with the resistor, as shown in Figure 25-37, so that the current is the same in the ammeter and the resistor. Because the ammeter has a very low (but finite) resistance, the current in the circuit decreases very slightly when the ammeter is inserted. Ideally, the ammeter should have a negligibly small resistance so that the current to be measured is only negligibly affected.

The potential difference across a resistor is measured by placing a voltmeter across the resistor (in parallel with the resistor), as shown in Figure 25-38, so that the potential drop is the same across both the voltmeter and the resistor. The voltmeter reduces the resistance between points a and b, thus increasing the total current in the circuit and changing the potential drop across the resistor. A voltmeter should have an extremely high resistance so that its effect on the current in the circuit is negligible.

The principal component of many commonly used ammeters and voltmeters is a **galvanometer,** a device that detects small currents passing through it. The galvanometer is designed so that the scale reading is proportional to the current passing through. The type of galvanometer used in many student laboratories consists of a coil of wire in the magnetic field of a permanent magnet. When there is current in the coil, the magnetic field exerts a torque on the coil, which causes the coil to rotate. A pointer attached to the coil indicates the reading on a scale. The coil itself contributes some resistance when the galvanometer is placed within a circuit.

To construct an ammeter from a galvanometer, we place a small resistor called a **shunt resistor** in *parallel* with the galvanometer. The resistance of the shunt resistor is usually much smaller than the resistance of the galvanometer so that the majority of the current is carried by the shunt resistor. The equivalent resistance of the ammeter is then approximately equal to the resistance of the shunt resistor, which is much smaller than the internal resistance of the galvanometer alone. To construct a voltmeter, we place a resistor that has a large resistance in *series* with the galvanometer so that the equivalent resistance of the voltmeter is much larger than the resistance of the galvanometer coil alone. Figure 25-39 illustrates the construction of an ammeter and voltmeter from a galvanometer. The resistance of the galvanometer R_g is shown separately in these schematic drawings, but it is actually part of the galvanometer.

A simple ohmmeter consists of a battery connected in series with a galvanometer and a resistor, as shown in Figure 25-40*a*.

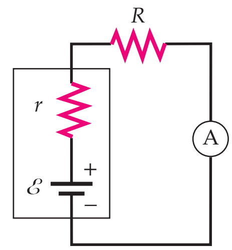

FIGURE 25-37 To measure the current in a resistor R, an ammeter A (circled) is placed in series with the resistor so that it carries the same current as the resistor.

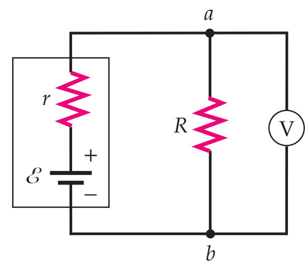

FIGURE 25-38 To measure the potential drop across a resistor, a voltmeter V (circled) is placed in parallel with the resistor so that the potential difference across the voltmeter is equal to the potential difference across the resistor.

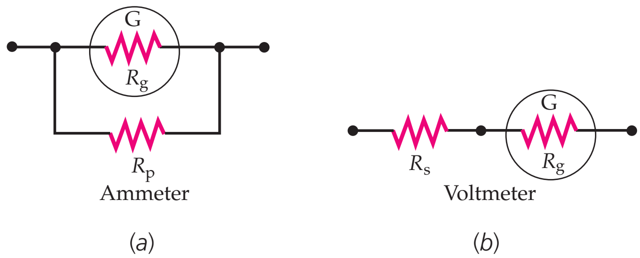

FIGURE 25-39 (*a*) An ammeter consists of a galvanometer G (circled) whose resistance is R_g and a small parallel resistance R_p. (*b*) A voltmeter consists of a galvanometer G (circled) and a large series resistance R_s.

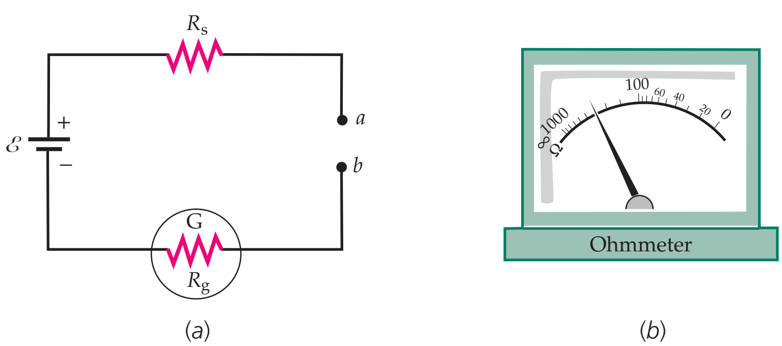

FIGURE 25-40 (*a*) An ohmmeter consists of a battery connected in series with a galvanometer and a resistor R_s, which is chosen so that the galvanometer gives full-scale deflection when points a and b are shorted. (*b*) When a resistor R is connected between terminals a and b, the galvanometer needle deflects by an amount that depends on the value of R. The galvanometer scale is calibrated to give a readout in ohms.

The resistance R_s is chosen so that when the terminals a and b are shorted (put in electrical contact with negligible resistance between them), the current through the galvanometer gives a full-scale deflection. Thus, a full-scale deflection indicates no resistance between terminals a and b. A zero deflection indicates an infinite resistance between the terminals. When the terminals are connected across an unknown resistance R, the current through the galvanometer depends on R, so the scale can be calibrated to give a direct reading of R, as shown in Figure 25-40*b*. Because an ohmmeter sends a current through the resistance to be measured, some caution must be exercised when using this instrument. For example, you would not want to try to measure the resistance of a sensitive galvanometer with an ohmmeter, because the current provided by the battery in the ohmmeter could possibly damage the galvanometer.

25-6 *RC* CIRCUITS

A circuit containing a resistor and a capacitor is called an ***RC* circuit.** The current in an *RC* circuit is in a single direction, as in all dc circuits, but the magnitude of the current varies with time. A practical example of an *RC* circuit is the circuit in the flash attachment of a camera. Before a flash photograph is taken, a battery in the flash attachment charges the capacitor through a resistor. When the capacitor is fully charged, the light is ready to flash. When the picture is taken, the capacitor discharges through the flashbulb. The battery then recharges the capacitor, and a short time later the flash is ready for another picture. Using Kirchhoff's rules, we can obtain equations for the charge Q and the current I as functions of time for both the charging and discharging of a capacitor through a resistor.

DISCHARGING A CAPACITOR

Figure 25-41 shows a capacitor that has an initial charge $+Q_0$ on the upper plate and an initial charge $-Q_0$ on the lower plate. The capacitor is connected to a resistor R and a switch S, which is initially open. The potential difference across the capacitor is initially $V_0 = Q_0/C$, where C is the capacitance.

We close the switch at time $t = 0$. Because there is now a potential difference across the resistor, there is also a current in the resistor. This initial current is

$$I_0 = \frac{V_0}{R} = \frac{Q_0}{RC} \qquad 25\text{-}30$$

The current is the rate of flow of positive charge from the positive plate of the capacitor to the negative plate through the resistor. (We model the charge carriers as being positively charged, when actually they are negatively charged electrons.) As time passes, the charge on the capacitor decreases. If we choose the positive direction to be clockwise, then the current equals the rate of decrease of the charge. If Q is the charge on the upper plate of the capacitor at time t, the current is related to Q by

$$I = -\frac{dQ}{dt} \qquad 25\text{-}31$$

(The minus sign is needed because while Q decreases, dQ/dt is negative.*) Traversing the circuit in the clockwise direction, we encounter a potential drop IR across the resistor and a potential increase Q/C across the capacitor. Thus, Kirchhoff's loop rule gives

$$\frac{Q}{C} - IR = 0 \qquad 25\text{-}32$$

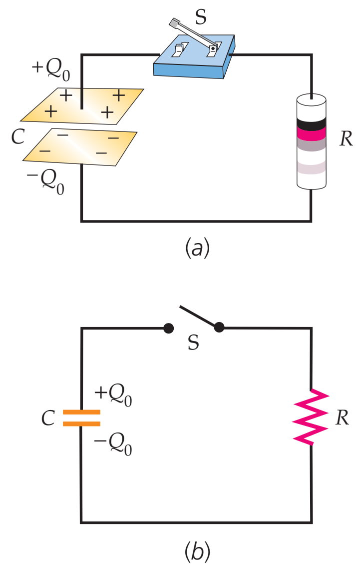

FIGURE 25-41 (*a*) A parallel-plate capacitor in series with a switch S and a resistor R. (*b*) A circuit diagram for Figure 25-41*a*.

* If the positive direction were chosen to be counterclockwise, then the sign in Equation 25-31 would be a plus sign.

where Q and I, both functions of time, are related by Equation 25-31. Substituting $-dQ/dt$ for I in Equation 25-32, we have

$$\frac{Q}{C} + R\frac{dQ}{dt} = 0$$

or

$$\frac{dQ}{dt} = -\frac{1}{RC}Q \qquad \text{25-33}$$

To solve this equation, we first separate the variables Q and t by multiplying both sides of the equation by dt/Q, and then we integrate both sides. Multiplying both sides by dt/Q, we obtain

$$\frac{dQ}{Q} = -\frac{1}{RC}dt \qquad \text{25-34}$$

The variables Q and t are now in separate terms. Integrating from Q_0 at $t = 0$ to Q' at time t' gives

$$\int_{Q_0}^{Q'} \frac{dQ}{Q} = -\frac{1}{RC}\int_0^{t'} dt$$

so

$$\ln\frac{Q'}{Q_0} = -\frac{t'}{RC}$$

Because t' is arbitrary, we can replace t' with t, and then $Q' = Q(t)$. Solving for $Q(t)$ gives

$$Q(t) = Q_0 e^{-t/(RC)} = Q_0 e^{-t/\tau} \qquad \text{25-35}$$

where τ, called the **time constant,** is the time it takes for the charge to decrease by a factor of e^{-1}:

$$\tau = RC \qquad \text{25-36}$$

DEFINITION—TIME CONSTANT

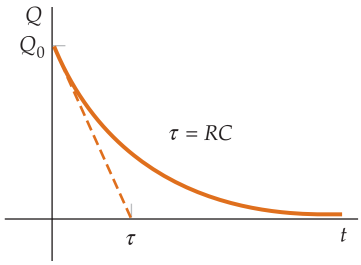

FIGURE 25-42 Plot of the charge on the capacitor versus time for the circuit shown in Figure 25-41. The switch is closed at time $t = 0$. The time constant $\tau = RC$ is the time it takes for the charge to decrease by a factor of e^{-1}. (The time constant is also the time it would take the capacitor to discharge fully if its discharge rate remains constant, as indicated by the dashed line.)

See **Math Tutorial** *for more information on*
Exponential Functions

Figure 25-42 shows the charge on the capacitor in the circuit of Figure 25-41 as a function of time. After a time $t = \tau$, the charge is $Q = e^{-1}Q_0 = 0.37Q_0$. After a time $t = 2\tau$, the charge is $Q = e^{-2}Q_0 = 0.135Q_0$, and so forth. After a time equal to several time constants, the charge Q is negligible. This type of decrease, which is called an **exponential decrease,** is very common in nature. It occurs whenever the rate at which a quantity decreases is proportional to the quantity itself.*

The decrease in the charge on a capacitor can be likened to the decrease in the amount of water in a bucket that has vertical sides and a small hole in the bottom. (The rate at which the water flows out of the hole is proportional to the difference in pressure of the water on either side of the hole, which is in turn proportional to the amount of water still in the bucket.)

The current is obtained by differentiating Equation 25-35

$$I = -\frac{dQ}{dt} = \frac{Q_0}{RC}e^{-t/(RC)}$$

Substituting, using Equation 25-30, we obtain

$$I = I_0 e^{-t/\tau} \qquad \text{25-37}$$

where $I_0 = V_0/R = Q_0/(RC)$ is the initial current. The current as a function of time is shown in Figure 25-43. As with the charge, the current decreases exponentially with time constant $\tau = RC$.

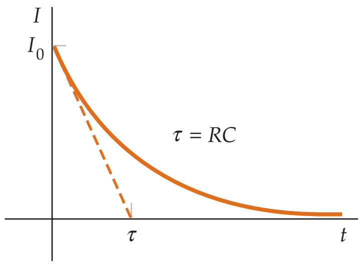

FIGURE 25-43 Plot of the current versus time for the circuit in Figure 25-41. The curve has the same shape as that in Figure 25-42. If the rate of decrease of the current remains constant, the current would reach zero after one time constant, as indicated by the dashed line.

* We encountered exponential decreases in Chapter 14 when we studied the damped oscillator.

Example 25-18 Discharging a Capacitor

A 4.0-μF capacitor is charged to 24 V and then connected across a 200-Ω resistor. Find (*a*) the initial charge on the capacitor, (*b*) the initial current through the 200-Ω resistor, (*c*) the time constant, and (*d*) the charge on the capacitor after 4.0 ms.

PICTURE The circuit diagram is the same as the circuit diagram shown in Figure 25-41.

SOLVE

(*a*) The initial charge is related to the capacitance and voltage:

$$Q_0 = CV_0 = (4.0\ \mu\text{F})(24\ \text{V}) = \boxed{96\ \mu\text{C}}$$

(*b*) The initial current is the initial voltage divided by the resistance:

$$I_0 = \frac{V_0}{R} = \frac{24\ \text{V}}{200\ \Omega} = \boxed{0.12\ \text{A}}$$

(*c*) The time constant is RC:

$$\tau = RC = (200\ \Omega)(4.0\ \mu\text{F}) = 800\ \mu\text{s} = \boxed{0.80\ \text{ms}}$$

(*d*) Substitute $t = 4.0$ ms into Equation 25-35 to find the charge on the capacitor at that time:

$$Q = Q_0 e^{-t/\tau} = (96\ \mu\text{C})e^{-(4.0\ \text{ms})/(0.80\ \text{ms})}$$
$$= (96\ \mu\text{C})e^{-5} = \boxed{0.65\ \mu\text{C}}$$

CHECK At the initial current of $I_0 = 0.12$ A it would take $Q_0/I_0 = 96\ \mu\text{C}/0.12\ \text{A} = 0.80$ ms for the capacitor to fully discharge. Because the current decreases exponentially during discharge, it is not surprising that it takes 4.0 ms for the charge to lose 99.3% of its initial charge.

TAKING IT FURTHER After five time constants, Q is less than 1 percent of its initial value.

PRACTICE PROBLEM 25-10 Find the current through the 200-Ω resistor at $t = 4.0$ ms.

CHARGING A CAPACITOR

Figure 25-44*a* shows a circuit for charging a capacitor. The capacitor is initially uncharged. The switch S, originally open, is closed at time $t = 0$. Charge immediately begins to flow through the battery (Figure 25-44*b*). If the charge on the rightmost plate of the capacitor at time t is Q, the current in the circuit is I, and clockwise is positive, then Kirchhoff's loop rule gives

$$\mathcal{E} - IR - \frac{Q}{C} = 0 \qquad 25\text{-}38$$

By inspecting this equation, we can see that when Q is zero (at $t = 0$) the current is $I = I_0 = \mathcal{E}/R$. The charge then increases and the current decreases. The charge approaches a maximum value of $Q_f = C\mathcal{E}$ as the current I approaches zero, as can also be seen from Equation 25-38.

In this circuit, we have chosen the positive direction so if I is positive Q is increasing. Thus,

$$I = +\frac{dQ}{dt}$$

Substituting dQ/dt for I in Equation 25-38 gives

$$\mathcal{E} - R\frac{dQ}{dt} - \frac{Q}{C} = 0 \qquad 25\text{-}39$$

Equation 25-39 can be solved in the same way that we solved Equation 25-33.

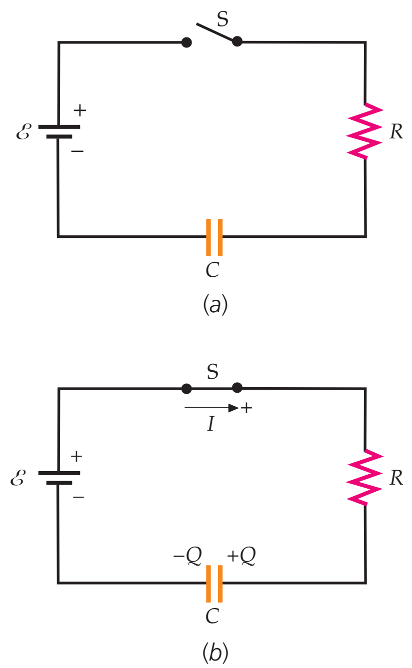

FIGURE 25-44 (*a*) A circuit for charging a capacitor to a potential difference $\mathcal{E}$. (*b*) After the switch is closed, there is both a current through and a potential drop across the resistor and both a charge on and a potential drop across the capacitor.

The details are left as a problem (see Problem 101). The result is

$$Q = C\mathcal{E}[1 - e^{-t/(RC)}] = Q_f(1 - e^{-t/\tau}) \qquad \text{25-40}$$

where $Q_f = C\mathcal{E}$ is the final charge. The current is obtained from $I = dQ/dt$:

$$I = \frac{dQ}{dt} = C\mathcal{E}\left[-\frac{-1}{RC}e^{-t/(RC)}\right] = \frac{\mathcal{E}}{R}e^{-t/(RC)}$$

or

$$I = \frac{\mathcal{E}}{R}e^{-t/(RC)} = I_0 e^{-t/\tau} \qquad \text{25-41}$$

where the initial current is $I_0 = \mathcal{E}/R$.

Figure 25-45 and Figure 25-46 show the charge and the current as functions of time.

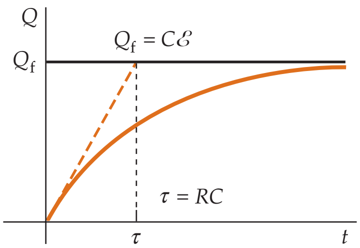

FIGURE 25-45 Plot of the charge on the capacitor versus time for the charging circuit of Figure 25-44 after the switch is closed (at $t = 0$). After a time $t = \tau = RC$, the charge on the capacitor is $0.63C\mathcal{E}$, where $C\mathcal{E}$ is its final charge. If the charging rate were constant, the capacitor would be fully charged after a time $t = \tau$.

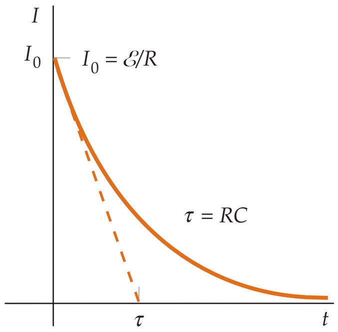

FIGURE 25-46 Plot of the current versus time for the charging circuit of Figure 25-44. The current is initially $\mathcal{E}/R$, and the current decreases exponentially with time.

PRACTICE PROBLEM 25-11

Show that Equation 25-40 does indeed satisfy Equation 25-39 by substituting the expressions for Q and dQ/dt into Equation 25-39.

PRACTICE PROBLEM 25-12

What fraction of the maximum charge is on the charging capacitor after a time $t = 2\tau$?

Example 25-19 Charging a Capacitor *Try It Yourself*

A 6.0-V battery that has a negligible internal resistance is used to charge a 2.0-μF capacitor through a 100-Ω resistor. Find (*a*) the initial current, (*b*) the final charge on the capacitor, (*c*) the time required for the charge to reach 90 percent of its final value, and (*d*) the charge when the current is half its initial value.

PICTURE The charge initially is zero so the voltage across the resistor is equal to the emf of the battery. Apply Ohm's law to the resistor and solve for the current. After a long time, the current is zero so the voltage across the capacitor is equal to the emf of the battery. Apply the definition of capacitance and solve for the charge. Use Equation 25-40 to relate the charge to the time, and use Kirchhoff's loop rule to relate the charge to the current.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
(*a*) Find the initial current from $I_0 = \mathcal{E}/R$.	$I_0 = 0.060\ \text{A} = \boxed{60\ \text{mA}}$
(*b*) Find the final charge from $Q = C\mathcal{E}$.	$Q_f = \boxed{12\ \mu\text{C}}$
(*c*) Set $Q = 0.90Q_f$ in Equation 25-40 and solve for t. (First solve for $e^{t/\tau}$, then take the natural log of both sides and solve for t.)	$t = 2.3\tau = \boxed{0.46\ \text{ms}}$
(*d*) 1. Apply Kirchhoff's loop rule to the circuit using Figure 25-44*b*.	$\mathcal{E} - IR - \dfrac{Q}{C} = 0$
2. Set $I = I_0/2$ and solve for Q.	$Q = \dfrac{Q_f}{2} = \boxed{6.0\ \mu\text{C}}$

CHECK The answer to Part (*d*) can be obtained by first solving for t using Equation 25-41, then substituting that time into Equation 25-40 and solving for Q. However, using the loop rule is certainly the more direct approach.

Example 25-20 Finding Values at Short and Long Times

The 6.0-μF capacitor in the circuit shown in Figure 25-47 is initially uncharged. Find the current through the 4.0-Ω resistor and the current through the 8.0-Ω resistor (*a*) immediately after the switch is closed and (*b*) a long time after the switch is closed. (*c*) Find the charge on the capacitor a long time after the switch is closed.

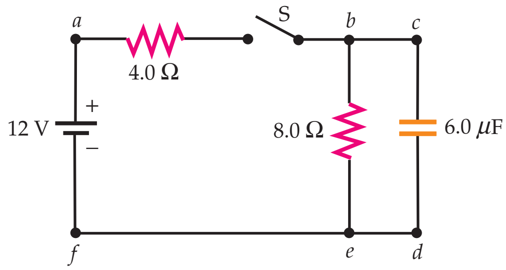

FIGURE 25-47

PICTURE Because the capacitor is initially uncharged (and the 4.0-Ω resistor limits the current through the battery), the initial potential difference across the capacitor is zero. The capacitor and the 8.0-Ω resistor are connected in parallel, and the difference in potential across each is the same. Thus, the initial potential difference across the 8.0-Ω resistor is also zero. The positive direction for the branch that has the battery is up the page, and the positive direction for the other two branches is down the page. Let Q be the charge on the upper plate of the capacitor.

SOLVE

(*a*) The charge on the capacitor initially is zero. Apply the loop rule to the outer loop and solve for the current through the 4.0-Ω resistor. Apply the loop rule to the loop containing the 8.0-Ω resistor and the capacitor and solve for the current through the 8.0-Ω resistor.

$$12\ \text{V} - (4.0\ \Omega)I_{4\Omega} - \frac{0}{C} = 0$$

$$I_{4\Omega} = \boxed{3.0\ \text{A}}$$

$$I_{8\Omega}(8\ \Omega) - \frac{0}{C} = 0$$

$$I_{8\Omega} = \boxed{0}$$

(*b*) After a long time, the capacitor is fully charged (no more charge flows onto its plates) and the current through both resistors is the same. Apply the loop rule to the loop on the left and solve for the current:

$$12\ \text{V} - (4.0\ \Omega)I_f - (8.0\ \Omega)I_f = 0$$

$$I_f = \boxed{1.0\ \text{A}}$$

(*c*) The potential difference across the 8.0-Ω resistor and the capacitor are equal. Use this to solve for Q_f:

$$I_f(8.0\ \Omega) = \frac{Q_f}{C}$$

$$Q_f = (1.0\ \text{A})(8.0\ \Omega)(6.0\ \mu\text{F}) = \boxed{48\ \mu\text{C}}$$

CHECK The analysis of this circuit at the extreme times when the capacitor is either uncharged or fully charged is simple. When the capacitor is uncharged, it acts like a good conductor (a short circuit) between points c and d; that is, the circuit is the same as the one shown in Figure 25-48*a* where we have replaced the capacitor by a wire of zero resistance. When the capacitor is fully charged, it acts like an open switch, as shown in Figure 25-48*b*.

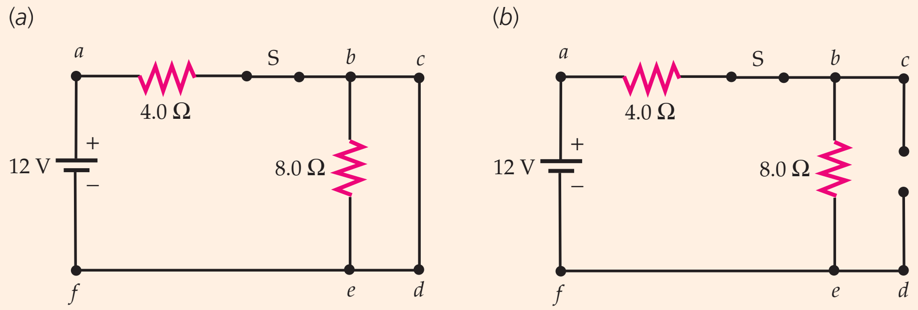

FIGURE 25-48

ENERGY CONSERVATION IN CHARGING A CAPACITOR

During the charging process, a total charge $Q_{\mathrm{f}} = \mathcal{E}C$ flows through the battery. The battery therefore does work

$$W = Q_{\mathrm{f}}\mathcal{E} = C\mathcal{E}^2$$

Half of this work is accounted for by the energy stored in the capacitor (see Equation 24-8):

$$U = \tfrac{1}{2}Q_{\mathrm{f}}\mathcal{E}$$

We now show that the other half of work done by the battery is dissipated as thermal energy by the resistance of the circuit. The rate at which energy is dissipated by the resistance R is

$$\frac{dW_R}{dt} = I^2R$$

where $I = (\mathcal{E}/R)e^{-t/(RC)}$ (Equation 25-41). Substituting for I we have

$$\frac{dW_R}{dt} = \left(\frac{\mathcal{E}}{R}e^{-t/(RC)}\right)^2 R = \frac{\mathcal{E}^2}{R}e^{-2t/(RC)}$$

We find the total energy dissipated by integrating from $t = 0$ to $t = \infty$:

$$W_R = \int_0^\infty \frac{\mathcal{E}^2}{R}e^{-2t/(RC)}\,dt = \frac{\mathcal{E}^2}{R}\int_0^\infty e^{-at}\,dt$$

where $a = 2/(RC)$. Thus,

$$W_R = \frac{\mathcal{E}^2}{R}\frac{e^{-at}}{-a}\bigg|_0^\infty = -\frac{\mathcal{E}^2}{Ra}(0-1) = \frac{\mathcal{E}^2}{R}\frac{1}{a} = \frac{\mathcal{E}^2}{R}\frac{RC}{2}$$

The total amount of Joule heating is thus

$$W_R = \frac{1}{2}\mathcal{E}^2C = \frac{1}{2}Q_{\mathrm{f}}\mathcal{E}$$

where $Q_{\mathrm{f}} = \mathcal{E}C$. This result is independent of the resistance R. Thus, when a capacitor is charged through a resistor by a constant source of emf, half the energy provided by the source of emf is stored in the capacitor and half goes into thermal energy. This thermal energy includes the energy that is dissipated by the internal resistance of the source of emf.

Physics Spotlight

Vehicle Electrical Systems: Driven to Innovation

During the 1930s, 6-volt batteries (7-volt charging) and electrical circuits were standard for automobiles in the United States. In the mid-1950s, manufacturers around the world recognized that this battery was inadequate for a car's electrical demands, and changed to 12-volt batteries (14-volt charging) that can support 14-volt electrical systems.[*] The changeover took several years.[†]

In the mid-1960s, demands on a car's electrical system included the starter, ignition, lights, radio, and air-conditioning in luxury cars.[‡] Today, the electrical system and electronics of a car[#] can include crash sensors, automatic braking systems, seat motors, power steering, power braking, windshield washers with intermittent timing, video-based entertainment systems, engine controllers, cruise control, and window motors. Some high-end luxury cars put further demands on their electrical systems with electronic throttle control, radar to detect the distance to objects,[°] electronic stability and suspension control, and heated seats.[§] The power requirement for an automobile is 1.5 to 2.0 kW today, and is expected to increase to 3.0 to 3.5 kW or more in the near future.[¶] The electrical system and electronics of a car now account for more than 20 percent of the manufacturing cost of the average car.[**]

Because demands on the electrical system of cars are expected to increase still further,[††] many people have suggested that it would be a good idea to upgrade the electrical system of cars to a 36-volt battery and a 42-volt system. (Because power is the product of voltage and current, this means that when the voltage increased, the current would decrease in order to supply the same power.) Many people were excited about the prospect of using smaller wires and lighter wiring harnesses to carry power to all the electrical devices.[‡‡] In addition, the higher voltage would mean smaller and lighter starter motors and alternators.

But switching over to a 42-volt system is proving to be more difficult than expected. Although a concept car was built with a 42-volt system, it was made from nonstandard customized parts.[##] In a 14-V system, a connection that has vibrated loose will not arc persistently over a gap that is about a millimeter. In a 42-V system, the same loose connection will arc, which creates the danger of an electrical fire.[°°] At 42 V, more expensive electrical connectors are required. By mid-2005, several manufacturers had confirmed that they were not interested in using 42-volt systems within the next few years.[§§,¶¶] A consortium of researchers continues to look at issues involving 42-volt automotive systems.[***] When the economics of a switch to the 42-volt systems make sense, then 42-volt electrical systems will be put into mass-production automobiles.

Summary

1. Ohm's law is an empirical law that holds only for certain materials.
2. Current, resistance, and emf are important *defined* quantities.
3. Kirchhoff's rules follow from the conservation of charge and the conservative nature of the electric field.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Electric Current	Electric current is the rate of flow of electric charge through a cross-sectional area. $$I = \frac{\Delta Q}{\Delta t}$$ in the limit that Δt approaches zero.	25-1
Drift velocity	In a conducting wire, electric current is the result of the slow drift of negatively charged electrons that are accelerated by an electric field in the wire and then collide with the lattice ions. Typical drift speeds of electrons in wires are of the order of a few millimeters per second. For mobile charges moving in the positive direction, $$I = qnAv_{\mathrm{d}}$$ where $q = -e$, n is the number density of free electrons, A is the cross-sectional area, and v_{d} is the drift speed.	25-3
Current density	The current density $\vec{J}$ is related to the drift velocity by $$\vec{J} = qn\vec{v}_{\mathrm{d}}$$ The current I through a cross-sectional surface is the flux of the current density through the surface.	25-4
2. Resistance		
Definition of resistance	$$R = \frac{V}{I}$$	25-7
Resistivity, ρ	$$R = \rho\frac{L}{A}$$	25-10
Temperature coefficient of resistivity, α	$$\alpha = \frac{(\rho - \rho_0)/\rho_0}{T - T_0}$$	25-12
3. Ohm's Law	For ohmic materials, the resistance does not depend on either the current or the potential drop: $$V = IR,\ R \text{ constant}$$	25-9
4. Power		
Supplied to a device or segment	$$P = IV$$	25-13
Delivered to a resistor	$$P = IV = I^2R = \frac{V^2}{R}$$	25-14
5. Emf		
Source of emf	A device that supplies electrical energy to a circuit.	
Power supplied by an ideal emf source	$$P = I\mathcal{E}$$	25-15
6. Battery		
Ideal	An ideal battery is a source of emf that maintains a constant potential difference between its two terminals, independent of the current through the battery.	
Real	A real battery can be considered as an ideal battery in series with a small resistance, called its internal resistance.	
Terminal voltage	$$V_a - V_b = \mathcal{E} - Ir$$ where in the battery the positive direction is the direction of increasing potential.	25-16

TOPIC	RELEVANT EQUATIONS AND REMARKS	
Total energy stored	$E_{\text{stored}} = Q\mathcal{E}$	25-18
7. Equivalent Resistance		
Resistors in series	$R_{\text{eq}} = R_1 + R_2 + R_3 + \ldots$	25-20
Resistors in parallel	$\frac{1}{R_{\text{eq}}} = \frac{1}{R_1} + \frac{1}{R_1} + \frac{1}{R_3} + \ldots$	25-25
8. Kirchhoff's Rules	1. When any closed loop is traversed, the algebraic sum of the changes in potential around the loop must equal zero. 2. At any junction (branch point) in a circuit where the current can divide, the sum of the currents into the junction must equal the sum of the currents out of the junction.	
9. Measuring Devices		
Ammeter	An ammeter is a very low resistance device that is placed in series with a circuit element to measure the current in the element.	
Voltmeter	A voltmeter is a very high resistance device that is placed in parallel with a circuit element to measure the potential difference across the element.	
Ohmmeter	An ohmmeter is a device containing a battery connected in series with a galvanometer and a resistor that is used to measure the resistance of a circuit element placed across its terminals.	
10. Discharging a Capacitor		
Charge on the capacitor	$Q(t) = Q_0 e^{-t/(RC)} = Q_0 e^{-t/\tau}$	25-35
Current in the circuit	$I = -\frac{dQ}{dt} = \frac{V_0}{R} e^{-t/(RC)} = I_0 e^{-t/\tau}$	25-37
Time constant	$\tau = RC$	25-36
11. Charging a Capacitor		
Charge on the capacitor	$Q = C\mathcal{E}[1 - e^{-t/(RC)}] = Q_f(1 - e^{-t/\tau})$	25-40
Current in the circuit	$I = \frac{\mathcal{E}}{R} e^{-t/(RC)} = I_0 e^{-t/\tau}$	25-41

Answers to Concept Checks

25-1 (*a*) The current is larger just after the switch is thrown because the bulb filament is a metal and is relatively cool, so its resistance is less than it will be when the bulb has been running for a while. Lower resistance means higher current. (*b*) Energy from the battery initially is delivered to the filament at a greater rate than the relatively cool filament releases heat. After a while, energy from the battery is delivered to the filament at the same rate that the now hot filament releases heat. Under these conditions the filament's temperature, and thus its resistance, remains constant.

Answers to Practice Problems

25-1 7.9 h

25-2 14 000

25-3 4.5 V

25-4 2.4 m

25-5 The color bands are colored, from top to bottom, brown, orange, blue, red, and brown. The value of the resistance is 13.6 kΩ and the tolerance is 1%.

25-6 (*a*) 45 W, (*b*) 270 J

25-7	(*a*) 6.0 Ω, (*b*) 1.3 Ω
25-8	(*a*) $R'_{eq} = 2.0\ \Omega$; (*b*) $I = 9.0$ A; (*c*) $V_2 = 18$ V, $V_0 = 0$, $V_{12} = 0$; (*d*) $I_2 = 9.0$ A, $I_0 = 9.0$ A, $I_{12} = 0$
25-9	(*a*) 3.0 A (*b*) 0.83 A
25-10	0.81 mA
25-12	0.86

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • In our study of electrostatics, we concluded that no electric field exists within the material of a conductor in electrostatic equilibrium. Why can we discuss electric fields within the material of conductors in this chapter?

2 • Figure 25-12 shows a mechanical analog of a simple electric circuit. Devise another mechanical analog in which the current is represented by a flow of water instead of marbles. In the water circuit, what would be analogous to the battery? What would be analogous to the wire? What would be analogous to the resistor?

3 • Wires A and B are both made of copper. The wires are connected in series, so we know they carry the same current. However, the diameter of wire A is twice the diameter of wire B. Which wire has the higher number density of charge carriers (number per unit charge)? (*a*) A, (*b*) B, (*c*) They have the same number density of charge carriers.

4 • The diameters of copper wires A and B are equal. The current carried by wire A is twice the current carried by wire B. In which wire do the charge carriers have the higher drift speed? (*a*) A, (*b*) B, (*c*) They have the same drift speed.

5 • Wire A and wire B are identical copper wires. The current carried by wire A is twice the current carried by wire B. Which wire has the higher current density? (*a*) A, (*b*) B, (*c*) They have the same current density. (*d*) None of the above

6 •• Consider a metal wire that has each end connected to a different terminal of the same battery. Your friend argues that no matter how long the wire is, the drift speed of the charge carriers in the wire is the same. Evaluate your friend's claim.

7 • In a resistor, the direction of the current must always be in the "downhill" direction, that is, in the direction of decreasing electric potential. Is it also the case that in a battery, the direction of the current must always be the "downhill"? Explain your answer.

8 • Discuss the distinction between an emf and a potential difference.

9 • Wire A and wire B are made of the same material and have the same length. The diameter of wire A is twice the diameter of wire B. If the resistance of wire B is R, then what is the resistance of wire A? (Neglet any effects that temperature may have on resistance.) (*a*) R, (*b*) $2R$, (*c*) $R/2$, (*d*) $4R$, (*e*) $R/4$

10 • Two cylindrical copper wires have the same mass. Wire A is twice as long as wire B. (Neglet any effects that temperature may have on resistance.) Their resistances are related by (*a*) $R_A = 8R_B$, (*b*) $R_A = 4R_B$, (*c*) $R_A = 2R_B$, (*d*) $R_A = R_B$.

11 • If the current in a resistor is I, the power delivered to the resistor is P. If the current in the resistor is increased to $3I$, what is the power then delivered to the resistor? (Assume the resistance of the resistor does not change.) (*a*) P, (*b*) $3P$, (*c*) $P/3$, (*d*) $9P$, (*e*) $P/9$

12 • If the potential drop across a resistor is V, the power delivered to the resistor is P. If the potential drop is increased to $2V$, what is the power delivered to the resistor then equal to? (*a*) P, (*b*) $2P$, (*c*) $4P$, (*d*) $P/2$, (*e*) $P/4$

13 • A heater consists of a variable resistor (a resistor whose resistance can be varied) connected across an ideal voltage supply. (An ideal voltage supply is one that has a constant emf and a negligible internal resistance.) To increase the heat output, should you decrease the resistance or increase the resistance? Explain your answer. SSM

14 • One resistor has a resistance R_1 and another resistor has a resistance R_2. The resistors are connected in parallel. If $R_1 \gg R_2$, the equivalent resistance of the combination is approximately (*a*) R_1, (*b*) R_2, (*c*) 0, (*d*) infinity.

15 • One resistor has a resistance R_1 and another resistor has a resistance R_2. The resistors are connected in series. If $R_1 \gg R_2$, the equivalent resistance of the combination is approximately (*a*) R_1, (*b*) R_2, (*c*) 0, (*d*) infinity.

16 • A parallel combination consisting of resistors A and B is connected across the terminals of a battery. The resistor A has twice the resistance of resistor B. If the current carried by resistor A is I, then what is the current carried by resistor B? (*a*) I, (*b*) $2I$, (*c*) $I/2$, (*d*) $4I$, (*e*) $I/4$

17 • A series combination consisting of resistors A and B is connected across the terminals of a battery. The resistor A has twice the resistance of resistor B. If the current carried by resistor A is I, then what is the current carried by resistor B? (*a*) I, (*b*) $2I$, (*c*) $I/2$, (*d*) $4I$, (*e*) $I/4$

18 • Kirchhoff's junction rule is considered to be a consequence of (*a*) conservation of charge, (*b*) conservation of energy, (*c*) Newton's laws, (*d*) Coulomb's law, (*e*) quantization of charge.

19 • True or false:

(*a*) An ideal voltmeter has a zero internal resistance.
(*b*) An ideal ammeter has a zero internal resistance.
(*c*) An ideal voltage source has a zero internal resistance.

20 • Before you and your classmates run an experiment, your professor lectures about safety. She reminds you that to measure the voltage across a resistor you connect a voltmeter in parallel with the resistor, and to measure the current in a resistor you connect an ammeter in series with the resistor. She also states that connecting a voltmeter in series with a resistor will not measure the voltage across the resistor, but also cannot do any damage to the circuit or the instrument. In addition, connecting an ammeter in parallel with a resistor will not measure the current in the resistor, but could cause significant damage to the circuit and the instrument. Explain why connecting a voltmeter in series with a resistor causes no damage while connecting an ammeter in parallel with a resistor can cause significant damage.

21 • The capacitor C in Figure 25-49 is initially uncharged. Just after the switch S is closed, (*a*) the voltage across C equals $\mathcal{E}$, (*b*) the voltage across R equals $\mathcal{E}$, (*c*) the current in the circuit is zero, (*d*) both (*a*) and (*c*) are correct.

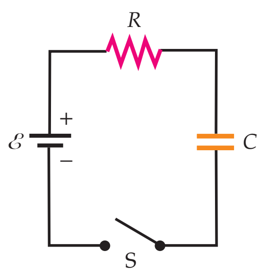

FIGURE 25-49 Problems 21 and 24

22 •• A capacitor is discharging through a resistor. If it takes a time T for the charge on a capacitor to drop to half its initial value, how long (in terms of T) does it take for the stored energy to drop to half its initial value?

23 •• In Figure 25-50, the values of the resistances are related as follows: $R_2 = R_3 = 2R_1$. If power P is delivered to R_1, what is the power delivered to R_2 and R_3? SSM

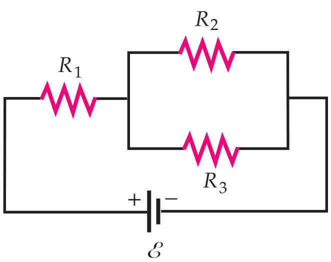

FIGURE 25-50 Problem 23

24 •• The capacitor in Figure 25-49 is initially uncharged. The switch S is closed and remains closed for a very long time. During this time, (*a*) the energy supplied by the battery is $\frac{1}{2}C\mathcal{E}^2$, (*b*) the energy dissipated in the resistor is $\frac{1}{2}C\mathcal{E}^2$, (*c*) the energy in the resistor is dissipated at a constant rate, (*d*) the total charge passing through the resistor is $\frac{1}{2}C\mathcal{E}$.

ESTIMATION AND APPROXIMATION

25 •• It is not a good idea to stick the ends of a metal paper clip into the two rectangular slots of a household electrical wall outlet in the United States. Explain why by estimating the current that a paper clip would carry until either the fuse blows or the breaker trips.

26 •• (*a*) Estimate the resistance of an automobile jumper cable. (*b*) Look up the current required to start a typical car. At that current, what is the potential drop that occurs across the jumper cable? (*c*) How much power is dissipated in the jumper cable when it carries that current?

27 •• **ENGINEERING APPLICATION, CONTEXT-RICH** Your manager wants you to design a new superinsulated water heater for the residential market. A coil of Nichrome wire is to be used as the heating element. Estimate the length of wire required. *Hint: You will need to determine the size of a typical water heater and a reasonable time period for creating hot water.*

28 •• A compact fluorescent lightbulb costs about \$6.00 and has a typical lifetime of 10 000 h. The bulb uses 20 W of power but produces illumination equivalent to that of a 75-W incandescent bulb. An incandescent bulb costs about \$1.50 and has a typical lifetime of 1000 h. Your family wonders whether it should buy fluorescent lightbulbs. Estimate the amount of money your household would save each year by using compact fluorescent lightbulbs instead of the incandescent bulbs.

29 •• **CONTEXT-RICH** The wires in a house must be large enough in diameter so that they do not get hot enough to start a fire. While working for a building contractor during the summer, you are involved in remodeling a house. The local building code states that the Joule heating of the wire used in houses should not exceed 2.0 W/m. Estimate the maximum gauge of the copper wire that you can use during the rewiring of the house with 20-A circuits.

30 •• A laser diode used in making a laser pointer is a highly nonlinear circuit element. Its behavior is as follows. For any voltage drop across it that is less than about 2.30 V, it behaves as if it has an infinite internal resistance, but for voltages higher than 2.30 V it has a very low internal resistance—effectively zero. (*a*) A laser pointer is made by putting two 1.55-V watch batteries in series across the laser diode. If the batteries each have an internal resistance between 1.00 Ω and 1.50 Ω, estimate the current in the laser diode. (*b*) About half of the power delivered to the laser diode goes into radiant energy. Using this fact, estimate the power of the laser beam, and compare this value to typical quoted values of about 3.00 mW. (*c*) If the batteries each have a capacity of 20.0 mA · h (i.e., they can deliver a constant current of 20.0 mA for approximately 1 hour before discharging), estimate how long one can continuously operate the laser pointer before replacing the batteries.

CURRENT, CURRENT DENSITY, DRIFT SPEED, AND THE MOTION OF CHARGES

31 • A 10-gauge copper wire carries a current equal to 20 A. Assuming copper has one free electron per atom, calculate the drift speed of the free electrons in the wire. SSM

32 •• A thin nonconducting ring that has a radius a and a linear charge density λ rotates with angular speed ω about an axis through its center and perpendicular to the plane of the ring. Find the current of the ring.

33 •• A length of 10-gauge copper wire and a length of 14-gauge copper wire are welded together end to end. The wires carry a current of 15 A. (*a*) If there is one free electron for each copper atom in each wire, find the drift speed of the electrons in each wire. (*b*) What is the ratio of the magnitude of the current density in the length of 10-gauge wire to the magnitude of the current density in the length of 14-gauge wire? SSM

34 •• An accelerator produces a beam of protons with a circular cross section that is 2.0 mm in diameter and has a current of 1.0 mA. The current density is uniformly distributed throughout the beam. The kinetic energy of each proton is 20 MeV. The beam strikes a metal target and is absorbed by the target. (*a*) What is the number density of the protons in the beam? (*b*) How many protons strike the target each minute? (*c*) What is the magnitude of the current density in this beam?

35 •• In one of the colliding beams of a planned proton *super-collider,* the protons are moving at nearly the speed of light and the beam current is 5.00 mA. The current density is uniformly distributed throughout the beam. (*a*) How many protons are there per meter of length of the beam? (*b*) If the cross-sectional area of the beam is $1.00 \times 10^{-6}\ \mathrm{m}^2$, what is the number density of protons? (*c*) What is the magnitude of the current density in this beam? SSM

36 •• **Context-Rich** The *solar wind* consists of protons from the Sun moving toward Earth (the wind actually consists of about 95% protons). The number density of protons at a distance from the Sun equal to the orbital radius of Earth is about 7.0 protons per cubic centimeter. Your research team monitors a satellite that is in orbit around the Sun at a distance from the Sun equal to Earth's orbital radius. You are in charge of the satellite's *mass spectrometer,* an instrument used to measure the composition and intensity of the solar wind. The aperture of your spectrometer is a circle of radius 25 cm. The rate of collection of protons by the spectrometer is such that they constitute a measured current of 85 nA. What is the speed of the protons in the solar wind? (Assume the protons enter the aperture at normal incidence.)

37 •• A gold wire has a 0.10-mm-diameter cross section. Opposite ends of this wire are connected to the terminals of a 1.5-V battery. If the length of the wire is 7.5 cm, how much time, on average, is required for electrons leaving the negative terminal of the battery to reach the positive terminal? Assume the resistivity of gold is $2.44 \times 10^{-8}\ \Omega \cdot \mathrm{m}$.

RESISTANCE, RESISTIVITY, AND OHM'S LAW

Note: **In this section, assume the resistors are ohmic (constant resistance) unless stated otherwise.**

38 • A 10-m-long wire has a resistance equal to $0.20\ \Omega$ and carries a current equal to 5.0 A. (*a*) What is the potential difference across the entire length of the wire? (*b*) What is the electric-field strength in the wire?

39 • A potential difference of 100 V across the terminals of a resistor produces a current of 3.00 A in the resistor. (*a*) What is the resistance of the resistor? (*b*) What is the current in the resistor when the potential difference is only 25.0 V? (Assume the resistance of the resistor remains constant.) SSM

40 • A block of carbon is 3.0 cm long and has a square cross-section whose sides are 0.50 cm long. A potential difference of 8.4 V is maintained across its length. (*a*) What is the resistance of the block? (*b*) What is the current in this resistor?

41 • An extension cord consists of a pair of 30-m-long 16-gauge copper wires. What is the potential difference that must be applied across one of the wires if it is to carry a current of 5.0 A? SSM

42 • (*a*) How long is a 14-gauge copper wire that has a resistance of $12.0\ \Omega$? (*b*) How much current will it carry if a 120-V potential difference is applied across its length?

43 • A cylinder of glass is 1.00 cm long and has a resistivity of $1.01 \times 10^{12}\ \Omega \cdot \mathrm{m}$. What length of copper wire that has the same cross-sectional area will have the same resistance as the glass cylinder?

44 •• **Engineering Application** While remodeling your garage, you need to temporarily splice, end to end, an 80-m-long copper wire that is 1.00 mm in diameter with a 49-m-long aluminum wire that has the same diameter. The maximum current in the wires is 2.00 A. (*a*) Find the potential drop across each wire of this system when the current is 2.00 A. (*b*) Find the electric field in each wire when the current is 2.00 A.

45 •• A 1.00-m-long wire has a resistance equal to $0.300\ \Omega$. A second wire made of identical material has a length of 2.00 m and a mass equal to the mass of the first wire. What is the resistance of the second wire? SSM

46 •• A 10-gauge copper wire can safely carry currents up to 30.0 A. (*a*) What is the resistance of a 100-m length of the wire? (*b*) What is the electric field in the wire when the current is 30.0 A? (*c*) How long does it take for an electron to travel 100 m in the wire when the current is 30.0 A?

47 •• A cube of copper has edges that are 2.00 cm long. If copper in the cube is drawn to form a length of 14-gauge wire, what will the resistance of the length of wire be? Assume the density of the copper does not change.

48 ••• Find an expression for the resistance between the ends of the half-ring shown in Figure 25-51. The resistivity of the material constituting the half-ring is ρ. *Hint: Model the half-ring as a parallel combination of a large number of thin half-rings. Assume the current is uniformly distributed on a cross section of the half-ring.*

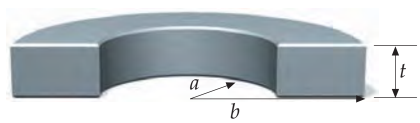

FIGURE 25-51 Problem 48

49 ••• Consider a wire of length L in the shape of a truncated cone. The radius of the wire varies with distance x from the narrow end according to $r = a + [(b - a)/L]x$, where $0 < x < L$. Derive an expression for the resistance of this wire in terms of its length L, radius a, radius b, and resistivity ρ. *Hint: Model the wire as a series combination of a large number of thin disks. Assume the current is uniformly distributed on a cross section of the cone.* SSM

50 ••• The space between two metallic concentric spherical shells is filled with a material that has a resistivity of $3.50 \times 10^{-5}\ \Omega \cdot \mathrm{m}$. If the inner metal shell has an outer radius of 1.50 cm and the outer metal shell has an inner radius of 5.00 cm, what is the resistance between the conductors? *Hint: Model the material as a series combination of a large number of thin spherical shells.*

51 ••• The space between two metallic coaxial cylinders that have the same length L is completely filled with a nonmetallic material having a resistivity ρ. The inner metal shell has an outer radius a and the outer metal shell has an inner radius b. (*a*) What is the resistance between the two cylinders? *Hint: Model the material as a series combination of a large number of thin cylindrical shells.* (*b*) Find the current between the two metallic cylinders if $\rho = 30.0\ \Omega \cdot \text{m}$, $a = 1.50$ cm, $b = 2.50$ cm, $L = 50.0$ cm, and a potential difference of 10.0 V is maintained between the two cylinders.

TEMPERATURE DEPENDENCE OF RESISTANCE

52 • A tungsten rod is 50 cm long and has a square cross section that has 1.0-mm-long edges. (*a*) What is its resistance at 20°C? (*b*) What is its resistance at 40°C?

53 • At what temperature will the resistance of a copper wire be 10 percent greater than its resistance at 20°C? SSM

54 •• **Engineering Application** You have a toaster that uses a Nichrome wire as a heating element. You need to determine the temperature of the Nichrome wire under operating conditions. First, you measure the resistance of the heating element at 20°C and find it to be 80.0 Ω. Then you measure the current immediately after you plug the toaster into a wall outlet—before the temperature of the Nichrome wire increases significantly. You find this startup current to be 8.70 A. When the heating element reaches its operating temperature, you measure the current to be 7.00 A. Use your data to determine the maximum operating temperature of the heating element.

55 •• **Engineering Application** Your electric space heater has a Nichrome heating element that has a resistance of 8.00 Ω at 20.0°C. When 120 V is applied, the electric current heats the Nichrome wire to 1000°C. (*a*) What is the initial current in the heating element at 20.0°C? (*b*) What is the resistance of the heating element at 1000°C? (*c*) What is the operating power of this heater?

56 •• A 10.0-Ω Nichrome resistor is wired into an electronic circuit using copper leads (wires) that have diameters equal to 0.600 mm. The copper leads have a total length of 50.0 cm. (*a*) What additional resistance is due to the copper leads? (*b*) What percentage error in the total resistance is produced by neglecting the resistance of the copper leads? (*c*) What change in temperature would produce a change in resistance of the Nichrome wire equal to the resistance of the copper leads? Assume that the Nichrome section is the only one whose temperature is changed.

57 ••• A wire that has a cross-sectional area A, a length L_1, a resistivity ρ_1, and a temperature coefficient α_1 is connected end to end to a second wire that has the same cross-sectional area, a length L_2, a resistivity ρ_2, and a temperature coefficient α_2, so that the wires carry the same current. (*a*) Show that if $\rho_1 L_1 \alpha_1 + \rho_2 L_2 \alpha_2 = 0$, then the total resistance is independent of temperature for small temperature changes. (*b*) If one wire is made of carbon and the other wire is made of copper, find the ratio of their lengths for which the total resistance is approximately independent of temperature. SSM

58 ••• The resistivity of tungsten increases approximately linearly with temperature from 56.0 nΩ·m at 293 K to 1.10 μΩ·m at 3500 K. A lightbulb is powered by a 100-V dc power supply. Under those operating conditions the temperature of the tungsten filament is 2500 K, the length of the filament is equal to 5.00 cm, and the power delivered to the filament is 40 W. Estimate (*a*) the resistance of the filament and (*b*) the diameter of the filament.

59 ••• A 5.00-V lightbulb used in an electronics class has a carbon filament that has a length of 3.00 cm and a diameter of 40.0 μm. At temperatures between 500 K and 700 K, the resistivity of the carbon used in making small lightbulb filaments is about $3.00 \times 10^{-5}\ \Omega \cdot \text{m}$. (*a*) Assuming that the bulb is a perfect blackbody radiator, calculate the temperature of the filament under operating conditions. (*b*) One concern about carbon filament bulbs, unlike tungsten filament bulbs, is that the resistivity of carbon decreases with increasing temperature. Explain why this decrease in resistivity is a concern.

ENERGY IN ELECTRIC CIRCUITS

60 • A 1.00-kW heater is designed to operate at 240 V. (*a*) What is the heater's resistance and what is the current in the wires that supply power to the heater? (*b*) What is the power delivered to the heater if it operates at 120 V? Assume that its resistance remains the same.

61 • A battery has an emf of 12 V. How much work does it do in 5.0 s if it delivers a current of 3.0 A?

62 • An automotive battery has an emf of 12.0 V. When supplying power to the starter motor, the current in the battery is 20.0 A and the terminal voltage of the battery is 11.4 V. What is the internal resistance of the battery?

63 • (*a*) How much power is delivered by the battery in Problem 62 due to the chemical reactions within the battery when the current in the battery is 20 A? (*b*) How much of this power is delivered to the starter when the current in the battery is 20 A? (*c*) By how much does the chemical energy of the battery decrease if the current in the starter is 20 A for 7.0 s? (*d*) How much energy is dissipated in the battery during those 7.0 seconds? SSM

64 • A battery that has an emf of 6.0 V and an internal resistance of 0.30 Ω is connected to a variable resistor with resistance R. Find the current and power delivered by the battery when R is (*a*) 0, (*b*) 5.0 Ω, (*c*) 10 Ω, and (*d*) infinite.

65 •• **Engineering Application, Context-Rich** A 12.0-V automobile battery that has a negligible internal resistance can deliver a total charge of 160 A·h. (*a*) What is the amount of energy stored in the battery? (*b*) After studying all night for a calculus test, you try to drive to class to take the test. However, you find that the car's battery is "dead" because you had left the headlights on! Assuming the battery was able to produce current at a constant rate until it died, how long were your lights on? Assume the pair of headlights together operates at a power of 150 W.

66 •• **Engineering Application** The measured current in a circuit in your uncle's house is 12.5 A. In this circuit, the only appliance that is on is a space heater that is being used to heat the bathroom. A pair of 12-gauge copper wires carries the current from the supply panel in your basement to the wall outlet in the bathroom, a distance of 30.0 m. You measure the voltage at the supply panel to be exactly 120 V. What is the voltage at the wall outlet in the bathroom that the space heater is connected to?

67 •• **Engineering Application** A lightweight electric car is powered by a series combination of ten 12.0-V batteries, each having negligible internal resistance. Each battery can deliver a charge of 160 A·h before needing to be recharged. At a speed of 80.0 km/h, the average force due to air drag and rolling friction is 1.20 kN. (*a*) What must be the minimum power delivered by the electric motor if the car is to travel at a speed of 80.0 km/h? (*b*) What is the

total charge, in coulombs, that can be delivered by the series combination of ten batteries before recharging is required? (*c*) What is the total electrical energy delivered by the ten batteries before recharging? (*d*) How far can the car travel (at 80.0 km/h) before the batteries must be recharged? (*e*) What is the cost per kilometer if the cost of recharging the batteries is 9.00 cents per kilowatt-hour? SSM

68 ••• A 100-W heater is designed to operate with an applied voltage of 120 V. (*a*) What is the heater's resistance, and what current does the heater carry? (*b*) Show that if the potential difference V across the heater changes by a small amount ΔV, the power P changes by a small amount ΔP, where $\Delta P/P \approx 2\,\Delta V/V$. *Hint: Approximate the changes by modeling them as differentials, and assume the resistance is constant.* (*c*) Using the Part (*b*) result, find the approximate power delivered to the heater if the potential difference is decreased to 115 V. Compare your result to the exact answer.

COMBINATIONS OF RESISTORS

69 • If the potential drop from point *a* to point *b* (Figure 25-52) is 12.0 V, find the current in each resistor. SSM

70 • If the potential drop between point *a* and point *b* (Figure 25-53) is 12.0 V, find the current in each resistor.

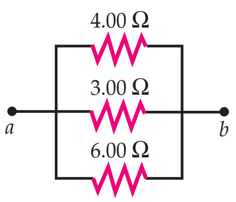

FIGURE 25-52 Problem 69

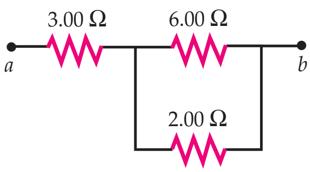

FIGURE 25-53 Problem 70

71 • (*a*) Show that the equivalent resistance between point *a* and point *b* in Figure 25-54 is R. (*b*) How would adding a fifth resistor that has resistance R between point *c* and point *d* affect the equivalent resistance between point *a* and point *b*?

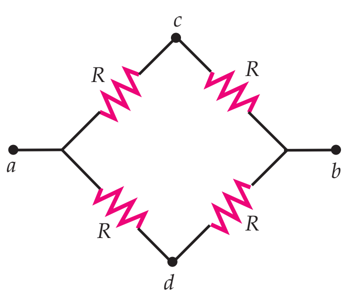

FIGURE 25-54 Problem 71

72 •• The battery in Figure 25-55 has negligible internal resistance. Find (*a*) the current in each resistor and (*b*) the power delivered by the battery.

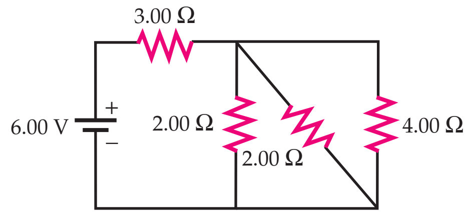

FIGURE 25-55 Problem 72

73 •• A 5.00-V power supply has an internal resistance of 50.0 Ω. What is the smallest resistor that can be put in series with the power supply so that the voltage drop across the resistor is larger than 4.50 V? SSM

74 •• **ENGINEERING APPLICATION** You have been handed an unknown battery. Using your multimeter, you determine that when a 5.00-Ω resistor is connected across the battery's terminals, the current in the battery is 0.500 A. When this resistor is replaced by an 11.0-Ω resistor, the current drops to 0.250 A. From those data, find (*a*) the emf and (*b*) internal resistance of the battery.

75 •• (*a*) Find the equivalent resistance between point *a* and point *b* in Figure 25-56. (*b*) If the potential drop between point *a* and point *b* is 12.0 V, find the current in each resistor.

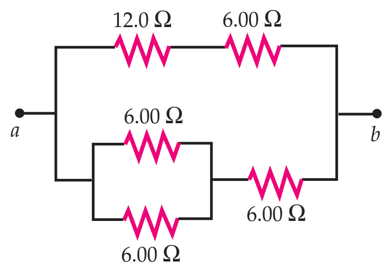

FIGURE 25-56 Problem 75

76 •• (*a*) Find the equivalent resistance between point *a* and point *b* in Figure 25-57. (*b*) If the potential drop between point *a* and point *b* is 12.0 V, find the current in each resistor.

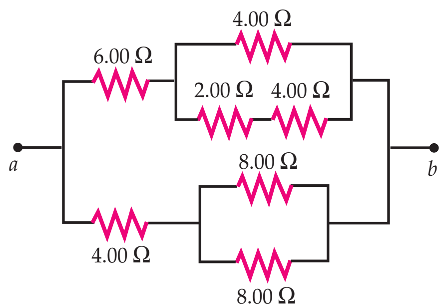

FIGURE 25-57 Problem 76

77 •• A length of wire has a resistance of 120 Ω. The wire is cut into pieces that have the same length, and then the wires are connected in parallel. The resistance of the parallel arrangement is 1.88 Ω. Find the number of pieces into which the wire was cut. SSM

78 •• A parallel combination of an 8.00-Ω resistor and a resistor of unknown resistance is connected in series with a 16.0-Ω resistor and an ideal battery. The circuit is disassembled and the three resistors are then connected in series with each other and the same battery. In both arrangements, the current through the 8.00-Ω resistor is the same. What is the resistance of the unknown resistor?

79 •• For the network shown in Figure 25-58, let R_{ab} denote the equivalent resistance between terminals *a* and *b*. Find (*a*) R_3, so that $R_{ab} = R_1$; (*b*) R_2, so that $R_{ab} = R_3$; and (*c*) R_1, so that $R_{ab} = R_1$.

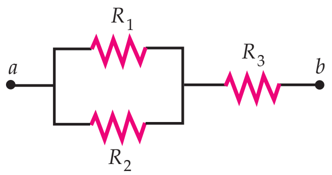

FIGURE 25-58 Problems 79 and 80

80 •• Check your results for Problem 79 using the following specific values: (*a*) $R_1 = 4.00\ \Omega$, $R_2 = 6.00\ \Omega$; (*b*) $R_1 = 4.00\ \Omega$, $R_3 = 3.00\ \Omega$; and (*c*) $R_2 = 6.00\ \Omega$, $R_3 = 3.00\ \Omega$.

KIRCHHOFF'S RULES

Note: **While simpler circuits in this section can be solved using the concepts of equivalent parallel and series resistor combinations, the intent is to gain practice using Kirchhoff's rules. Use them to solve all the problems in this section.**

81 • In Figure 25-59, the battery's emf is 6.00 V and *R* is 0.500 Ω. The rate of Joule heating in *R* is 8.00 W. (*a*) What is the current in the circuit? (*b*) What is the potential difference across *R*? (*c*) What is the resistance *r*? SSM

82 • The batteries in the circuit in Figure 25-60 have negligible internal resistance. (*a*) Find the current using Kirchhoff's loop rule. (*b*) Find the power delivered to or supplied by each battery. (*c*) Find the rate of Joule heating in each resistor.

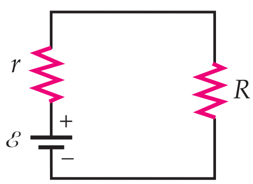

FIGURE 25-59 Problem 81

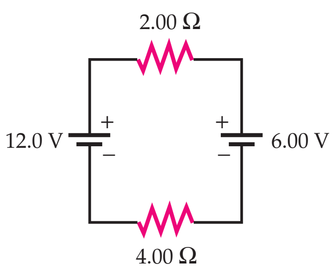

FIGURE 25-60 Problem 82

83 •• **ENGINEERING APPLICATION** An old car battery that has an emf of $\mathcal{E}_1 = 11.4$ V and an internal resistance of 50.0 mΩ is connected to a 2.00-Ω resistor. In an attempt to recharge the battery, you connect a second battery that has an emf of $\mathcal{E}_2 = 12.6$ V and an internal resistance of 10.0 mΩ in parallel with the first battery and the resistor with a pair of jumper cables. (*a*) Draw a diagram of the circuit. (*b*) Find the current in each branch of the circuit. (*c*) Find the power supplied by the second battery and discuss where that power is delivered. Assume that the emfs and internal resistances of both batteries remain constant.

84 •• In the circuit in Figure 25-61, the reading of the ammeter is the same when both switches are open and when both switches are closed. What is the unknown resistance *R*?

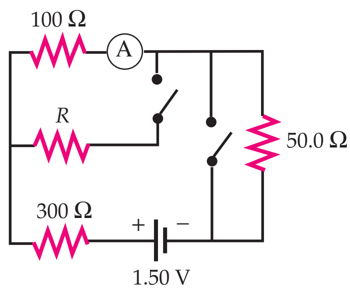

FIGURE 25-61 Problem 84

85 •• In the circuit shown in Figure 25-62, the batteries have negligible internal resistance. Find (*a*) the current in each branch of the circuit, (*b*) the potential difference between point *a* and point *b*, and (*c*) the power supplied by each battery. SSM

86 •• In the circuit shown in Figure 25-63, the batteries have negligible internal resistance. Find (*a*) the current in each branch of the circuit, (*b*) the potential difference between point *a* and point *b*, and (*c*) the power supplied by each battery.

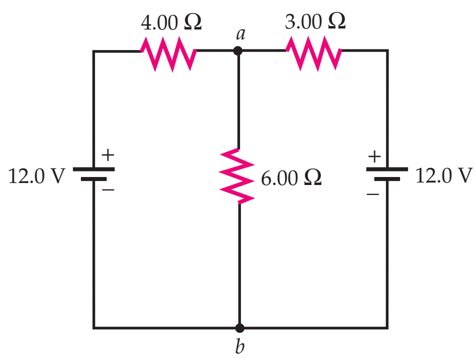

FIGURE 25-62 Problem 85

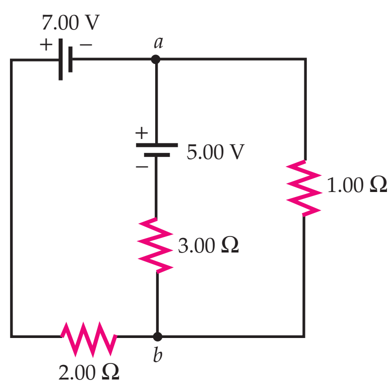

FIGURE 25-63 Problem 86

87 ••• Two identical batteries, each having an emf $\mathcal{E}$ and an internal resistance r, can be connected across a resistance R with the batteries connected either in series or in parallel. In each situation, determine explicitly whether the power supplied to R is greater when R is less than r or when R is greater than r.

88 •• **ENGINEERING APPLICATION** The circuit fragment shown in Figure 25-64 is called a *voltage divider.* (*a*) If R_{load} is not attached, show that $V_{out} = VR_2/(R_1 + R_2)$. (*b*) If $R_1 = R_2 = 10\ \text{k}\Omega$, what is the smallest value of R_{load} that can be used so that V_{out} drops by less than 10 percent from its unloaded value? (V_{out} is measured with respect to ground.)

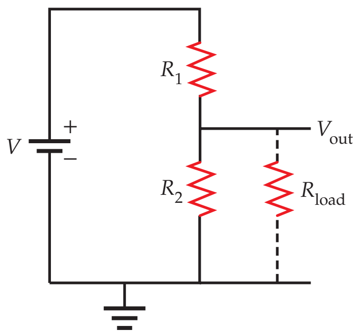

FIGURE 25-64 Problem 88

89 ••• For the circuit shown in Figure 25-65, find the potential difference between point a and point b. SSM

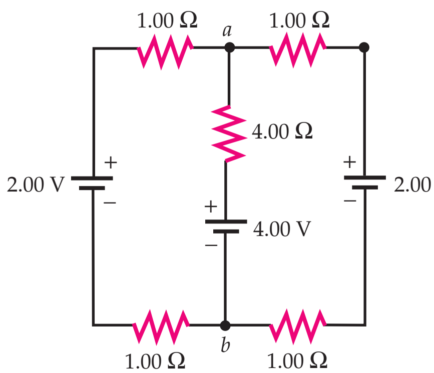

FIGURE 25-65 Problem 89

90 ••• For the circuit shown in Figure 25-66, find (*a*) the current in each resistor, (*b*) the power supplied by each source of emf, and (*c*) the power delivered to each resistor.

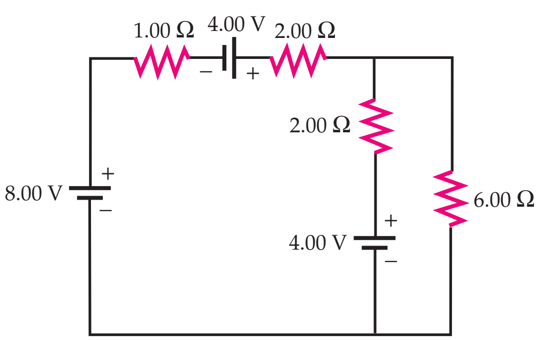

FIGURE 25-66 Problem 90

AMMETERS AND VOLTMETERS

91 •• The voltmeter shown in Figure 25-67 can be modeled as an ideal voltmeter (a voltmeter that has an infinite internal resistance) in parallel with a 10.0-MΩ resistor. Calculate the reading on the voltmeter when (*a*) $R = 1.00\ \text{k}\Omega$, (*b*) $R = 10.0\ \text{k}\Omega$, (*c*) $R = 1.00\ \text{M}\Omega$, (*d*) $R = 10.0\ \text{M}\Omega$, and (*e*) $R = 100\ \text{M}\Omega$. (*f*) What is the largest value of R possible if the measured voltage is to be within 10 percent of the *true* voltage (i.e., the voltage drop across R without the voltmeter in place)? SSM

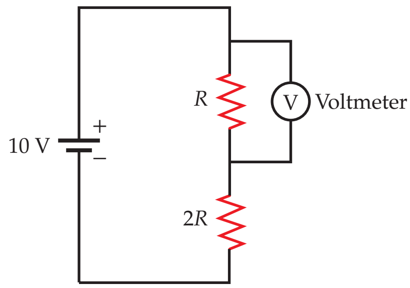

FIGURE 25-67 Problem 91

92 •• You are given a D'Arsonval galvanometer that will deflect full scale if a current of 50.0 μA runs through the galvanometer. At that current, there is a voltage drop of 0.250 V across the meter. What is the internal resistance of the galvanometer?

93 •• You are given a D'Arsonval galvanometer that will deflect full scale if a current of 50.0 μA runs through the galvanometer. At that current, there is a voltage drop of 0.250 V across the meter. You wish to use the galvanometer to construct an ammeter that can measure currents up to 100 mA. Show that this can be done by placing a resistor in parallel with the meter, and find the value of its resistance.

94 •• You are given a D'Arsonval galvanometer that will deflect full scale if a current of 50.0 μA runs through the galvanometer. At that current, there is a voltage drop of 0.250 V across the meter. You wish to use the galvanometer to construct a voltmeter that can measure potential differences up to 10.0 V. Show that this can be done by placing a large resistance in series with the meter movement, and find the resistance needed.

RC CIRCUITS

95 • For the circuit shown in Figure 25-68, $C = 6.00\ \mu\text{F}$, $\mathcal{E} = 100$ V, and $R = 500\ \Omega$. After having been at contact a for a long time, the switch throw is rotated to contact b. (*a*) What is the charge on the upper plate of the capacitor just as the switch throw is moved to contact b? (*b*) What is the current just after the switch throw is rotated to contact b? (*c*) What is the time constant of this circuit? (*d*) How much charge is on the upper plate of the capacitor 6.00 ms after the switch throw is rotated to contact b?

96 • At $t = 0$ the switch throw in Figure 25-68 is rotated to contact b after having been at contact a for a long time. (*a*) How much energy is stored in the capacitor at $t = 0$? (*b*) For $t > 0$, find the energy stored in the capacitor as a function of time. (*c*) Sketch a plot of the energy stored in the capacitor versus time t.

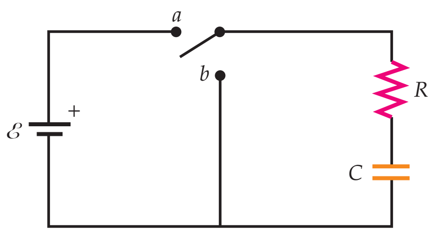

FIGURE 25-68 Problems 95, 96, and 98

97 •• In the circuit in Figure 25-69, the emf equals 50.0 V and the capacitance equals 2.00 μF. Switch S is opened after having been closed for a long time, and 4.00 s later the voltage drop across the resistor is 20.0 V. Find the resistance of the resistor. SSM

98 •• For the circuit shown in Figure 25-68, $C = 0.120\ \mu$F and $\mathscr{E} = 100$ V. The switch throw is rotated to contact b after having been at contact a for a long time, and 4.00 s later the potential difference across the capacitor is equal to $\frac{1}{2}\mathscr{E}$. What is the value of R?

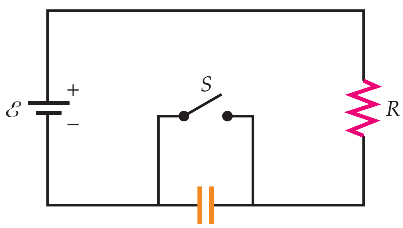

FIGURE 25-69 Problems 97 and 99

99 •• In the circuit in Figure 25-69, the emf equals 6.00 V and has negligible internal resistance. The capacitance equals 1.50 μF and the resistance equals 2.00 MΩ. Switch S has been closed for a long time. Switch S is opened. After a time interval equal to one time constant of the circuit has elapsed, find (a) the charge on the capacitor plate on the right, (b) the rate at which the charge is increasing, (c) the current, (d) the power supplied by the battery, (e) the power delivered to the resistor, and (f) the rate at which the energy stored in the capacitor is increasing.

100 •• A constant charge of 1.00 mC is on the positively charged plate of the 5.00-μF capacitor shown in Figure 25-70. Find (a) the battery current and (b) the resistances R_1, R_2, and R_3.

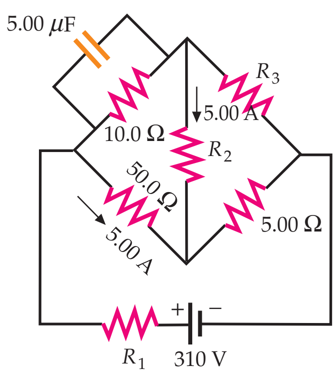

FIGURE 25-70 Problem 100

101 •• Show that Equation 25-39 can be rearranged and written as $\frac{dQ}{\mathscr{E}C - Q} = \frac{dt}{RC}$. Integrate this equation to derive the solution given by Equation 25-40.

102 •• Switch S, shown in Figure 25-71, is closed after having been open for a long time. (a) What is the initial value of the battery current just after switch S is closed? (b) What is the battery current a long time after switch S is closed? (c) What are the charges on the plates of the capacitors a long time after switch S is closed? (d) Switch S is reopened. What are the charges on the plates of the capacitors a long time after switch S is reopened?

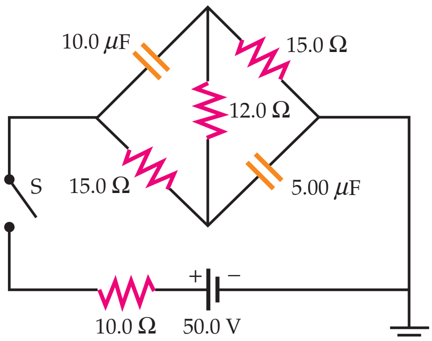

FIGURE 25-71 Problem 102

103 ••• For the circuit shown in Figure 25-72, switch S has been open for a long time. At time $t = 0$ the switch is then closed. (a) What is the battery current just after switch S is closed? (b) What is the battery current a long time after switch S is closed? (c) What is the current in the 600-Ω resistor as a function of time?

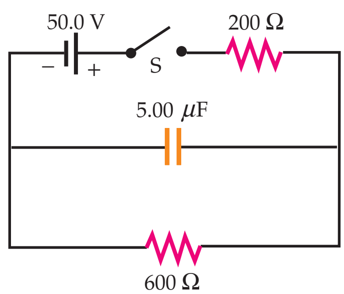

FIGURE 25-72 Problem 103

104 ••• For the circuit shown in Figure 25-73, switch S has been open for a long time. At time $t = 0$ the switch is then closed. (a) What is the battery current just after switch S is closed? (b) What is the battery current a long time after switch S is closed? (c) The switch has been closed for a long time. At time $t = 0$ the switch is then opened. Find the current through the 600-kΩ resistor as a function of time.

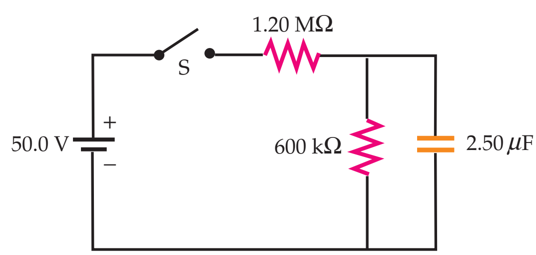

FIGURE 25-73 Problem 104

105 ••• In the circuit shown in Figure 25-74, the capacitor has a capacitance of 2.50 μF and the resistor has a resistance of 0.500 MΩ. Before the switch is closed, the potential drop across the capacitor is 12.0 V, as shown. Switch S is closed at $t = 0$. (*a*) What is the current immediately after switch S is closed? (*b*) At what time t is the voltage across the capacitor 24.0 V? SSM

106 ••• Repeat Problem 105 if the initial polarity of the capacitor is opposite to that shown in Figure 25-74.

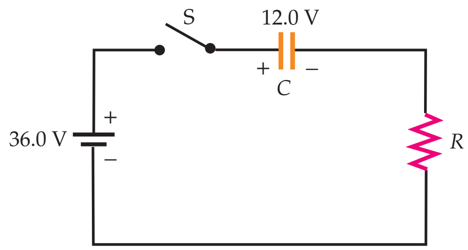

FIGURE 25-74 Problems 105 and 106

GENERAL PROBLEMS

107 •• In Figure 25-75, $R_1 = 4.00\ \Omega$, $R_2 = 6.00\ \Omega$, $R_3 = 12.0\ \Omega$, and the battery emf is 12.0 V. Denote the currents through the resistors as I_1, I_2, and I_3, respectively. (*a*) Decide which of the following inequalities holds for the circuit. Explain your answer conceptually. (1) $I_1 > I_2 > I_3$, (2) $I_2 = I_3$, (3) $I_3 > I_2$, (4) None of the above (*b*) To verify that your answer to Part (*a*) is correct, calculate all three currents. SSM

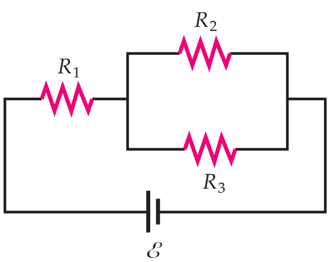

FIGURE 25-75 Problem 107

108 •• A 120 V, 25.0-W lightbulb is connected in series with a 120 V, 100-W lightbulb and a potential difference of 120 V is placed across the combination. Assume the bulbs have constant resistance. (*a*) Which bulb should be brighter under those conditions? Explain your answer conceptually. *Hint: What does the phrase "25.0-W lightbulb" mean? That is, under what conditions is 25 W of power delivered to the bulb?* (*b*) Determine the power delivered to each bulb under those conditions. Do your results support your answer to Part (*a*)?

109 •• The circuit shown in Figure 25-76 is a *Wheatstone bridge*, and the variable resistor is being used as a slide-wire potentiometer. The resistance R_0 is known. This "bridge" is used to determine an unknown resistance R_x. The resistances R_1 and R_2 comprise a wire 1.00 m long. Point *a* is a sliding contact that is moved along the wire to vary the resistances. Resistance R_1 is proportional to the distance from the left end of the wire (labeled 0.00 cm) to point *a*, and R_2 is proportional to the distance from point *a* to the right end of the wire (labeled 100 cm). The sum of R_1 and R_2 remains constant. When points *a* and *b* are at the same potential, there is no current in the galvanometer and the bridge is said to be balanced. (Because the galvanometer is used to detect the absence of a current, it is called a *null detector.*) If the fixed resistance $R_0 = 200\ \Omega$, find the unknown resistance R_x if (*a*) the bridge balances at the 18.0-cm mark, (*b*) the bridge balances at the 60.0-cm mark, and (*c*) the bridge balances at the 95.0-cm mark.

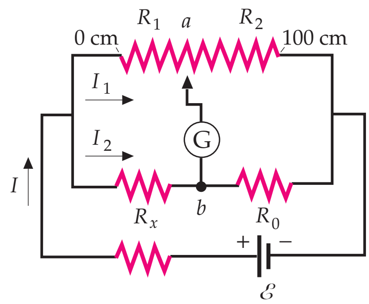

FIGURE 25-76 Problems 109 and 110

110 •• For the Wheatstone bridge in Problem 109, suppose the bridge balances at the 98.0-cm mark. (*a*) What is the unknown resistance? (*b*) What is the percentage error in the measured value of R_x if there is an error of 2.00 mm in the location of the balance point? (*c*) To what value should R_0 be changed to so that the balance point for the unknown resistor will be nearer the 50.0-cm mark? (*d*) If the balance point is at the 50.0-cm mark, what is the percentage error in the measured value of R_x if there is an error of 2.00 mm in the location of the balance point?

111 •• You are running an experiment that uses an accelerator that produces a 3.50-μA proton beam. Each proton in the beam has 60.0 MeV of kinetic energy. The protons impinge on, and come to rest inside, a 50.0-g copper target within a vacuum chamber. You are concerned that the target will get too hot and melt the solder on some connecting wires that are crucial to the experiment. (*a*) Determine the number of protons that strike the target per second. (*b*) Find the amount of energy delivered to the target each second. (*c*) Determine how much time elapses before the target temperature increases to 300°C. (Neglect any heat released by the target.) SSM

112 •• The belt of a Van de Graaff generator carries a surface charge density of 5.00 mC/m^2. The belt is 0.500 m wide and moves at 20.0 m/s. (*a*) What current does the belt carry? (*b*) If the potential of the dome of the generator is 100 kV above ground, what is the minimum power of the motor needed to drive the belt?

113 •• **ENGINEERING APPLICATION** Large conventional electromagnets use water cooling to prevent excessive heating of the magnet coils. A large laboratory electromagnet has a current equal to 100 A when a voltage of 240 V is applied to the terminals of the energizing coils. To cool the coils, water at an initial temperature of 15°C is circulated around the coils. How many liters of water must circulate by the coils each second if the temperature of the coils is not to exceed 50°C?

114 ••• (*a*) Give support to the assertion that a leaky capacitor (one for which the resistance of the dielectric is finite) can be modeled as a capacitor that has an infinite resistance in parallel with a resistor. (*b*) Show that the time constant for discharging the capacitor is given by $\tau = \kappa \mathcal{E}_0 \rho$. (For simplicity, assume the capacitor is a parallel-plate variety filled completely with a leaky dielectric.) (*c*) Mica has a dielectric constant equal to about 5.0 and a resistivity equal to about $9.0 \times 10^{13}\ \Omega \cdot$m. Calculate the time it takes for the charge of a mica-filled capacitor to decrease to 10 percent of its initial value.

115 ••• **ENGINEERING APPLICATION** Figure 25-77 shows the basis of the sweep circuit used in an oscilloscope. Switch S is an electronic switch that closes whenever the potential across the switch increases to a value V_c and opens when the potential across the switch decreases to 0.200 V. The emf $\mathcal{E}$, which is much greater than V_c,

charges the capacitor C through a resistor R_1. The resistor R_2 represents the small but finite resistance of the electronic switch. In a typical circuit, $\mathcal{E} = 800$ V, $V_c = 4.20$ V, $R_2 = 1.00$ mΩ, $R_1 = 0.500$ MΩ, and $C = 20.0$ nF. (*a*) What is the time constant for charging of the capacitor C? (*b*) Show that as the potential across switch S increases from 0.200 V to 4.20 V, the potential across the capacitor increases almost linearly with time. *Hint*: *Use the approximation* $e^x \approx 1 + x$, for $|x| \ll 1$. (*This approximation of* e^x *can be derived using the differential approximation*.) (*c*) What should the value of R_1 be changed to so that the capacitor charges from 0.200 V to 4.20 V in 0.100 s? (*d*) How much time elapses during the discharge of the capacitor when switch S closes? (*e*) At what average rate is energy delivered to the resistor R_1 during charging and to the switch resistance R_2 during discharge?

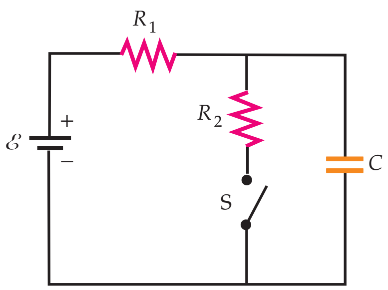

FIGURE 25-77 Problem 115

116 ••• In the circuit shown in Figure 25-78, $R_1 = 2.00$ MΩ, $R_2 = 5.00$ MΩ, and $C = 1.00$ μF. The capacitor is initially without charge on either plate. At $t = 0$, switch S is closed, and at $t = 2.00$ s switch S is opened. (*a*) Sketch a graph of the voltage across C and the current in R_2 between $t = 0$ and $t = 10.0$ s. (*b*) Find the voltage across the capacitor at $t = 2.00$ s and at $t = 8.00$ s.

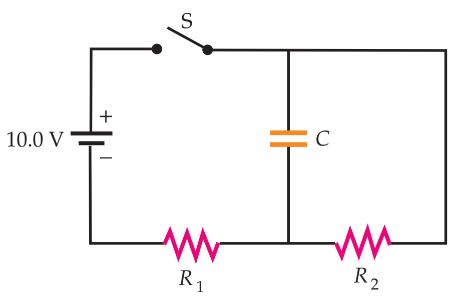

FIGURE 25-78 Problem 116

117 ••• Two batteries that have emfs $\mathcal{E}_1$ and $\mathcal{E}_2$ and internal resistances r_1 and r_2 are connected in parallel. Prove that if a resistor of resistance R is connected in parallel with combination, the optimal load resistance (the value of R at which maximum power is delivered) is given by $R = r_1 r_2/(r_1 + r_2)$.

118 ••• Capacitors C_1 and C_2 are connected to a resistor of resistance R and an ideal battery that has $\mathcal{E}$ as shown in Figure 25-79. The throw of switch S is initially at contact a and both capacitors are without charge. The throw is then rotated to contact b and left there for a long time. Finally, at time $t = 0$, the throw is returned to contact a. (*a*) Quantitatively compare the total energy stored in the two capacitors at $t = 0$ and a long time later. (*b*) Find the current

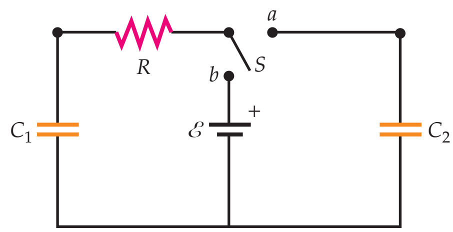

FIGURE 25-79 Problem 118

through R as a function of t for $t > 0$. (*c*) Find the energy delivered to the resistor as a function of t for $t > 0$. (*d*) Find the total energy dissipated in the resistor after $t = 0$ and compare it with the loss of stored energy found in Part (*a*).

119 ••• (*a*) Calculate the equivalent resistance (in terms of R, the resistance of each individual resistor) between points a and b for the infinite ladder of resistors shown in Figure 25-80 assuming the resistors are identical. That is, assuming $R = R_1 = R_2$. (*b*) Repeat Part (*a*) but do not assume that $R_1 = R_2$ and express your answer in terms of R_1 and R_2. (*c*) Check your results by showing that your result from Part (*b*) agrees with your result from Part (*a*) if you substitute R for both R_1 and R_2.

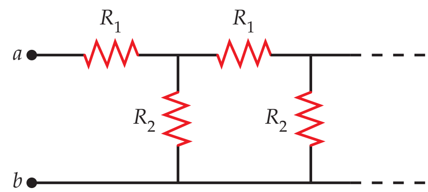

FIGURE 25-80 Problem 119

120 ••• A graph of current as a function of voltage for an Esaki diode is shown in Figure 25-81. (*a*) Make a graph of the differential resistance of the diode as a function of voltage. The differential resistance R_d of a circuit element is defined as $R_d = dV/dI$, where V is the voltage drop across the element and I is the current in the element. (*b*) At what value of the voltage drop does the differential resistance become negative? (*c*) What is the maximum differential resistance for this diode in the range shown and at what voltage does it occur? (*d*) Are there any places in the voltage range shown where the diode exhibits a differential resistance equal to zero? If so, under what value(s) of the voltage does this (do these) occur?

CHAPTER 26

THE AURORA BOREALIS APPEARS WHEN THE SOLAR WIND, CHARGED PARTICLES PRODUCED BY NUCLEAR FUSION REACTIONS IN THE SUN, BECOMES TRAPPED BY EARTH'S MAGNETIC FIELD. *(Atlas Photo Bank/Photo Researchers, Inc.)*

The Magnetic Field

? How does Earth's magnetic field act on subatomic particles? (See Example 26-1.)

More than 2000 years ago, the Greeks were aware that a certain type of stone (now called magnetite) attracts pieces of iron, and written references exist which describe the use of magnets for navigation dating from the twelfth century.

In 1269, Pierre de Maricourt discovered that a needle laid at various positions on a spherical natural magnet orients itself along lines that pass through points at opposite ends of the sphere. He called these points the *poles of the magnet*. Subsequently, many experimenters noted that every magnet of any shape has two poles, called the north and the south pole, where the force exerted by the magnet is strongest. It was also noted that the *like poles* of two magnets repel each other and the *unlike poles* of two magnets attract each other.

In 1600, William Gilbert discovered that Earth is a natural magnet and has magnetic poles near the north and south geographic poles. Because the north pole of a compass needle points toward the south pole of a given magnet, what we call the north pole of Earth is actually a south magnetic pole, as illustrated in Figure 26-1. Thus, the north and south poles of a magnet are sometimes referred to as the north-seeking and south-seeking poles, respectively.

Although electric charges and magnetic poles are similar in many respects, there is an important difference: Magnetic poles always occur in pairs. When a magnet is broken in half, equal and opposite poles appear at either side of the break point. The result is two magnets, each with a north and a south pole.

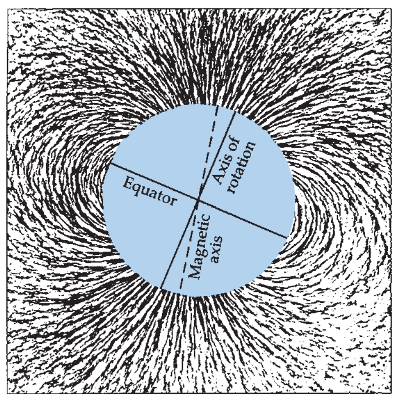

FIGURE 26-1 Magnetic field lines of Earth depicted by iron filings around a uniformly magnetized sphere. The field lines exit from the north magnetic pole, which is near the south geographic pole, and enter the south magnetic pole, which is near the north geographic pole.

There has long been speculation about the existence of an isolated magnetic pole, and in recent years considerable experimental effort has been made to find such an object. Thus far, there is no conclusive evidence that an isolated magnetic pole exists.

In this chapter, we consider the effects of a given magnetic field on moving charges and on wires carrying currents. The sources of magnetic fields are discussed in the next chapter.

26-1 THE FORCE EXERTED BY A MAGNETIC FIELD

The existence of a magnetic field $\vec{B}$ at some point in space can be demonstrated using a compass needle. If there is a magnetic field, the needle will align itself in the direction of the field.*

It has been experimentally observed that, when a particle that has charge q and velocity $\vec{v}$ is in a region with a magnetic field $\vec{B}$, a force acts on the particle that is proportional to q, to v, to B, and to the sine of the angle between the directions of $\vec{v}$ and $\vec{B}$. Surprisingly, the force is perpendicular to both the velocity and the megnetic field. These experimental results can be summarized as follows: When a particle that has a charge q and a velocity $\vec{v}$ is in a region with a magnetic field $\vec{B}$, the magnetic force $\vec{F}$ on the particle is

$$\vec{F} = q\vec{v} \times \vec{B} \qquad 26\text{-}1$$

MAGNETIC FORCE ON A MOVING CHARGED PARTICLE

Because $\vec{F}$ is perpendicular to both $\vec{v}$ and $\vec{B}$, $\vec{F}$ is perpendicular to the plane defined by these two vectors. The direction of $\vec{v} \times \vec{B}$ is given by the right-hand rule as $\vec{v}$ is rotated into $\vec{B}$, as illustrated in Figure 26-2. If q is positive, then $\vec{F}$ is in the same direction as $\vec{v} \times \vec{B}$.

Examples of the direction of the forces exerted on moving charged particles when the magnetic field vector $\vec{B}$ is in the vertical direction are shown in Figure 26-3.

The direction of any particular magnetic field $\vec{B}$ can be found experimentally by measuring $\vec{F}$ and $\vec{v}$ for several velocities in different directions and then applying Equation 26-1.

Equation 26-1 defines the **magnetic field** $\vec{B}$ in terms of the force exerted on a moving charged particle. The SI unit of magnetic field is the **tesla** (T). A particle that has a charge of one coulomb and is moving with a velocity of one meter per second perpendicular to a magnetic field of one tesla experiences a force of one newton:

$$1\ \text{T} = 1\frac{\text{N}}{\text{C}\cdot\text{m/s}} = 1\ \text{N/(A}\cdot\text{m)} \qquad 26\text{-}2$$

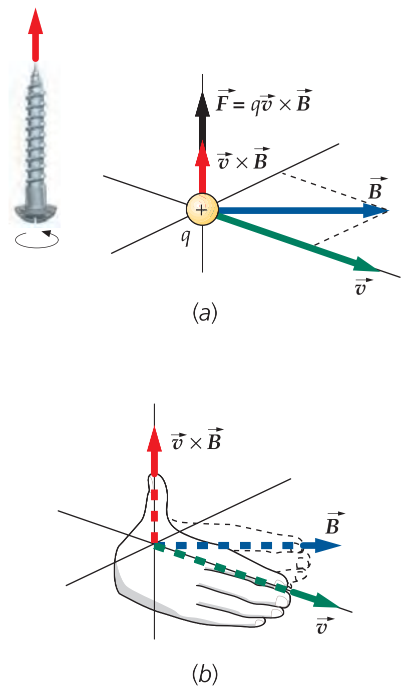

FIGURE 26-2 Right-hand rule for determining the direction of a force exerted on a charged particle moving in a magnetic field. If q is positive, then $\vec{F}$, is in the same direction as $\vec{v} \times \vec{B}$. (*a*) The vector product $\vec{v} \times \vec{B}$ is perpendicular to both $\vec{v}$ and $\vec{B}$ and is in the direction of the advance of a right-hand-threaded screw if turned in the same direction as to rotate $\vec{v}$ into $\vec{B}$. (*b*) If the fingers of the right hand are in the direction of $\vec{v}$ so that they can be curled toward $\vec{B}$, the thumb points in the direction of $\vec{v} \times \vec{B}$.

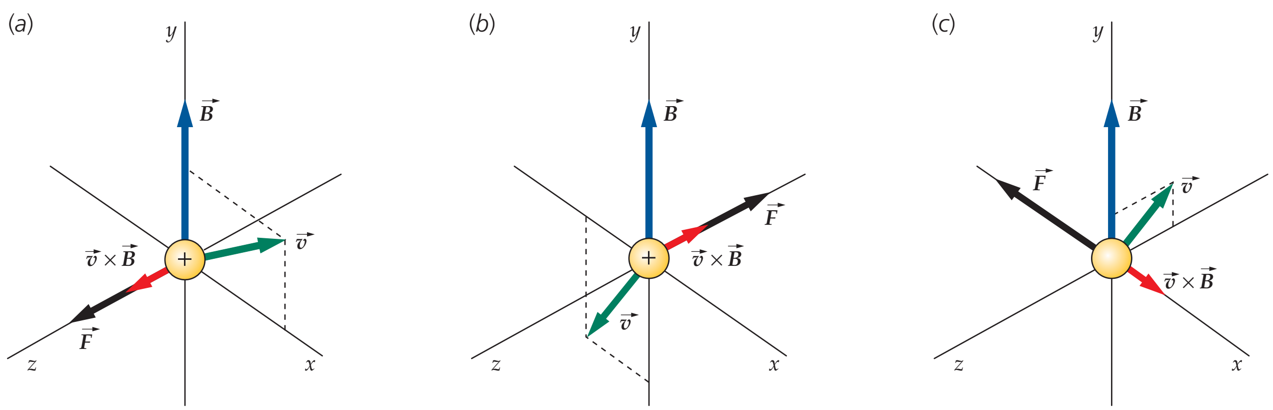
FIGURE 26-3 Part (*a*) and (*b*) show the direction of the magnetic force on a positively charged particle moving with velocity $\vec{v}$ in a magnetic field $\vec{B}$. In Concept Check 26-2 (see page 889), you are asked to find the sign of the charge on the particle shown in part (*c*) of this figure.



* Compass needles are suspended so they remain horizontal. This results in the compass needle aligning itself in the horizontal component of the magnetic field. A compass needle with an unrestricted suspension would align itself in the magnetic field.

CONCEPT CHECK 26-1

The direction of any magnetic field $\vec{B}$ is specified as the direction that the north pole of a compass needle points toward when the needle is aligned in the field. Suppose that the direction of the magnetic field $\vec{B}$ were instead specified as the direction pointed toward by the south pole of a compass needle aligned in the field. Would the right-hand rule shown in Figure 26-2 then give the direction of the magnetic force on the moving positive charge, or would a left-hand rule be required? Explain your answer.

CONCEPT CHECK 26-2

The particle in Figure 26-3(*c*) (*a*) is positively charged, (*b*) is negatively charged, (*c*) could be either positively or negatively charged. Explain your answer.

Like the farad, the tesla is a large unit. The magnetic field strength of Earth has a magnitude somewhat less than 10^{-4} T on Earth's surface. The magnetic field strengths near powerful permanent magnets are about 0.1 T to 0.5 T, and powerful laboratory and industrial electromagnets produce fields of 1 T to 2 T. Fields greater than 10 T are extremely difficult to produce because the resulting magnetic forces will either tear the magnets apart or crush the magnets. A commonly used unit, derived from the cgs system, is the **gauss** (G), which is related to the tesla as follows:

$$1\ \text{G} = 10^{-4}\ \text{T} \tag{26-3}$$

DEFINITION—GAUSS

Because magnetic fields are often given in gauss, which is not an SI unit, you need to remember to convert from gauss to teslas when making calculations.

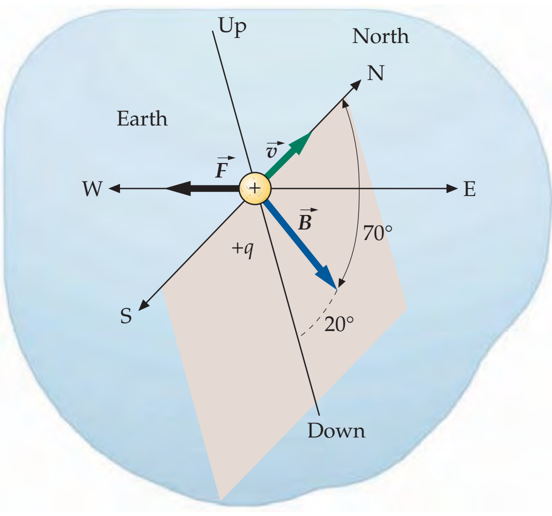


FIGURE 26-4

Example 26-1 Force on a Proton Going North

The magnetic field strength of Earth is measured at a point on the surface to have a magnitude of about 0.6 G and is tilted downward in the northern hemisphere, making an angle of about 70° with the horizontal, as shown in Figure 26-4. (Earth's magnetic field varies from place to place. These data are approximately correct for the central United States.) A proton ($q = +e$) is moving horizontally in the northward direction with speed $v = 1.0 \times 10^7$ m/s. Calculate the magnetic force on the proton (*a*) using $F = qvB\sin\theta$ and (*b*) by first expressing $\vec{v}$ and $\vec{B}$ in terms of the unit vectors $\hat{i}$, $\hat{j}$, and $\hat{k}$, and then computing $\vec{F} = q\vec{v} \times \vec{B}$.

PICTURE Let the x and y directions be to the east and to the north, respectively, and let the z direction be vertically upward (Figure 26-5). The velocity vector is then in the $+y$ direction.

SOLVE

(*a*) Calculate $F = qvB\sin\theta$ using $\theta = 70°$. From Figure 26-4, we see that the direction of the force is westward.

$$F = qvB\sin 70°$$
$$= (1.6 \times 10^{-19}\ \text{C})(10 \times 10^6\ \text{m/s})(0.6 \times 10^{-4}\ \text{T})(0.94)$$
$$= \boxed{9.0 \times 10^{-17}\ \text{N}}$$

(*b*) 1. The magnetic force is the vector product of $q\vec{v}$ and $\vec{B}$:

$$\vec{F} = q\vec{v} \times \vec{B}$$

2. Express $\vec{v}$ and $\vec{B}$ in terms of their components:

$$\vec{v} = v_y\hat{j}$$
$$\vec{B} = B_y\hat{j} + B_z\hat{k}$$

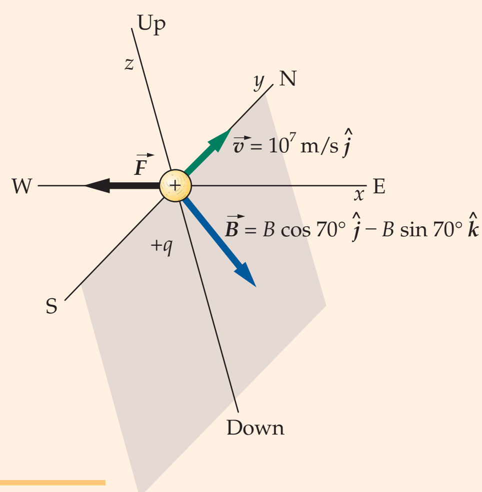

FIGURE 26-5

3. Write $\vec{F} = q\vec{v} \times \vec{B}$ in terms of these components:

$$\vec{F} = q\vec{v} \times \vec{B} = q(v_y\hat{j}) \times (B_y\hat{j} + B_z\hat{k})$$
$$= qv_yB_y(\hat{j} \times \hat{j}) + qv_yB_z(\hat{j} \times \hat{k}) = qv_yB_z\hat{i}$$

4. Evaluate $\vec{F}$:

$$\vec{F} = qv(-B\sin\theta)\hat{i}$$
$$= -(1.6 \times 10^{-19}\,\mathrm{C})(10^{7}\,\mathrm{m/s})(0.6 \times 10^{-4}\,\mathrm{T})\sin 70^\circ\ \hat{i}$$
$$= \boxed{-9.0 \times 10^{-17}\,\mathrm{N}\,\hat{i}}$$

CHECK The Part (*a*) result is equal to the magnitude of the Part (*b*) result.

TAKING IT FURTHER Note that the direction of $\hat{i}$ is to the east, so the force is directed to the west as shown in Figure 26-5.

PRACTICE PROBLEM 26-1 Find the force on a proton moving with velocity $\vec{v} = 4 \times 10^6\,\mathrm{m/s}\ \hat{i}$ in a magnetic field $\vec{B} = 2.0\,\mathrm{T}\,\hat{k}$.

When a current-carrying wire is in a region that has a magnetic field, there is a force on the wire that is equal to the sum of the magnetic forces on the individual charge carriers in the wire. Figure 26-6 shows a short segment of wire that has cross-sectional area A, length L, and current I. If the wire is in a magnetic field $\vec{B}$, the magnetic force on each charge is $q\vec{v}_d \times \vec{B}$, where $\vec{v}_d$ is the drift velocity of the charge carriers (the drift velocity is the same as the average velocity). The number of charges in the wire segment is the number n per unit volume multiplied by the volume AL. Thus, the total force on the wire segment is

$$\vec{F} = (q\vec{v}_d \times \vec{B})nAL$$

From Equation 25-3, the current in the wire is

$$I = nqv_dA$$

Hence, the force can be written

$$\vec{F} = I\vec{L} \times \vec{B} \qquad 26\text{-}4$$

MAGNETIC FORCE ON A STRAIGHT SEGMENT OF CURRENT-CARRYING WIRE

where $\vec{L}$ is a vector whose magnitude is the length of the segment and whose direction is the same as that of the current.* For the current in the $+x$ direction (Figure 26-7) and the magnetic field vector at the segment in the xy plane, the force on the wire is in the $+z$ direction.

When using Equation 26-4, it is assumed that the wire segment is straight and that the magnetic field does not vary over its length. The equation can be generalized for an arbitrarily shaped wire in any magnetic field. If we choose a very short wire segment that has length $d\vec{\ell}$ and write the force on this segment as $d\vec{F}$, we have

$$d\vec{F} = I\,d\vec{\ell} \times \vec{B} \qquad 26\text{-}5$$

MAGNETIC FORCE ON A CURRENT ELEMENT

where $\vec{B}$ is the magnetic field vector at the location of the segment. The quantity $I\,d\vec{\ell}$ is called a **current element.** We find the total magnetic force on a current-carrying wire by summing (integrating) the magnetic forces due to all the current elements in the wire. (Note that Equation 26-5 is the same as Equation 26-1 with the current element $I\,d\vec{\ell}$ replacing $q\vec{v}$.)

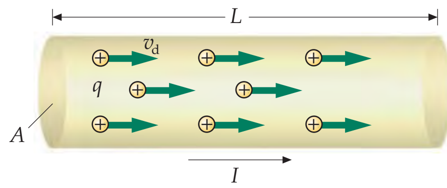

FIGURE 26-6 Wire segment that has a length L and carries a current I. If the wire is in a magnetic field $\vec{B}$, there will be a force on each charge carrier resulting in a force on the wire.

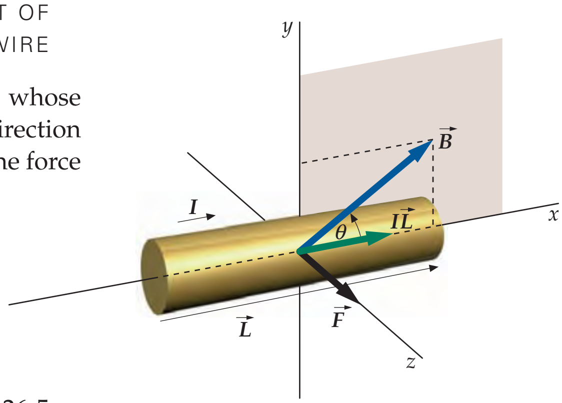

FIGURE 26-7 Magnetic force on a current-carrying segment of wire in a magnetic field. The current is in the x direction, and the magnetic field is in the xy plane and makes an angle θ with the $+x$ direction. The force $\vec{F}$ is in the $+z$ direction, perpendicular to both $\vec{B}$ and $\vec{L}$, and has magnitude $ILB\sin\theta$.

* By the direction of the current we mean the direction of the current-density vector $\vec{J}$.

Just as the electric field $\vec{E}$ can be represented by electric field lines, the magnetic field $\vec{B}$ can be represented by **magnetic field lines.** In both cases, the direction of the field is indicated by the direction of the field lines and the magnitude of the field is indicated by the density (number per unit area) of the lines on surface perpendicular to the lines. There are, however, two important differences between electric field lines and magnetic field lines:

1. Electric field lines are in the direction of the electric force on a positive charge, but the magnetic field lines are perpendicular to the magnetic force on a moving charge.
2. Electric field lines begin on positive charges and end on negative charges; magnetic field lines neither begin nor end.

Figure 26-8 shows the magnetic field lines both inside and outside a bar magnet.

! Do not think the field lines for the magnetic field of a magnet begin on magnetic south poles and end on magnetic north poles. In reality, they neither begin nor end. Instead they enter the magnet at one end and exit the magnet at the other end.

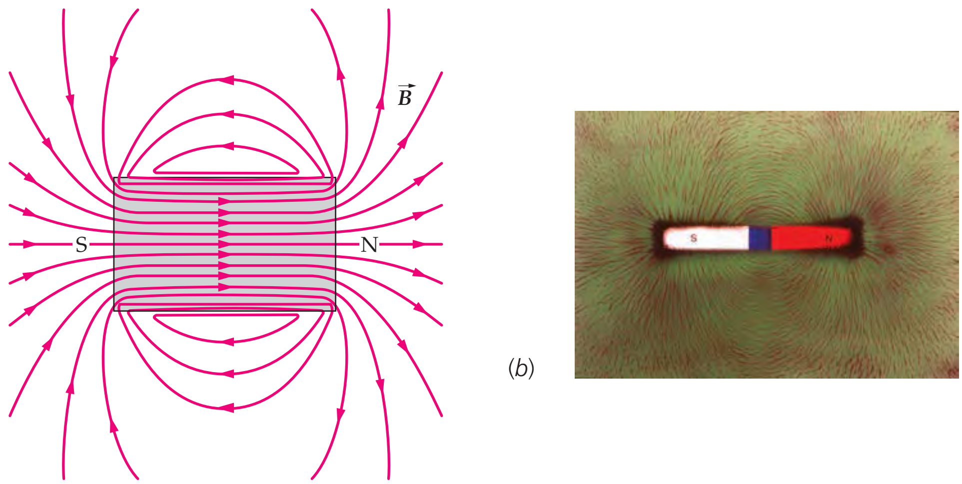

FIGURE 26-8 (*a*) Magnetic field lines inside and outside a bar magnet. The lines emerge from the north pole and enter the south pole, but they have no beginning or end. Instead, they form closed loops. (*b*) Magnetic field lines outside a bar magnet as indicated by iron filings. *(© 1995 Tom Pantages.)*

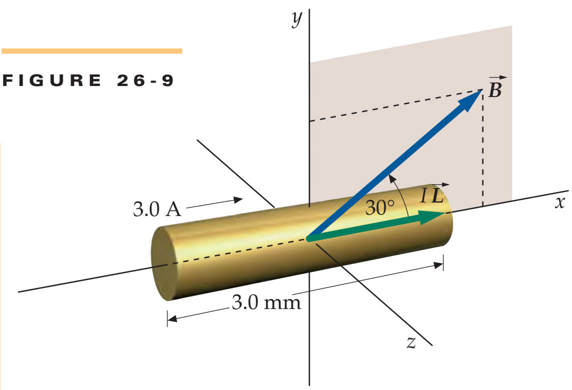
Example 26-2 Force on a Straight Wire

A 3.0-mm-long segment of wire carries a current of 3.0 A in the $+x$ direction. It lies in a magnetic field of magnitude 0.020 T that is in the xy plane and makes an angle of 30° with the $+x$ direction, as shown in Figure 26-9. What is the magnetic force exerted on the wire segment?

FIGURE 26-9



PICTURE The magnetic force is in the direction of $\vec{L} \times \vec{B}$, which we see from Figure 26-9 is in the $+z$ direction.

SOLVE

1. The magnetic force is given by Equation 26-4:

$$\vec{F} = I\vec{L} \times \vec{B} = ILB \sin 30^\circ\,\hat{k}$$
$$= (3.0\text{ A})(0.0030\text{ m})(0.020\text{ T})(\sin 30^\circ)\hat{k}$$
$$= \boxed{9.0 \times 10^{-5}\text{ N}\hat{k}}$$

CHECK The force is perpendicular to the wire, as expected.

Example 26-3 Force on a Bent Wire

A wire bent into a semicircular loop of radius R lies in the xy plane. It carries a current I from point a to point b, as shown in Figure 26-10. Throughout the region there is a uniform magnetic field $\vec{B} = B\hat{k}$ that is perpendicular to the plane of the loop. Find the magnetic force acting on the semicircular loop section of the wire.

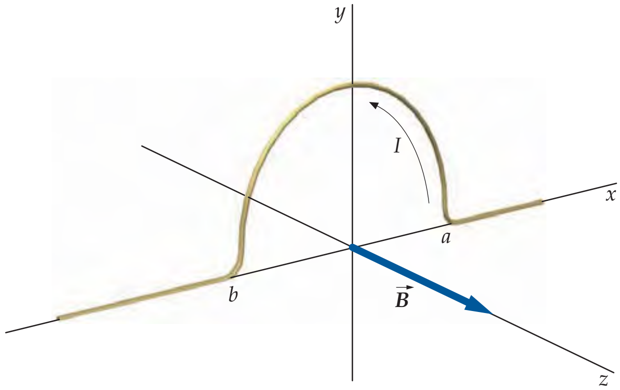


FIGURE 26-10

PICTURE The magnetic force $d\vec{F}$ is exerted on a segment of the semicircular wire that lies in the xy plane, as shown in Figure 26-11. We find the total magnetic force by expressing the x and y components of $d\vec{F}$ in terms of θ and integrating them separately from $\theta = 0$ to $\theta = \pi$.

SOLVE

1. Write the force $d\vec{F}$ on a current element $I\,d\vec{\ell}$.
$$d\vec{F} = I\,d\vec{\ell} \times \vec{B}$$

2. Express $d\vec{\ell}$ in terms of the unit vectors $\hat{i}$ and $\hat{j}$:
$$d\vec{\ell} = -d\ell\,\sin\theta\,\hat{i} + d\ell\,\cos\theta\,\hat{j}$$

3. Compute $I\,d\vec{\ell}$ using $d\ell = R\,d\theta$ and $\vec{B} = B\hat{k}$:
$$\begin{aligned} d\vec{F} &= I\,d\vec{\ell} \times \vec{B} \\ &= I(-R\sin\theta\,d\theta\,\hat{i} + R\cos\theta\,d\theta\,\hat{j}) \times B\hat{k} \\ &= IRB\sin\theta\,d\theta\,\hat{j} + IRB\cos\theta\,d\theta\,\hat{i} \end{aligned}$$

4. Integrate each component of $d\vec{F}$ from $\theta = 0$ to $\theta = \pi$.
$$\begin{aligned} \vec{F} &= \int d\vec{F} = IRB\hat{i}\int_0^\pi \cos\theta\,d\theta + IRB\hat{j}\int_0^\pi \sin\theta\,d\theta \\ &= IRB\hat{i}(0) + IRB\hat{j}(2) = \boxed{2IRB\hat{j}} \end{aligned}$$

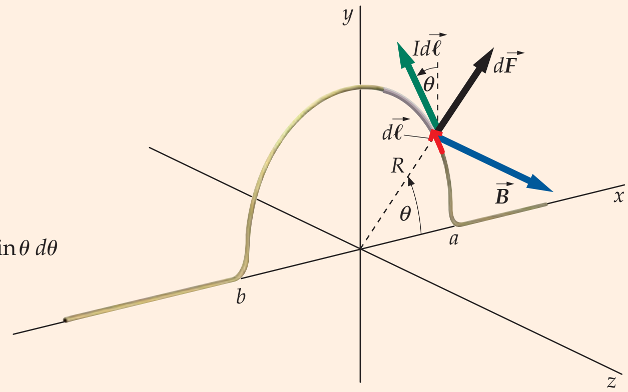

FIGURE 26-11

CHECK The result that the x component of $\vec{F}$ is zero can be seen from symmetry. For the right half of the loop, $d\vec{F}$ tilts to the right; for the left half of the loop, $d\vec{F}$ tilts to the left.

TAKING IT FURTHER The net force on the semicircular wire is the same as if the semicircle were replaced by a straight-line segment of length $2R$ connecting points a and b. (This is a general result that is derived in Problem 26.)

26-2 MOTION OF A POINT CHARGE IN A MAGNETIC FIELD

The magnetic force on a charged particle moving through a region with a magnetic field is always perpendicular to the velocity of the particle. The magnetic force thus changes the direction of the velocity but not the magnitude of the velocity (the speed). Therefore, *magnetic forces do no work on particles and do not change their kinetic energy*.

In the special case where the velocity of a charged particle is perpendicular to a uniform magnetic field, as shown in Figure 26-12, the particle moves in a circular orbit. The magnetic force provides the force in the centripetal direction that is necessary for circular motion. We can use Newton's second law to relate the radius of the circle to the magnetic field and the speed of the particle. If the velocity is $\vec{v}$, the magnetic force on a particle that has charge q is given by $\vec{F} = q\vec{v} \times \vec{B}$. The magnitude of the net force is equal to qvB, because $\vec{v}$ and $\vec{B}$ are perpendicular.

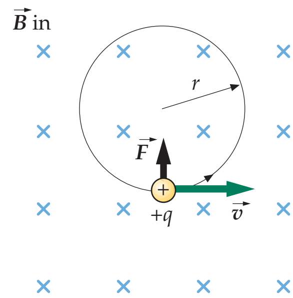

FIGURE 26-12 Charged particle moving in a plane perpendicular to a uniform magnetic field. The magnetic field is into the page as indicated by the crosses. (Each cross represents the tail feathers of an arrow. A field out of the plane of the page would be indicated by dots, each dot representing the point of an arrow.) The magnetic force is perpendicular to the velocity of the particle, causing it to move in a circular orbit.

Newton's second law gives

$$F = ma$$

$$qvB = m\frac{v^2}{r}$$

or

$$r = \frac{mv}{qB} \qquad 26\text{-}6$$

where m is the mass of the particle.

The period of the circular motion is the time it takes the particle to travel once around the circumference of the circle. The period is related to the speed by

$$T = \frac{2\pi r}{v}$$

Substituting $mv/(qB)$ for r (Equation 26-6), we obtain the period of the particle's circular orbit, which is called the **cyclotron period:**

$$T = \frac{2\pi(mv/qB)}{v} = \frac{2\pi m}{qB} \qquad 26\text{-}7$$

CYCLOTRON PERIOD

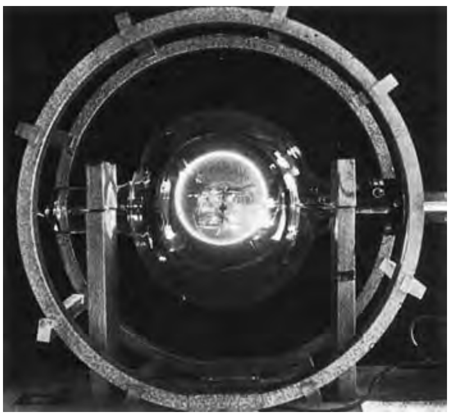
The frequency of the circular motion, called the **cyclotron frequency**, is the reciprocal of the period:

$$f = \frac{1}{T} = \frac{qB}{2\pi m} \quad \text{so} \quad \omega = 2\pi f = \frac{q}{m}B \qquad 26\text{-}8$$

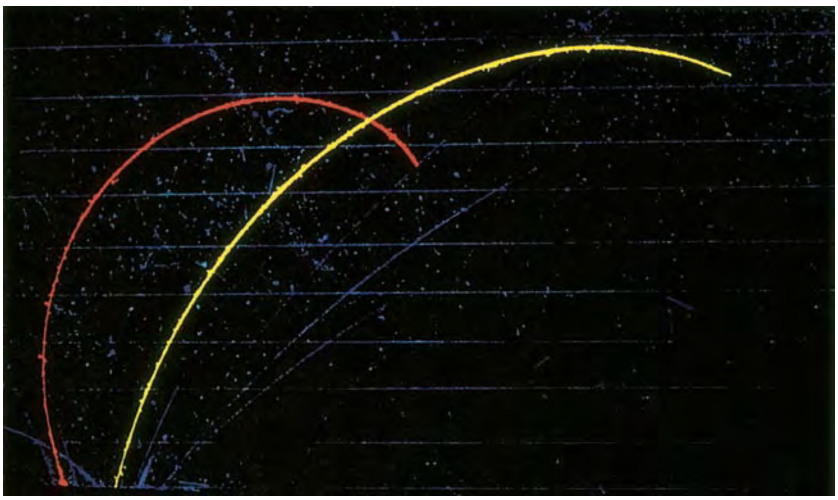
CYCLOTRON FREQUENCY

Note that the period and the frequency given by Equations 26-7 and 26-8 depend on the charge-to-mass ratio q/m, but the period and the frequency are independent of the velocity v or the radius r. Two important applications of the circular motion of charged particles in a uniform magnetic field, the mass spectrometer and the cyclotron, are discussed later in this section.

(*a*)



(*b*)



(*a*) Circular path of electrons moving in the magnetic field produced by the current in two large coils. The electrons ionize the dilute gas in the tube, causing it to give off a glow that indicates the path of the beam. (*b*) False-color photograph showing tracks of a 1.6-MeV proton (red) and a 7-MeVα particle (yellow) in a cloud chamber. The radius of curvature is proportional to the momentum and inversely proportional to the charge of the particle. For these energies, the momentum of the α particle, which has twice the charge of the proton, is about four times that of the proton and so its radius of curvature is greater. *((a) Larry Langrill. (b) © Lawrence Berkeley Laboratory/Science Photo Library.)*

Example 26-4 Cyclotron Period

A proton has a mass equal to 1.67×10^{-27} kg, has a charge equal to 1.60×10^{-19} C, and moves in a circle of radius $r = 21.0$ cm perpendicular to a magnetic field equal to 4000 G. Find (*a*) the speed of the proton and (*b*) the period of the motion.

PICTURE Apply Newton's second law to find the speed, and use distance equals speed multiplied by time to find the period.

SOLVE

(*a*) 1. Apply Newton's second law ($F = ma$):

$$F = ma \quad \Rightarrow \quad qvB = m\frac{v^2}{r}$$

2. Solve for the speed:

$$v = \frac{rqB}{m} = \frac{(0.210\text{ m})(1.60 \times 10^{-19}\text{ C})(0.400\text{ T})}{1.67 \times 10^{-27}\text{ kg}}$$

$$= \boxed{8.05 \times 10^6\text{ m/s} = 0.0268c}$$

(*b*) Use distance equals speed multiplied by time and solve for the period:

$$2\pi r = vT$$

so

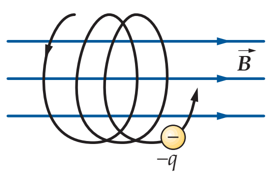
$$T = \frac{2\pi r}{v} = \frac{2\pi(0.210\text{ m})}{(8.05 \times 10^6\text{ m/s})} = 1.64 \times 10^{-7}\text{ s} = \boxed{164\text{ ns}}$$

TAKING IT FURTHER The radius of the circular orbit is proportional to the speed, but the period of the orbit is independent of both the speed and radius.

Suppose that a charged particle is in a region that has a uniform magnetic field and is moving with a velocity that is not perpendicular to $\vec{B}$. There is no magnetic force component, and thus no acceleration component, parallel to $\vec{B}$, so the component of the velocity that is parallel to $\vec{B}$ remains constant. The magnetic force on the particle is perpendicular to $\vec{B}$, so the change in motion of the particle due to this force is the same as that just discussed. The path of the particle is thus a helix, as shown in Figure 26-13.

The motion of charged particles in nonuniform magnetic fields can be quite complex. Figure 26-14 shows a *magnetic bottle,* an interesting magnetic field configuration in which the field is weak at the center and strong at both ends. A detailed analysis of the motion of a charged particle in such a field shows that the particle spirals around the field lines and becomes trapped, oscillating back and forth between points P_1 and P_2 in the figure. Such magnetic field configurations are used to confine dense beams of charged particles, called plasmas, in nuclear fusion research. A similar phenomenon is the oscillation of ions back and forth between Earth's magnetic poles in the Van Allen belts (Figure 26-15).

(*a*)



(*b*)

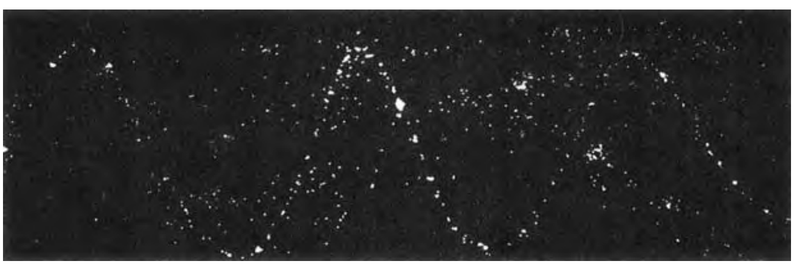


FIGURE 26-13 (*a*) When a particle has a velocity component parallel to a magnetic field as well as a velocity component perpendicular to the magnetic field the particle moves in a helical path around the field lines. (*b*) Cloud-chamber photograph of the helical path of an electron moving in a magnetic field. The path of the electron is made visible by the condensation of water droplets in the cloud chamber. *(Carl E. Nielson.)*

Review Helix

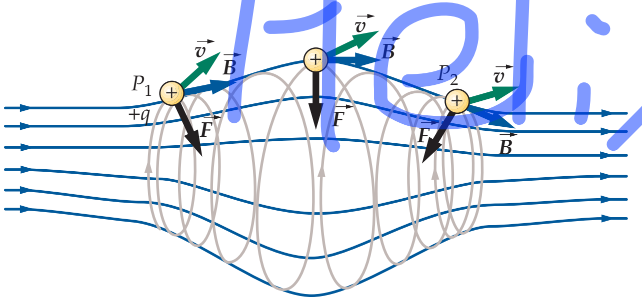

FIGURE 26-14 Magnetic bottle. When a charged particle moves in such a field, which is strong at both ends and weak in the middle, the particle becomes trapped and moves back and forth, spiraling around the field lines.

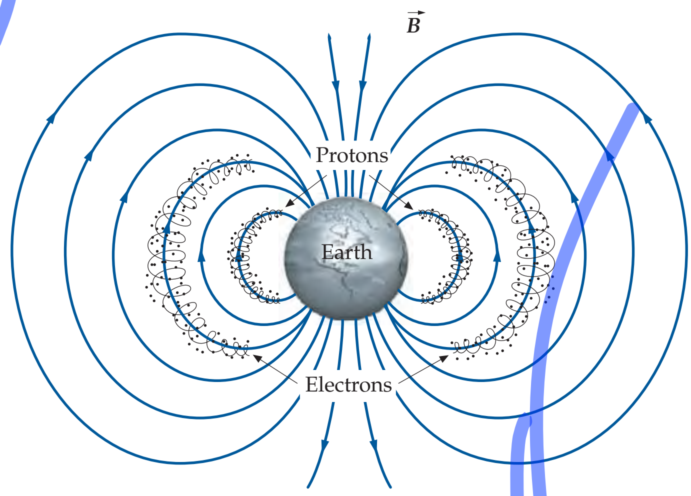

FIGURE 26-15 Van Allen belts. Protons (inner belts) and electrons (outer belts) are trapped in Earth's magnetic field and spiral around the field lines between the north and south poles.

*THE VELOCITY SELECTOR

The magnetic force on a charged particle moving in a uniform magnetic field can be balanced by an electric force if the magnitudes and directions of the magnetic field and the electric field are properly chosen. Because the electric force is in the direction of the electric field (for particles with positive charge) and the magnetic force is perpendicular to the magnetic field, the electric and magnetic fields in the region through which the particle is moving must be perpendicular to each other if the forces are to balance. Such a region is said to have **crossed fields.**

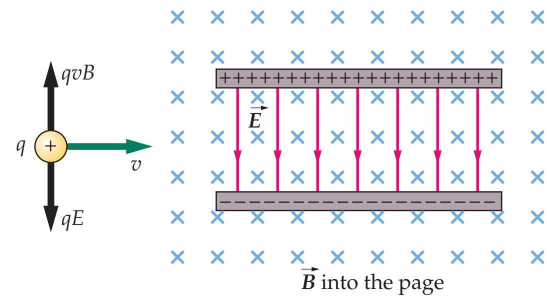

FIGURE 26-16 Crossed electric and magnetic fields. When a particle that has a positive charge moves to the right, the particle experiences a downward electric force and an upward magnetic force. These forces balance if the speed of the particle is related to the field strengths by $vB = E$.

Figure 26-16 shows a region of space between the plates of a capacitor where there is an electric field and a perpendicular magnetic field (produced by a magnet that has one pole on each side of this sheet of paper). Consider a particle that has charge q entering this space from the left. The net force on the particle is

$$\vec{F} = q\vec{E} + q\vec{v} \times \vec{B}$$

If q is positive, the electric force of magnitude qE is down the page and the magnetic force of magnitude qvB is up the page. If the charge is negative, the direction of each of these forces is reversed. The two forces balance if $qE = qvB$ that is, if

$$v = \frac{E}{B} \qquad \text{26-9}$$

For given magnitudes of the electric and magnetic fields, the forces balance only for particles that have the exact speed given by Equation 26-9. Any particle that has this speed, regardless of its mass or charge, will traverse the space undeflected. A particle that has a greater speed will be deflected toward the direction of the magnetic force, and a particle that has a lesser speed will be deflected in the direction of the electric force. This arrangement of fields is often used as a **velocity selector,** which is a device that allows only particles with the speed specified by Equation 26-9 to pass.

PRACTICE PROBLEM 26-2

A proton is moving in the $+x$ direction in a region of crossed fields where $\vec{E} = 2.00 \times 10^5$ N/C $\hat{k}$ and $\vec{B} = 0.300$ T $\hat{j}$. (*a*) What is the speed of the proton if it is not deflected? (*b*) If the proton moves with twice this speed, in which direction will it be deflected?

*THOMSON'S MEASUREMENT OF q/m FOR ELECTRONS

An example of the use of crossed electric and magnetic fields is the famous experiment performed by J. J. Thomson in 1897 where he showed that the rays of a cathode-ray tube can be deflected by electric and magnetic fields, indicating that they must consist of charged particles. By measuring the deflections of these particles, Thomson showed that all the particles have the same charge-to-mass ratio q/m. He also showed that particles that have this charge-to-mass ratio can be obtained using any material for a source, which means that these particles, now called electrons, are a fundamental constituent of all matter.

Figure 26-17 shows a schematic diagram of the cathode-ray tube Thomson used. Electrons are emitted from the cathode C, which is at a negative potential relative to the potential at slits A and B. An electric field in the direction from A toward C accelerates the electrons, and some of the electrons pass through slits A and B into a field-free region. The electrons then enter the electric field between the capacitor plates D and F that is perpendicular to the velocity of the electrons. This field accelerates the electrons vertically for the short time that they are between the plates. The electrons are deflected and strike the phosphorescent screen S at the far right side of the tube at some deflection Δy from the point at which they strike when there is no electric field between the plates. The screen glows where the electrons strike the screen, indicating the location of the beam. The speed of the electrons v_0 is determined by introducing a magnetic field $\vec{B}$ between the plates in a direction that is perpendicular to both the electric field and the initial velocity of the electrons. The magnitude of $\vec{B}$ is adjusted until the beam is not deflected. The speed is then found from Equation 26-9.

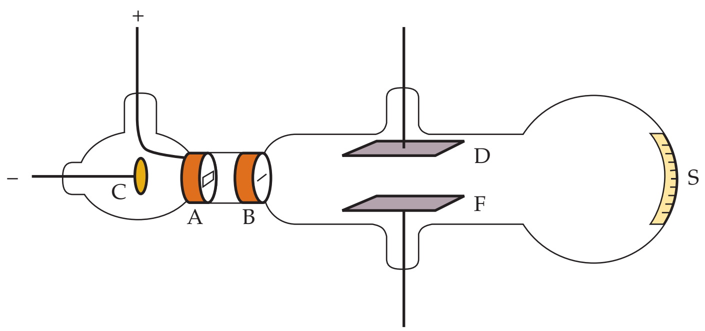

FIGURE 26-17 Thomson's tube for measuring q/m for the particles of cathode rays (electrons). Electrons from the cathode C pass through the slits at A and B and strike a phosphorescent screen S. The beam can be deflected by an electric field between plates D and F or by a magnetic field (not shown).

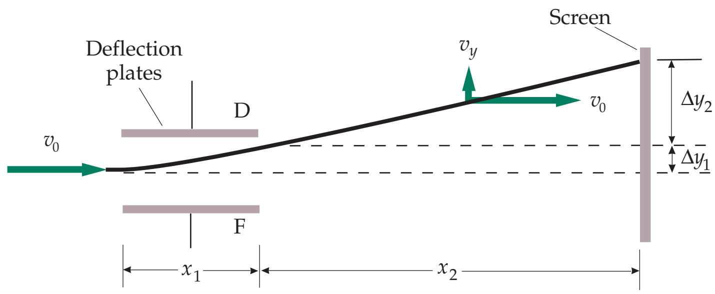

FIGURE 26-18 The total deflection of the beam in the J. J. Thomson experiments consists of the deflection Δy_1 while the electrons are between the plates plus the deflection Δy_2 that occurs in the field-free region between the plates and the screen.

With the magnetic field turned off, the beam is deflected by an amount Δy, which consists of two parts: the deflection Δy_1, which occurs while the electrons are between the plates, and the deflection Δy_2, which occurs after the electrons leave the region between the plates (Figure 26-18).

Let x_1 be the horizontal distance across the deflection plates D and F. If the electron is moving horizontally with speed v_0 when it enters the region between the plates, the time spent between the plates is $t_1 = x_1/v_0$, and the vertical velocity when it leaves the plates is

$$v_y = a_y t_1 = \frac{qE_y}{m} t_1 = \frac{qE_y}{m}\frac{x_1}{v_0}$$

where E_y is the upward component of the electric field between the plates. The deflection in this region is

$$\Delta y_1 = \frac{1}{2} a_y t_1^2 = \frac{1}{2}\frac{qE_y}{m}\left(\frac{x_1}{v_0}\right)^2$$

The electron then travels an additional horizontal distance x_2 in the field-free region from the deflection plates to the screen. Because the velocity of the electron is constant in this region, the time to reach the screen is $t_2 = x_2/v_0$, and the additional vertical deflection is

$$\Delta y_2 = v_y t_2 = \frac{qE_y}{m}\frac{x_1}{v_0}\frac{x_2}{v_0}$$

The total deflection at the screen is therefore

$$\Delta y = \Delta y_1 + \Delta y_2 = \frac{1}{2}\frac{qE_y}{mv_0^2}x_1^2 + \frac{qE_y}{mv_0^2}x_1 x_2 \qquad \text{26-10}$$

The measured deflection Δy can be used to determine the charge-to-mass ratio, q/m, from Equation 26-10.

Example 26-5 Electron Beam Deflection

Electrons pass undeflected through the plates of Thomson's apparatus when the electric field is 3000 V/m and there is a crossed magnetic field of 0.140 mT. If the plates are 4.00 cm long and the ends of the plates are 30.0 cm from the screen, find the deflection on the screen when the magnetic field is turned off.

PICTURE The mass and charge of the electron are known: $m = 9.11 \times 10^{-31}$ kg and $q = -e = -1.60 \times 10^{-19}$ C. The speed of the electron can be found from the ratio of the magnetic and electric fields.

SOLVE

1. The total deflection of the electron is given by Equation 26-10:

$$\Delta y = \Delta y_1 + \Delta y_2 = \frac{1}{2}\frac{qE_y}{mv_0^2}x_1^2 + \frac{qE_y}{mv_0^2}x_1 x_2$$

2. The speed v_0 equals E/B:

$$v_0 = \frac{E}{B} = \frac{3000\text{ V/m}}{1.40 \times 10^{-4}\text{ T}} = 2.14 \times 10^7\text{ m/s}$$

3. Substitute the value for v_0 determined in step 2, the given value of E, and the known values for m and q into Equation 26-10 to find Δy:

$$\Delta y_1 = \frac{1}{2}\frac{(-1.60 \times 10^{-19}\text{ C})(-3000\text{ V/m})}{(9.11 \times 10^{-31}\text{ kg})(2.14 \times 10^7\text{ m/s})^2}(0.0400\text{ m})^2 = 9.20 \times 10^{-4}\text{ m}$$

$$\Delta y_2 = \frac{(-1.60 \times 10^{-19}\text{ C})(-3000\text{ V/m})}{(9.11 \times 10^{-31}\text{ kg})(2.14 \times 10^7\text{ m/s})^2}(0.0400\text{ m})(0.300\text{ m}) = 1.38 \times 10^{-2}\text{ m}$$

$$\Delta y = \Delta y_1 + \Delta y_2 = 9.20 \times 10^{-4}\text{ m} + 1.38 \times 10^{-2}\text{ m} = 0.92\text{ mm} + 13.8\text{ mm} = \boxed{14.7\text{ mm}}$$

CHECK As expected, Δy_2 is an order of magnitude greater than Δy_1. This was expected because the distance from the plates to the screen is an order of magnitude greater than the length of the plates.

*THE MASS SPECTROMETER

The **mass spectrometer,** first designed by Francis William Aston in 1919, was developed as a means of measuring the masses of isotopes. Such measurements are important in determining both the presence of isotopes and their abundance in nature. On Earth, for example, naturally occurring magnesium has been found to consist of 78.7 percent ^{24}Mg, 10.1 percent ^{25}Mg, and 11.2 percent ^{26}Mg. These isotopes have masses in the approximate ratio 24:25:26.

Figure 26-19 shows a simple schematic drawing of a mass spectrometer. Positive ions are formed by bombarding atoms with X rays or a beam of electrons. (Electrons are knocked out of the atoms by the X rays or bombarding electrons to form positive ions.) The ions are accelerated by an electric field and enter a uniform magnetic field. If the positive ions start from rest and move through a potential difference ΔV, the ions' kinetic energy when they enter the magnetic field equals their loss in potential energy, $q|\Delta V|$:

$$\tfrac{1}{2}mv^2 = q|\Delta V| \qquad \text{26-11}$$

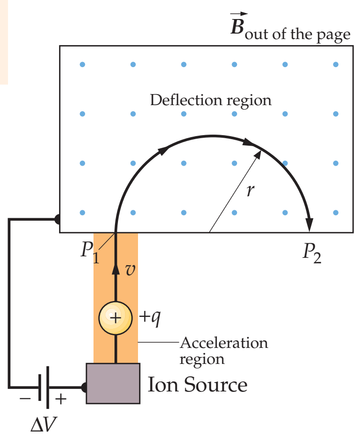

FIGURE 26-19 Schematic drawing of a mass spectrometer. Positive ions from an ion source are accelerated through a potential difference ΔV and enter a uniform magnetic field at P_1. The magnetic field is out of the plane of the page as indicated by the dots. The ions are bent into a circular arc and emerge at P_2. The radius r of the circle varies with the mass of the ion.

The ions move in a semicircle of radius r given by Equation 26-6, $r = mv/qB$, and strike a photographic plate at point P_2, a distance $2r$ from the point P_1 where the ions entered the magnetic field.

The speed v can be eliminated from Equations 26-6 and 26-11 to find m/q in terms of the known quantities V, B, and r. We first solve Equation 26-6 for v and square each term, which gives

$$v^2 = \frac{r^2q^2B^2}{m^2}$$

Substituting this expression for v^2 into Equation 26-11, we obtain

$$\frac{1}{2}m\left(\frac{r^2q^2B^2}{m^2}\right) = q|\Delta V|$$

Simplifying this equation and solving for m/q, we obtain

$$\frac{m}{q} = \frac{B^2r^2}{2|\Delta V|} \qquad \text{26-12}$$

In Aston's original mass spectrometer, mass differences could be measured to a precision of about 1 part in 10,000. The precision has been improved by introducing a velocity selector between the ion source and the magnet, which increases the degree of accuracy with which the speeds of the incoming ions can be determined.

Example 26-6 Separating Isotopes of Nickel

A ^{58}Ni ion that has a charge equal to $+e$ and a mass equal to 9.62×10^{-26} kg is accelerated through a potential drop of 3.00 kV and deflected in a magnetic field of 0.120 T. (*a*) Find the radius of curvature of the orbit of the ion. (*b*) Find the difference in the radii of curvature of ^{58}Ni ions and ^{60}Ni ions. (Assume that the mass ratio is 58:60.)

PICTURE The radius of curvature r can be found using Equation 26-12. Using the mass dependence of r, we can find the radius of curvature for the orbit of the ^{60}Ni ions from the radius of curvature for the orbit of the ^{58}Ni ions, and then take the difference between the two radii.

SOLVE

(*a*) Solve Equation 26-12 for r:

$$r = \sqrt{\frac{2m|\Delta V|}{qB^2}} = \left[\frac{2(9.62 \times 10^{-26}\text{ kg})(3000\text{ V})}{(1.60 \times 10^{-19}\text{ C})(0.120\text{ T})^2}\right]^{1/2}$$
$$= \boxed{0.501\text{ m}}$$

(*b*) 1. Let r_1 and r_2 be the radius of the orbit of the ^{58}Ni ion and the ^{60}Ni ion, respectively. Use the result in Part (*a*) to find the ratio of r_2 to r_1:

$$\frac{r_2}{r_1} = \sqrt{\frac{m_2}{m_1}} = \sqrt{\frac{60}{58}} = 1.017$$

2. Use the result of the previous step to calculate r_2 for ^{60}Ni:

$$r_2 = 1.017r_1 = (1.017)(0.501\text{ m}) = 0.510\text{ m}$$

3. The difference in orbital radii is $r_2 - r_1$:

$$r_2 - r_1 = 0.510\text{ m} - 0.501\text{ m} = \boxed{9\text{ mm}}$$

CHECK The difference in the orbital radii is less than 2 percent of the radius of curvature of either orbit. This result is expected for two ions whose masses differ by less than 4 percent.

THE CYCLOTRON

The cyclotron was invented by E. O. Lawrence and M. S. Livingston in 1934 to accelerate particles, such as protons or deuterons, to large kinetic energies.* The high-energy particles are used to bombard atomic nuclei, causing nuclear reactions that

* A deuteron is the nucleus of heavy hydrogen, ^{2}H, which consists of a proton and neutron tightly bound together.

are then studied to obtain information about nuclei. High-energy protons and deuterons are also used to produce radioactive materials and for medical purposes.

Figure 26-20 is a schematic drawing of a cyclotron. The particles move in two semicircular metal containers called *dees* (because they are the shape of the letter "D"). The dees are housed in a vacuum chamber that is in a region with a uniform magnetic field provided by an electromagnet. The region in which the particles move must be evacuated so that the particles will not be scattered in collisions with air molecules. A potential difference ΔV, which alternates in time with a period T, is maintained between the dees. The period is chosen to be the cyclotron period $T = 2\pi m/(qB)$ (Equation 26-7). The potential difference creates an electric field across the gap between the dees. At the same time, there is no electric field within each dee because the metal dees act as shields.

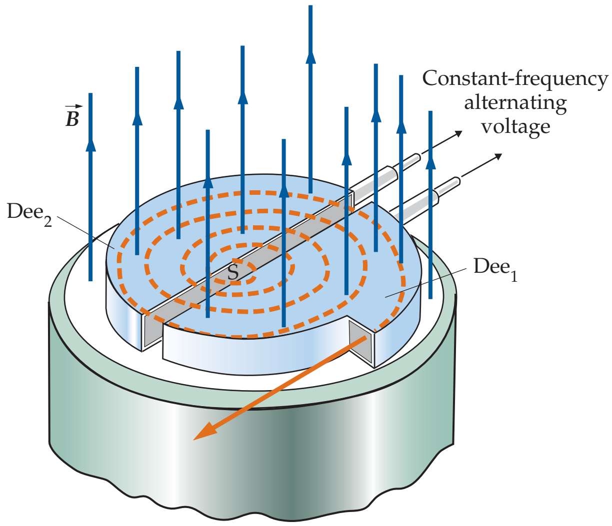

FIGURE 26-20 Schematic drawing of a cyclotron. The upper-pole face of the magnet has been omitted. Charged particles, such as protons, are accelerated from a source S at the center by the potential difference across the gap between the dees. When the charged particles arrive at the gap again the potential difference has changed sign so they are again accelerated across the gap and move in a larger circle. The potential difference across the gap alternates with the cyclotron frequency of the particle, which is independent of the radius of the circle.

Positively charged particles are initially injected into dee$_1$ with a small velocity from an ion source S near the center of the dees. They move in a semicircle in dee$_1$ and arrive at the gap between dee$_1$ and dee$_2$ after a time $\frac{1}{2}T$. The potential is adjusted so that dee$_1$ is at a higher potential than dee$_2$ when the particles arrive at the gap between them. Each particle is therefore accelerated across the gap by the electric field and gains kinetic energy equal to $q\Delta V$.

Because the particle now has more kinetic energy, the particle moves in a semicircle of larger radius in dee$_2$. It arrives at the gap again after a time $\frac{1}{2}T$, because the period is independent of the particle's speed. By this time, the potential difference between the dees has been reversed so that dee$_2$ is now at the higher potential. Once more the particle is accelerated across the gap and gains additional kinetic energy equal to $q\Delta V$. Each time the particle arrives at the gap, it is accelerated and gains kinetic energy equal to $q\Delta V$. Thus, the particle moves in larger and larger semicircular orbits until it eventually leaves the magnetic field. In the typical cyclotron, each particle may make 50 to 100 revolutions and exit with energies of up to several hundred megaelectron volts.

The kinetic energy of a particle leaving a cyclotron can be calculated by setting r in Equation 26-6 equal to the maximum radius of the dees and solving the equation for v:

$$r = \frac{mv}{qB} \quad \Rightarrow \quad v = \frac{qBr}{m}$$

Then

$$K = \frac{1}{2}mv^2 = \frac{1}{2}\left(\frac{q^2B^2}{m}\right)r^2 \qquad \text{26-13}$$

Example 26-7 Energy of Accelerated Proton

A cyclotron for accelerating protons has a magnetic field of 0.150 T and a maximum radius of 0.500 m. (*a*) What is the cyclotron frequency? (*b*) What is the kinetic energy of the protons when they emerge?

PICTURE Apply Newton's second law ($F = ma$) with $F = |q\vec{v} \times \vec{B}|$. Use $v = r\omega$ and solve for the frequency and the speed.

SOLVE

(*a*) 1. Apply $F = ma$, where F is the magnetic force and a is the centripetal acceleration. Substitute ωr for v and solve for ω:

$$F = ma$$

$$qvB = m\frac{v^2}{r}$$

$$q\omega rB = m\frac{\omega^2 r^2}{r}$$

$$\omega = \frac{qB}{m} = \frac{(1.60 \times 10^{-19}\ \text{C})(0.150\ \text{T})}{1.67 \times 10^{-27}\ \text{kg}}$$

$$= 1.44 \times 10^7\ \text{rad/s}$$

2. Use $2\pi f = \omega$ to calculate the frequency in cycles per second (hertz):

$$f = \frac{\omega}{2\pi} = \frac{1.44 \times 10^7\ \text{rad/s}}{2\pi\ \text{rad}}$$

$$= 2.29 \times 10^6\ \text{Hz} = \boxed{2.29\ \text{MHz}}$$

(*b*) 1. Calculate the kinetic energy:

$$K = \frac{1}{2}mv^2 = \frac{1}{2}m\omega^2 r^2$$

$$= \frac{1}{2}(1.67 \times 10^{-27}\ \text{kg})(1.44 \times 10^7\ \text{rad/s})^2(0.500\ \text{m})^2$$

$$= 4.33 \times 10^{-14}\ \text{J}$$

2. The energies of protons and other elementary particles are usually expressed in electron volts. Use $1\ \text{eV} = 1.60 \times 10^{-19}\ \text{J}$ to convert to eV:

$$K = 4.33 \times 10^{-14}\ \text{J} \times \frac{1\ \text{eV}}{1.60 \times 10^{-19}\ \text{J}} = \boxed{271\ \text{keV}}$$

CHECK The exit speed of the proton is $v = r\omega = (0.500\ \text{m})(1.44 \times 10^7\ \text{rad/s}) = 7.20 \times 10^6\ \text{m/s}$. The speed of light is $3.00 \times 10^8\ \text{m/s}$. Our calculated value of 1.44×10^7 rad/s for the angular frequency is plausible because it is a high speed that is less than ten percent of the speed of light.

26-3 TORQUES ON CURRENT LOOPS AND MAGNETS

A current-carrying loop experiences no net force in a uniform magnetic field, but it does experience a net torque. The orientation of the loop can be described conveniently by a unit vector $\hat{n}$ that is normal to the plane of the loop, as illustrated in Figure 26-21. If the fingers of the right hand curl around the loop in the direction of the current, the thumb points in the direction of $\hat{n}$.

Figure 26-22 shows the forces exerted by a uniform magnetic field on a rectangular current-carrying loop whose vector $\hat{n}$ makes an angle θ with the direction of the magnetic field $\vec{B}$. The net force on the loop is zero. The forces $\vec{F}_1$ and $\vec{F}_2$ have the magnitude

$$F_1 = F_2 = IaB$$

The forces form a couple, so the torque they exert is the same about any point. Point P in Figure 26-22 is a convenient point about which to compute the torque. The magnitude of the torque is

$$\tau = F_2 b \sin\theta = IaBb \sin\theta = IAB \sin\theta$$

where $A = ab$ is the area of the loop. For a loop that has N turns, the torque has the magnitude

$$\tau = NIAB \sin\theta$$

This torque tends to twist the loop so that $\hat{n}$ is in the same direction as $\vec{B}$.

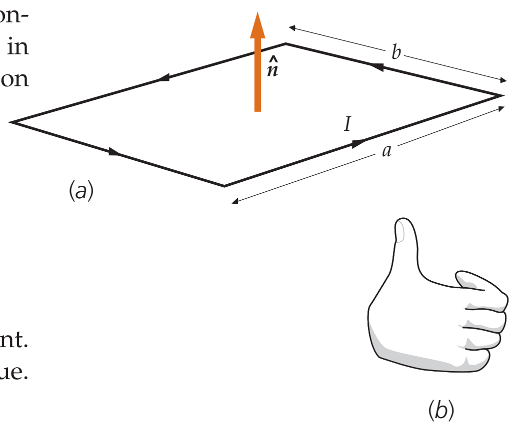

FIGURE 26-21 (*a*) The orientation of a current loop is described by the unit vector $\hat{n}$ perpendicular to the plane of the loop. (*b*) Right-hand rule for determining the direction of $\hat{n}$. If the fingers of the right hand curl around the loop in the direction of the current, the thumb points in the direction of $\hat{n}$.

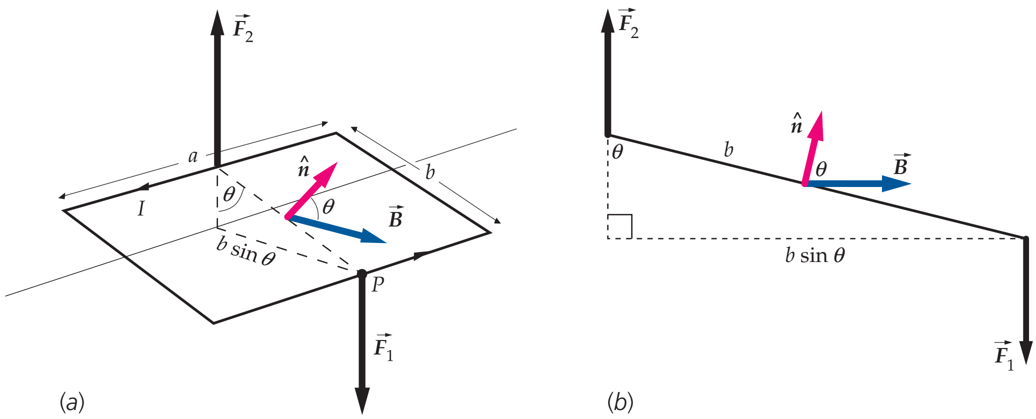

FIGURE 26-22 (*a*) Rectangular current loop whose unit normal $\hat{n}$ makes an angle θ with a uniform magnetic field $\vec{B}$. (*b*) An edge-on view of the current loop. The torque on the loop has magnitude $IAB \sin\theta$ and is in the direction such that $\hat{n}$ tends to rotate so as to align itself with $\vec{B}$.

The torque can be written conveniently in terms of the **magnetic dipole moment** $\vec{\mu}$ (also referred to simply as the **magnetic moment**) of the current loop, which is defined as

$$\vec{\mu} = NIA\hat{n} \qquad 26\text{-}14$$

MAGNETIC DIPOLE MOMENT OF A CURRENT LOOP

The SI unit of magnetic moment is the ampere-square meter ($A \cdot m^2$). In terms of the magnetic dipole moment, the torque on the current loop is given by

$$\vec{\tau} = \vec{\mu} \times \vec{B} \qquad 26\text{-}15$$

TORQUE ON A CURRENT LOOP

Equation 26-15, which we have derived for a rectangular loop, holds in general for a loop of any shape that lies in a single plane. The torque on any such loop is the vector product of the magnetic moment $\vec{\mu}$ of the loop and the magnetic field $\vec{B}$, where the magnetic moment (Figure 26-23) is defined as a vector that has a magnitude equal to NIA and has the same direction as $\hat{n}$. Comparing Equation 26-15 with Equation 21-11 ($\vec{\tau} = \vec{p} \times \vec{E}$) for the torque on an electric dipole, we see that the expression for the torque on a magnetic dipole in a magnetic field has the same form as that for the torque on an electric dipole in an electric field.

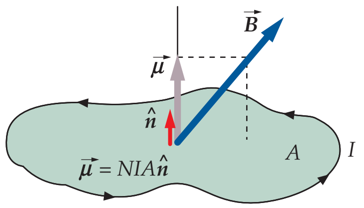

FIGURE 26-23 A flat current loop of arbitrary shape is described by its magnetic moment $\vec{\mu} = NIA\hat{n}$. In a magnetic field $\vec{B}$, the loop experiences a torque $\vec{\mu} \times \vec{B}$.

Example 26-8 Torque on a Current Loop

A circular loop has a radius equal to 2.00 cm, has 10 turns of wire, and carries a current equal to 3.00 A. The axis of the loop makes an angle of 30.0° with a magnetic field of 8000 G. Find the magnitude of the torque on the loop.

PICTURE The torque on a current loop is given by $\vec{\tau} = \vec{\mu} \times \vec{B}$ (Equation 26-15) where $\vec{\mu} = NIA\hat{n}$ (Equation 26-14).

SOLVE

The magnitude of the torque is given by Equation 26-15:

$$\begin{aligned}\tau &= |\vec{\mu} \times \vec{B}| = \mu B \sin\theta = NIAB \sin\theta \\ &= (10.0)(3.00\text{ A})\pi(0.0200\text{ m})^2(0.800\text{ T})\sin 30.0° \\ &= \boxed{1.51 \times 10^{-2}\text{ N}\cdot\text{m}}\end{aligned}$$

CHECK From $\vec{F} = I\vec{L} \times \vec{B}$ (Equation 26-4) we can see that the SI unit for magnetic field (the tesla) must have units of $N/(A \cdot m)$. With this in mind, one can see by inspection that the units for the right-hand side of the equation in the solution work out to $N \cdot m$, which are SI units for torque.

Example 26-9 Tilting a Loop

Try It Yourself

A circular wire loop that has a radius R, a mass m, and a current I lies on a horizontal surface (Figure 26-24). There is a horizontal magnetic field $\vec{B}$. How large can the current I be before one edge of the loop will lift off the surface?

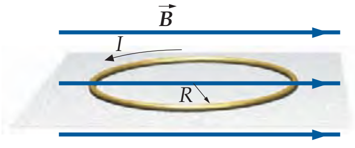

FIGURE 26-24

PICTURE The loop (Figure 26-25) will start to rotate when the magnitude of the net torque on the loop is greater than zero. To eliminate the torque due to the normal force, we calculate torques about the point of contact between the surface and the loop. The magnetic torque is given by $\vec{\tau} = \vec{\mu} \times \vec{B}$. The magnetic torque is the same about any point because the magnetic torque consists of couples. The lever arm for the gravitational torque is the radius of the loop.

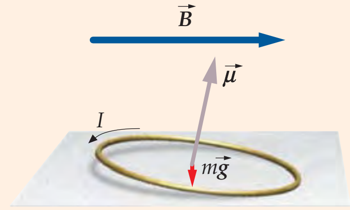

FIGURE 26-25

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. Find the magnitude of the magnetic torque acting on the loop.	$\tau_m = \mu B \sin(90°) = I\pi R^2 B$
2. Find the magnitude of the gravitational torque exerted on the loop.	$\tau_g = mgR$
3. Equate the magnitudes of the torques and solve for the current I.	$I = \boxed{\dfrac{mg}{\pi RB}}$

CHECK The current is directly proportional to the mass for constant B, which makes sense. The larger the mass, the more current is needed to start to rotate the ring.

POTENTIAL ENERGY OF A MAGNETIC DIPOLE IN A MAGNETIC FIELD

When a torque is exerted on a rotating object, work is done. When a magnetic dipole is rotated through an angle $d\theta$, the work done is

$$dW = -\tau\, d\theta = -\mu B \sin\theta\, d\theta$$

where θ is the angle between $\vec{\mu}$ and $\vec{B}$. The minus sign arises because the magnetic torque tends to decrease θ. Setting this work equal to the decrease in potential energy U, we have

$$dU = -dW = +\mu B \sin\theta\, d\theta$$

Integrating, we obtain

$$U = -\mu B \cos\theta + U_0$$

We choose the potential energy to be zero when $\theta = 90°$. Then $U_0 = 0$ and the potential energy of the dipole is given by

$$U = -\mu B \cos\theta = -\vec{\mu} \cdot \vec{B} \qquad 26\text{-}16$$

POTENTIAL ENERGY OF A MAGNETIC DIPOLE

Equation 26-16 gives the potential energy of a magnetic dipole at an angle θ to the direction of a magnetic field.

Example 26-10 Torque on a Coil

A square 12-turn coil has an edge-length equal to 40.0 cm and carries a current of 3.00 A. It lies in the $z = 0$ plane, as shown in a uniform magnetic field $\vec{B} = 0.300\text{ T}\,\hat{i} + 0.400\text{ T}\,\hat{k}$. The current is counterclockwise when viewed from a point on the positive z axis. Find (*a*) the magnetic moment of the coil and (*b*) the torque exerted on the coil. (*c*) Find the potential energy of the coil.

PICTURE From Figure 26-26, we see that the magnetic moment of the loop is in the $+z$ direction.

SOLVE

(a) Calculate the magnetic moment of the loop:

$$\vec{\mu} = NIA\hat{k} = (12)(3.00\text{ A})(0.400\text{ m})^2\hat{k} = \boxed{5.76\text{ A}\cdot\text{m}^2\,\hat{k}}$$

(b) The torque on the current loop is given by Equation 26-15:

$$\vec{\tau} = \vec{\mu}\times\vec{B} = (5.76\text{ A}\cdot\text{m}^2\,\hat{k})\times(0.300\text{ T}\,\hat{i} + 0.400\text{ T}\,\hat{k}) = \boxed{1.73\text{ N}\cdot\text{m}\,\hat{j}}$$

(c) The potential energy is the negative dot product of $\vec{\mu}$ and $\vec{B}$:

$$U = -\vec{\mu}\cdot\vec{B} = -(5.76\text{ A}\cdot\text{m}^2\,\hat{k})\cdot(0.300\text{ T}\,\hat{i} + 0.400\text{ T}\,\hat{k}) = \boxed{-2.30\text{ J}}$$

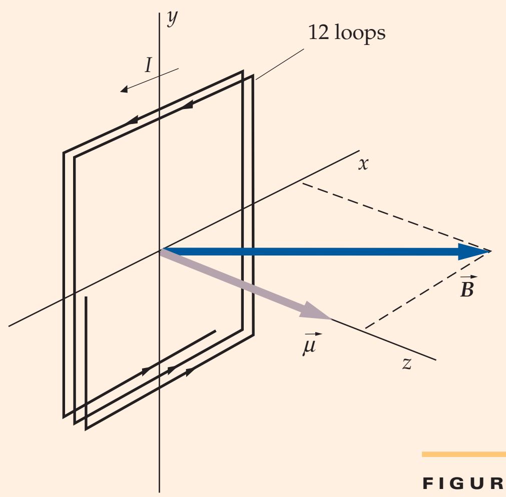

FIGURE 26-26

CHECK The torque in the Part (*b*) result is perpendicular to both the magnetic moment vector and the magnetic field vector, as is expected for a vector product.

PRACTICE PROBLEM 26-3 The potential energy of a current-carrying coil in a uniform magnetic field $\vec{B}$ is equal to zero when the angle between the magnetic dipole moment of the coil $\vec{\mu}$ and the magnetic field is 90°. Calculate the potential energy of the system if the coil is oriented so $\vec{B}$ and $\vec{\mu}$ are (*a*) in the same direction and (*b*) in opposite directions.

When a permanent magnet, such as a compass needle or a bar magnet, is placed in a region where there is a magnetic field $\vec{B}$, the field exerts a torque on the magnet that tends to rotate the magnet so that it lines up with the field. (This effect also occurs with previously unmagnetized iron filings, which become magnetized in the presence of a field $\vec{B}$.) The bar magnet is characterized by a magnetic moment $\vec{\mu}$, a vector that points in the same direction as an arrow drawn from the south pole of the magnet to the north pole of the magnet. A short bar magnet thus behaves like a current loop.

Example 26-11 $\vec{\mu}$ of a Spinning Disk

A thin nonconducting disk that has a mass m, a radius a, and a uniform surface charge per unit area σ spins with angular velocity $\vec{\omega}$ about an axis through the center of the disk and perpendicular to the plane of the disk. Find the magnetic moment of the spinning disk.

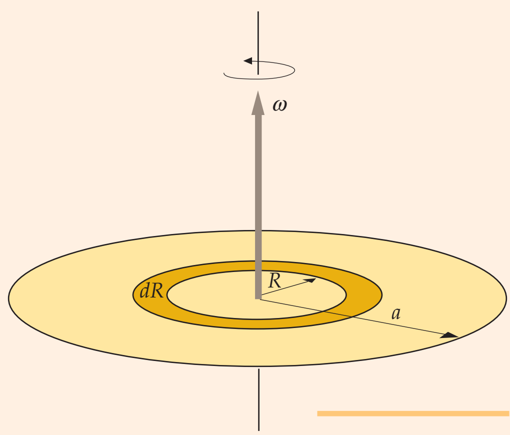

FIGURE 26-27

PICTURE We find the magnetic moment of a circular element that has a radius R and a width dR and integrate (Figure 26-27). The charge on the element is $dq = \sigma\,dA = \sigma 2\pi R\,dR$. If the charge is positive, the magnetic moment is in the direction of $\vec{\omega}$, so we need only calculate its magnitude.

SOLVE

1. The magnitude of the magnetic moment of the strip shown is the current multiplied by the area of the loop:

$$d\mu = A\,dI = \pi R^2\,dI$$

2. The current in the strip is the total charge dq on the strip divided by the period T. During one period the charge dq passes by a point not rotating with the strip. The period is equal to the reciprocal of the frequency f of rotation $1/T = f = \omega/(2\pi)$:

$$dI = \frac{dq}{T} = \frac{\omega}{2\pi}dq = \frac{\omega}{2\pi}\sigma\,dA = \frac{\omega}{2\pi}\sigma 2\pi R\,dR = \sigma\omega R\,dR$$

3. Substitute to obtain the magnitude of the magnetic moment of the strip $d\mu$ in terms of r and dr:

$$d\mu = \pi R^2\,dI = \pi R^2\sigma\omega R\,dR = \pi\sigma\omega R^3\,dR$$

4. Integrate from $r = 0$ to $r = a$:

$$\mu = \int_0^a \pi\sigma\omega R^3\,dR = \frac{1}{4}\pi\sigma\omega a^4$$

5. Use the fact that $\vec{\mu}$ is parallel to $\vec{\omega}$ (if σ is positive) to express the magnetic moment as a vector:

$$\vec{\mu} = \boxed{\tfrac{1}{4}\pi\sigma a^4\vec{\omega}}$$

CHECK Consider a thin spinning ring, also of radius a, carrying the same charge, $Q = \sigma\pi a^2$, as the disk. The magnitude of the magnetic moment of the ring is given by $\mu = IA = \frac{Q}{T}\pi a^2 = \frac{\sigma\pi a^2}{2\pi/\omega}\pi a^2 = \frac{1}{2}\pi\sigma a^4\omega$, which is twice the step-5 result. The step-5 result is smaller than the magnitude of the magnetic moment of the ring, which is what one would expect.

TAKING IT FURTHER In terms of the total charge $Q = \sigma\pi a^2$, the magnetic moment is $\vec{\mu} = \frac{1}{4}Qa^2\vec{\omega}$. The angular momentum of the disk is $\vec{L} = (\frac{1}{2}ma^2)\vec{\omega}$, so the magnetic moment can be written $\vec{\mu} = \frac{Q}{2m}\vec{L}$, which is a more general result. (See Problem 57.)

26-4 THE HALL EFFECT

As we have seen, charges moving in a region where there is a magnetic field each experience a force perpendicular to their motion. When these charges are traveling in a conducting wire, they will be pushed to one side of the wire. This results in a separation of charge in the wire—a phenomenon called the **Hall effect.** This phenomenon allows us to determine the sign of the charge on the charge carriers and the number of charge carriers per unit volume n in a conductor. The Hall effect also provides a convenient method for measuring magnetic fields.

Figure 26-28 shows two conducting strips; each conducting strip carries a current I to the right because the left sides of the strips are connected to the positive terminal of a battery and the right sides are connected to the negative terminal. A magnetic field $\vec{B}$ is directed into the paper. Let us suppose the current in the strip is due to positively charged particles moving to the right, as shown in Figure 26-28*a*. On average, the magnetic force on these particles is $q\vec{v}_d \times \vec{B}$ (where $\vec{v}_d$ is the drift velocity). This force is directed up the page. The positively charged particles therefore move up the page to the top edge of the strip, leaving the bottom edge of the strip with an excess negative charge. This separation of charge produces an electric field $\vec{E}$ in the strip that exerts a force on the particles that opposes the magnetic force on them. When the electric and magnetic forces balance, the charge carriers no longer drift up the page. Because the electric field points in the direction of decreasing potential, the upper edge of the strip is at a higher potential than is the lower edge of the strip. This potential difference can be measured using a sensitive voltmeter.

On the other hand, suppose the current is due to negatively charged particles moving to the left, as shown in Figure 26-28*b*. (The negatively charged particles in the strip must move to the left because the current, as before, is to the right.) The magnetic force $q\vec{v}_d \times \vec{B}$ is again up the page, because the signs of both q and the direction of $\vec{v}_d$ have been reversed. Again the carriers are forced to the upper edge of the strip, but the upper edge of the strip now carries a negative charge (because the charge carriers are negative) and the lower edge of the strip now carries a positive charge.

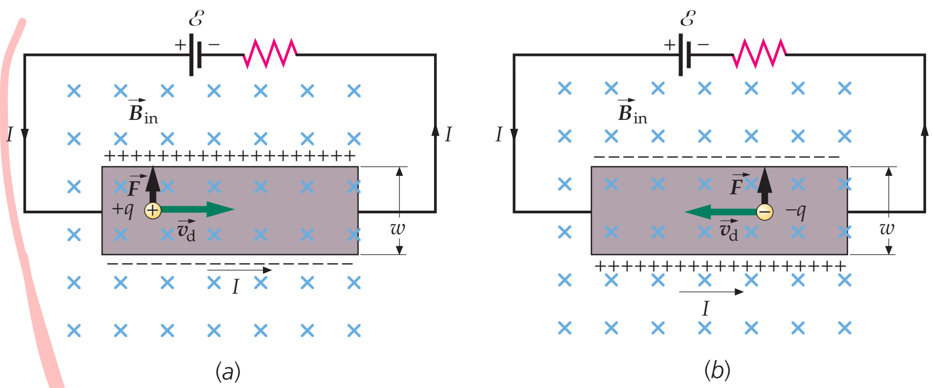

FIGURE 26-28 The Hall effect. The magnetic field is directed into the plane of the page as indicated by the crosses. The magnetic force on a charged particle is upward for a current to the right whether the current is due to (*a*) positive particles moving to the right or (*b*) negative particles moving to the left.

A measurement of the sign of the potential difference between the upper and lower parts of the strip tells us the sign of the charge carriers. In semiconductors, the charge carriers may be negative electrons or positive "holes." A measurement of the sign of the potential difference tells us which are dominant for a particular semiconductor. For a metal strip, we find that the upper edge of the strip in Figure 26-28*b* is at a lower potential than is the lower edge of the strip—which means that the upper part must carry a negative charge. Thus, Figure 26-28*b* is the correct illustration of the current in a metal strip. It was a measurement like this which led to the discovery that the charge carriers in metals are negatively charged.

The potential difference between the top of the strip and the bottom of the strip is called the **Hall voltage**. We can calculate the magnitude of the Hall voltage in terms of the drift velocity. The magnitude of the magnetic force on the charge carriers in the strip is qv_dB. This magnetic force is balanced by the electrostatic force of magnitude qE_H, where E_H is the electric field due to the charge separation. Thus, we have $E_H = v_dB$. If the width of the strip is w, the potential difference is E_Hw. The Hall voltage is therefore

$$V_H = E_Hw = v_dBw \qquad 26\text{-}17$$

PRACTICE PROBLEM 26-4

A conducting strip of width $w = 2.0$ cm is placed in a magnetic field of 0.80 T. The Hall voltage is measured to be 0.64 μV. Calculate the drift velocity of the electrons.

Because the drift velocity for ordinary currents is very small, we can see from Equation 26-17 that the Hall voltage is very small for ordinary-sized strips and magnetic fields. From measurements of the Hall voltage for a strip of a given size, we can determine the number of charge carriers per unit volume in the strip.

The magnitude of the current is given by Equation 26-3:

$$|I| = |q|nv_{\mathrm{d}}A$$

where A is the cross-sectional area of the strip. For a strip of width w and thickness t, the cross-sectional area is $A = wt$. Because the charge carriers are electrons, the quantity $|q|$ is the charge on one electron e. The number density of charge carriers n is thus given by

$$n = \frac{|I|}{A|q|v_{\mathrm{d}}} = \frac{|I|}{wtev_{\mathrm{d}}} \qquad 26\text{-}18$$

Substituting V_{H}/B for $v_{\mathrm{d}}w$ (Equation 26-17), we have

$$n = \frac{|I|B}{teV_{\mathrm{H}}} \qquad 26\text{-}19$$

Example 26-12 Charge Carrier Number Density in Silver

A silver slab has a thickness equal to 1.00 mm, a width equal to 1.50 cm, and a current equal to 2.50 A in a region where there is a magnetic field of magnitude 1.25 T perpendicular to the slab. The Hall voltage is measured to be 0.334 μV. (*a*) Calculate the number density of the charge carriers. (*b*) Calculate the number density of atoms in silver, which has a mass density of $\rho = 10.5\ \mathrm{g/cm^3}$ and a molar mass of $M = 107.9\ \mathrm{g/mol}$, and compare the number density of atoms in silver with the Part (*a*) result.

PICTURE We can use Equation 26-19 to find the number density of charge carriers. The number density of atoms can be obtained from knowledge of the density and the molar mass.

SOLVE

(*a*) Substitute numerical values into Equation 26-19 to find n:

$$n = \frac{|I|B}{teV_{\mathrm{H}}} = \frac{(2.50\ \mathrm{A})(1.25\ \mathrm{T})}{(1.00 \times 10^{-3}\ \mathrm{m})(1.60 \times 10^{-19}\ \mathrm{C})(3.34 \times 10^{-7}\ \mathrm{V})}$$

$$= \boxed{5.85 \times 10^{28}\ \mathrm{electrons/m^3}}$$

(*b*) 1. The number of atoms per unit volume is $\rho N_{\mathrm{A}}/M$:

$$n_{\mathrm{a}} = \rho\frac{N_{\mathrm{A}}}{M} = (10.5\ \mathrm{g/cm^3})\frac{6.02 \times 10^{23}\ \mathrm{atoms/mol}}{107.9\ \mathrm{g/mol}}$$

$$= \boxed{5.86 \times 10^{22}\ \mathrm{atoms/cm^3} = 5.86 \times 10^{28}\ \mathrm{atoms/m^3}}$$

2. Compare the Part (*b*) step-1 result with the Part (*a*) result:

These results indicate that the number of charge carriers in silver is very nearly one per atom.

CHECK We should expect the number density of charge carriers and the number density of atoms in a metal to be the same order of magnitude. Our results validate that expectation.

The Hall voltage provides a convenient method for measuring magnetic fields. If we rearrange Equation 26-19, we can write for the Hall voltage

$$V_{\mathrm{H}} = \frac{|I|}{nte}B \qquad 26\text{-}20$$

A given strip can be calibrated by measuring the Hall voltage for a given current in a known magnetic field. The strip can then be used to measure an unknown magnetic field B by measuring the Hall voltage for a given current.

*THE QUANTUM HALL EFFECTS

According to Equation 26-20, the Hall voltage should increase linearly with magnetic field strength B for a given current in a given slab. In 1980, while studying the Hall effect in semiconductors at very low temperatures and very large magnetic fields, Klaus von Klitzing discovered that a plot of V_H versus B resulted in a series of plateaus, as shown in Figure 26-29, rather than a straight line. That is, the Hall voltage is quantized. For the discovery of the integer quantum Hall effect, von Klitzing won the Nobel Prize in Physics in 1985.

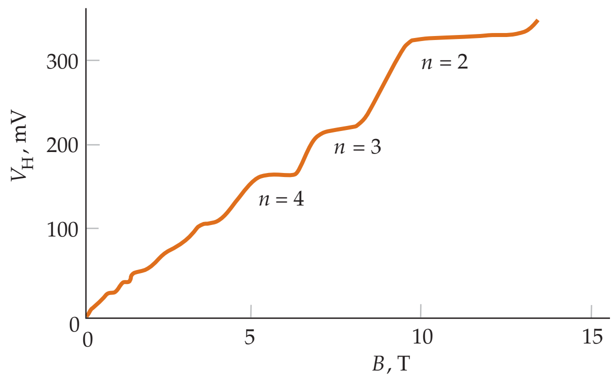

FIGURE 26-29 A plot of the Hall voltage versus applied magnetic field shows plateaus, indicating that the Hall voltage is quantized. The data were taken at a temperature of 1.39 K with the current I held fixed at 25.52 μA.

In the theory of the integer quantum Hall effect, the Hall resistance, defined as $R_H = V_H/I$, can take on only the values

$$R_H = \frac{V_H}{I} = \frac{R_K}{n} \qquad n = 1, 2, 3, \ldots \tag{26-21}$$

where n is an integer, and R_K, called the **von Klitzing constant,** is related to the fundamental electric charge e and Planck's constant h by

$$R_K = \frac{h}{e^2} \tag{26-22}$$

Because the von Klitzing constant can be measured to an accuracy of a few parts per billion, the quantum Hall effect is now used to define a standard of resistance. As of January 1990, the **ohm** is defined in terms of the conventional value* of the von Klitzing constant R_{K-90}, which has the value

$$R_{K-90} = 25\,812.8076\ \Omega \text{ (exact)} \tag{26-23}$$

In 1982, it was observed that under certain special conditions the Hall resistance is given by Equation 26-22 but with the integer n replaced by a series of rational fractions. This is called the *fractional quantum Hall effect*. For the discovery and explanation of the fractional quantum Hall effect, American professors Laughlin, Störmer, and Tsui won the Nobel Prize in Physics in 1998.

* The value of R_{K-90} differs only slightly from that of R_K. The currently used value of the von Klitzing constant is $R_K = (25\,812.807\,572 \pm 0.000\,095)\ \Omega$.

Physics Spotlight

Earth and the Sun—Magnetic Changes

Sunspots are regions where the magnetic field strength is very high. They are darker than the surrounding surface because the temperature in the sunspot is cooler than the temperature of the surrounding area. *(SOHO/NASA.)*

The magnetic fields of the Sun and Earth have been measured almost constantly in recent years by satellite and ground-based magnetic observatories.[*] Geologists and physicists have collaborated to study the paleomagnetic fields of both Earth[†] and the Sun.[‡] The paleomagnetic studies and the ongoing observations show that the magnetic fields of the Earth and Sun are continuously changing.

Earth's magnetic field has been used as a navigational aid for over 900 years.[#] Navigators were soon aware that magnetic north does not coincide with celestial north, and that the magnetic declination (the difference in direction between magnetic north and celestial north) varied from place to place. Measurements of magnetic declination taken in the same places dating from the sixteenth century[°] showed that the apparent location of magnetic north varied with time at the same place.[§] These measurements are the first evidence that Earth's magnetic field is dynamic.

In the 1960s, drill cores showed many layers of magnetic reversals in volcanic rocks.[¶] It became clear that Earth's magnetic field reverses around every 200 000 years, but there have been durations of over six million years during which there were no geomagnetic reversals. Immediately surrounding the reversal, the record shows that the field strength decreases, reverses, and then increases over a period of a few thousand years.[**] The last geomagnetic reversal was 700 000 years ago. Lately, Earth's magnetic field strength has been decreasing. From 1840 to the present, Earth's magnetic field has decreased by 15 nT/y,[††] which is a decrease of 3% per century, and reconstruction of data from ships' logs shows a decrease of about 2 nT/y from 1590 to 1840.

In the early twentieth century, G. E. Hale noted that sunspots, which had been observed for hundreds of years, had magnetic fields. He demonstrated that during a 22-year sunspot cycle, the Sun's magnetic field gradually decreased, reversed, increased, and returned back to the original configuration.[‡‡] Sunspots themselves have been measured with a magnetic field strength in excess of 200 mT.[##] Recent observation has shown that sunspots are magnetically powered vortices in the Sun. Although the surface of the Sun has an apparent average field of 0.10 mT in regions without sunspots, small areas of such regions have magnetic strengths varying from below 20 mT up to 100 mT.[°°]

The solar wind, which consists of charged sub-atomic particles ejected from the Sun at around 400 km/s,[§§] carries a magnetic field. Satellite data show that the interplanetary magnetic field is complex and dynamic.[¶¶,***] Near Earth, the strength of the interplanetary magnetic field varies between 1 and 37 nT. Sometimes, the Sun ejects a large burst of charged particles. When a large burst arrives at Earth's magnetic field, it causes a magnetic storm that can block radio communications and cause widespread power blackouts. The *Voyager 1* spacecraft was more than 94 AU from the Sun when it measured the strength of the interplanetary magnetic field as 0.03 nT.[†††,‡‡‡] The solar wind still carries a measurable magnetic field well beyond the orbit of Pluto.

Summary

1. The magnetic field describes the condition in space in which moving charges experience a force perpendicular to their velocity.
2. The magnetic force is part of the electromagnetic interaction, one of the three known fundamental interactions in nature.
3. The magnitude and direction of a magnetic field $\vec{B}$ are defined by the formula $\vec{F} = q\vec{v} \times \vec{B}$, where $\vec{F}$ is the force exerted on a particle with charge q moving with velocity $\vec{v}$.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Magnetic Force		
On a moving charge	$\vec{F} = q\vec{v} \times \vec{B}$	26-1
On a current element	$d\vec{F} = I\, d\vec{\ell} \times \vec{B}$	26-5
Unit of the magnetic field	The SI unit of magnetic fields is the tesla (T). A commonly used unit is the gauss (G), which is related to the tesla by $1\text{ G} = 10^{-4}\text{ T}$	26-3
2. Motion of Point Charges	A particle of mass m and charge q moving with speed v in a plane perpendicular to a uniform magnetic field moves in a circular orbit. The period and frequency of the circular motion are independent of the radius of the orbit and of the speed of the particle.	
Newton's second law	$qvB = m\dfrac{v^2}{r}$	26-6
Cyclotron period	$T = \dfrac{2\pi m}{qB}$	26-7
Cyclotron frequency	$f = \dfrac{1}{T} = \dfrac{qB}{2\pi m}$	26-8
*Velocity selector	A velocity selector consists of crossed electric and magnetic fields so that the electric and magnetic forces balance for a particle moving with speed v. $v = \dfrac{E}{B}$	26-9
*Thomson's measurement of q/m	The deflection of a charged particle in an electric field depends on the speed of the particle and is proportional to the charge-to-mass ratio q/m of the particle. J. J. Thomson used crossed electric and magnetic fields to measure the speed of cathode rays and then measured q/m for these particles by deflecting them in an electric field. He showed that all cathode rays consist of particles which all have the same charge-to-mass ratio. These particles are now called electrons.	
*Mass spectrometer	The mass-to-charge ratio of an ion of known speed can be determined by measuring the radius of the circular path taken by the ion in a known magnetic field.	
3. Current Loops		
Magnetic dipole moment	$\vec{\mu} = NIA\hat{n}$	26-14
Torque	$\vec{\tau} = \vec{\mu} \times \vec{B}$	26-15
Potential energy of a magnetic dipole	$U = -\vec{\mu} \cdot \vec{B}$	26-16
Net force	The net force on a current loop in a *uniform* magnetic field is zero.	

TOPIC	RELEVANT EQUATIONS AND REMARKS	
4. The Hall Effect	When a conducting strip carrying a current is placed in a magnetic field, the magnetic force on the charge carriers causes a separation of charge called the Hall effect. This results in a voltage V_H, called the Hall voltage. The sign of the charge carriers can be determined from a measurement of the sign of the Hall voltage, and the number of carriers per unit volume can be determined from the magnitude of V_H.	
Hall voltage	$V_H = E_H w = v_d B w = \frac{\lvert I \rvert}{nte} B$	26-17, 26-20
*Quantum Hall effects	Measurements at very low temperatures in very large magnetic fields indicate that the Hall resistance $R_H = V_H/I$ is quantized and can take on only the values given by $R_H = \frac{V_H}{I} = \frac{R_K}{n} \quad n = 1, 2, 3, \ldots$	26-21
*Conventional von Klitzing constant (definition of ohm)	$R_{K-90} = 25\,812.8076\ \Omega$ (exact)	26-23

Answers to Concept Checks

26-1 A left-hand rule is one way to answer the question. The definition for the direction of $\vec{B}$ is a convention. If the definition for the direction of $\vec{B}$ were changed as described in the question statement, a correct force law could be written $\vec{F} = q\vec{v} \otimes \vec{B}$, where the symbol $\otimes$ denotes the same operation as the symbol $\times$, except the product denoted by $\otimes$ requires using the left-hand rule instead of the right-hand rule. Alternatively, the force law could be revised to $\vec{F} = \vec{B} \times q\vec{v}$ and then you could stay with the right-hand rule.

26-2 (*b*) Negatively charged. The force $\vec{F}$ and the vector $\vec{v} \times \vec{B}$ are in opposite directions only if the particle is negatively charged. This is consistent with the relation $\vec{F} = q\vec{v} \times \vec{B}$.

Answers to Practice Problems

26-1 $-1.3 \times 10^{-12}\ \mathrm{N}\ \hat{j}$

26-2 (*a*) 667 km/s, (*b*) in the $-z$ direction

26-3 (*a*) -2.88 J. Note that this potential energy is lower than the potential energy calculated in the example. (The potential energy is lowest when $\vec{\mu}$ and $\vec{B}$ are in the same direction.) (*b*) $+2.88$ J

26-4 4.0×10^{-5} m/s

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • When the axis of a cathode-ray tube is horizontal in a region in which there is a magnetic field that is directed vertically upward, the electrons emitted from the cathode follow one of the dashed paths to the face of the tube in Figure 26-30. The correct path is (*a*) 1, (*b*) 2, (*c*) 3, (*d*) 4, (*e*) 5. SSM

2 •• We define the direction of the electric field to be the same as the direction of the force on a positive test charge. Why then do we *not* define the direction of the magnetic field to be the same as the direction of the magnetic force on a moving positive test charge?

3 • A *flicker bulb* is a lightbulb that has a long, thin flexible filament. It is meant to be plugged into an ac outlet that delivers current at a frequency of 60 Hz. There is a small permanent magnet

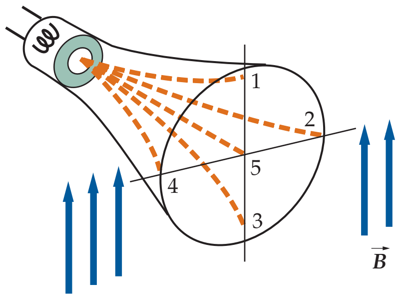

FIGURE 26-30 Problem 1

inside the bulb. When the bulb is plugged in the filament oscillates back and forth. At what frequency does it oscillate? Explain your answer. SSM

4 • In a cyclotron, the potential difference between the dees oscillates with a period given by $T = 2\pi m/(qB)$. Show that the expression to the right of the equal sign has units of seconds if $q, B,$ and m have units of coulombs, teslas, and kilograms, respectively.

5 • A ^{7}Li nucleus has a charge equal to $+3e$ and a mass that is equal to the mass of seven protons. A ^{7}Li nucleus and a proton are both moving perpendicular to a uniform magnetic field $\vec{B}$. The magnitude of the momentum of the proton is equal to the magnitude of the momentum of the nucleus. The path of the proton has a radius of curvature equal to R_p and the path of the ^{7}Li nucleus has a radius of curvature equal to R_{Li}. The ratio R_p/R_{Li} is closest to (*a*) 3/1, (*b*) 1/3, (*c*) 1/7, (*d*) 7/1, (*e*) 3/7, (*f*) 7/3.

6 • An electron moving in the $+x$ direction enters a region that has a uniform magnetic field in the $+y$ direction. When the electron enters this region, it will (*a*) be deflected toward the $+y$ direction, (*b*) be deflected toward the $-y$ direction, (*c*) be deflected toward the $+z$ direction, (*d*) be deflected toward the $-z$ direction, (*e*) continue undeflected in the $+x$ direction.

7 • In a velocity selector, the speed of the undeflected charged particle is given by the ratio of the magnitude of the electric field to the magnitude of the magnetic field. Show that E/B in fact does have the units of m/s if E and B are in units of volts per meter and teslas, respectively. SSM

8 • How are the properties of magnetic field lines similar to the properties of electric field lines? How are they different?

9 • True or false:

(*a*) The magnetic moment of a bar magnet points from its north pole to its south pole.
(*b*) Inside the material of a bar magnet, the magnetic field due to the bar magnet points from the magnet's south pole toward its north pole.
(*c*) If a current loop simultaneously has its current doubled and its area cut in half, then the magnitude of its magnetic moment remains the same.
(*d*) The maximum torque on a current loop placed in a magnetic field occurs when the plane of the loop is perpendicular to the direction of the magnetic field.

10 •• Show that the von Klitzing constant, h/e^2, gives the SI unit for resistance (the ohm) if h and e are in units of joule-seconds and coulombs, respectively.

11 ••• The theory of relativity states that no law of physics can be described using the absolute velocity of an object, which is in fact impossible to define due to a lack of an absolute reference frame. Instead, the behavior of interacting objects can only be described by the relative velocities between the objects. New physical insights result from this idea. For example, in Figure 26-31 a magnet moving at high speed relative to some observer passes by an electron that is at rest relative to the same observer. Explain why you are sure that a force must be acting on the electron. In what direction will the force point at the instant the north pole of the magnet passes directly underneath the electron? Explain your answer.

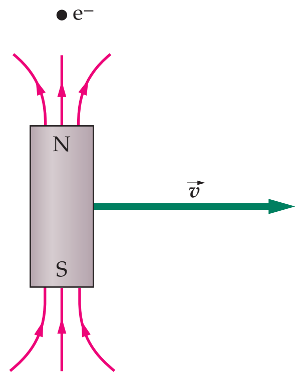

FIGURE 26-31 Problem 11

ESTIMATION AND APPROXIMATION

12 • Estimate the maximum magnetic force per meter that Earth's magnetic field could exert on a current-carrying wire in a 20-A circuit in your house.

13 •• CONTEXT-RICH Your friend wants to be a magician and intends to use Earth's magnetic field to suspend a current-carrying wire above the stage. He asks you to estimate the minimum current needed to suspend the wire just above Earth's surface at the equator (where Earth's magnetic field is horizontal). Assume the wire has a linear mass density of 10 g/m. Would you advise him to proceed with his plans for this act?

THE FORCE EXERTED BY A MAGNETIC FIELD

14 • Find the magnetic force on a proton moving in the $+x$ direction at a speed of 0.446 Mm/s in a uniform magnetic field of 1.75 T in the $+z$ direction.

15 • A point particle has a charge equal to -3.64 nC and a velocity equal to 2.75×10^3 m/s $\hat{i}$. Find the force on the charge if the magnetic field is (*a*) 0.38 T $\hat{j}$, (*b*) 0.75 T $\hat{i}$ + 0.75 T $\hat{j}$, (*c*) 0.65 T $\hat{i}$, and (*d*) 0.75 T $\hat{i}$ + 0.75 T $\hat{k}$.

16 • A uniform magnetic field equal to 1.48 T $\hat{k}$ is in the $+z$ direction. Find the force exerted by the field on a proton if the velocity of the proton is (*a*) 2.7 km/s $\hat{i}$, (*b*) 3.7 km/s $\hat{j}$, (*c*) 6.8 km/s $\hat{k}$, and (*d*) 4.0 km/s $\hat{i}$ + 3.0 km/s $\hat{j}$.

17 • A straight wire segment that is 2.0 m long makes an angle of 30° with a uniform 0.37-T magnetic field. Find the magnitude of the force on the wire if the wire has a current of 2.6 A.

18 • A straight segment of a current-carrying wire has a current element $I\vec{L}$, where $I = 2.7$ A and $\vec{L} = 3.0$ cm $\hat{i}$ + 4.0 cm $\hat{j}$. The segment is in a region with a uniform magnetic field given by 1.3 T $\hat{i}$. Find the force on the segment of wire.

19 • What is the force on an electron that has a velocity equal to 2.0×10^6 m/s $\hat{i} - 3.0 \times 10^6$ m/s $\hat{j}$ when it is in a region with a magnetic field given by 0.80 T $\hat{i}$ + 0.60 T $\hat{j}$ − 0.40 T $\hat{k}$?

20 •• The section of wire shown in Figure 26-32 carries a current equal to 1.8 A from a to b. The segment is in a region that has a magnetic field whose value is $1.2\ \mathrm{T}\ \hat{k}$. Find the total force on the wire and show that the total force is the same as if the wire were in the form of a straight wire directly from a to b and carrying the same current.

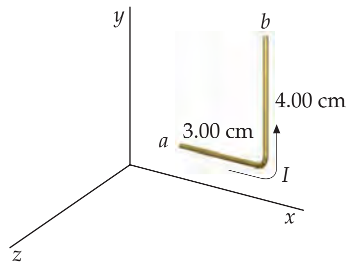

FIGURE 26-32 Problem 20

21 •• A straight, stiff, horizontal 25-cm-long wire that has a mass equal to 50 g is connected to a source of emf by light, flexible leads. A magnetic field of 1.33 T is horizontal and perpendicular to the wire. Find the current necessary to "float" the wire, that is, when the wire is released from rest it remains at rest.

22 •• **ENGINEERING APPLICATION** In your physics laboratory class, you have constructed a simple *gaussmeter* for measuring the horizontal component of magnetic fields. The setup consists of a stiff 50-cm wire that hangs vertically from a conducting pivot so that its free end makes contact with a pool of mercury in a dish below (Figure 26-33). The mercury provides an electrical contact without constraining the movement of the wire. The wire has a mass of 5.0 g and conducts a current downward. (*a*) What is the equilibrium angular displacement of the wire from vertical if the horizontal component of the magnetic field is 0.040 T and the current is 0.20 A? (*b*) What is the sensitivity of this gaussmeter? That is, what is the ratio of the output to the input (in radians per tesla)?

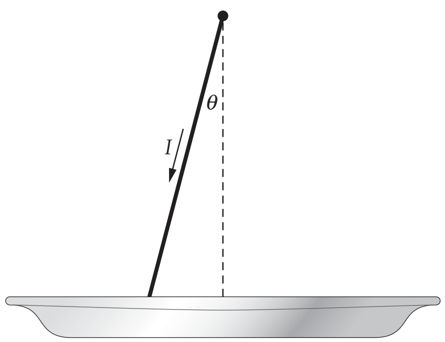

FIGURE 26-33 Problem 22

23 •• A 10-cm-long straight wire is parallel with the x axis and carries a current of 2.0 A in the $+x$ direction. The force on this wire due to the presence of a magnetic field $\vec{B}$ is $3.0\ \mathrm{N}\ \hat{j} + 2.0\ \mathrm{N}\ \hat{k}$. If this wire is rotated so that it is parallel with the y axis with the current in the $+y$ direction, the force on the wire becomes $-3.0\ \mathrm{N}\ \hat{i} - 2.0\ \mathrm{N}\ \hat{k}$. Determine the magnetic field $\vec{B}$. SSM

24 •• A 10-cm-long straight wire is parallel with the z axis and carries a current of 4.0 A in the $+z$ direction. The force on this wire due to a uniform magnetic field $\vec{B}$ is $-0.20\ \mathrm{N}\ \hat{i} + 0.20\ \mathrm{N}\ \hat{j}$. If this wire is rotated so that it is parallel with the x axis with the current in the $+x$ direction, the force on the wire becomes $0.20\ \hat{k}\ \mathrm{N}$. Find $\vec{B}$.

25 •• A current-carrying wire is bent into a closed semicircular loop of radius R that lies in the xy plane (Figure 26-34). The wire is in a uniform magnetic field that is in the $+z$ direction, as shown. Verify that the force acting on the loop is zero. SSM

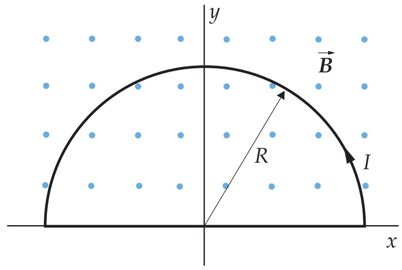

FIGURE 26-34 Problem 25

26 ••• A wire bent in some arbitrary shape carries a current I. The wire is in a region with a uniform magnetic field $\vec{B}$. Show that the total force on the part of the wire from some arbitrary point on the wire (designated as a) to some other arbitrary point on the wire (designated as b) is $\vec{F} = I\vec{L} \times \vec{B}$, where $\vec{L}$ is the vector from point a to point b. In other words, show that the force on an arbitrary section of the bent wire is the same as the force on a straight section wire carrying the same current and connecting the two endpoints of the arbitrary section.

MOTION OF A POINT CHARGE IN A MAGNETIC FIELD

27 • A proton moves in a 65-cm-radius circular orbit that is perpendicular to a uniform magnetic field of magnitude 0.75 T. (*a*) What is the orbital period for the motion? (*b*) What is the speed of the proton? (*c*) What is the kinetic energy of the proton? SSM

28 • A 4.5-keV electron (an electron that has a kinetic energy equal to 4.5 keV) moves in a circular orbit that is perpendicular to a magnetic field of 0.325 T. (*a*) Find the radius of the orbit. (*b*) Find the frequency and period of the orbital motion.

29 •• A proton, deuteron, and an alpha particle in a region with a uniform magnetic field each follow circular paths that have the same radius. The deuteron has a charge that is equal to the charge a proton has, and an alpha particle has a charge that is equal to twice the charge a proton has. Assume that $m_\alpha = 2m_d = 4m_p$. Compare (*a*) their speeds, (*b*) their kinetic energies, and (*c*) the magnitudes of their angular momenta about the centers of the orbits.

30 •• A particle has a charge q, a mass m, a linear momentum of magnitude p, and a kinetic energy K. The particle moves in a circular orbit of radius R perpendicular to a uniform magnetic field $\vec{B}$. Show that (*a*) $p = BqR$ and (*b*) $K = \frac{1}{2}B^2q^2R^2/m$.

31 •• A beam of particles with velocity $\vec{v}$ enters a region that has a uniform magnetic field $\vec{B}$ in the $+x$ direction. Show that when the x component of the displacement of one of the particles is $2\pi(m/qB)v\cos\theta$, where θ is the angle between $\vec{v}$ and $\vec{B}$, the velocity of the particle is in the same direction as it was when the particle entered the field. SSM

32 •• A proton that has a speed equal to 1.00×10^6 m/s enters a region with a uniform magnetic field that has a magnitude of 0.800 T and points into the page, as shown in Figure 26-35. The proton enters the region at an angle $\theta = 60°$. Find the exit angle ϕ and the distance d.

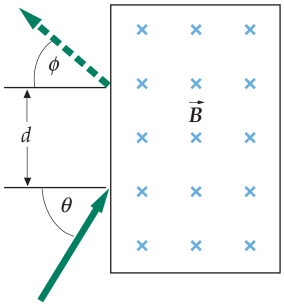

FIGURE 26-35
Problems 32 and 33

33 •• Suppose that in Figure 26-35, the magnetic field has a magnitude of 60 mT, the distance d is 40 cm, and θ is 24°. Find the speed v at which a particle enters the region and the exit angle ϕ if the particle is (*a*) a proton and (*b*) a deuteron. Assume that $m_d = 2m_p$. SSM

34 •• The galactic magnetic field in some region of interstellar space has a magnitude of 1.00×10^{-9} T. A particle of interstellar dust has a mass of 10.0 μg and a total charge of 0.300 nC. How many years does it take for the particle to complete a revolution of the circular orbit caused by its interaction with the magnetic field?

APPLICATIONS OF THE MAGNETIC FORCE ACTING ON CHARGED PARTICLES

35 • A velocity selector has a magnetic field that has a magnitude equal to 0.28 T and is perpendicular to an electric field that has a magnitude equal to 0.46 MV/m. (*a*) What must the speed of a particle be for that particle to pass through the velocity selector undeflected? What kinetic energy must (*b*) protons and (*c*) electrons have in order to pass through the velocity selector undeflected? SSM

36 •• A beam of protons is moving in the $+x$ direction with a speed of 12.4 km/s through a region in which the electric field is perpendicular to the magnetic field. The beam is not deflected in this region. (*a*) If the magnetic field has a magnitude of 0.85 T and points in the $+y$ direction, find the magnitude and direction of the electric field. (*b*) Would electrons that have the same velocity as the protons be deflected by these fields? If so, in what direction would they be deflected? If not, why not?

37 •• The plates of a Thomson q/m apparatus are 6.00 cm long and are separated by 1.20 cm. The end of the plates is 30.0 cm from the tube screen. The kinetic energy of the electrons is 2.80 keV. If a potential difference of 25.0 V is applied across the deflection plates, by how much will the point where the beam of electrons strikes the screen be displaced?

38 •• Chlorine has two stable isotopes, ^{35}Cl and ^{37}Cl. Chlorine gas which consists of singly ionized ions is to be separated into its isotopic components using a mass spectrometer. The magnetic field strength in the spectrometer is 1.2 T. What is the minimum value of the potential difference through which these ions must be accelerated so that the separation between them, after they complete their semicircular path, is 1.4 cm?

39 •• In a mass spectrometer, a singly ionized ^{24}Mg ion has a mass equal to 3.983×10^{-26} kg and is accelerated through a 2.50-kV potential difference. It then enters a region where it is deflected by a magnetic field of 557 G. (*a*) Find the radius of curvature of the ion's orbit. (*b*) What is the difference in the orbital radii of the ^{26}Mg and ^{24}Mg ions? Assume that their mass ratio is 26:24. SSM

40 •• A beam of singly ionized ^{6}Li and ^{7}Li ions passes through a velocity selector and enters a region of uniform magnetic field with a velocity that is perpendicular to the direction of the field. If the diameter of the orbit of the ^{6}Li ions is 15 cm, what is the diameter of the orbit for ^{7}Li ions? Assume their mass ratio is 7:6.

41 •• Using Example 26-6, determine the time required for a ^{58}Ni ion and a ^{60}Ni ion to complete the semicircular path.

42 •• Before entering a mass spectrometer, ions pass through a velocity selector consisting of parallel plates that are separated by 2.0 mm and have a potential difference of 160 V. The magnetic field strength is 0.42 T in the region between the plates. The magnetic field strength in the mass spectrometer is 1.2 T. Find (*a*) the speed of the ions entering the mass spectrometer and (*b*) the difference in the diameters of the orbits of singly ionized ^{238}U and ^{235}U. The mass of a ^{235}U ion is 3.903×10^{-25} kg.

43 •• A cyclotron for accelerating protons has a magnetic field strength of 1.4 T and a radius of 0.70 m. (*a*) What is the cyclotron's frequency? (*b*) Find the kinetic energy of the protons when they emerge. (*c*) How will your answers change if deuterons are used instead of protons? SSM

44 •• A certain cyclotron that has a magnetic field whose magnitude is 1.8 T is designed to accelerate protons to a kinetic energy of 25 MeV. (*a*) What is the cyclotron frequency for this cyclotron? (*b*) What must the minimum radius of the magnet be to achieve this energy? (*c*) If the alternating potential difference applied to the dees has a maximum value of 50 kV, how many revolutions must the protons make before emerging with kinetic energies of 25 MeV?

45 •• Show that for a given cyclotron the cyclotron frequency for accelerating deuterons is the same as the frequency for accelerating alpha particles and is half the frequency for accelerating protons in the same magnetic field. The deuteron has a charge that is equal to the charge a proton has, and an alpha particle has a charge that is equal to twice the charge a proton has. Assume that $m_\alpha = 2m_d = 4m_p$.

46 ••• Show that the radius of the orbit of a charged particle in a cyclotron is proportional to the square root of the number of orbits completed.

TORQUES ON CURRENT LOOPS, MAGNETS, AND MAGNETIC MOMENTS

47 • A small circular coil consisting of 20 turns of wire lies in a region with a uniform magnetic field whose magnitude is 0.50 T. The arrangement is such that the normal to the plane of the coil makes an angle of 60° with the direction of the magnetic field. The radius of the coil is 4.0 cm, and the wire carries a current of 3.0 A. (*a*) What is the magnitude of the magnetic moment of the coil? (*b*) What is the magnitude of the torque exerted on the coil? SSM

48 • What is the maximum torque on a 400-turn circular coil of radius 0.75 cm that carries a current of 1.6 mA and is in a region with a uniform magnetic field of 0.25 T?

49 • A current-carrying wire is in the shape of a square of edge length 6.0 cm. The square lies in the $z = 0$ plane. The wire carries a current of 2.5 A. What is the magnitude of the torque on the wire if it is in a region with a uniform magnetic field of magnitude 0.30 T that points in the (*a*) $+z$ direction and (*b*) $+x$ direction? SSM

50 • A current-carrying wire is in the shape of an equilateral triangle of edge length 8.0 cm. The triangle lies in the $z = 0$ plane. The wire carries a current of 2.5 A. What is the magnitude of the torque on the wire if it is in a region with a uniform magnetic field of magnitude 0.30 T that points in the (*a*) $+z$ direction and (*b*) $+x$ direction?

51 •• A rigid wire is in the shape of a square of edge length L. The square has mass m and the wire carries current I. The square lies on a flat horizontal surface in a region where there is a magnetic field of magnitude B that is parallel to two edges of the square. What is the minimum value of B so that one edge of the square will lift off the surface?

52 •• A rectangular current-carrying 50-turn coil, as shown in Figure 26-36, is pivoted about the z axis. (*a*) If the wires in the $z = 0$ plane make an angle $\theta = 37°$ with the y axis, what angle does the magnetic moment of the coil make with the unit vector $\hat{\boldsymbol{i}}$? (*b*) Write an expression for $\hat{\boldsymbol{n}}$ in terms of the unit vectors $\hat{\boldsymbol{i}}$ and $\hat{\boldsymbol{j}}$, where $\hat{\boldsymbol{n}}$ is a unit vector in the direction of the magnetic moment. (*c*) What is the magnetic moment of the coil? (*d*) Find the torque on the coil when there is a uniform magnetic field $\vec{\boldsymbol{B}} = 1.5\ \mathrm{T}\ \hat{\boldsymbol{j}}$ in the region occupied by the coil. (*e*) Find the potential energy of the coil in this field. (The potential energy is zero when $\theta = 0$.)

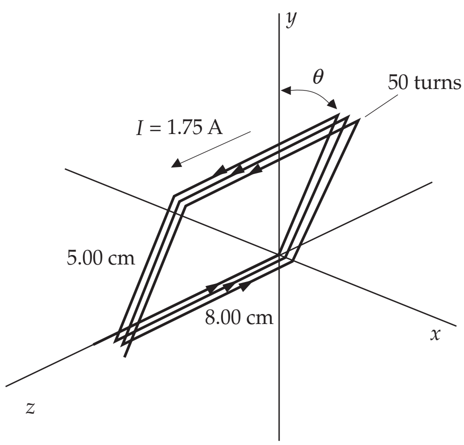

FIGURE 26-36
Problems 52 and 53

53 •• For the coil in Problem 52 the magnetic field is now $\vec{\boldsymbol{B}} = 2.0\ \mathrm{T}\ \hat{\boldsymbol{j}}$. Find the torque exerted on the coil when $\hat{\boldsymbol{n}}$ is equal to (*a*) $\hat{\boldsymbol{i}}$, (*b*) $\hat{\boldsymbol{j}}$, (*c*) $-\hat{\boldsymbol{j}}$, and (*d*) $(\hat{\boldsymbol{i}} + \hat{\boldsymbol{j}})/\sqrt{2}$. SSM

54 •• A small bar magnet has a length equal to 6.8 cm and its magnetic moment is aligned with a uniform magnetic field of magnitude 0.040 T. The bar magnet is then rotated through an angle of 60° about an axis perpendicular to its length. The observed torque on the bar magnet has a magnitude of $0.10\ \mathrm{N \cdot m}$. (*a*) Find the magnetic moment of the magnet. (*b*) Find the potential energy of the magnet.

55 •• A wire loop consists of two semicircles connected by straight segments (Figure 26-37). The inner and outer radii are 0.30 m and 0.50 m, respectively. A current of 1.5 A is in this wire and the current in the outer semicircle is in the clockwise direction. What is the magnetic moment of this current loop?

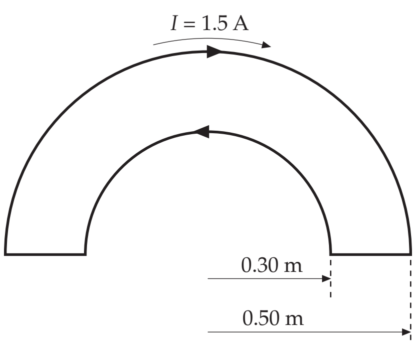

FIGURE 26-37
Problem 55

56 •• A wire of length L is wound into a circular coil that has N turns. Show that when the wire carries a current I, the magnetic moment of the coil has a magnitude given by $IL^2/(4\pi N)$.

57 •• A particle that has a charge q and a mass m moves with angular velocity ω in a circular path of radius r. (*a*) Show that the average current created by this moving particle is $\omega q/(2\pi)$ and that the magnetic moment of its orbit has a magnitude of $\frac{1}{2}q\omega r^2$. (*b*) Show that the angular momentum of this particle has the magnitude of $mr^2\omega$ and that the magnetic moment and angular momentum vectors are related by $\vec{\boldsymbol{\mu}} = \frac{1}{2}(q/m)\,\vec{\boldsymbol{L}}$, where $\vec{\boldsymbol{L}}$ is the angular momentum about the center of the circle. SSM

58 ••• A uniformly charged nonconducting cylindrical shell (Figure 26-38) has length L, inner and outer radii R_i and R_o, respectively, a charge density ρ, and an angular velocity ω about its axis. Derive an expression for the magnetic moment of the cylinder.

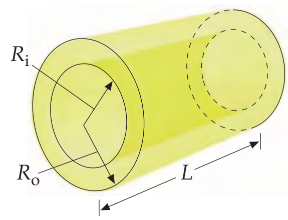

FIGURE 26-38 **Problem 58**

59 ••• A uniform nonconducting thin rod of mass m and length L has a uniform charge per unit length λ and rotates with angular speed ω about an axis through one end and perpendicular to the rod. (*a*) Consider a small segment of the rod of length dx and charge $dq = \lambda\, dr$ at a distance r from the pivot (Figure 26-39). Show that the average current created by this moving segment is $\omega\, dq/(2\pi)$ and show that the magnetic moment of this segment is $\frac{1}{2}\lambda\omega r^2\, dx$. (*b*) Use this to show that the magnitude of the magnetic moment of the rod is $\frac{1}{6}\lambda\omega L^3$. (*c*) Show that the magnetic moment $\vec{\boldsymbol{\mu}}$ and angular momentum $\vec{\boldsymbol{L}}$ are related by $\vec{\boldsymbol{\mu}} = \frac{1}{2}(Q/m)\vec{\boldsymbol{L}}$, where Q is the total charge on the rod. SSM

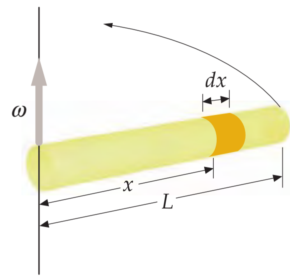

FIGURE 26-39
Problem 59

60 ••• A nonuniform, nonconducting thin disk of mass m, radius R, and total charge Q has a charge per unit area σ that varies as $\sigma_0 r/R$ and a mass per unit area σ_m that is given by $(m/Q)\sigma$. The disk rotates with angular speed ω about its central axis. (*a*) Show that the magnetic moment of the disk has a magnitude $\frac{1}{5}\pi\omega\sigma_0 R^4$, which can be alternatively rewritten as $\frac{3}{10}\omega Q R^2$. (*b*) Show that the magnetic moment $\vec{\boldsymbol{\mu}}$ and angular momentum $\vec{\boldsymbol{L}}$ are related by $\vec{\boldsymbol{\mu}} = \frac{1}{2}(Q/m)\vec{\boldsymbol{L}}$.

61 ••• A spherical shell of radius R carries a constant surface charge density σ. The shell rotates about its diameter with angular speed ω. Find the magnitude of the magnetic moment of the rotating spherical shell. SSM

62 ••• A uniform, solid, uniformly charged sphere of radius R has a volume charge density ρ. The sphere rotates about an axis through its center with angular speed ω. Find the magnitude of the magnetic moment of the rotating sphere.

63 ••• A uniform, thin, uniformly charged disk of mass m, radius R, and uniform surface charge density σ rotates with angular speed ω about an axis through its center and perpendicular to the disk (Figure 26-40). The disk is in a region with a uniform magnetic field $\vec{B}$ that makes an angle θ with the rotation axis. Calculate (*a*) the magnitude of the torque exerted on the disk by the magnetic field and (*b*) the precession frequency of the disk in the magnetic field.

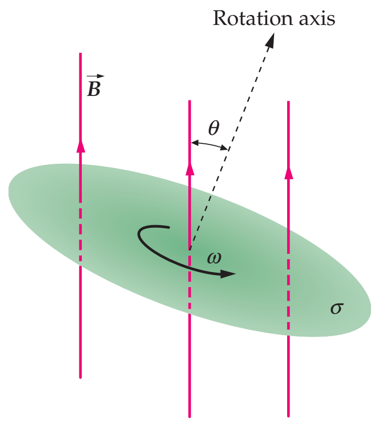

FIGURE 26-40 Problem 63

THE HALL EFFECT

64 • A metal strip that is 2.00 cm wide and 0.100 cm thick carries a current of 20.0 A in a region with a uniform magnetic field of 2.00 T, as shown in Figure 26-41. The Hall voltage is measured to be 4.27 μV. (*a*) Calculate the drift speed of the free electrons in the strip. (*b*) Find the number density of the free electrons in the strip. (*c*) Is point *a* or point *b* at the higher potential? Explain your answer.

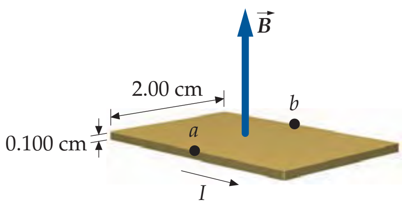

FIGURE 26-41 Problems 64 and 65

65 •• The number density of free electrons in copper is 8.47×10^{22} electrons per cubic centimeter. If the metal strip in Figure 26-41 is copper and the current is 10.0 A, find (*a*) the drift speed v_d and (*b*) the potential difference $V_a - V_b$. Assume that the magnetic field strength is 2.00 T. SSM

66 •• **Engineering Application** A copper strip has 8.47×10^{22} free electrons per cubic centimeter, is 2.00 cm wide, is 0.100 cm thick, and is used to measure the magnitudes of unknown magnetic fields that are perpendicular to it. Find the magnitude B when the current is 20.0 A and the Hall voltage is (*a*) 2.00 μV, (*b*) 5.25 μV, and (*c*) 8.00 μV.

67 •• **Biological Application** Because blood contains ions, moving blood in the presence of a magnetic field develops a Hall voltage across the diameter of an artery. A large artery that has a diameter of 0.85 cm can have blood flowing through it with a maximum speed of 0.60 m/s. If a section of the artery is in a magnetic field of 0.20 T, what is the maximum potential difference across the diameter of the artery?

68 •• The Hall coefficient R_H is a property of conducting material (just as resistivity is). It is defined as $R_H = E_y/(J_x B_z)$, where J_x is the x component of the current density in the material, B_z is the z component of the magnetic field, and E_y is the y component of the resulting Hall electric field. Show that the Hall coefficient is equal to $1/(nq)$, where q is the charge of the charge carriers ($-e$ if they are electrons). (The Hall coefficients of monovalent metals, such as copper, silver, and sodium, are therefore negative.)

69 •• Aluminum has a density of 2.7×10^3 kg/m^3 and a molar mass of 27 g/mol. The Hall coefficient of aluminum is $R = -0.30 \times 10^{-10}$ m^3/C. (See Problem 68 for the definition of R.) What is the number of conduction electrons per aluminum atom? SSM

GENERAL PROBLEMS

70 • A long wire parallel to the x axis carries a current of 6.50 A in the $+x$ direction. The wire occupies a region that has a uniform magnetic field $\vec{B} = 1.35\text{ T}\,\hat{j}$. Find the magnetic force per unit length on the wire.

71 • An alpha particle (charge $+2e$) travels in a circular path of radius 0.50 m in a region with a magnetic field whose magnitude is 0.10 T. Find (*a*) the period, (*b*) the speed, and (*c*) the kinetic energy (in electron volts) of the alpha particle. (The mass of an alpha particle is 6.65×10^{-27} kg.)

72 •• The pole strength q_m of a bar magnet is defined by $\vec{\mu} = q_m \vec{\ell}$, where $\vec{\mu}$ is the magnetic moment of the magnet and $\vec{\ell}$ is the position of the north-pole end of the magnet relative to the south-pole end. Show that the torque exerted on a bar magnet in a uniform magnetic field $\vec{B}$ is the same as if a force $+q_m\vec{B}$ is exerted on the north pole of the magnet and a force $-q_m\vec{B}$ is exerted on the south pole.

73 •• A particle of mass m and charge q enters a region where there is a uniform magnetic field $\vec{B}$ parallel with the x axis. The initial velocity of the particle is $\vec{v} = v_{0x}\hat{i} + v_{0y}\hat{j}$, so the particle moves in a helix. (*a*) Show that the radius of the helix is $r = mv_{0y}/qB$. (*b*) Show that the particle takes a time $\Delta t = 2\pi m/qB$ to complete each turn of the helix. (*c*) What is the x component of the displacement of the particle during the time given in Part (*b*)? SSM

74 •• A metal cross-bar of mass m rides on a parallel pair of long horizontal conducting rails separated by a distance L and connected to a device that supplies constant current I to the circuit, as shown in Figure 26-42. The circuit is in a region with a uniform magnetic field $\vec{B}$ whose direction is vertically downward. There is no friction and the bar starts from rest at $t = 0$. (*a*) In which direction will the bar start to move? (*b*) Show that at time t the bar has a speed of $(BIL/m)t$.

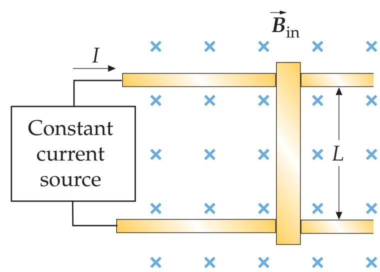

FIGURE 26-42 Problems 74 and 75

75 •• Assume that the rails Problem 74 are frictionless but tilted upward so that they make an angle θ with the horizontal, and with the current source attached to the low end of the rails. The magnetic field is still directed vertically downward. (*a*) What minimum value of B is needed to keep the bar from sliding down the rails? (*b*) What is the acceleration of the bar if B is twice the value found in Part (*a*)? SSM

76 •• A long, narrow bar magnet that has magnetic moment $\vec{\boldsymbol{\mu}}$ parallel to its long axis is suspended at its center as a frictionless compass needle. When placed in region with a horizontal magnetic field $\vec{\boldsymbol{B}}$, the needle lines up with the field. If it is displaced by a small angle θ, show that the needle will oscillate about its equilibrium position with frequency $f = \frac{1}{2\pi}\sqrt{\frac{\mu B}{I}}$, where I is the moment of inertia of the needle about the point of suspension.

77 •• A straight 20-m-long conducting wire is parallel to the y axis and is moving in the $+x$ direction with a speed of 20 m/s in a region that has a magnetic field given by 0.50 T $\hat{\boldsymbol{k}}$. (*a*) A magnetic force acting on the conduction electrons leaves one end negatively charged due to an electron surplus and the other end positively charged due to an electron deficit. This charge separation process continues until the electric field due to the accumulated positive and negative charges exerts forces on the remaining conduction electrons that exactly balance the magnetic forces acting on them. Find the magnitude and direction of this electric field in the steady-state situation. (*b*) Which end of the wire is positively charged and which end is negatively charged? (*c*) Suppose the moving wire is 2.0 m long. What is the potential difference between its two ends due to this electric field?

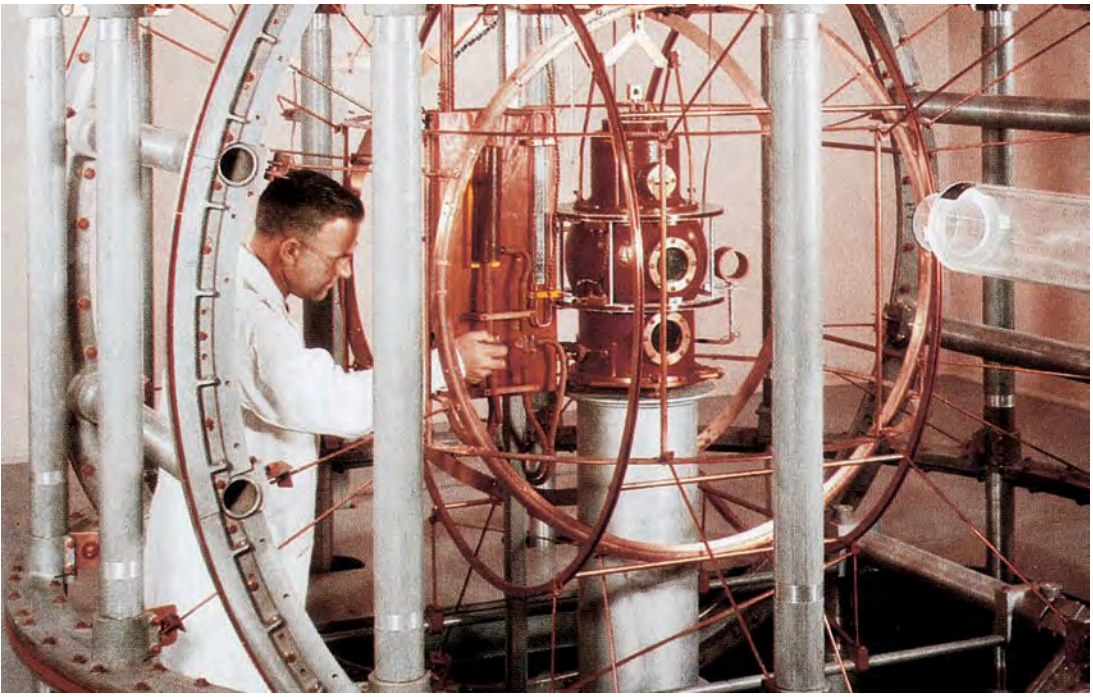
78 ••• A circular loop of wire that has a mass m and a constant current I is in a region with a uniform magnetic field. It is initially in equilibrium and its magnetic moment is aligned with the magnetic field. The loop is given a small angular displacement about an axis through its center and perpendicular to the magnetic field and then released. What is the period of the subsequent motion? (Assume that the only torque exerted on the loop is due to the magnetic field and that there are no other forces acting on the loop.)

79 ••• A small bar magnet has a magnetic moment $\vec{\boldsymbol{\mu}}$ that makes an angle θ with the x axis. The magnet is in a region that has a *nonuniform* magnetic field given by $\vec{\boldsymbol{B}} = B_x(x)\hat{\boldsymbol{i}} + B_y(y)\hat{\boldsymbol{j}}$. Using $F_x = -\partial U/\partial x$, $F_y = -\partial U/\partial y$, and $F_z = -\partial U/\partial z$, show that there is a net magnetic force on the magnet that is given by

$$\vec{\boldsymbol{F}} = \mu_x \frac{\partial B_x}{\partial x}\hat{\boldsymbol{i}} + \mu_y \frac{\partial B_y}{\partial y}\hat{\boldsymbol{j}}$$

80 •• A proton, a deuteron, and an alpha particle all have the same kinetic energy. They are moving in a region with a uniform magnetic field that is perpendicular to each of their velocities. Let R_p, R_d, and R_α be the radii of their circular orbits, respectively. The deuteron has a charge that is equal to the charge a proton has, and an alpha particle has a charge that is equal to twice the charge a proton has. Find the ratios R_d/R_p and R_α/R_p. Assume that $m_\alpha = 2m_d = 4m_p$.

81 ••• **ENGINEERING APPLICATION, CONTEXT-RICH** Your forensic chemistry group, working closely with local law enforcement agencies, has acquired a mass spectrometer similar to that discussed in the text. It employs a uniform magnetic field that has a magnitude of 0.75 T. To calibrate the mass spectrometer, you decide to measure the masses of various carbon isotopes by measuring the position of impact of the various singly ionized carbon ions that have entered the spectrometer with a kinetic energy of 25 keV. A wire chamber with position sensitivity of 0.50 mm is part of the apparatus. What will be the limit on its mass resolution (in kg) for ions in this mass range, that is, those whose mass is on the order of that of a carbon atom?



CHAPTER 27

THESE COILS AT THE KETTERING MAGNETICS LABORATORY AT OAKLAND UNIVERSITY ARE CALLED HELMHOLTZ COILS. THEY ARE USED TO CANCEL EARTH'S MAGNETIC FIELD AND TO PROVIDE A UNIFORM MAGNETIC FIELD IN A SMALL REGION OF SPACE FOR STUDYING THE MAGNETIC PROPERTIES OF MATTER. *(Bob Williamson, Oakland University, Rochester, Michigan.)*

Sources of the Magnetic Field

? Do you know how to calculate the magnitude of the magnetic field of a current-carrying coil? (See Example 27-2.)

As we discussed in Chapter 26, an awareness of the power of permanent magnets has been around since the year 1000. However, the study of magnets as they relate to electricity did not occur until 1819 when a Danish physicist, Hans Christian Oersted, discovered that a compass needle is deflected by an electric current. Just a month after Oersted's discovery, Jean-Baptiste Biot and Félix Savart announced the results of their measurements of the torque on a magnet near a long, current-carrying wire and they analyzed these results in terms of the magnetic field produced by each element of the current. André-Marie Ampère did additional experiments and showed that current elements also experience a force in the presence of a magnetic field and that two current elements exert forces on each other.

In this chapter, we begin by considering the magnetic field produced by a single moving charge and by the moving charges in a current element. We then calculate the magnetic fields produced by some common current configurations, such as a straight-wire segment; a long, straight wire; a current loop; and a solenoid. Next we discuss Ampère's law. Finally, we consider the magnetic properties of matter.

27-1 THE MAGNETIC FIELD OF MOVING POINT CHARGES

When a point charge q moves with velocity $\vec{v}$, the moving point charge produces a magnetic field $\vec{B}$ in space, given by*

$$\vec{B} = \frac{\mu_0}{4\pi}\frac{q\vec{v}\times\hat{r}}{r^2} \qquad 27\text{-}1$$

MAGNETIC FIELD OF A MOVING POINT CHARGE

where $\hat{r}$ is a unit vector (see Figure 27-1) that points to the field point P from the charge q moving with velocity $\vec{v}$, and μ_0 is a constant of proportionality called the **magnetic constant (permeability of free space),**† which, by definition, has the exact value

$$\mu_0 = 4\pi \times 10^{-7}\,\mathrm{T\cdot m/A} = 4\pi \times 10^{-7}\,\mathrm{N/A^2} \qquad 27\text{-}2$$

The units of μ_0 are such that B is in teslas when q is in coulombs, v is in meters per second, and r is in meters. The unit $\mathrm{N/A^2}$ comes from the fact that $1\,\mathrm{T} = 1\,\mathrm{N\cdot s/(C\cdot m)}$. The constant $1/(4\pi)$ is arbitrarily included in Equation 27-1 so that the factor 4π does not appear in Ampère's law (Equation 27-16), which we will study in Section 27-4.

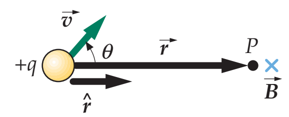


FIGURE 27-1 A positive point charge q moving with velocity $\vec{v}$ produces a magnetic field $\vec{B}$ at a field point P. The magnetic field at P is in the direction of $\vec{v}\times\hat{r}$, where $\vec{v}$ is the velocity of the point charge and $\hat{r}$ is the unit vector pointing from the charge to the field point. The field varies inversely as the square of the distance from the charge to the field point and is proportional to the sine of the angle between $\vec{v}$ and $\hat{r}$. (The blue $\times$ at the field point indicates that the direction of the field is into the page.)

Example 27-1 Magnetic Field of a Moving Point Charge

A point particle that has charge $q = 4.5\,\mu\mathrm{C}$ is moving with velocity $\vec{v} = 3.0\,\mathrm{m/s}\,\hat{i}$ along the line $y = 3.0$ m in the $z = 0$ plane. Find the magnetic field at the origin produced by this charge when the charge is at the point $x = -4.0$ m, $y = 3.0$ m, as shown in Figure 27-2.

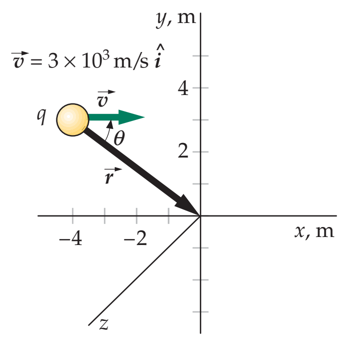

FIGURE 27-2

PICTURE The magnetic field associated with a moving charged particle is given by Equation 27-1.

SOLVE

1. The magnetic field is given by Equation 27-1:
$$\vec{B} = \frac{\mu_0}{4\pi}\frac{q\vec{v}\times\hat{r}}{r^2} \quad \text{where} \quad \vec{v} = v\hat{i}$$

2. Find $\hat{r}$ and r from Figure 27-2 and write $\hat{r}$ in terms of $\hat{i}$ and $\hat{j}$:
$$\vec{r} = 4.0\,\mathrm{m}\,\hat{i} - 3.0\,\mathrm{m}\,\hat{j}$$
$$r = \sqrt{4.0^2 + 3.0^2}\,\mathrm{m} = 5.0\,\mathrm{m}$$
$$\hat{r} = \frac{\vec{r}}{r} = \frac{4.0\,\mathrm{m}\,\hat{i} - 3.0\,\mathrm{m}\,\hat{j}}{5.0\,\mathrm{m}} = 0.80\,\hat{i} - 0.60\,\hat{j}$$

3. Substitute the above results in Equation 27-1:
$$\vec{B} = \frac{\mu_0}{4\pi}\frac{q\vec{v}\times\hat{r}}{r^2} = \frac{\mu_0}{4\pi}\frac{q(v\hat{i})\times(0.80\hat{i} - 0.60\hat{j})}{r^2} = \frac{\mu_0}{4\pi}\frac{q(-0.60v\hat{k})}{r^2}$$
$$= -(10^{-7}\,\mathrm{T\cdot m/A})\frac{(4.5\times 10^{-6}\,\mathrm{C})(0.60)(3.0\,\mathrm{m/s})}{(5.0\,\mathrm{m})^2}\hat{k}$$
$$= \boxed{-3.2\times 10^{-14}\,\mathrm{T}\,\hat{k}}$$

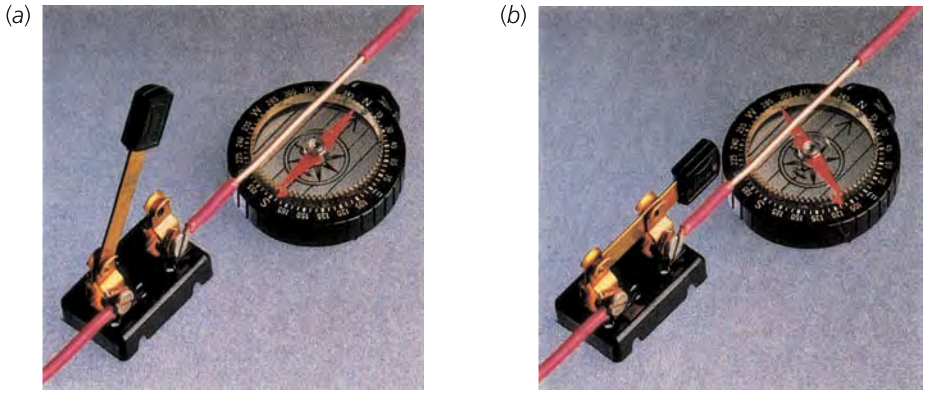
CHECK It is also possible to obtain $\vec{B}$ without finding an explicit expression for the unit vector $\hat{r}$. From Figure 27-2 we note that $\vec{v}\times\hat{r}$ is in the $-z$ direction. In addition, the magnitude of $\vec{v}\times\hat{r}$ is $v\sin\theta$, where $\sin\theta = (3.0\,\mathrm{m})/(5.0\,\mathrm{m}) = 0.60$. Combining these results, we have $\vec{v}\times\hat{r} = v\sin\theta(-\hat{k}) = -v(0.60)\hat{k}$, in agreement with our result in line 1 of step 3.

PRACTICE PROBLEM 27-1 At the same instant, find the magnetic field on the y axis both at $y = 3.0$ m and at $y = 6.0$ m.

---

* This expression is used only for speeds much much less than the speed of light.

† Some care must be taken not to confuse the constant μ_0 with the magnitude of the magnetic moment vector $\vec{\mu}$.



Oersted's experiment. (*a*) When no current exists in the wire, the compass needle points north. (*b*) When the wire carries a current, the compass needle is deflected in the direction of the resultant magnetic field. The current in the wire is directed upward, from left to right. The insulation has been stripped from the wire to improve the contrast of the photograph. *(© 1990 Richard Menga/Fundamental Photographs.)*

27-2 THE MAGNETIC FIELD OF CURRENTS: THE BIOT–SAVART LAW

In the previous chapter, we extended our discussion of forces on point charges to forces on current elements by substituting $q\vec{v}$ with the current element $I\,d\vec{\ell}$. We do the same for the magnetic field produced by a current element. The magnetic field $d\vec{B}$ produced by a current element $I\,d\vec{\ell}$ is given by Equation 27-1, where $q\vec{v}$ is replaced by $I\,d\vec{\ell}$:

$$d\vec{B} = \frac{\mu_0}{4\pi}\frac{I\,d\vec{\ell} \times \hat{r}}{r^2} \qquad 27\text{-}3$$

BIOT–SAVART LAW

Equation 27-3, known as the **Biot–Savart law,** was also deduced by Ampère. The Biot–Savart law and Equation 27-1 are analogous to Coulomb's law for the electric field of a point charge. The source of the magnetic field is a moving charge $q\vec{v}$ or a current element $I\,d\vec{\ell}$, just as the charge q is the source of the electrostatic field. The magnetic field decreases with the square of the distance from the moving charge or current element, just as the electric field decreases with the square of the distance from a point charge. However, the directional aspects of the electric and magnetic fields are quite different. Whereas the electric field points in the radial direction $\hat{r}$ from the point charge to the field point (for a positive charge), the magnetic field is perpendicular to both $\hat{r}$ and $\vec{v}$, in the case of a point charge, or $\hat{r}$ and $d\vec{\ell}$ in the case of a current element. At a point along the line of a current element, such as point P_2 in Figure 27-3, the magnetic field due to that current element is zero. (Equation 27-3 gives $d\vec{B} = 0$ if $d\vec{\ell}$ and $\hat{r}$ are either parallel or antiparallel.)

The magnetic field due to the total current in a circuit can be calculated by using the Biot–Savart law to find the field due to each current element, and then summing (integrating) over all the current elements in the circuit. This calculation is challenging for all but the simplest circuit geometries.

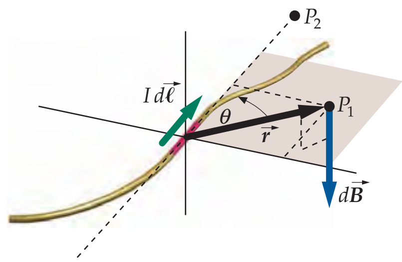


FIGURE 27-3 The current element $I\,d\vec{\ell}$ produces a magnetic field $d\vec{B}$ at point P_1 that is in the direction of $I\,d\vec{\ell} \times \hat{r}$, and thus perpendicular to both $d\vec{\ell}$ and $\hat{r}$. The current element produces no magnetic field at point P_2, which is along the line of $d\vec{\ell}$.

$\vec{B}$ DUE TO A CURRENT LOOP

Figure 27-4 shows a current element $I\,d\vec{\ell}$ of a current loop of radius R and the unit vector $\hat{r}$ that is directed from the element to the center of the loop. The magnetic field at the center of the loop due to this element is directed along the axis of the loop, and its magnitude, obtained by taking the magnitude of both sides of Equation 27-3, is given by

$$dB = \frac{\mu_0}{4\pi}\frac{I\,d\ell\,\sin\theta}{R^2} \qquad 27\text{-}4$$

where θ is the angle between $d\vec{\ell}$ and $\hat{r}$, which is 90° for each current element, so $\sin\theta = 1$. The resultant magnetic field due to all the current elements in the loop is found by integrating Equation 27-4 over all the current elements in the loop.

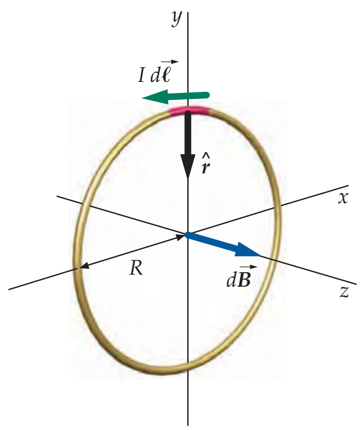

FIGURE 27-4 Current element for calculating the magnetic field at the center of a circular current loop. Each element produces a magnetic field that is directed along the axis of the loop.

center

Because I and R are the same for all elements, we obtain

$$B = \frac{\mu_0}{4\pi}\frac{I}{R^2}\oint d\ell$$

The integral of $d\ell$ around the complete loop gives the total length $2\pi R$, the circumference of the loop. The magnetic field due to the entire loop is thus

$$B = \frac{\mu_0}{4\pi}\frac{I}{R^2}2\pi R = \frac{\mu_0 I}{2R} \qquad 27\text{-}5$$

B AT THE CENTER OF A CURRENT LOOP

PRACTICE PROBLEM 27-2

Find the current in a circular loop of radius 8.0 cm that will produce a magnetic field of 0.20 mT at the center of the loop.

Figure 27-5 shows the geometry for calculating the magnetic field at a point on the axis of a circular current loop a distance z from the circular loop's center. We first consider the current element at the top of the loop. Here, as everywhere on the loop, $I\,d\vec{\ell}$ is tangent to the loop and perpendicular to the vector $\vec{r}$ from the current element to the field point P. The magnetic field $d\vec{B}$ due to this element is in the direction shown in the figure, perpendicular to $\hat{r}$ and also perpendicular to $I\,d\vec{\ell}$. The magnitude of $d\vec{B}$ is

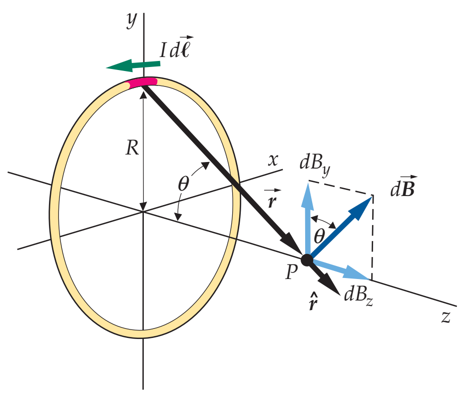

FIGURE 27-5 Geometry for calculating the magnetic field at a point on the axis of a circular current loop.

$$|d\vec{B}| = \frac{\mu_0}{4\pi}\frac{I|d\hat{\ell} \times \hat{r}|}{r^2} = \frac{\mu_0}{4\pi}\frac{I\,d\ell}{(z^2 + R^2)}$$

where we have used the facts that $r^2 = z^2 + R^2$ and that $d\vec{\ell}$ and $\hat{r}$ are perpendicular, so $|d\vec{\ell} \times \hat{r}| = d\ell$.

When we sum around all the current elements in the loop, the components of $d\vec{B}$ perpendicular to the axis of the loop, such as dB_y in Figure 27-5, sum to zero, which leave only the components dB_z that are parallel to the axis. We thus compute only the z component of the field. From Figure 27-5, we have

$$dB_z = dB\sin\theta = \left(\frac{\mu_0}{4\pi}\frac{I\,d\ell}{(z^2 + R^2)}\right)\left(\frac{R}{\sqrt{z^2 + R^2}}\right) = \frac{\mu_0}{4\pi}\frac{IR\,d\ell}{(z^2 + R^2)^{3/2}}$$

To find the field due to the entire loop of current, we integrate dB_z around the loop:

$$B_z = \oint dB_z = \oint \frac{\mu_0}{4\pi}\frac{IR}{(z^2 + R^2)^{3/2}}\,d\ell$$

Because neither z nor R varies as we sum over the elements in the loop, we can remove those quantities from the integral. Then,

$$B_z = \frac{\mu_0}{4\pi}\frac{IR}{(z^2 + R^2)^{3/2}}\oint d\ell$$

The integral of $d\ell$ around the loop gives $2\pi R$. Thus,

$$B_z = \frac{\mu_0}{4\pi}\frac{IR}{(z^2 + R^2)^{3/2}}2\pi R = \frac{\mu_0}{4\pi}\frac{2\pi R^2 I}{(z^2 + R^2)^{3/2}} \qquad 27\text{-}6$$

B ON THE AXIS OF A CURRENT LOOP

PRACTICE PROBLEM 27-3

Show that Equation 27-6 reduces to $B_z = \frac{1}{2}\mu_0 I/R$ (Equation 27-5) at the center of the loop.

At great distances from the loop, $|z|$ is much greater than R, so $(z^2 + R^2)^{3/2} \approx (z^2)^{3/2} = |z|^3$. Then,

$$B_z = \frac{\mu_0}{4\pi}\frac{2I\pi R^2}{|z|^3}$$

or

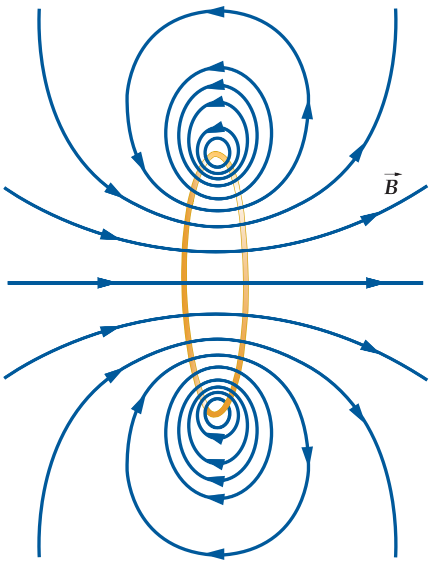
$$B_z = \frac{\mu_0}{4\pi}\frac{2\mu}{|z|^3} \qquad 27\text{-}7$$

MAGNETIC-DIPOLE FIELD ON THE AXIS OF THE DIPOLE

where $\mu = I\pi R^2$ is the magnitude of the magnetic moment of the loop. Note the similarity of this expression and the electric field on the axis of an electric dipole whose electric dipole moment has magnitude p (Equation 21-10):

$$E_z = \frac{1}{4\pi\epsilon_0}\frac{2p}{|z|^3}$$

Although it has not been demonstrated, our result that a current loop produces a magnetic dipole field far away holds in general for any point whether it is on the axis of the loop or off of the axis of the loop. Thus, a current loop behaves as a magnetic dipole because it experiences a torque $\vec{\mu} \times \vec{B}$ when placed in an external magnetic field (as was shown in Chapter 26) and it also produces a magnetic dipole field at field points far from the current loop. Figure 27-6 shows the magnetic field lines for a current loop.



(a)

(b)

FIGURE 27-6 (*a*) The magnetic field lines of a circular current loop. (*b*) The magnetic field lines of a circular current loop indicated by iron filings. *(© 1990 Richard Menga/Fundamental Photographs.)*

Example 27-2 Find $\vec{B}$ on Axis of Coil

A circular coil has a radius equal to 5.00 cm, has 12 turns, lies in the $z = 0$ plane, and is centered at the origin. It carries a current of 4.00 A, and the magnetic moment of the coil is in the $+z$ direction. Using Equation 27-6, find the magnetic field on the z axis at (*a*) $z = 0$, (*b*) $z = 15.0$ cm, and (*c*) $z = 3.00$ m. (*d*) Using Equation 27-7, find the magnetic field on the z axis at $z = 3.00$ m.

PICTURE The magnetic field due to a loop that has N turns is N times that due to a single turn. (*a*) At $z = 0$, $B = \frac{1}{2}\mu_0 N/R$ (from Equation 27-5). Equation 27-6 gives the magnetic field on the axis due to the current in a single turn. Far from the loop, as in Part (*c*), the field can be found using Equation 27-7. In that case, because we have N loops, the magnetic moment is $\mu = NIA$, where $A = \pi R^2$.

SOLVE

(*a*) B_z at the center is N times that given by Equation 27-5 for a single turn of the coil:

$$B_z = \frac{\mu_0 NI}{2R} = (4\pi \times 10^{-7}\,\mathrm{T\cdot m/A})\frac{(12)(4.00\,\mathrm{A})}{2(0.0500\,\mathrm{m})} = \boxed{6.03 \times 10^{-4}\,\mathrm{T}}$$

(*b*) B_z on the axis is N times that given by Equation 27-6:

$$B_z = \frac{\mu_0}{4\pi}\frac{2\pi R^2 NI}{(z^2 + R^2)^{3/2}} = (10^{-7}\,\mathrm{T\cdot m/A})\frac{2\pi(0.0500\,\mathrm{m})^2(12)(4.00\,\mathrm{A})}{\left[(0.1500\,\mathrm{m})^2 + (0.0500\,\mathrm{m})^2\right]^{3/2}} = \boxed{1.91 \times 10^{-5}\,\mathrm{T}}$$

(*c*) Use Equation 27-6 again:

$$B_z = \frac{\mu_0}{4\pi}\frac{2\pi R^2 NI}{(z^2 + R^2)^{3/2}} = (10^{-7}\,\mathrm{T\cdot m/A})\frac{2\pi(0.0500\,\mathrm{m})^2(12)(4.00\,\mathrm{A})}{\left[(3.00\,\mathrm{m})^2 + (0.0500\,\mathrm{m})^2\right]^{3/2}} = \boxed{2.79 \times 10^{-9}\,\mathrm{T}}$$

(*d*) 1. Because 3.00 m is much greater than the radius $R = 0.0500$ m, we can use Equation 27-7 for the magnetic field far from the loop:

$$B_z = \frac{\mu_0}{4\pi}\frac{2\mu}{|z|^3}$$

2. The magnitude of the magnetic moment of the loop is N/A:

$$\mu = NI\pi R^2 = (12)(4.00\,\mathrm{A})\pi(0.0500\,\mathrm{m})^2 = 0.377\,\mathrm{A\cdot m^2}$$

3. Substitute $\mu = 0.377\,\mathrm{A\cdot m^2}$ and $z = 3.00$ m into the expression for B_z in step 1:

$$B_z = \frac{\mu_0}{4\pi}\frac{2\mu}{|z|^3} = (10^{-7}\,\mathrm{T\cdot m/A})\frac{2(0.377\,\mathrm{A\cdot m^2})}{(3.00\,\mathrm{m})^3} = \boxed{2.79 \times 10^{-9}\,\mathrm{T}}$$

CHECK In Part (*d*) $z = 60R$, so we were able to use an approximation that is valid for $z \gg R$. The result differs from the exact value, calculated in Part (*c*), by less than one part in 279.

Example 27-3 Calculating the Amount of Mobile Charge

In the coil described in Example 27-2, the current is 4.00 A. Assuming the drift speed is 1.40×10^{-4} m/s, find the number of coulombs of mobile charge (free electrons) in the wire. (The drift speed for a wire carrying a current of 1 A was found to be 3.5×10^{-5} m/s in Example 25-1.)

PICTURE The amount of moving charge Q in the wire is the product of the rate at which charge enters one end of the wire and the time it takes the charge to travel the length of the wire. The rate at which charge enters one end of the wire is the current I, and the time for the charge to travel the length L of the wire is L/v_d, where v_d is the drift speed.

SOLVE

1. The amount of moving charge is the product of the current and the time for a charge carrier to travel the length of the wire:

$$Q = I\,\Delta t$$

2. The drift speed is the length of the wire divided by the time:

$$v_d = \frac{L}{\Delta t}$$

3. The length L is the number of turns multiplied by the length per turn. Also, we solve the step-2 result for the time:

$$L = N2\pi R = (12)2\pi(0.0500\text{ m}) = 3.77\text{ m}$$

and

$$\Delta t = \frac{L}{v_d} = \frac{3.77\text{ m}}{1.40 \times 10^{-4}\text{ m/s}} = 2.69 \times 10^4\text{ s}$$

4. Solve the step 1 result for the amount of moving charge in the wire:

$$Q = I\,\Delta t = (4.00\text{ A})(2.69 \times 10^4\text{ s})$$
$$= \boxed{1.08 \times 10^5\text{ C}}$$

CHECK There is approximately one conduction electron for each atom in a metal. If the wire is made of copper (with an molar mass equal to 63.5 g/mol), it is plausible that 3.77 m of the wire would have a mass approximately equal to 63.5 g. Thus, we estimate about one mole of copper exists in the wire. That means the number of conduction electrons in the wire is approximately equal to Avogadro's number. The total charge Q carried by these electrons is the number of electrons multiplied by the charge per electron. That is, $Q = -N_A e = -(6.02 \times 10^{23})(1.60 \times 10^{-19}\text{ C}) = -0.965 \times 10^5\text{ C}$. The magnitude of this result is very close to our step-4 result.

TAKING IT FURTHER The current consists of about 10^5 C of moving charges. In comparison to the amount of charge stored in an ordinary capacitor, this amount is an enormous amount of charge.

Example 27-4 Torque on a Bar Magnet

Try It Yourself

A small bar magnet that has a magnetic moment whose magnitude is 0.0300 A·m² is placed at the center of the coil of Example 27-2 so that its magnetic moment vector lies in the $x = 0$ plane and makes an angle of 30° with the $+z$ direction as shown. Neglecting any variation in $\vec{B}$ over the region occupied by the magnet, find the torque on the magnet.

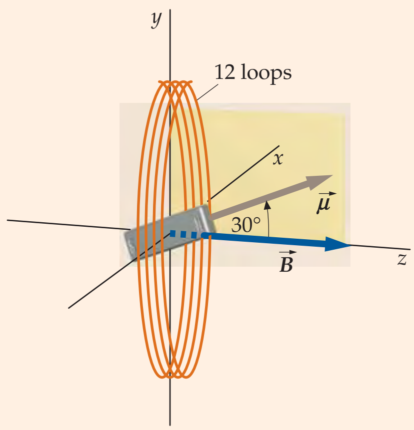


FIGURE 27-7

PICTURE The torque on a magnetic moment is given by $\vec{\tau} = \vec{\mu} \times \vec{B}$. $\vec{B}$ is in the $+z$ direction, so you can use the right-hand rule to show that $\vec{\mu} \times \vec{B}$ is in the $+x$ direction (Figure 27-7).

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. Compute the magnitude of the torque from $\vec{\tau} = \vec{\mu} \times \vec{B}$.	$\tau = 9.04 \times 10^{-6}\text{ N}\cdot\text{m}$
2. Indicate the direction using a unit vector.	$\vec{\tau} = \boxed{(9.04 \times 10^{-6}\text{ N}\cdot\text{m})\hat{i}}$

CHECK We expect the torque to tend to align the magnetic moment with the magnetic field. Thus, a torque vector in the $+x$ direction is as expected.

$\vec{B}$ DUE TO A CURRENT IN A SOLENOID

A **solenoid** is a conducting wire wound into a helix of closely spaced turns, as illustrated in Figure 27-8. A solenoid is used to produce a strong, uniform magnetic field in the region surrounded by its loops. The solenoid's role in magnetism is analogous to that of the parallel-plate capacitor, which produces a strong, uniform electric field between its plates.

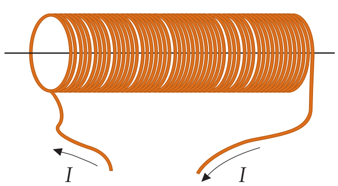

FIGURE 27-8 A tightly wound solenoid can be considered as a set of circular current loops placed side by side that carry the same current. The solenoid produces a uniform magnetic field inside the loops and distant from the ends of the solenoid.

The magnetic field of a solenoid is essentially that of a set of N identical current loops placed side by side. Figure 27-9 shows the magnetic field lines for two such loops.

Figure 27-10*a* shows the magnetic field lines for a tightly wound solenoid. Inside the solenoid and away from the ends, the field lines are approximately parallel to the axis and are closely and uniformly spaced, indicating a strong, uniform magnetic field. Outside the solenoid (above and below it) the lines are much less dense. In addition, the field lines become farther apart as you move away from either end of the solenoid. Comparing this figure with Figure 27-10*b*, we see that the magnetic field of a solenoid, both inside and outside the solenoid, are virtually identical to the magnetic field of a bar magnet of the same size and shape as the solenoid. In Figure 27-10*c*, iron filings align with the field of a current-carrying solenoid.

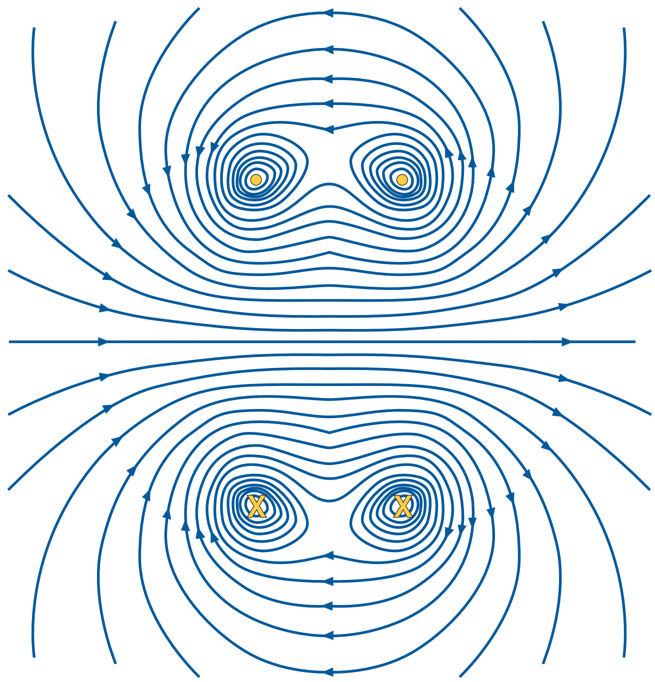

FIGURE 27-9 Magnetic field lines due to two identical coaxial loops carrying the same current. The points where the loops intersect the plane of the page are each marked by an × where the current enters the page and by a dot • where the current emerges from the page. In the region between the loops near the axis the magnetic fields of the individual loops superpose, so the resultant field is strong and surprisingly uniform. The region where the field is uniform is greatest if the planes of the two loops are separated by a distance equal to the radius of the loops.

FIGURE 27-10 (*a*) Magnetic field lines of a solenoid. The lines are identical to those of a bar magnet of the same shape, as in (*b*). (*c*) Magnetic field lines of a solenoid shown by iron filings. *(© 1990 Richard Menga/Fundamental Photographs.)*

(*c*)

Example 27-5 The Field of a Long, Tightly Wound Solenoid — Conceptual

The previous paragraph asserts that magnetic field inside and far from the ends of a long, tightly wound, current-carrying solenoid is uniform and parallel with the axis of the solenoid, and that the magnetic field is zero outside the solenoid. Validate this assertion by modeling the solenoid as a tightly packed stack of current-carrying rings, and by using the field line drawing of a single current-carrying ring (Figure 27-11).

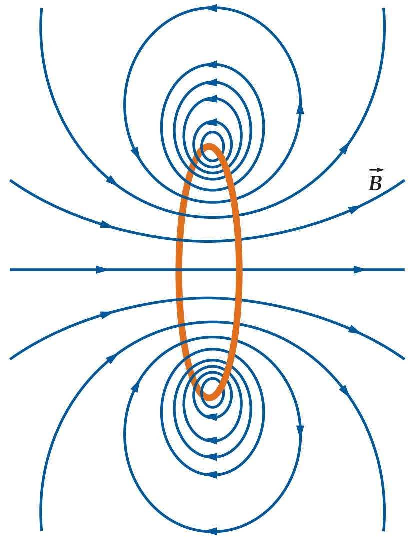

FIGURE 27-11

PICTURE Figure 27-12 shows three equally spaced current-carrying rings representing three loops of a long, tightly wound solenoid. At each of points A, B, and C, where A is just inside loop 2, B is just outside loop 2, and C is at the center of loop 2, sketch the three magnetic field vectors due to the three loops shown. Use the field line drawing of a single current-carrying ring (Figure 27-11) to obtain the directions and relative magnitudes of the three fields. Using your sketch, present an argument that the resultant magnetic fields at points A and B are equal in magnitude and are parallel with the axis of the solenoid. Using your sketch, present an argument that the resultant magnetic field at point C is zero.

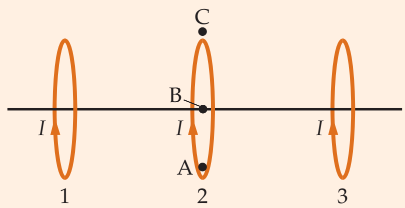

FIGURE 27-12

SOLVE

1. At point A, sketch the magnetic-field vectors $\vec{B}_1$, $\vec{B}_2$, and $\vec{B}_3$ due to the currents in loops 1, 2, and 3, respectively (Figure 27-13). Use Figure 27-11 for guidance:

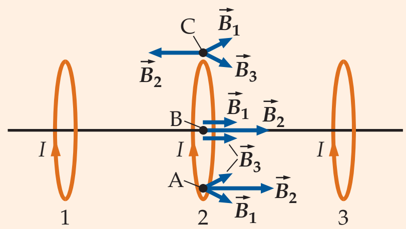

FIGURE 27-13

2. The magnitude of the magnetic field is greater where the field lines are closer together. An examination of the field lines in Figure 27-11 reveals that magnitude of the field $\vec{B}_2$ (due to loop 2) at point A is greater than it is at point B:

The magnitude of the field $\vec{B}_2$ (due to loop 2) is greater at point A than the magnitude of $\vec{B}_2$ is at point B. However, because $\vec{B}_1$, $\vec{B}_2$ and $\vec{B}_3$ are in the same direction, it is feasible that the resultant field ($\vec{B}_1 + \vec{B}_2 + \vec{B}_3$) at point B has the same magnitude as the resultant magnetic field at A.

3. An examination of the field lines in Figure 27-11 reveals that in the plane of the current-carrying ring, at points outside the ring the magnetic field is in the opposite direction than it is at points inside the ring:

At point C, the direction of $\vec{B}_2$ is to the left and the direction of $\vec{B}_1 + \vec{B}_3$ is to the right. In addition, additional loops in the solenoid that are near loops 1 and 3 will produce additional magnetic fields at C whose vector sum is to the right. It is feasible, therefore, that the resultant magnetic field at C is zero.

TAKING IT FURTHER The arguments presented in this example only hold for those sections of the solenoid located far from either end of the solenoid. Suppose loop 2 in Figure 27-13 is not near the center of a long solenoid, but is the last loop at the right end of the solenoid. Then, loop 3 would be absent from the picture, and the three vectors labeled $\vec{B}_3$ would be absent as well.

Consider a solenoid that has a length L, consists of N turns, and carries a current I. We choose the axis of the solenoid to be the z axis, with the left end at $z = z_1$ and the right end at $z = z_2$, as shown in Figure 27-14. We will calculate the magnetic field at field point P on the z axis a distance z from the origin. The figure shows an element of the solenoid of length dz' at a distance z' from the origin. If $n = N/L$ is the number of turns per unit length, there are $n\,dz'$ turns of wire in this element,

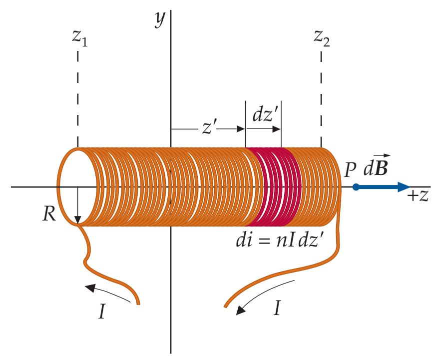

FIGURE 27-14 Geometry for calculating the magnetic field inside a solenoid on its axis. The number of turns in the element dz' is $n\,dz'$, where $n = N/L$ is the number of turns per unit length. The element dz' is treated as a current loop carrying a current $di = nI\,dz'$.

with each turn carrying a current I. The element is thus equivalent to a single loop carrying a current $di = nI\,dz'$. The magnetic field at a point on the z axis due to a loop at the origin carrying current di is given by Equation 27-6:

$$dB_z = \tfrac{1}{2}\mu_0 \frac{R^2\,di}{(z^2 + R^2)^{3/2}}$$

where z is the distance between the loop and the field point. For a loop at $z = z'$ carrying current $di = nI\,dz'$, the distance between the loop and the field point P is $z - z'$, so

$$dB_z = \tfrac{1}{2}\mu_0 \frac{R^2 nI\,dz'}{\left[(z - z')^2 + R^2\right]^{3/2}}$$

We find the magnetic field at P due to the entire solenoid by integrating the expression from $z' = z_1$ to $z' = z_2$:

$$B_z = \tfrac{1}{2}\mu_0 nIR^2 \int_{z_1}^{z_2} \frac{dz'}{\left[(z - z')^2 + R^2\right]^{3/2}} \qquad 27\text{-}8$$

The integral in Equation 27-8 can be evaluated using trigonometric substitution with $z - z' = R\tan\theta$. Also, the integral can be looked up in standard tables of integrals. The integral's value is

$$\int_{z_1}^{z_2} \frac{dz'}{\left[(z - z')^2 + R^2\right]^{3/2}} = \frac{1}{R^2}\left(\frac{z - z_1}{\sqrt{(z - z_1)^2 + R^2}} - \frac{z - z_2}{\sqrt{(z - z_2)^2 + R^2}}\right)$$

***See* Math Tutorial *for more information on* Integrals**

Substituting this into Equation 27-8, we obtain

$$B_z(z) = \tfrac{1}{2}\mu_0 nI\left(\frac{z - z_1}{\sqrt{(z - z_1)^2 + R^2}} - \frac{z - z_2}{\sqrt{(z - z_2)^2 + R^2}}\right) \qquad 27\text{-}9$$

B_z ON THE AXIS OF A SOLENOID

A solenoid is called a long solenoid if its length L is much greater than its radius R. Inside and far from the ends of a long solenoid, the fraction on the left in the parentheses approaches $+1$ and the fraction on the right approaches -1. This means the expression in the parentheses tends toward $+2$. Thus, in the region inside and far from either end of the solenoid the magnetic field is given by

$$B_z = \mu_0 nI \qquad 27\text{-}10$$

B_z INSIDE A LONG SOLENOID

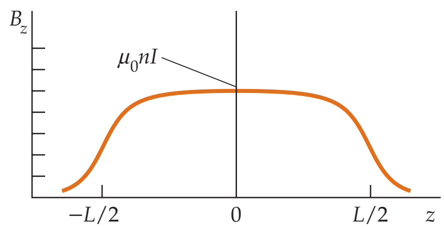

FIGURE 27-15 Graph of the magnetic field on the axis inside a solenoid versus the position z on the axis. The field inside the solenoid is nearly constant except near the ends. The length L of the solenoid is ten times longer than the radius.

To evaluate B_z at the right end of the solenoid we use Equation 27-9 with $z = z_2$. This gives $B_z(z_2) = \tfrac{1}{2}\mu_0 nI\,L/\sqrt{L^2 + R^2}$, where $L = z_2 - z_1$. Then, if $L \gg R$, the ratio $L/\sqrt{L^2 + R^2}$ becomes very close to one, so $B_z(z_2) \approx \tfrac{1}{2}\mu_0 nI$. Thus, B_z at either end of a long solenoid is half the value of B at points deep inside the solenoid (distant from either end). Figure 27-15 gives a plot of the magnetic field on the axis of a solenoid versus position z on the axis (with the origin at the center of the solenoid). The approximation that the field is uniform (independent of the position) along the axis is good, except for near the ends.

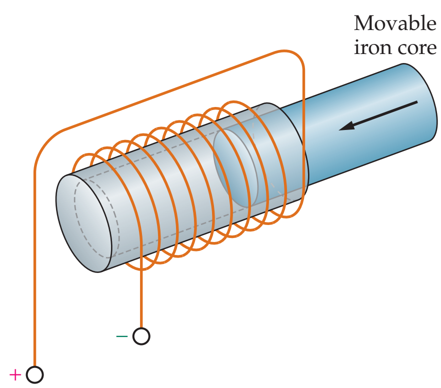

FIGURE 27-16 An automotive starter solenoid. When the solenoid is energized, its magnetic field pulls in the iron core. This engages gears that connect the starter motor to the flywheel of the engine. Once the current to the solenoid is interrupted, a spring disengages the gears and pushes the iron core to the right.

Example 27-6 $\vec{B}$ at Center of a Solenoid

Find the magnetic field at the center of a solenoid that has a length equal to 20.0 cm, a radius equal to 1.40 cm, 600 turns, and a current equal to 4.00 A.

PICTURE To find B on the axis of the solenoid we apply Equation 27-9 with the origin at the center of the solenoid.

SOLVE

1. We will calculate the field exactly, using Equation 27-9:

$$B_z(z) = \tfrac{1}{2}\mu_0 nI\left(\frac{z - z_1}{\sqrt{(z - z_1)^2 + R^2}} - \frac{z - z_2}{\sqrt{(z - z_2)^2 + R^2}}\right)$$

2. To find the magnetic field at the middle of the solenoid, we choose the middle of the solenoid as the origin. Then we set $z = 0$, $z_1 = -\tfrac{1}{2}L$, and $z_2 = \tfrac{1}{2}L$:

$$B_z(0) = \tfrac{1}{2}\mu_0 nI\left(\frac{0 - \left(-\tfrac{1}{2}L\right)}{\sqrt{\left[0 - (-\tfrac{1}{2}L)\right]^2 + R^2}} - \frac{0 - \left(\tfrac{1}{2}L\right)}{\sqrt{\left[\left(0 - \left(\tfrac{1}{2}L\right)\right)^2\right] + R^2}}\right)$$

$$= \tfrac{1}{2}\mu_0 nI\frac{L}{\sqrt{\tfrac{1}{4}L^2 + R^2}} = \mu_0 nI\frac{L}{\sqrt{L^2 + 4R^2}}$$

3. Substituting in the given information, we have:

$$\frac{L}{\sqrt{L^2 + 4R^2}} = \frac{20.0\text{ cm}}{\sqrt{(20.0\text{ cm})^2 + 4(1.40\text{ cm})^2}} = 0.990$$

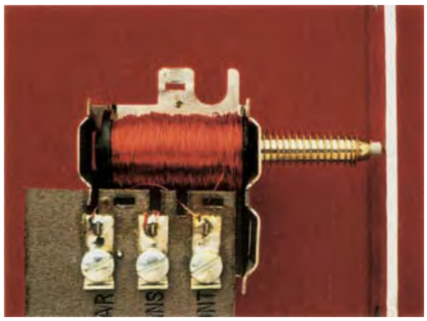
$$B_z(0) = 0.990\,\mu_0 nI$$

$$= 0.990(4\pi \times 10^{-7}\text{ T}\cdot\text{m/A})\frac{600}{0.200\text{ m}}(4.00\text{ A})$$

$$= \boxed{1.50 \times 10^{-2}\text{ T}}$$

CHECK Note that the approximation obtained using Equation 27-10 amounts to replacing 0.990 by 1 in step 3. Doing so gives a result that differs from the step-3 result by only one percent. This result is expected for a solenoid whose length to radius ratio is 20 cm/1.4 cm ≈ 14.

PRACTICE PROBLEM 27-4 Calculate B on the axis a distance halfway between the center and one end of the solenoid. Compare this result with the step-3 result.



A cross section of a doorbell. When the solenoid is energized, its magnetic field pulls on the plunger, causing it to strike the bell (not shown). The spring returns the plunger to its normal position. *(© Bruce Iverson.)*

$\vec{B}$ DUE TO A CURRENT IN A STRAIGHT WIRE

Figure 27-17 shows the geometry for calculating the magnetic field $\vec{B}$ at a point P due to the current in the straight-wire segment shown. We choose R to be the perpendicular distance from the wire to point P, and we choose the x axis to be along the wire with $x = 0$ at the projection of P onto the x axis.

A typical current element $I\,d\vec{\ell}$ at a distance x from the origin is shown. The vector $\vec{r}$ points from the element to the field point P. The direction of the magnetic field at P due to this element is the direction of $I\,d\vec{\ell} \times \hat{r}$, which is out of the paper. Note that at P, the magnetic fields due to all the current elements of the wire are in

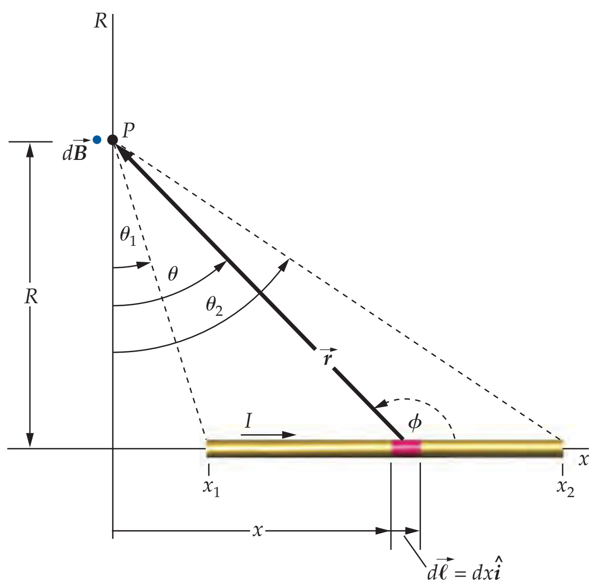


FIGURE 27-17 Geometry for calculating the magnetic field at point P due to a straight current segment. Each element of the segment contributes to the total magnetic field at point P, which is directed out of the paper. The result is expressed in terms of the angles θ_1 and θ_2.

this same direction. Thus, we need to compute only the magnitude of the field. The field due to the current element shown has the magnitude (Equation 27-3)

$$dB = \frac{\mu_0}{4\pi}\frac{Idx}{r^2}\sin\phi$$

It is more convenient to write this in terms of θ rather than ϕ:

$$dB = \frac{\mu_0}{4\pi}\frac{I\,dx}{r^2}\cos\theta \qquad 27\text{-}11$$

To sum over all the current elements, we need to relate the variables θ, r, and x. It turns out to be easiest to express x and r in terms of θ. We have

$$x = R\tan\theta$$

Then, taking the differential of each side with R as a constant gives

$$dx = R\sec^2\theta\,d\theta = R\frac{r^2}{R^2}d\theta = \frac{r^2}{R}d\theta$$

where we have used $\sec\theta = r/R$. Substituting this expression for dx into Equation 27-11, we obtain

$$dB = \frac{\mu_0}{4\pi}\frac{I}{r^2}\frac{r^2\,d\theta}{R}\cos\theta = \frac{\mu_0}{4\pi}\frac{I}{R}\cos\theta\,d\theta$$

We sum over these elements by integrating from $\theta = \theta_1$ to $\theta = \theta_2$, where θ_1 and θ_2 are shown in Figure 27-17. This calculation gives

$$B = \int_{\theta_1}^{\theta_2}\frac{\mu_0}{4\pi}\frac{I}{R}\cos\theta\,d\theta = \frac{\mu_0}{4\pi}\frac{I}{R}\int_{\theta_1}^{\theta_2}\cos\theta\,d\theta$$

Evaluating the integral, we obtain

$$B = \frac{\mu_0}{4\pi}\frac{I}{R}(\sin\theta_2 - \sin\theta_1) \qquad 27\text{-}12$$

B DUE TO A STRAIGHT-WIRE SEGMENT

This result gives the magnetic field due to any straight, current-carrying wire segment in terms of the perpendicular distance R and θ_1 and θ_2, which are the angles subtended at the field point by the ends of the wire. If the length of the wire approaches infinity in both directions, θ_2 approaches $+90°$ and θ_1 approaches $-90°$. The result for such a very long wire is obtained from Equation 27-12, by setting $\theta_1 = -90°$ and $\theta_2 = +90°$:

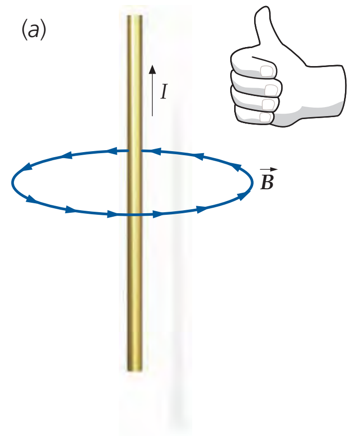
$$B = \frac{\mu_0}{4\pi}\frac{2I}{R} \qquad 27\text{-}13$$

B DUE TO AN INFINITELY LONG, STRAIGHT WIRE

At any point in space, the magnetic field lines of a long, straight, current-carrying wire are tangent to a circle of radius R about the wire, where R is the perpendicular distance from the wire to the field point. The direction of $\vec{B}$ can be determined by applying the right-hand rule, as shown in Figure 27-18*a*. The magnetic field lines thus encircle the wire, as shown in Figure 27-18*b*.

The result expressed by Equation 27-13 was found experimentally by Biot and Savart in 1820. From their analysis, Biot and Savart were able to discover the expression given in Equation 27-3 for the magnetic field due to a current element.

(a)



(b)

FIGURE 27-18 (*a*) Right-hand rule for determining the direction of the magnetic field due to a long, straight, current-carrying wire. The magnetic field lines encircle the wire in the direction of the fingers of the right hand when the thumb points in the direction of the current. (*b*) Magnetic field lines due to a long wire, which is indicated by iron filings. *(© 1990 Richard Menga/Fundamental Photographs.)*

Example 27-7 $\vec{B}$ at Center of Square Current Loop

Find the magnetic field at the center of a square current loop that has an edge length L, which is equal to 50 cm, and carries a current equal to 1.5 A.

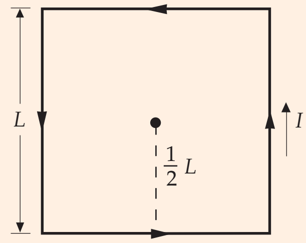


FIGURE 27-19

PICTURE The magnetic field at the center of the loop is the sum of the contributions from each of the four sides of the loop. From Figure 27-19, we can see that each side of the loop produces a field of equal magnitude pointing out of the page. Thus, we use Equation 27-12 for a given side, then multiply by 4 for the total field.

SOLVE

1. The magnitude of the resultant field is 4 times the magnitude of the field B_s due to a single side:

$$B = 4B_s$$

2. Calculate the magnitude of the magnetic field B_s due to a single side of the loop. Note from the figure that $R = \frac{1}{2}L$ and $\theta_1 = -45°$ and $\theta_2 = +45°$:

$$B_s = \frac{\mu_0}{4\pi}\frac{I}{R}(\sin\theta_2 - \sin\theta_1) = \frac{\mu_0}{4\pi}\frac{I}{\frac{1}{2}L}[\sin(+45°) - \sin(-45°)]$$

$$= (10^{-7}\ \mathrm{T \cdot m/A})\frac{1.5\ \mathrm{A}}{0.25\ \mathrm{m}}2\sin 45° = 8.5 \times 10^{-7}\ \mathrm{T}$$

3. Multiply this value by 4 to find the magnitude of the resultant field:

$$B = 4B_s = 4(8.5 \times 10^{-7}\ \mathrm{T}) = \boxed{3.4 \times 10^{-6}\ \mathrm{T}}$$

CHECK Practice Problem 27-5 serves as a check.

PRACTICE PROBLEM 27-5 Compare the magnetic field at the center of a circular current loop of radius R with the magnetic field at the center of a square current loop of side $L = 2R$ carrying the same current. Which is larger?

PRACTICE PROBLEM 27-6 Find the distance from a long, straight wire carrying a current of 12 A to a point where the magnetic field due to the current in the wire has a magnitude equal to 60 μT.

A current gun used to measure electric current. The jaws of the current gun clamp around a current-carrying wire without touching the wire. The magnetic field produced by the wire is measured with a Hall-effect device mounted in the current gun. The Hall-effect device puts out a voltage proportional to the magnetic field, which in turn is proportional to the current in the wire. *(Courtesy of F. W. Bell.)*

Example 27-8 $\vec{B}$ Due to Two Parallel Wires

A long, straight wire carries a current of 1.7 A in the $+z$ direction and lies along the line $x = -3.0$ cm, $y = 0$. A second such wire carries a current of 1.7 A in the $+z$ direction and lies along the line $x = +3.0$ cm, $y = 0$, as shown in Figure 27-20. Find the magnetic field at a point P on the y axis at $y = 6.0$ cm.

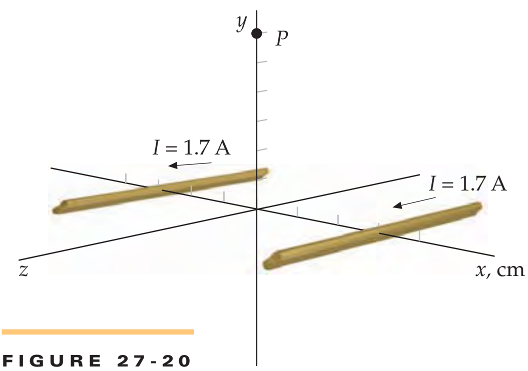

FIGURE 27-20

PICTURE The magnetic field at point P is the vector sum of the field $\vec{B}_L$ due to the wire on the left in Figure 27-21, and the field $\vec{B}_R$ due to the wire on the right. Because each wire carries the same current and each wire is the same distance from point P, the magnitudes B_L and B_R are equal. $\vec{B}_L$ is perpendicular to the radius from the left wire to point P, and $\vec{B}_R$ is perpendicular to the radius from the right wire to the point P.

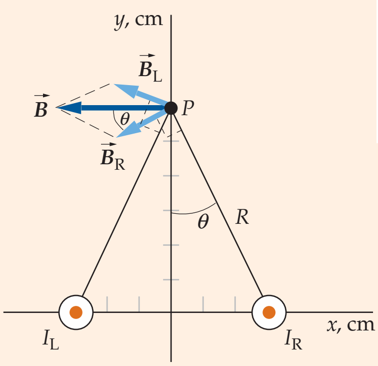

FIGURE 27-21

SOLVE

1. The field at P is the vector sum of the fields $\vec{B}_{\mathrm{L}}$ and $\vec{B}_{\mathrm{R}}$:

$$\vec{B} = \vec{B}_{\mathrm{L}} + \vec{B}_{\mathrm{R}}$$

2. From Figure 27-21 we see that the resultant magnetic field is in the $-x$ direction and has the magnitude $2B_{\mathrm{L}} \cos\theta$.

$$\vec{B} = -2B_{\mathrm{L}} \cos\theta\, \hat{\boldsymbol{i}}$$

3. The magnitudes of $\vec{B}_{\mathrm{L}}$ and $\vec{B}_{\mathrm{R}}$ are given by Equation 27-13:

$$B_{\mathrm{L}} = B_{\mathrm{R}} = \frac{\mu_0}{4\pi}\frac{2I}{R}$$

4. R is the radial distance from each wire to the point P. We find R from the figure and substitute R into the expression for B_{L} and B_{R}:

$$R = \sqrt{(3.0\text{ cm})^2 + (6.0\text{ cm})^2} = 6.7\text{ cm}$$

so

$$B_{\mathrm{L}} = B_{\mathrm{R}} = (10^{-7}\,\mathrm{T \cdot m/A})\frac{2(1.7\text{ A})}{0.067\text{ m}} = 5.07 \times 10^{-6}\,\mathrm{T}$$

5. We obtain $\cos\theta$ from the figure:

$$\cos\theta = \frac{6.0\text{ cm}}{R} = \frac{6.0\text{ cm}}{6.7\text{ cm}} = 0.894$$

6. Substitute the values of $\cos\theta$ and B_{L} into the equation in step 2 for $\vec{B}$:

$$\vec{B} = -2(5.07 \times 10^{-6}\,\mathrm{T})(0.894)\hat{\boldsymbol{i}} = \boxed{-9.1 \times 10^{-6}\,\mathrm{T}\,\hat{\boldsymbol{i}}}$$

CHECK The magnitude of the step-6 result is less than twice the step-4 result, which is expected because the vectors being added are not parallel.

PRACTICE PROBLEM 27-7 Find $\vec{B}$ at the origin.

PRACTICE PROBLEM 27-8 Find $\vec{B}$ at the origin assuming that the direction of the current is reversed in the wire along the line $x = 3.0$ cm, $y = 0$.

MAGNETIC FORCE BETWEEN PARALLEL WIRES

We can use Equation 27-13 for the magnetic field due to a long, straight, current-carrying wire and $d\vec{F} = I\,d\vec{\ell} \times \vec{B}$ (Equation 26-5) for the force exerted by a magnetic field on a segment of a current-carrying wire to find the magnetic force exerted by one long, straight, current-carrying wire on another. Figure 27-22 shows two long parallel wires carrying currents in the same direction. We consider the force on a segment $d\vec{\ell}_2$ carrying current I_2, as shown. The magnetic field $\vec{B}_1$ at this segment due to current I_1 is perpendicular to the segment $d\vec{\ell}_2$, as shown. This is true for all current elements along wire 2. That the force, given by $d\vec{F}_{12} = I_2\,d\vec{\ell}_2 \times \vec{B}_1$, on current element $I_2\,d\vec{\ell}_2$ is directed toward wire 1 can be revealed by applying the right hand rule. Similarly, a current segment $I_1\,d\vec{\ell}_1$ will experience a magnetic force directed toward current I_2, due to a magnetic field $\vec{B}_2$ arising from current I_2, given by $d\vec{F}_{21} = I_1\,d\vec{\ell}_1 \times \vec{B}_2$. Thus, two parallel currents attract each other. If one of the currents is reversed, the forces will be reversed, so two antiparallel currents will repel each other. The attraction or repulsion of parallel or antiparallel currents was discovered experimentally by Ampère one week after he heard of Oersted's discovery of the effect of a current on a compass needle.

The magnitude of the magnetic force on the current element $I_2\,d\vec{\ell}_2$ is

$$dF_{12} = |I_2\,d\vec{\ell}_2 \times \vec{B}_1|$$

Because the magnetic field at current element $I_2\,d\vec{\ell}_2$ is perpendicular to the current element, we have

$$dF_{12} = I_2\,d\ell_2 B_1$$

If the distance R between the wires is much less than their lengths, the magnetic field at $I_2\,d\vec{\ell}_2$ due to current I_1 will approximate the field due to an infinitely long, current-carrying wire, which is given by Equation 27-13. The magnitude of the force on the segment $I_2\,d\vec{\ell}_2$ is therefore

$$dF_{12} = I_2\,d\ell_2\frac{\mu_0 I_1}{2\pi R}$$

and the force per unit length is

$$\frac{dF_{12}}{d\ell_2} = \frac{\mu_0}{2\pi}\frac{I_1 I_2}{R} \tag{27-14}$$

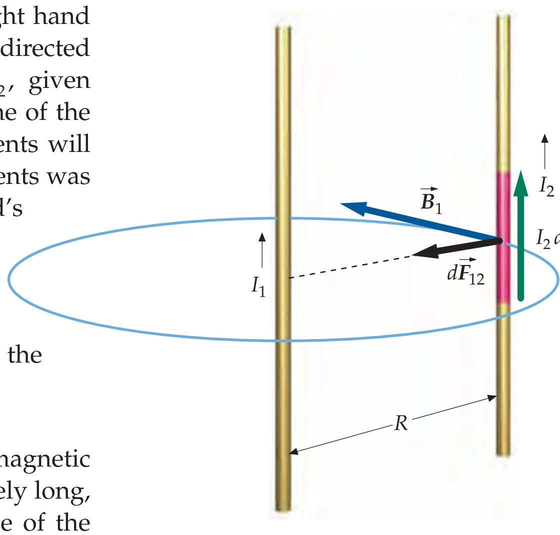

FIGURE 27-22 Two long, straight, wires carrying parallel currents. The magnetic field $\vec{B}_1$ due to current I_1 is perpendicular to current I_2. The force on current I_2 is toward current I_1. There is an equal and opposite force exerted by current I_2 on I_1. The current-carrying wires thus attract each other.

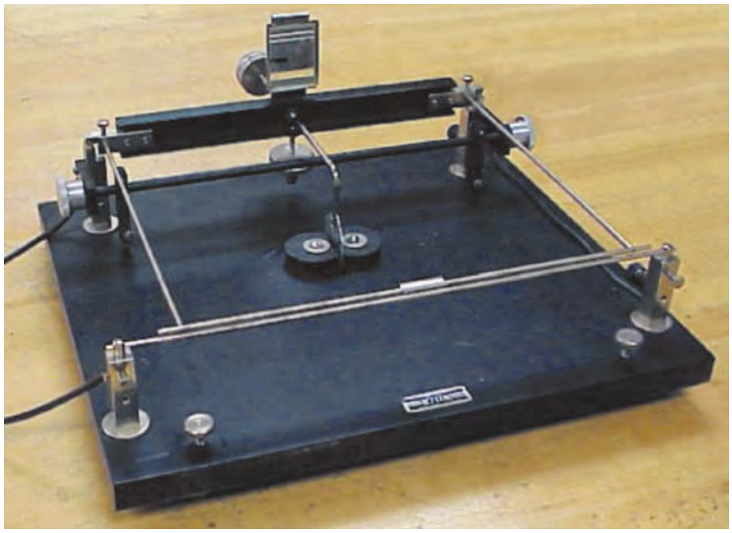
In Chapter 21, the coulomb was defined in terms of the ampere, but the definition of the ampere was deferred. The ampere is defined as follows:

> The ampere is that constant current which, if maintained in two straight, parallel conductors of infinite length and of negligible circular cross sections placed one meter apart in a vacuum, would produce a force between the conductors equal to 2×10^{-7} newton per meter of length.
>
> DEFINITION—AMPERE

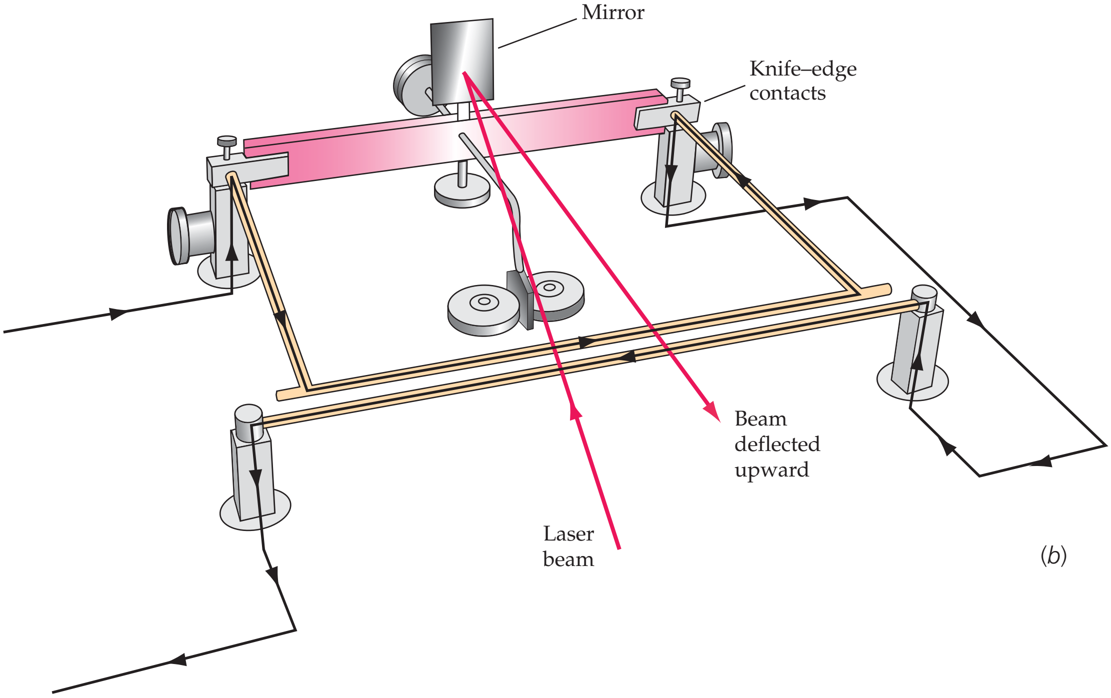
That definition of the ampere allows the unit of current (and therefore the unit of electric charge) to be determined by a mechanical measurement. In practice, currents much closer together than 1 m are used so that the force can be measured more accurately.

Figure 27-23 shows a **current balance,** which is a device that can be used to calibrate an ammeter from the definition of the ampere. The upper conductor, directly above the lower conductor, is pivoted on knife-edge contacts and is balanced so that the wires (or conducting rods) are a small distance apart. The conductors are connected in series to carry the same current but in opposite directions so that the currents will repel each other. Weights are placed on the upper conductor until it balances again at the original separation. The force of repulsion is thus determined by measuring the total weight required to balance the upper conductor.



(*a*)

FIGURE 27-23 (*a*) A picture of a current balance used in a general physics lab. (*b*) A schematic diagram of a current balance. The two parallel rods in front carry equal but oppositely directed currents and therefore repel each other. The force of repulsion is balanced by weights placed on the upper rod, which is part of a rectangle that is balanced on knife edges at the back. The mirror on top is used to reflect a beam of laser light to accurately determine the position of the upper rod. *(Photo by Gene Mosca.)*



(*b*)

Example 27-9 Balancing the Magnetic Force — *Try It Yourself*

Two straight 50.0-cm-long rods have central axes that are 1.50 mm apart in a current balance, and carry currents of 15.0 A each in opposite directions. What mass must be placed on the upper rod to balance the magnetic force of repulsion?

PICTURE Equation 27-14 gives the magnitude of the magnetic force per unit length exerted by the lower rod on the upper rod. Find this force for a rod of length L and set it equal to the weight mg.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. Set the weight mg equal to the magnetic force of repulsion of the rods.	$mg = \frac{\mu_0}{2\pi}\frac{I_1 I_2}{R}L$
2. Solve for the mass m.	$m = 1.53 \times 10^{-3}\ \text{kg} = \boxed{1.53\ \text{g}}$

TAKING IT FURTHER Because only 1.53 g is required to balance the system, we see that the magnetic force between two straight current-carrying wires is relatively small, even for currents as large as 15.0 A separated by only 1.50 mm.

27-3 GAUSS'S LAW FOR MAGNETISM

The magnetic field lines shown in Figure 27-6, Figure 27-9, and Figure 27-10 differ from electric field lines because the lines of $\vec{B}$ form closed curves, whereas lines of $\vec{E}$ begin and end on electric charges. The magnetic equivalent of an electric charge is a magnetic pole, such as appears to be at the ends of a bar magnet. Magnetic field lines appear to diverge from the north-pole end of a bar magnet (Figure 27-10*b*) and appear to converge on the south-pole end. Inside the magnet, however, the magnetic field lines neither diverge from a point near the north-pole end, nor do they converge on a point near the south-pole end. Instead, the magnetic field lines pass through the bar magnet from the south-pole end to the north-pole end, as shown in Figure 27-10*b*. If a Gaussian surface encloses one end of a bar magnet, the number of magnetic field lines that penetrate the surface from the inside is exactly equal to the number of magnetic field lines that penetrate the surface from the outside. That is, the net flux $\phi_{\text{m net}}$ of the magnetic field $\vec{B}$ through any closed surface S is always zero.*

$$\phi_{\text{m net}} = \oint_S \vec{B} \cdot \hat{n}\, dA = \oint_S B_{\text{n}}\, dA = 0 \qquad \text{27-15}$$

GAUSS'S LAW FOR MAGNETISM

where B_{n} is the component of $\vec{B}$ normal to surface S at area element dA. The definition of the magnetic flux ϕ_{m} is exactly analogous to the definition of electric flux, with $\vec{B}$ replacing $\vec{E}$. This result is called *Gauss's law for magnetism*. It is the mathematical statement that no point in space exists from which magnetic field lines diverge, or to which magnetic field lines converge. That is, isolated magnetic poles do not exist.† The fundamental unit of magnetism is the magnetic dipole.

* Recall that the net flux of the electric field is a measure of the net number of field lines that leave a closed surface and is equal to $Q_{\text{inside}}/\epsilon_0$.

† The existence of magnetic monopoles is a subject of great debate, and the search for magnetic monopoles remains active. To date, however, none have been discovered.

Figure 27-24 compares the field lines of $\vec{B}$ for a magnetic dipole with the field lines of $\vec{E}$ for an electric dipole. Note that far from the dipoles the field lines are identical. But inside the dipole, the field lines of $\vec{E}$ are directed opposite to the field lines of $\vec{B}$. The field lines of $\vec{E}$ diverge from the positive charge and converge to the negative charge, whereas the field lines of $\vec{B}$ are continuous loops.

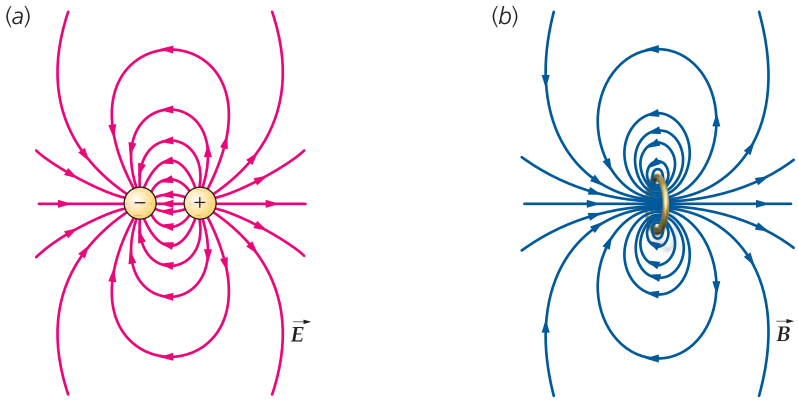


FIGURE 27-24 (*a*) Electric field lines of an electric dipole. (*b*) Magnetic field lines of a magnetic dipole. Far from the dipoles, the field lines are identical. In the region between the charges in (*a*), the electric field lines are approximately opposite the direction of the dipole moment, whereas inside the loop in (*b*), the magnetic field lines are approximately parallel to the direction of the dipole moment.

27-4 AMPÈRE'S LAW

In Chapter 22, we found that for highly symmetric charge distributions we could calculate the electric field more easily using Gauss's law than Coulomb's law. A similar situation exists in magnetism. Ampère's law relates the tangential component B_t of the magnetic field summed (integrated) around a closed curve C to the current I_C that passes through any surface bounded by C. This law can be used to obtain an expression for the magnetic field in situations that have a high degree of symmetry. In mathematical form, **Ampère's law** is

$$\oint_C B_t\, d\ell = \oint_C \vec{B} \cdot d\vec{\ell} = \mu_0 I_C \quad C \text{ is any closed curve} \qquad 27\text{-}16$$

AMPÈRE'S LAW

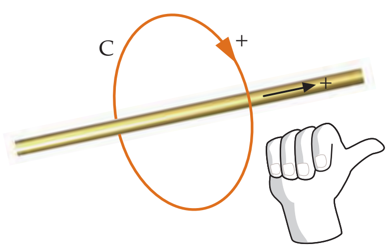

FIGURE 27-25 The positive direction for the path integral for Ampère's law is related to the positive direction for the current passing through the surface by a right-hand rule.

where I_C is the net current that penetrates any surface S bounded by the curve C. The positive tangential direction for the path integral along C is related to the choice for the positive direction for the current I_C through S by the right-hand rule shown in Figure 27-25. Ampère's law holds *as long as the currents are steady and continuous.* This means the current does not change in time and that charge is not accumulating anywhere. Ampère's law is useful in calculating the magnetic field $\vec{B}$ in situations that have a high degree of symmetry so that the line integral $\oint_C \vec{B} \cdot d\vec{\ell}$ can be written as $B \oint_C d\ell$ (the product of B and some distance). The integral $\oint_C \vec{B} \cdot d\vec{\ell}$ is called a **circulation integral.** More specifically, $\oint_C \vec{B} \cdot d\vec{\ell}$ is called the circulation of $\vec{B}$ around curve C. Ampère's law and Gauss's law are both of considerable theoretical importance, and both laws hold whether there is symmetry or there is no symmetry. If there is no symmetry, neither law is very useful in calculating electric or magnetic fields.

! Ampère's law holds as long as the currents are steady and continuous.

The simplest application of Ampère's law is to find the magnetic field due to the current in an infinitely long, straight wire. Figure 27-26 shows a circular curve C around a long wire with its center at the wire. We know the direction of the magnetic field due to each current element is tangent to this circle from the Biot–Savart law. Assuming that the magnetic field $\vec{B}$ is tangent to this circle, is in the same direction as $d\vec{\ell}$, and has the same magnitude B at any point on the circle, Ampère's law ($\oint_C B_t\, d\ell = \mu_0 I_C$) then gives

$$B \oint_C d\ell = \mu_0 I_C$$

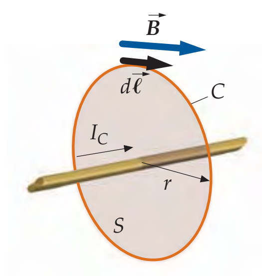

FIGURE 27-26 Geometry for calculating the magnetic field of a long, straight, current-carrying wire using Ampère's law. The magnetic field is tangent to the circle and the magnitude of the magnetic field is the same everywhere in the circle.

where $B = B_t$. We can factor B out of the integral because B has the same value everywhere on the circle. The integral of $d\ell$ around the circle equals $2\pi R$ (the circumference of the circle). The current I_C is the current I in the wire. We thus obtain $B2\pi R = \mu_0 I$, or

$$B = \frac{\mu_0 I}{2\pi R}$$

which is Equation 27-13.

Example 27-10 The Direction of the Magnetic Field — *Conceptual*

A long, straight cylindrical shell carries a current. Show that the direction of the magnetic field due to the current in the shell is tangent to a circle coaxial with the shell (Figure 27-27).

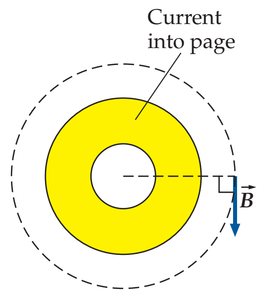

FIGURE 27-27

PICTURE Model the cylindrical shell as a bundle of thin, long, straight wires, each parallel to the central axis and each carrying a small fraction of the total current. Pick a field point P at an arbitrary location. Divide the shell in half with an imaginary plane that contains both P and the central axis of the shell. Using the right-hand rule (Figure 27-25), find the direction of the magnetic field at P due to the current in one of the thin wires in the model. Identify the symmetric counterpart to the thin wire in the other half of the shell. The counterpart is the wire equidistant from the plane and opposite the initially identified wire. Find the direction of the magnetic field at P due to the current in the counterpart thin wire. The direction of the magnetic field at P is midway between the directions of the magnetic fields due to currents in the thin wire and its counterpart.

SOLVE

1. Choose a field point P. Use the right-hand rule (Figure 27-25) to find the directions of the magnetic fields at P due to the current in a thin wire and the current in its symmetric counterpart. Draw a sketch of these two wires and their magnetic fields at the field point (Figure 27-28). Also show the sum of the two magnetic fields:

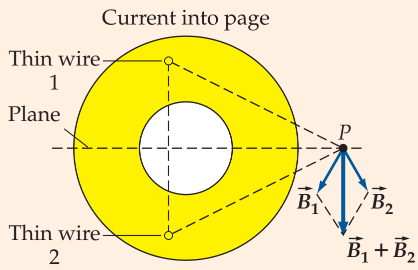

FIGURE 27-28

2. The resultant magnetic field at P is the sum of the magnetic fields due to all the thin wires that make up the cylindrical shell:

   The resultant magnetic field at P is in the same direction as the sum $\vec{B}_1 + \vec{B}_2$. This is because the sum of the magnetic fields due to the currents in any thin wire and its symmetric counterpart will point in the same direction as $\vec{B}_1 + \vec{B}_2$.

3. If the field point P is inside the shell, the magnetic field at P due to the currents in the thin wires to the right of P (Figure 27-29) will point in the opposite direction of those to the left of P (Figure 27-28):

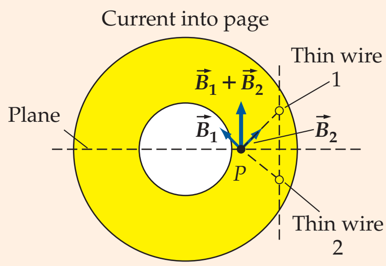

FIGURE 27-29

Example 27-11 $\vec{B}$ Inside and Outside a Wire

A long, straight wire has a radius R and carries a current I that is uniformly distributed over the circular cross section of the wire. Find the magnetic field both outside the wire and inside the wire.

PICTURE We can use Ampère's law to calculate $\vec{B}$ because of the high degree of symmetry. At a distance r (Figure 27-30), we know that $\vec{B}$ is tangent to the circle of radius r about the wire and $\vec{B}$ is constant in magnitude everywhere on the circle. The expression for the current through the surface S that is bounded by C depends on whether r is less than or greater than the radius of the wire R.

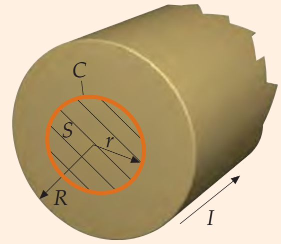

FIGURE 27-30

SOLVE

1. Ampère's law is used to relate the circulation of $\vec{B}$ around curve C to the current passing through the surface S bounded by C:
$$\oint_C \vec{B} \cdot d\vec{\ell} = \mu_0 I_C$$

2. Evaluate the circulation of $\vec{B}$ around a circle of radius r that is coaxial with the wire:
$$\oint_C \vec{B} \cdot d\vec{\ell} = B \oint_C d\ell = B2\pi r$$

3. Substitute into Ampère's law and solve for B:

$B2\pi r = \mu_0 I_C$

so

$B = \frac{\mu_0 I_C}{2\pi r}$

4. Outside the wire, $r > R$, and the total current passes through the surface bounded by C:

$I_C = I$

or

$$B = \boxed{\frac{\mu_0}{2\pi}\frac{I}{r} \qquad r \geq R}$$

5. Inside the wire, $r < R$. Assume that the current is distributed uniformly to solve for I_C. Solve for B:

$\frac{I_C}{\pi r^2} = \frac{I}{\pi R^2}$

or

$\left(I_C = \frac{r^2}{R^2} I\right)$

so

$$B = \frac{\mu_0}{2\pi}\frac{I_C}{r} = \frac{\mu_0}{2\pi}\frac{(r^2/R^2)I}{r} = \boxed{\frac{\mu_0 I}{2\pi R^2} r \leq R}$$

CHECK The step 4 and step 5 results give the same expression for B for $r = R$, as expected.

TAKING IT FURTHER Inside the wire, the field increases with distance from the center of the wire. Figure 27-31 shows the graph of B versus r for this example.

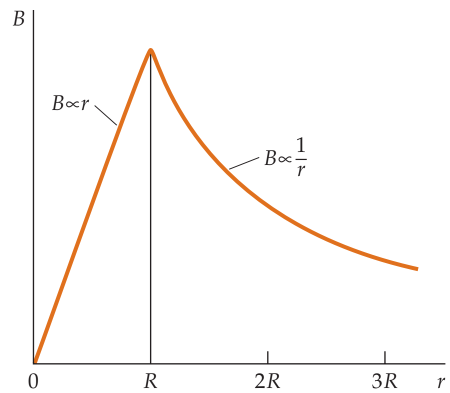

FIGURE 27-31

We see from Example 27-11 that the magnetic field due to a current uniformly distributed over a wire of radius R is given by

$$B = \begin{cases} \frac{\mu_0 I}{2\pi R^2} r & r \leq R \\ \frac{\mu_0}{2\pi}\frac{I}{r} & r \geq R \end{cases} \qquad 27\text{-}17$$

B FOR A LONG STRAIGHT WIRE

For the next application of Ampère's law, we calculate the magnetic field of a tightly wound **toroid,** which consists of loops of wire wound around a doughnut-shaped form, as shown in Figure 27-32. There are N turns of wire, each carrying a current I. To calculate B, we evaluate the line integral $\oint_C \vec{B} \cdot d\vec{\ell}$ around a circle of radius r that is coaxial with the toroid and is inside its loops. By symmetry, $\vec{B}$ is tangent to this circle and constant in magnitude at every point on the circle. Then,

$$\oint_C \vec{B} \cdot d\vec{\ell} = B2\pi r = \mu_0 I_C$$

Let a and b be the inner and outer radii of the toroid, respectively. The total current through the surface S bounded by a circle of radius r for $a < r < b$ is $I_C = NI$. Ampère's law then gives

$$\oint_C \vec{B} \cdot d\vec{\ell} = \mu_0 I_C \qquad \text{or} \qquad (B2\pi r = \mu_0 NI)$$

or

$$B = \frac{\mu_0 NI}{2\pi r} \qquad a < r < b \qquad 27\text{-}18$$

B INSIDE A TIGHTLY WOUND TOROID

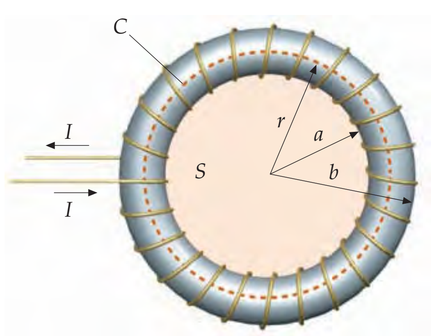

FIGURE 27-32 A toroid consists of loops of wire wound around an imaginary doughnut-shaped form. The magnetic field at any distance r can be found by applying Ampère's law to the circle of radius r. The surface S is bounded by curve C. The wire penetrates S once for each turn.

If r is less than a, there is no current through the surface S. If r is greater than b, the total current through S is zero because for each turn of the wire the current penetrates the surface S twice (Figure 27-33), once going into the page and once coming out of the page. Thus, the magnetic field is zero for both the region $r < a$ and the region $r > b$:

$$B = 0, \qquad r < a \text{ or } r > b$$

The magnetic field intensity inside the toroid is not uniform but decreases with increasing r. However, if $b - a$ (the diameter of the loops of the coil) is much less than $2b$, the variation in r from $r = a$ to $r = b$ is small, so the variation of B inside the loops is also small.

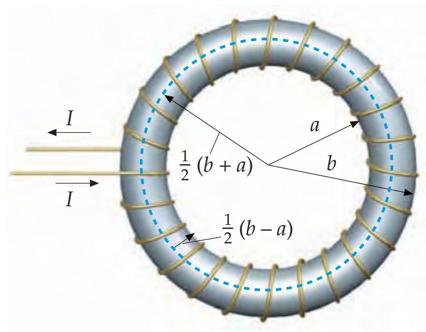

FIGURE 27-33 The toroid has mean radius $r = \frac{1}{2}(b + a)$, where a and b are the inner and outer radii of the toroid. Each turn of the wire is a circle of radius $\frac{1}{2}(b - a)$.

(*a*) The Tokamak fusion-test reactor is a large toroid that produces a magnetic field for confining charged particles. Coils containing over 10 km of water-cooled copper wire carry a pulsed current, which has a peak value of 73,000 A and produces a magnetic field of 5.2 T for about 3 s. (*b*) Inspection of the assembly of the Tokamak reactor from inside the toroid. *(Courtesy of Princeton University Plasma Physics Laboratory.)*

LIMITATIONS OF AMPÈRE'S LAW

Ampère's law is useful for calculating the magnetic field only when there is both a steady and continuous current and a high degree of symmetry. Consider the current loop shown in Figure 27-34. According to Ampère's law, the line integral $\oint_C \vec{B} \cdot d\vec{\ell} = \oint_C B_t \, d\ell$ around a curve, such as curve C in the figure, equals μ_0 multiplied by the current I in the loop. Although Ampère's law is valid for this curve, the tangential component of magnetic field B_t is not constant along any curve encircling the current. Thus, there is not enough symmetry in this situation to allow us to evaluate the integral $\oint_C B_t \, d\ell$ and solve for B_t.

Figure 27-35 shows a finite current segment of length ℓ. We wish to find the magnetic field at point P, which is equidistant from the ends of the segment and at a distance r from the center of the segment. A direct application of Ampère's law gives

$$B = \frac{\mu_0}{2\pi} \frac{I}{r}$$

This result is the same as for an infinitely long wire, because the same symmetry arguments apply. It does not agree with the result obtained from the Biot–Savart law, which depends on the length of the current segment and

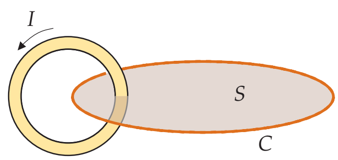

FIGURE 27-34 Ampère's law holds for the curve C encircling the current in the circular loop, but it is not useful for finding B_t because B_t cannot be factored out of the circulation integral.

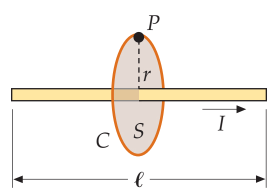

FIGURE 27-35 The application of Ampère's law to find the magnetic field on the bisector of a finite current segment gives an incorrect result.

which agrees with experiment. If the current segment is just one part of a continuous circuit carrying a current, as shown in Figure 27-36, Ampère's law for curve C is valid, but it cannot be used to find the magnetic field at point P because there is insufficient symmetry.

In Figure 27-37, the current in the segment arises from a small spherical conductor that has an initial charge $+Q$ at the left of the segment and another small spherical conductor at the right that has a charge $-Q$. When they are connected, a current $I = -dQ/dt$ exists in the segment for a short time, until the spheres are uncharged. For this case, we *do* have the symmetry needed to assume that $\vec{B}$ is tangential to the curve and $\vec{B}$ is constant in magnitude along the curve. For a situation like this, in which the current is discontinuous in space, Ampère's law is not valid. In Chapter 30, we will see how Maxwell was able to modify Ampère's law so that it holds for all currents. When Maxwell's generalized form of Ampère's law is used to calculate the magnetic field for a current segment, such as the current segment shown in Figure 27-37, the result agrees with the result found from the Biot–Savart law.

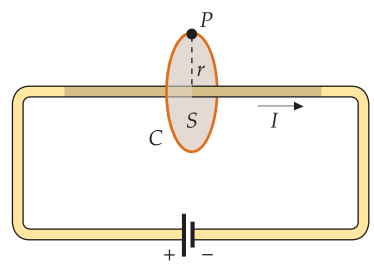

FIGURE 27-36 If the current segment in Figure 27-34 is part of a complete circuit, Ampère's law for the curve C is valid, but there is not enough symmetry to use Ampère's law to find the magnetic field at point P.

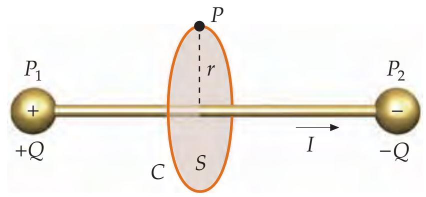

FIGURE 27-37 If the current segment in Figure 27-35 is due to a momentary flow of charge from a small conductor on the left to a small conductor on the right, there is enough symmetry to use Ampère's law to compute the magnetic field at P, but Ampère's law is not valid because the current is not steady.

27-5 MAGNETISM IN MATTER

Atoms have magnetic dipole moments due to the motion of their electrons and due to the intrinsic magnetic dipole moment associated with the spin of the electrons. Unlike the situation with electric dipoles, the alignment of magnetic dipoles parallel to an external magnetic field tends to *increase* the field. We can see this difference by comparing the electric field lines of an electric dipole with the magnetic field lines of a magnetic dipole, such as a small current loop, as was shown in Figure 27-24. Far from the dipoles, the field lines are identical. However, between the charges of the electric dipole, the electric field lines are opposite the direction of the dipole moment, whereas inside the current loop, the magnetic field lines are parallel to the magnetic dipole moment. Thus, inside a magnetically polarized material, the magnetic dipoles create a magnetic field that is parallel to the magnetic dipole moment vectors.

Materials fall into three categories—**paramagnetic, ferromagnetic,** and **diamagnetic**—according to the behavior of their magnetic moments in an external magnetic field. Paramagnetism arises from the partial alignment of the electron spins (in metals) or from the atomic or molecular magnetic moments by an applied magnetic field in the direction of the field. In paramagnetic materials, the magnetic dipoles do not interact strongly with each other and are normally randomly oriented. In the presence of an applied magnetic field, the dipoles are partially aligned in the direction of the field, thereby increasing the field. However, in external magnetic fields of ordinary strength at ordinary temperatures, only a very small fraction of the atoms are aligned because thermal motion tends to randomize their orientation. The increase in the total magnetic field is therefore very small. Ferromagnetism is much more complicated. Because of a strong interaction between neighboring magnetic dipoles, a high degree of alignment occurs even in weak external magnetic fields, which causes a very large increase in the total field. Even when there is no external magnetic field, a ferromagnetic material may have its magnetic dipoles aligned, as in permanent magnets. Diamagnetism arises from the orbital magnetic dipole moments induced by an applied magnetic field. These magnetic moments are opposite the direction of the applied magnetic field, thereby decreasing the field. This effect actually occurs in all materials; however, because the induced magnetic moments are very small compared to the permanent magnetic moments, diamagnetism is often masked by paramagnetic or ferromagnetic effects. Diamagnetism is thus observed only in materials whose atoms have no permanent magnetic moments.

MAGNETIZATION AND MAGNETIC SUSCEPTIBILITY

When some material is placed in a strong magnetic field, such as that of a solenoid, the magnetic field of the solenoid tends to align the magnetic dipole moments (either permanent or induced) inside the material and the material is said to be magnetized. We describe a magnetized material by its **magnetization** $\vec{M}$, which is defined as the net magnetic dipole moment per unit volume of the material:

$$\vec{M} = \frac{d\vec{\mu}}{dV} \qquad 27\text{-}19$$

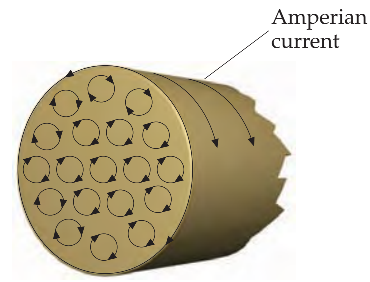

FIGURE 27-38 A model of atomic current loops in which all the atomic dipoles are parallel to the axis of the cylinder. The net current at any point inside the material is zero due to cancellation of neighboring atoms. The result is a surface current similar to that of a solenoid.

Long before we had any understanding of atomic or molecular structure, Ampère proposed a model of magnetism in which the magnetization of materials is due to microscopic current loops inside the magnetized material. We now know that these current loops are a classical model for the orbital motion and spin of the electrons in atoms. Consider a cylinder of magnetized material. Figure 27-38 shows atomic current loops in the cylinder aligned with their magnetic moments along the axis of the cylinder. Because of cancellation of neighboring current loops, the net current at any point inside the material is zero, leaving a net current on the surface of the material (Figure 27-39). This surface current, called an **amperian current,** is similar to the real current in the windings of the solenoid.

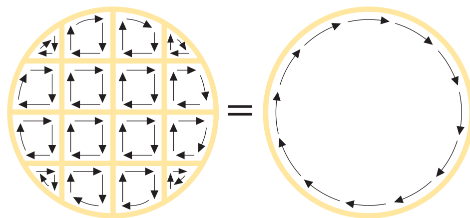

FIGURE 27-39 The currents in the adjacent current loops in the interior of a uniformly magnetized material cancel, leaving only a surface current. Cancellation occurs at every interior point independent of the shape of the very small loops.

Figure 27-40 shows a short cylinder of cross-sectional area A, length $d\ell$, and volume $dV = A\,d\ell$. Let di be the amperian current on the curved surface of the disk. The magnitude of the magnetic dipole moment of the disk is the same as that of a current loop that has an area A and carries a current di:

$$d\mu = A\,di$$

The magnitude of the magnetization of the disk is the magnetic moment per unit volume:

$$M = \frac{d\mu}{dV} = \frac{A\,di}{A\,d\ell} = \frac{di}{d\ell} \qquad 27\text{-}20$$

Thus, the magnitude of the magnetization vector is the amperian current per unit length along the surface of the magnetized material. We see from this result that the SI units for magnetization M are amperes per meter.

Consider a cylinder that has a uniform magnetization $\vec{M}$ parallel to its axis. The effect of the magnetization is the same as if the cylinder carried a surface current per unit length of magnitude M. This current is similar to the current carried by a tightly wound solenoid. For a solenoid, the current per unit length is nI, where n is the number of turns per unit length and I is the current in each turn. The magnitude of the magnetic field B_{m} inside the cylinder and far from its ends is thus given by $B = \mu_0 nI$ (Equation 27-10) for a solenoid with nI replaced by M:

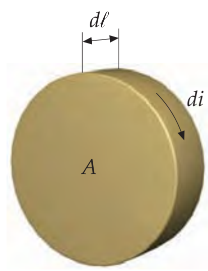

FIGURE 27-40 A disk element for relating the magnetization M to the surface current per unit length $di/d\ell$.

$$B_{\mathrm{m}} = \mu_0 M \qquad 27\text{-}21$$

Suppose we place a cylinder of magnetic material inside a long solenoid that has n turns per unit length and carries a current I. The applied field of the solenoid $\vec{B}_{\mathrm{app}}$ ($B_{\mathrm{app}} = \mu_0 nI$) magnetizes the material so that it has a magnetization $\vec{M}$. The resultant magnetic field at a point inside the solenoid and far from its ends due to the current in the solenoid plus the magnetized material is

$$\vec{B} = \vec{B}_{\mathrm{app}} + \mu_0\vec{M} \qquad 27\text{-}22$$

For paramagnetic and ferromagnetic materials, $\vec{M}$ is in the same direction as $\vec{B}_{\mathrm{app}}$; for diamagnetic materials, $\vec{M}$ is opposite to $\vec{B}_{\mathrm{app}}$. For paramagnetic and diamagnetic materials, the magnetization is found to be proportional to the applied magnetic field that produces the alignment of the magnetic dipoles in the material. We can thus write

$$\vec{M} = \chi_{\mathrm{m}}\frac{\vec{B}_{\mathrm{app}}}{\mu_0} \qquad 27\text{-}23$$

where the proportionality constant χ_m is a dimensionless number called the **magnetic susceptibility.** Equation 27-22 is then

$$\vec{B} = \vec{B}_{app} + \mu_0\vec{M} = \vec{B}_{app}(1 + \chi_m) = K_m\vec{B}_{app} \quad 27\text{-}24$$

where

$$K_m = 1 + \chi_m \quad 27\text{-}25$$

is called the **relative permeability** of the material. For paramagnetic materials, χ_m is a small positive number that depends on temperature. For diamagnetic materials (other than superconductors), it is a small negative constant independent of temperature. Table 27-1 lists the magnetic susceptibility of various paramagnetic and diamagnetic materials. We see that the magnetic susceptibility for the solids listed is of the order of 10^{-5}, and $K_m \approx 1$.

The magnetization of ferromagnetic materials, which we discuss shortly, is much more complicated. The relative permeability K_m defined as the ratio B/B_{app} is not constant and has maximum values ranging from 5000 to 100,000. In the case of permanent magnets, K_m is not even defined because such materials exhibit magnetization even in the absence of an applied field.

Table 27-1 Magnetic Susceptibility of Various Materials at

Material	χ_m
Aluminum	2.3×10^{-5}
Bismuth	-1.66×10^{-5}
Copper	-0.98×10^{-5}
Diamond	-2.2×10^{-5}
Gold	-3.6×10^{-5}
Magnesium	1.2×10^{-5}
Mercury	-3.2×10^{-5}
Silver	-2.6×10^{-5}
Sodium	-0.24×10^{-5}
Titanium	7.06×10^{-5}
Tungsten	6.8×10^{-5}
Hydrogen (1 atm)	-9.9×10^{-9}
Carbon dioxide (1 atm)	-2.3×10^{-9}
Nitrogen (1 atm)	-5.0×10^{-9}
Oxygen (1 atm)	2090×10^{-9}

ATOMIC MAGNETIC MOMENTS

The magnetization of a paramagnetic or ferromagnetic material can be related to the permanent magnetic moments of the individual atoms or electrons of the material. The orbital magnetic moment of an atomic electron can be derived semiclassically, even though it is quantum mechanical in origin. Consider a particle of mass m and charge q moving with speed v in a circle of radius r, as shown in Figure 27-41. The magnitude of the angular momentum of the particle about the center of the circle is

$$L = mvr \quad 27\text{-}26$$

The magnitude of the magnetic moment is the product of the current and the area of the circle:

$$\mu = IA = I\pi r^2$$

If T is the time for the charge to complete one revolution, the current (the charge passing a point per unit time) is q/T. Because the period T is the distance $2\pi r$ divided by the velocity v, the current is

$$I = \frac{q}{T} = \frac{qv}{2\pi r}$$

The magnetic moment is then

$$\mu = IA = \frac{qv}{2\pi r}\pi r^2 = \tfrac{1}{2}qvr \quad 27\text{-}27$$

Using $vr = L/m$ from Equation 27-26, we have for the magnetic moment

$$\mu = \frac{q}{2m}L$$

If the charge q is positive, the angular momentum and magnetic moment are in the same direction. We can therefore write

$$\vec{\mu} = \frac{q}{2m}\vec{L} \quad 27\text{-}28$$

CLASSICAL RELATION BETWEEN MAGNETIC MOMENT AND ANGULAR MOMENTUM

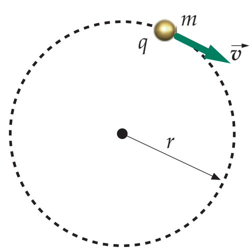

FIGURE 27-41 A particle of charge q and mass m moving with speed v in a circle of radius r. The angular momentum is directed into the paper and has a magnitude mvr. The magnetic moment is directed into the paper (if q is positive) and has a magnitude $\frac{1}{2}qvr$.

Equation 27-28 is the general classical relation between magnetic moment and angular momentum. It also holds in the quantum theory of the atom for orbital angular momentum, but the equation does not hold for the intrinsic spin angular momentum of the electron. For electron spin, the magnetic moment is twice that predicted by the equation.* The extra factor of 2, which is accounted for by quantum theory, has no analog in classical mechanics.

Because angular momentum is quantized, the magnetic moment of an atom is also quantized. The quantum of angular momentum is $\hbar = h/(2\pi)$, where h is Planck's constant, so we express the magnetic moment in terms of $\vec{L}/\hbar$:

$$\vec{\boldsymbol{\mu}} = \frac{q\hbar}{2m}\frac{\vec{\boldsymbol{L}}}{\hbar}$$

For an electron, $m = m_e$ and $q = -e$, so the magnetic moment of the electron due to its orbital motion is

$$\vec{\boldsymbol{\mu}}_\ell = -\frac{e\hbar}{2m_\mathrm{e}}\frac{\vec{\boldsymbol{L}}}{\hbar} = -\mu_\mathrm{B}\frac{\vec{\boldsymbol{L}}}{\hbar} \qquad 27\text{-}29$$

MAGNETIC MOMENT DUE TO THE ORBITAL MOTION OF AN ELECTRON

where

$$\mu_\mathrm{B} = \frac{e\hbar}{2m_\mathrm{e}} = 9.27 \times 10^{-24}\ \mathrm{A\cdot m^2} = 9.27 \times 10^{-24}\ \mathrm{J/T}$$
$$= 5.79 \times 10^{-5}\,\mathrm{eV/T} \qquad 27\text{-}30$$

BOHR MAGNETON

is the quantum unit of magnetic moment called a **Bohr magneton.** The magnetic moment of an electron due to its intrinsic spin angular momentum $\vec{\boldsymbol{S}}$ is

$$\vec{\boldsymbol{\mu}}_\mathrm{s} = -2 \times \frac{e\hbar}{2m_\mathrm{e}}\frac{\vec{\boldsymbol{S}}}{\hbar} = -2\mu_\mathrm{B}\frac{\vec{\boldsymbol{S}}}{\hbar} \qquad 27\text{-}31$$

MAGNETIC MOMENT DUE TO ELECTRON SPIN

Although the calculation of the magnetic moment of any atom is a complicated problem in quantum theory, the result for all electrons, according to both theory and experiment, is that the magnetic moment is of the order of a few Bohr magnetons. In addition, any atom that has an angular momentum equal to zero has a net magnetic moment equal to zero. (This topic is further discussed in Chapter 36.)

If all the atoms in a sample of material have their magnetic moments aligned, the magnetic moment per unit volume of the sample is the product of the number of atoms per unit volume n and the magnetic moment μ of each atom. For this extreme case, the **saturation magnetization** M_s is

$$M_\mathrm{s} = n\mu \qquad 27\text{-}32$$

The number of atoms per unit volume can be found from the molar mass M, the density ρ of the material, and Avogadro's number N_A:

$$n = \frac{N_\mathrm{A}\,(\mathrm{atoms/mol})}{M\,(\mathrm{kg/mol})}\rho(\mathrm{kg/m^3}) \qquad 27\text{-}33$$

* This result and the phenomenon of electron spin was predicted in 1927 by Paul Dirac, who combined special relativity and quantum mechanics into a relativistic wave equation called the Dirac equation. Precise measurements indicate that the magnetic moment of the electron due to its spin is 2.00232 times that predicted by Equation 27-28. The fact that the intrinsic magnetic moment of the electron is approximately twice what we would expect makes it clear that the simple model of the electron as a spinning ball is not to be taken literally.

Example 27-12 Saturation Magnetization for Iron

Find the saturation magnetization of a sample of iron and find the magnetic field it produces deep within the sample. Assume that each iron atom has a magnetic moment of 1 Bohr magneton.

PICTURE We find the number of atoms per unit volume from the density of iron, $\rho = 7.87 \times 10^3\ \text{kg/m}^3$, and its molar mass $M = 55.8 \times 10^{-3}\ \text{kg/mol}$.

SOLVE

1. The saturation magnetization is the product of the number of atoms per unit volume and the magnetic moment of each molecule:

$$M_s = n\mu$$

2. Calculate the number of atoms per unit volume from Avogadro's number, the molar mass, and the density:

$$n = \frac{N_A}{M}\rho = \frac{6.02 \times 10^{23}\ \text{atoms/mol}}{55.8 \times 10^{-3}\ \text{kg/mol}}(7.87 \times 10^3\ \text{kg/m}^3)$$
$$= 8.49 \times 10^{28}\ \text{atoms/m}^3$$

3. Substitute this result and $\mu = 1$ Bohr magneton to calculate the saturation magnetization:

$$M_s = n\mu$$
$$= (8.49 \times 10^{28}\ \text{atoms/m}^3)(9.27 \times 10^{-24}\ \text{A}\cdot\text{m}^2)$$
$$= \boxed{7.88 \times 10^5\ \text{A/m}}$$

4. The magnetic field on the axis inside and far from the ends of a long iron cylinder resulting from this maximum magnetization is given by $B = \mu_0 M_s$:

$$B = \mu_0 M_s$$
$$= (4\pi \times 10^{-7}\ \text{T}\cdot\text{A})(7.86 \times 10^5\ \text{A/m})$$
$$= \boxed{0.990\ \text{T} \approx 1\ \text{T}}$$

CHECK The step-4 result of $B \approx 1$ T is a large magnetic field. This result is as expected for the saturation magnetic field inside a ferromagnetic material.

TAKING IT FURTHER The measured saturation magnetic field of annealed iron is about 2.16 T, indicating that the magnetic moment of an iron atom is slightly greater than 2 Bohr magnetons. This magnetic moment is due mainly to the spins of two unpaired electrons in the iron atom.

*PARAMAGNETISM

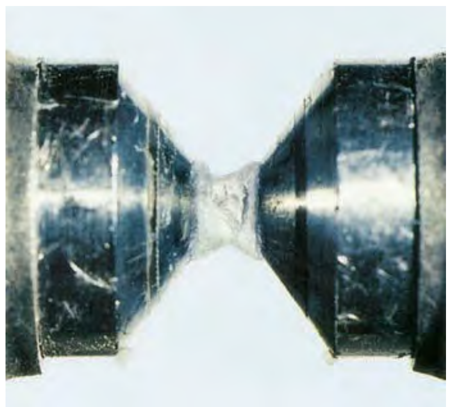
Paramagnetism occurs in materials whose atoms have permanent magnetic moments that interact with each other only very weakly, resulting in a very small, positive magnetic susceptibility χ_m. When there is no external magnetic field, these magnetic moments are randomly oriented. In the presence of an external magnetic field, the magnetic moments tend to line up parallel to the field, but this is counteracted by the tendency for the magnetic moments to be randomly oriented due to thermal motion. The degree to which the moments line up with the field depends on the strength of the field and on the temperature. This degree of alignment usually is small because the energy of a magnetic moment in an external magnetic field is typically much smaller than the thermal energy of an atom of the material, which is of the order of kT, where k is Boltzmann's constant and T is the absolute temperature.

The potential energy of a magnetic dipole of moment $\vec{\mu}$ in an external magnetic field $\vec{B}$ is given by Equation 27-16:

$$U = -\mu B\cos\theta = -\vec{\mu}\cdot\vec{B}$$

The potential energy U_{min} when the moment and the field are parallel ($\theta = 0$) is thus lower than the potential energy U_{max} when the moment and the field are antiparallel ($\theta = 180°$) by $2\mu B$. For a typical atomic magnetic moment of 1 Bohr magneton and a typical strong magnetic field of 1 T, the difference in these potential energies is

$$\Delta U = 2\mu_B B = 2(5.79 \times 10^{-5}\ \text{eV/T})(1\ \text{T}) = 1.16 \times 10^{-4}\ \text{eV}$$



Liquid oxygen, which is paramagnetic, is attracted by the magnetic field of a permanent magnet. A net force is exerted on the magnetic dipoles because the magnetic field is not uniform. *(J. F. Allen, St. Andrews University, Scotland.)*

At a normal temperature of $T = 300$ K, the typical thermal energy kT is

$$kT = (8.62 \times 10^{-5}\ \text{eV/K})(300\ \text{K}) = 2.59 \times 10^{-2}\ \text{eV}$$

which is more than 200 times greater than $2\mu_B B$. Thus, even in a very strong magnetic field of 1 T, most of the magnetic moments will be randomly oriented because of thermal motions (unless the temperature is very low).

Figure 27-42 shows a plot of the magnetization M versus an applied external magnetic field B_{app} at a given temperature. In very strong applied fields, nearly all the magnetic moments are aligned with the field and $M \approx M_s$. (For magnetic fields attainable in the laboratory, this can occur only for very low temperatures.) When $B_{\text{app}} = 0$, $M = 0$, indicating that the orientation of the moments is completely random. In weak fields, the magnetization is approximately proportional to the applied field, as indicated by the orange dashed line in the figure. In this region, the magnetization is given by

$$M = \frac{1}{3}\frac{\mu B_{\text{app}}}{kT}M_s \qquad 27\text{-}34$$

CURIE'S LAW

Note that $\mu B_{\text{app}}/(kT)$ is the ratio of the maximum energy of a dipole in the magnetic field to the characteristic thermal energy. The result that the magnetization varies inversely with the absolute temperature was discovered experimentally by Pierre Curie and is known as **Curie's law.**

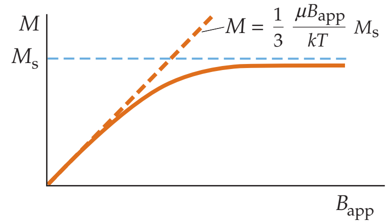


FIGURE 27-42 Plot of magnetization M versus an applied magnetic field B_{app}. In very strong fields, the magnetization approaches the saturation value M_s. This can be achieved only at very low temperatures. In weak fields, the magnetization is approximately proportional to B_{app}, a result known as Curie's law.

Example 27-13 Applying Curie's Law

If $\mu = \mu_B$, at what temperature will the magnetization be 1.00 percent of the saturation magnetization in an applied magnetic field of 1.00 T?

PICTURE Using Equation 27-34, solve for the temperature when M/M_s equals 0.0100.

SOLVE

1. Curie's law relates M, T, M_s, and B_{app}:
$$M = \frac{1}{3}\frac{\mu B_{\text{app}}}{kT}M_s$$

2. Solve for T using $\mu = \mu_B$ and $M/M_s = 0.0100$:
$$T = \frac{\mu_B B_{\text{app}}}{3k}\frac{M_s}{M} = \frac{(5.79 \times 10^{-5}\ \text{eV/T})(1.00\ \text{T})}{3(8.62 \times 10^{-5}\ \text{eV/K})}100$$
$$= \boxed{22.4\ \text{K}}$$

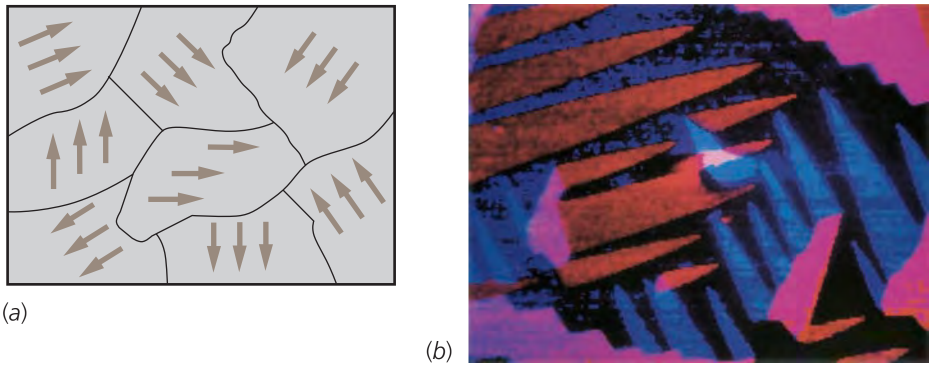
CHECK The step-2 result is greater than absolute zero, as expected.

TAKING IT FURTHER From this example, we see that even in a strong applied magnetic field of 1.00 T, the magnetization is less than 1.00 percent of saturation at temperatures above 22.4 K.

PRACTICE PROBLEM 27-9 If $\mu = \mu_B$, what fraction of the saturation magnetization is M at 300 K for an external magnetic field of 1.5 T?

*FERROMAGNETISM

Ferromagnetism occurs in pure iron, cobalt, and nickel as well as in alloys of those metals with each other. It also occurs in gadolinium, dysprosium, and a few compounds. Ferromagnetism arises from a strong interaction between the electrons in a partially full band in a metal or between the localized electrons that form magnetic moments on neighboring atoms. This interaction, called the **exchange interaction,** lowers the energy of a pair of electrons with parallel spins.



(a) (b)

FIGURE 27-43 (*a*) Schematic illustration of ferromagnetic domains. Within a domain, the magnetic dipoles are aligned, but the direction of alignment varies from domain to domain so that the net magnetic moment is zero. A small external magnetic field may cause the enlargement of those domains that are aligned parallel to the field (at the expense of the neighboring domains), or it may cause the alignment within a domain to rotate. In either case, the result is a net magnetic moment parallel to the field. (*b*) Magnetic domains on the surface of a 97 percent Fe–3 percent Si crystal observed using a scanning electron microscope with polarization analysis. A chunk of magnetite (lodestone) attracts the needle of a compass. *(© Paul Silverman/Fundamental Photographs.)*

Ferromagnetic materials have very large positive values of magnetic susceptibility χ_m (as measured under conditions described, which follow). In samples of these substances, a small external magnetic field can produce a very large degree of alignment of the atomic magnetic dipole moments. In some cases, the alignment can persist even when the external magnetizing field is removed. This alignment persists because the magnetic dipole moments exert strong forces on their neighbors so that over a small region of space the moments are aligned with each other even when there is no external field. The region of space over which the magnetic dipole moments are aligned is called a **magnetic domain.** The size of a domain is usually microscopic. Within the domain, all the permanent atomic magnetic moments are aligned, but the direction of alignment varies from domain to domain so that the net magnetic moment of a macroscopic piece of ferromagnetic material is zero in the normal state. Figure 27-43 illustrates this situation. The dipole forces that produce this alignment are predicted by quantum theory and cannot be explained with classical physics. At temperatures above a critical temperature, called the **Curie temperature,** thermal agitation is great enough to break up this alignment and ferromagnetic materials become paramagnetic.

When an external magnetic field is applied, the boundaries of the domains may shift or the direction of alignment within a domain may change so that there is a net macroscopic magnetic moment in the direction of the applied field. Because the degree of alignment is large for even a small external field, the magnetic field produced in the material by the dipoles is often much greater than the external field.

Current from an audio amplifier is sent to wires around a magnetic core in the recording head where it produces a magnetic field. When the tape passes over a gap in the core of the recording head, the fringing magnetic field encodes information on the tape. *((a) Akira Tonomura, Hitachi Advanced Research Library, Hatomaya, Japan; (b) © Bruce Iverson.)*

Let us consider what happens when we magnetize a long iron rod by placing it inside a solenoid and gradually increase the current in the solenoid windings. We assume that the rod and the solenoid are long enough to permit us to neglect end effects. Because the induced magnetic moments are in the same direction as the applied field, $\vec{B}_{app}$ and $\vec{M}$ are in the same direction. Then,

$$B = B_{app} + \mu_0 M = \mu_0 nI + \mu_0 M \qquad 27\text{-}35$$

In ferromagnetic materials, the magnetic field $\mu_0 M$ due to the magnetic moments is often greater than the magnetizing field B_{app} by a factor of several thousand.

Figure 27-44 shows a plot of B versus the magnetizing field B_{app}. As the current is gradually increased from zero, B increases from zero along the part of the curve from the origin O to point P_1. The flattening of this curve near point P_1 indicates that the magnetization M is approaching its saturation value M_s, at which all the atomic magnetic moments are aligned. Above saturation, B increases only because the magnetizing field $B_{app} = \mu_0 nI$ increases. When B_{app} is gradually decreased from point P_1, there is not a corresponding decrease in the magnetization. The shift of the domains in a ferromagnetic material is not completely reversible, and some magnetization remains even when B_{app} is reduced to zero, as indicated in the figure. This effect is called **hysteresis,** from the Greek word *hysteros* meaning later or behind, and the curve in Figure 27-44 is called a **hysteresis curve.** The value of the magnetic field at point P_4 when B_{app} is zero is called the **remnant field** B_{rem}. At that point, the iron rod is a permanent magnet. If the current in the solenoid is now reversed so that B_{app} is in the opposite direction, the magnetic field B is gradually brought to zero at point c. The remaining part of the hysteresis curve is obtained by further increasing the current in the opposite direction until point P_2 is reached, which corresponds to saturation in the opposite direction, and then decreasing the current to zero at point P_3 and increasing it again in its original direction.

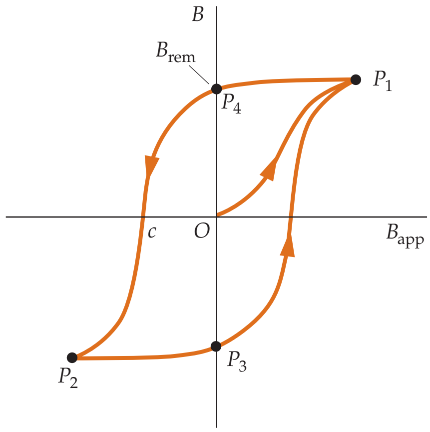

FIGURE 27-44 Plot of B versus the applied magnetizing field B_{app}. The outer curve is called a hysteresis curve. The field B_{rem} is called the remnant field. It remains when the applied field returns to zero.

Because the magnetization M depends on the previous history of the material, and because it can have a large value even when the applied field is zero, it is not simply related to the applied field B_{app}. However, if we confined ourselves to that part of the magnetization curve from the origin to point P_1 in Figure 27-44, $\vec{B}_{app}$ and $\vec{M}$ are parallel and M is zero when B_{app} is zero. We can then define the magnetic susceptibility as in Equation 27-23,

$$M = \chi_m \frac{B_{app}}{\mu_0}$$

and

$$B = B_{app} + \mu_0 M = B_{app}(1 + \chi_m) = K_m \mu_0 nI = \mu nI \qquad 27\text{-}36$$

where

$$\mu = (1 + \chi_m)\mu_0 = K_m \mu_0 \qquad 27\text{-}37$$

is called the **permeability** of the material. [For paramagnetic and diamagnetic materials, χ_m is much less than 1 so the permeability μ and the magnetic constant (permeability of empty space) μ_0 are very nearly equal.]

Because B does not vary linearly with B_{app}, as can be seen from Figure 27-44, the relative permeability is not constant. The maximum value of K_m occurs at a magnetization that is considerably less than the saturation magnetization. Table 27-2 lists the saturation magnetic field $\mu_0 M_s$ and the maximum values of K_m for some ferromagnetic materials. Note that the maximum values of K_m are much greater than 1.

The area enclosed by the hysteresis curve is proportional to the energy dissipated as heat in the irreversible process of magnetizing and demagnetizing. If the hysteresis effect is small, so that the area inside the curve is small, indicating a small energy loss, the material is called **magnetically soft.** Soft iron (chemically pure iron) is an example. The hysteresis curve for a magnetically soft material is shown in Figure 27-45. Here the remnant field B_{rem} is nearly zero, and the energy loss per cycle is small. Magnetically soft materials are used for transformer cores to allow the magnetic field B to change without incurring large energy losses as the field changes.

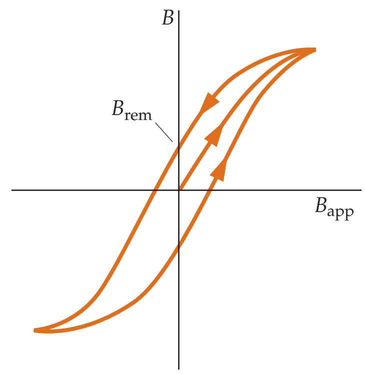

FIGURE 27-45 Hysteresis curve for a magnetically soft material. The remnant field is very small compared with the remnant field for a magnetically hard material such as that shown in Figure 27-44.

Table 27-2 Maximum Values of and for Some Ferromagnetic Materials

Material	$\mu_0 M_s$, T	K_m
Iron (annealed)	2.16	5500
Iron–silicon (96 percent Fe, 4 percent Si)	1.95	7000
Permalloy (55 percent Fe, 45 percent Ni)	1.60	25,000
Mu-metal (77 percent Ni, 16 percent Fe, 5 percent Cu, 2 percent Cr)	0.65	100,000

On the other hand, a large remnant field is desirable in a permanent magnet. **Magnetically hard** materials, such as carbon steel, the alloy Alnico 5, and the rare earths samarium and neodymium (samarium–cobalt and neodymium–iron–boron) are used for permanent magnets.

Example 27-14 Solenoid with Iron Core

A long solenoid has 12 turns per centimeter and a core of soft iron. When the current is 0.500 A, the magnetic field inside the iron core is 1.36 T. Find (*a*) the applied field B_{app}, (*b*) the relative permeability K_m, and (*c*) the magnetization M.

PICTURE The applied field is just that of a long solenoid given by $B_{app} = \mu_0 nI$. Because the total magnetic field is given, we can find the relative permeability from its definition ($K_m = B/B_{app}$) and we can find M from $B = B_{app} + \mu_0 M$.

SOLVE

(*a*) The applied field is given by Equation 27-10:

$$B_{app} = \mu_0 nI$$
$$= (4\pi \times 10^{-7}\ \mathrm{T \cdot m/A})(1200\ \mathrm{m^{-1}})(0.500\ \mathrm{A})$$
$$= \boxed{7.54 \times 10^{-4}\ \mathrm{T}}$$

(*b*) The relative permeability is the ratio of B to B_{app}:

$$K_m = \frac{B}{B_{app}} = \frac{1.36\ \mathrm{T}}{7.54 \times 10^{-4}\ \mathrm{T}} = \boxed{1.80 \times 10^3}$$

(*c*) The magnetization M is found from Equation 27-35:

$$\mu_0 M = B - B_{\text{app}}$$
$$= 1.36\text{ T} - 7.54 \times 10^{-4}\text{ T} \approx B = 1.36\text{ T}$$
$$M = \frac{B}{\mu_0} = \frac{1.36\text{ T}}{4\pi \times 10^{-7}\text{ T}\cdot\text{m/A}} = \boxed{1.08 \times 10^6\text{ A/m}}$$

CHECK Table 27-2 gives 5500 for the maximum value for K_m. Our Part (*b*) result is less than this maximum value, as expected.

TAKING IT FURTHER The applied magnetic field of 7.54×10^{-4} T is a negligible fraction of the total field of 1.36 T.

*DIAMAGNETISM

Diamagnetic materials are those materials that have very small negative values of magnetic susceptibility χ_m. Diamagnetism was discovered by Michael Faraday in 1845 when Faraday found that a piece of bismuth is repelled by either pole of a magnet, indicating that the external field of the magnet induces a magnetic moment in bismuth in the direction opposite the field.

We can understand this effect qualitatively from Figure 27-46, which shows two positive charges moving in circular orbits with the same speed but in opposite directions. Their magnetic moments are in opposite directions and therefore cancel.* In the presence of an external magnetic field $\vec{B}$ directed into the paper, the charges experience an extra force $q\vec{v} \times \vec{B}$, which is along the radial direction. For the charge on the left, this extra force is inward, increasing the centripetal force. If the charge is to remain in the same circular orbit, it must speed up so that mv^2/r equals the total centripetal force.† Its magnetic moment, which is out of the page, is thus increased. For the charge on the right, the additional force is outward, so the particle must slow down to maintain its circular orbit. Its magnetic moment, which is into the page, is decreased. In each case, the *change* in the magnetic moment of the charges is in the direction out of the page, opposite that of the external applied field. Because the permanent magnetic moments of the two charges are equal and oppositely directed they add to zero, leaving only the induced magnetic moments, which are both in the direction opposite to the direction of the applied magnetic field.

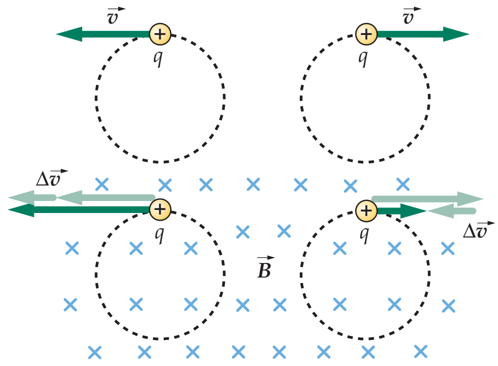

FIGURE 27-46 (*a*) A positive charge moving counterclockwise in a circle has its magnetic moment directed out of the paper. When an external magnetic field directed into the page is turned on, the magnetic force increases the centripetal force so the speed of the particle must increase. The change in the magnetic moment is out of the page. (*b*) A positive charge moving clockwise in a circle has its magnetic moment directed into the page. When an external magnetic field directed into the page is turned on, the magnetic force decreases the centripetal force so the speed of the particle must decrease. As in (*a*), the change in the magnetic moment is directed out of the page.

A material is diamagnetic if its atoms have zero net angular momentum and therefore no permanent magnetic moment. (The net angular momentum of an atom depends on the electronic structure of the atom, which is presented in Chapter 36.) The induced magnetic moments that cause diamagnetism have magnitudes of the order of 10^{-5} Bohr magnetons. Because this is much smaller than the permanent magnetic moments of the atoms of paramagnetic or ferromagnetic materials, the diamagnetic effect in these atoms is masked by the alignment of their permanent magnetic moments. However, because this alignment decreases with temperature, all materials are theoretically diamagnetic at sufficiently high temperatures.

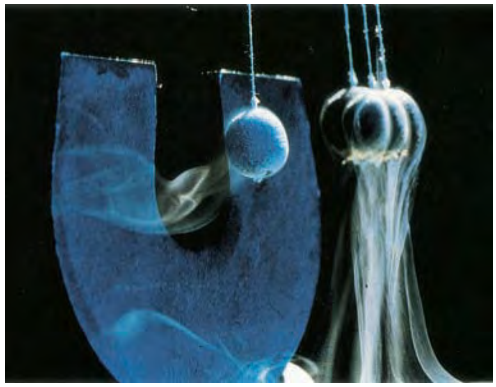
When a superconductor is placed in an external magnetic field, electric currents are induced on the superconductor's surface so that the net magnetic field in the superconductor is zero. Consider a superconducting rod inside a solenoid of n turns per unit length. When the solenoid is connected to a source of emf so that it carries a current I, the magnetic field due to the solenoid is $\mu_0 nI$. A surface current of $-nI$ per unit length is induced on the superconducting rod that cancels out the field due to the solenoid so that the net field inside the superconductor is zero. From Equation 27-24,

$$\vec{B} = \vec{B}_{\text{app}}(1 + \chi_m) = 0$$

so

$$\chi_m = -1$$

A superconductor is thus a perfect diamagnet with a magnetic susceptibility of -1.

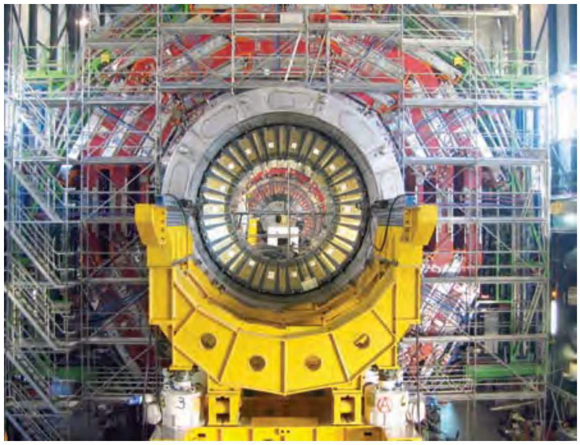


A superconductor is a perfect diamagnet. Here the superconducting pendulum bob is repelled by the permanent magnet. (*© Bill Pierce/ Time Magazine, Inc.*)

* It is simpler to consider positive charges even though negatively charged electrons provide the magnetic moments in matter.
† The electron speeds up because of an electric field induced by the changing magnetic field, an effect called induction, which we discuss in Chapter 28.

Physics Spotlight

Solenoids at Work



The world's largest superconducting solenoid magnet first reached its full field strength of 4 T in December 2006. Weighing in at over 10,000 tonnes, the magnet is built around a 6-m diameter, 13-m long superconducting solenoid. The solenoid, which is at CERN, will be used as part of a muon detector. *(CERN.)*

Why solenoids? Unlike gears, solenoids do not depend on friction for transferring motion, which means that solenoid-based movement is less likely to wear out machine parts. Solenoid valves, switches, and actuators are all based on the same principle—a central core in the solenoid is moved when current exists in the solenoid coils. Solenoid valves to control the flow of liquids and gases are the most popular mechanical use of solenoids. Some solenoid valves are opened directly by the motion of solenoid cores. When the solenoids turn off, springs return the valves to the off position.[*] Other solenoid valves, known as pilot-operated valves, use solenoid cores as switches for pistons that have very large ports, or use the motion of solenoid cores to open small pilot ports, which cause enough of a pressure differential in the main fluid line to open the main valve port.[†]

Because the cost of replacing a small valve is large due to lost time on a manufacturing line, manufacturers often choose solenoid valves in these lines.[‡] Some solenoid valves have been rated at several million cycles.[#] Solenoid valves also have been designed for use in very challenging environments. Solenoid valves can operate in corrosive[°,§] areas and in areas that have explosive atmospheres.[¶] Landscaping and irrigation applications[**] require solenoids that can operate outdoors. Solenoids are increasingly used for complex automated manufacturing processes.[††]

Because of their high reliability, long duty life, and low power draw compared to strictly mechanical systems, solenoids are used in robotics, aviation, and automotive applications. In robotics, solenoids often control air valves. In automotive applications, some solenoids control fluid pressure in the transmission, while others control automatic door locks.

One shortcoming of solenoids is that they are liable to overheating if they are overpowered[‡‡] or if the solenoid continually receives the power that is required to originally turn the solenoid on.[##] Overheating can fuse solenoid coils, shut down manufacturing lines, keep engines from starting, and even start fires. Because of these problems, designers are very careful to fit the solenoid to the use and the circuit.

Not all solenoids are used in mechanical applications. Some of the most powerful solenoids on Earth are used to provide large uniform magnetic fields for particle physics experiments. Many of these solenoids use cryogenically cooled superconductors to reach their full strength without overheating. A 5-T superconducting solenoid is set up at the Deutsches Elektronen-Synchrotron, or DESY. This magnet produces a magnetic field of 5.25 T when it carries currents of up to 1000 A. For the superconductors in the coil to work most efficiently, as well as to prevent overheating, the DESY solenoid must be cooled to 4.4 K.[°°] In Cessy, France, the largest superconducting solenoid magnet on Earth, the Compact Muon Solenoid, is scheduled to begin operating in November 2007.[§§] The coils of the solenoid contain 1947 km of superconducting niobium/titanium strands, and the solenoid has an internal diameter of 6.0 m. When it is cooled to 4.5 K, a current of more than 56 kA produces a magnetic field of 4 T.[¶¶] Whether very large solenoids for particle physics or miniature solenoids for chemical plants, the reliability and predictability of solenoids are prized assets.

Summary

1. Magnetic fields arise from moving charges, and therefore from currents.
2. The Biot–Savart law describes the magnetic field produced by a current element.
3. Ampère's law relates the line integral of the magnetic field along some closed curve to the current that passes through any surface bounded by the curve.
4. The magnetization vector $\vec{M}$ describes the magnetic dipole moment per unit volume of matter.
5. The classical relation $\vec{\mu} = [q/(2m)]\vec{L}$ is derived from the definitions of angular momentum and magnetic moment.
6. The Bohr magneton is a convenient unit for atomic and nuclear magnetic moments.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Magnetic Field $\vec{B}$		
Due to a moving point charge	$\vec{B} = \frac{\mu_0}{4\pi}\frac{q\vec{v} \times \hat{r}}{r^2}$	27-1
	where $\hat{r}$ is a unit vector that points to the field point P from the charge q moving with velocity $\vec{v}$, and μ_0 is a constant of proportionality called the magnetic constant (the permeability of empty space):	
	$\mu_0 = 4\pi \times 10^{-7}\,\text{T}\cdot\text{m/A} = 4\pi \times 10^{-7}\,\text{N/A}^2$	27-2
Due to a current element (Biot–Savart law)	$d\vec{B} = \frac{\mu_0}{4\pi}\frac{I\,d\vec{\ell} \times \hat{r}}{r^2}$	27-3
On the axis of a current loop	$B_z = \frac{\mu_0}{4\pi}\frac{2\pi R^2 I}{(z^2 + R^2)^{3/2}}$	27-6
Inside a long solenoid, far from the ends	$B_z = \mu_0 n I$	27-10
	where n is the number of turns per unit length.	
Due to a straight-wire segment	$B = \frac{\mu_0}{4\pi}\frac{I}{R}(\sin\theta_2 - \sin\theta_1)$	27-12
	where R is the perpendicular distance to the wire and θ_1 and θ_2 are the angles subtended at the field point by the ends of the wire.	
Due to a long, straight wire	Use Equation 27-12 with $\theta_2 = 90°$ and $\theta_2 = -90°$, or derive using Ampere's law.	
	The direction of $\vec{B}$ is such that the magnetic field lines of $\vec{B}$ encircle the wire in the direction of the fingers of the right hand if the thumb points in the direction of the current.	
Inside the loops of a tightly wound toroid	$B = \frac{\mu_0}{2\pi}\frac{NI}{r}$	27-18
2. Magnetic Field Lines	Magnetic lines neither begin nor end. Either they form closed loops or they continue indefinitely.	
3. Gauss's Law for Magnetism	$\phi_{\text{m net}} = \oint_S \vec{B}\cdot\hat{n}\,dA = \oint_S B_n\,dA = 0$	27-15
4. Magnetic Poles	Magnetic poles always occur in north–south pairs. Isolated magnetic poles have not been found.	
5. Ampère's Law	$\oint_C \vec{B}\cdot d\vec{\ell} = \oint_C B_t\,d\ell = \mu_0 I_C$	27-16
	where C is any closed curve.	

TOPIC	RELEVANT EQUATIONS AND REMARKS
Validity of Ampère's law	Ampère's law is valid only if the currents are steady and continuous. It can be used to derive expressions for the magnetic field for situations with a high degree of symmetry, such as a long, straight, current-carrying wire or a long, tightly wound solenoid.
6. Magnetism in Matter	Matter can be classified as paramagnetic, ferromagnetic, or diamagnetic.
Magnetization	A magnetized material is described by its magnetization vector $\vec{M}$, which is defined as the magnetic dipole moment per unit volume of the material: $$\vec{M} = \frac{d\vec{\mu}}{dV} \quad \text{27-19}$$ The magnetic field due to a uniformly magnetized cylinder is the same as if the cylinder carried a current per unit length of magnitude M on its surface. This current, which is due to the intrinsic motion of the atomic charges in the cylinder, is called an amperian current.
7. $\vec{B}$ in Magnetic Materials	$$\vec{B} = \vec{B}_{\text{app}} + \mu_0 \vec{M} \quad \text{27-22}$$
Magnetic susceptibility χ_{m}	$$\vec{M} = \chi_{\text{m}} \frac{\vec{B}_{\text{app}}}{\mu_0} \quad \text{27-23}$$ For paramagnetic materials, χ_{m} is a small positive number that depends on temperature. For diamagnetic materials (other than superconductors), it is a small negative constant independent of temperature. For superconductors, $\chi_{\text{m}} = -1$. For ferromagnetic materials, the magnetization depends not only on the magnetizing current but also on the past history of the material.
Relative permeability	$$\vec{B} = K_{\text{m}} \vec{B}_{\text{app}} \quad \text{27-24}$$ where $$K_{\text{m}} = 1 + \chi_{\text{m}} \quad \text{27-25}$$
8. Atomic Magnetic Moments	$$\vec{\mu} = \frac{q}{2m} \vec{L} \quad \text{27-28}$$ where $\vec{L}$ is the orbital angular momentum of the particle.
Bohr magneton	$$\mu_{\text{B}} = \frac{e\hbar}{2m_{\text{e}}} = 9.27 \times 10^{-24}\ \text{A}\cdot\text{m}^2$$ $$= 9.27 \times 10^{-24}\ \text{J/T} = 5.79 \times 10^{-5}\ \text{eV/T} \quad \text{27-30}$$
Due to the orbital motion of an electron	$$\vec{\mu}_\ell = -\mu_{\text{B}} \frac{\vec{L}}{\hbar} \quad \text{27-29}$$
Due to electron spin	$$\vec{\mu}_{\text{s}} = -2\mu_{\text{B}} \frac{\vec{S}}{\hbar} \quad \text{27-31}$$
***9. Paramagnetism**	Paramagnetic materials have permanent atomic magnetic moments that have random directions in the absence of an applied magnetic field. In an applied field these dipoles are aligned with the field to some degree, producing a small contribution to the total field that adds to the applied field. The degree of alignment is small except in very strong fields and at very low temperatures. At ordinary temperatures, thermal motion tends to maintain the random directions of the magnetic moments.
Curie's law	In weak fields, the magnetization is approximately proportional to the applied field and inversely proportional to the absolute temperature. $$M = \frac{1}{3} \frac{\mu B_{\text{app}}}{kT} M_{\text{s}} \quad \text{27-34}$$

TOPIC	RELEVANT EQUATIONS AND REMARKS
***10. Ferromagnetism**	Ferromagnetic materials have small regions of space called magnetic domains in which all the permanent atomic magnetic moments are aligned. When the material is unmagnetized, the direction of alignment in one domain is independent of that in another domain so that no net magnetic field is produced. When the material is magnetized, the domains of a ferromagnetic material are aligned, producing a very strong contribution to the magnetic field. This alignment can persist in magnetically hard materials, even when the external field is removed, thus leading to permanent magnets.
***11. Diamagnetism**	Diamagnetic materials are those materials in which the magnetic moments of all electrons in each atom cancel, leaving each atom with a zero magnetic moment in the absence of an external field. In an applied magnetic field, a very small magnetic moment is induced that tends to weaken the field. This effect is independent of temperature. Superconductors are diamagnetic with a magnetic susceptibility equal to -1.

Answers to Practice Problems

27-1	$\vec{B} = 0, \vec{B} = 3.2 \times 10^{-14}\ \mathrm{T}\ \hat{k}$
27-2	25 A
27-4	1.48×10^{-2} T. This is about 2 percent less than the step-3 result.
27-5	B at the center is larger for the circle.
27-6	$R = 4.0$ cm
27-7	0
27-8	$\vec{B} = 2.3 \times 10^{-5}\ \mathrm{T}\ \hat{j}$
27-9	$M/M_s = 1.12 \times 10^{-3}$

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • Sketch the field lines for the electric dipole and the magnetic dipole shown in Figure 27-47. How do the field lines differ in appearance close to the center of each dipole?

Electric dipole Magnetic dipole

FIGURE 27-47 Problem 1

2 • Two wires lie in the plane of the page and carry equal currents in opposite directions, as shown in Figure 27-48. At a point midway between the wires, the magnetic field is (*a*) zero, (*b*) into the page, (*c*) out of the page, (*d*) toward the top or bottom of the page, (*e*) toward one of the two wires.

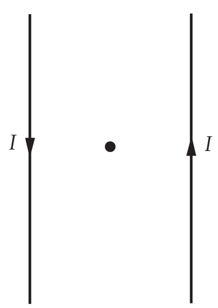

FIGURE 27-48 Problem 2

3 • Parallel wires 1 and 2 carry currents I_1 and I_2, respectively, where $I_2 = 2I_1$. The two currents are in the same direction. The magnitudes of the magnetic force by current 1 on wire 2

and by current 2 on wire 1 are F_{12} and F_{21}, respectively. These magnitudes are related by (*a*) $F_{12} = F_{21}$, (*b*) $F_{21} = 2F_{12}$, (*c*) $2F_{21} = F_{12}$, (*d*) $F_{21} = 4F_{12}$, (*e*) $4F_{21} = F_{12}$.

4 • Make a field-line sketch of the magnetic field due to the currents in the pair of identical coaxial coils shown in Figure 27-49. Consider two cases: (*a*) the currents in the coils have the same magnitude and have the same direction and (*b*) the currents in the coils have the same magnitude and have the opposite directions.

FIGURE 27-49
Problem 4

5 • Discuss the differences and similarities between Gauss's law for magnetism and Gauss's law for electricity. SSM

6 • Explain how you would modify Gauss's law if scientists discovered that single, isolated magnetic poles actually existed.

7 • You are facing directly into one end of a long solenoid and the magnetic field inside of the solenoid points away from you. From your perspective, is the direction of the current in the solenoid coils clockwise or counterclockwise? Explain your answer. SSM

8 • Opposite ends of a helical metal spring are connected to the terminals of a battery. Do the spacings between the coils of the spring tend to increase, decrease, or remain the same when the battery is connected? Explain your answer.

9 • The current density is constant and uniform in a long, straight wire that has a circular cross section. True or false:

(*a*) The magnitude of the magnetic field produced by the wire is greatest at the surface of the wire.
(*b*) The magnetic field strength in the region surrounding the wire varies inversely with the square of the distance from the wire's central axis.
(*c*) The magnetic field is zero at all points on the wire's central axis.
(*d*) The magnitude of the magnetic field inside the wire increases linearly with the distance from the wire's central axis.

10 • If the magnetic susceptibility of a material is positive, (*a*) paramagnetic effects or ferromagnetic effects must be greater than diamagnetic effects, (*b*) diamagnetic effects must be greater than paramagnetic effects, (*c*) diamagnetic effects must be greater than ferromagnetic effects, (*d*) ferromagnetic effects must be greater than paramagnetic effects, (*e*) paramagnetic effects must be greater than ferromagnetic effects.

11 • Of the four gases listed in Table 27-1, which are diamagnetic and which are paramagnetic? SSM

12 • When a current is passed through the wire in Figure 27-50, will the wire tend to bunch up or will it tend to form a circle? Explain your answer.

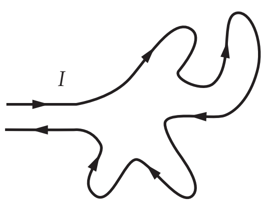

FIGURE 27-50
Problem 12

THE MAGNETIC FIELD OF MOVING POINT CHARGES

13 • At time $t = 0$, a particle has a charge of 12 μC, is located in the $z = 0$ plane at $x = 0$, $y = 2.0$ m, and has a velocity equal to 30 m/s $\hat{i}$. Find the magnetic field in the $z = 0$ plane at (*a*) the origin, (*b*) $x = 0, y = 1.0$ m, (*c*) $x = 0, y = 3.0$ m, and (*d*) $x = 0, y = 4.0$ m. SSM

14 • At time $t = 0$, a particle has a charge of 12 μC, is located in the $z = 0$ plane at $x = 0$, $y = 2.0$ m, and has a velocity equal to 30 m/s $\hat{i}$. Find the magnetic field in the $z = 0$ plane at (*a*) $x = 1.0$ m, $y = 3.0$ m, (*b*) $x = 2.0$ m, $y = 2.0$ m, and (*c*) $x = 2.0$ m, $y = 3.0$ m.

15 • A proton has a velocity of 1.0×10^2 m/s $\hat{i} + 2.0 \times 10^2$ m/s $\hat{j}$ and is located in the $z = 0$ plane at $x = 3.0$ m, $y = 4.0$ m at some time $t = T$. Find the magnetic field in the $z = 0$ plane at (*a*) $x = 2.0$ m, $y = 2.0$ m, (*b*) $x = 6.0$ m, $y = 4.0$ m, and (*c*) $x = 3.0$ m, $y = 6.0$ m.

16 •• In a pre–quantum-mechanical model of the hydrogen atom, an electron orbits a proton at a radius of 5.29×10^{-11} m. According to this model, what is the magnitude of the magnetic field at the proton due to the orbital motion of the electron? Neglect any motion of the proton.

17 •• Two equal point charges q are, at some instant, located at (0, 0, 0) and at (0, b, 0). They are both moving with speed v in the $+x$ direction (assume $v \ll c$). Find the ratio of the magnitude of the magnetic force to the magnitude of the electric force on each charge.

THE MAGNETIC FIELD USING THE BIOT–SAVART LAW

18 • A small current element at the origin has a length of 2.0 mm and carries a current of 2.0 A in the $+z$ direction. Find the magnetic field due to the current element (*a*) on the x axis at $x = 3.0$ m, (*b*) on the x axis at $x = -6.0$ m, (*c*) on the z axis at $z = 3.0$ m, and (*d*) on the y axis at $y = 3.0$ m.

19 • A small current element at the origin has a length of 2.0 mm and carries a current of 2.0 A in the $+z$ direction. Find the magnitude and direction of the magnetic field due to this current element at the point (0, 3.0 m, 4.0 m). SSM

20 • A small current element at the origin has a length of 2.0 mm and carries a current of 2.0 A in the $+z$ direction. Find the magnitude of the magnetic field due to this current element and indicate its direction on a diagram at (*a*) $x = 2.0$ m, $y = 4.0$ m, $z = 0$ and (*b*) $x = 2.0$ m, $y = 0$, $z = 4.0$ m.

THE MAGNETIC FIELD DUE TO CURRENT LOOPS AND COILS

21 • A single conducting loop has a radius equal to 3.0 cm and carries a current equal to 2.6 A. What is the magnitude of the magnetic field on the line through the center of the loop and perpendicular to the plane of the loop (*a*) at the center of the loop, (*b*) 1.0 cm from the center, (*c*) 2.0 cm from the center, and (*d*) 35 cm from the center?

22 ••• **SPREADSHEET** A pair of identical coils, each having a radius of 30 cm, are separated by a distance equal to their radii, that is, 30 cm. Called *Helmholtz coils*, they are coaxial and carry equal currents in directions such that their axial fields are in the same direction. A feature of Helmholtz coils is that the resultant magnetic field in the region between the coils is very uniform. Assume the current in each is 15 A and there are 250 turns for each coil. Using a spreadsheet program, calculate and graph the magnetic field as a function of z, the distance from the center of the coils along the common axis, for -30 cm $< z < +30$ cm. Over what range of z does the field vary by less than 20%?

23 ••• A pair of Helmholtz coils that have radii R have their axes along the z axis (see Problem 22). One coil is in the $z = -\frac{1}{2}R$ plane and the second coil is in the $z = +\frac{1}{2}R$ plane. Show that on the z axis at $z = 0$ $dB_z/dz = 0$, $d^2B_z/dz^2 = 0$, and $d^3B_z/dz^3 = 0$. (*Note:* These results show that the magnitude and direction of the magnetic field in the region to either side of the midpoint are approximately equal to the magnitude and direction of the magnetic field at the midpoint.)

24 ••• **ENGINEERING APPLICATION** *Anti-Helmholtz* coils are used in many physics applications, such as laser cooling and trapping, where a field with a uniform gradient is desired. These coils have the same construction as a Helmholtz coil, except that the currents have opposite directions, so that the axial fields are in opposite directions, and the coil separation is $\sqrt{3}R$ rather than R. Graph the magnetic field as a function of z, the axial distance from the center of the coils, for an anti-Helmholtz coil using the same parameters as in Problem 22. Over what interval of the z axis is dB_z/dz within one percent of its value at the midpoint between the coils?

THE MAGNETIC FIELD DUE TO STRAIGHT-LINE CURRENTS

Problems 25 to 30 refer to Figure 27-51 which shows two long, straight wires in the *xy* plane and parallel to the *x* axis. One wire is at $y = -6.0$ cm and the other wire is at $y = +6.0$ cm. The current in each wire is 20 A.

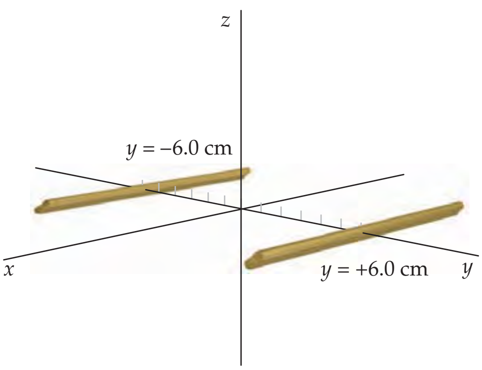

FIGURE 27-51 Problems 25–30

25 •• If the currents are both in the $-x$ direction, find the magnetic field at the following points on the y axis: (*a*) $y = -3.0$ cm, (*b*) $y = 0$, (*c*) $y = +3.0$ cm, and (*d*) $y = +9.0$ cm. SSM

26 •• **SPREADSHEET** Using a spreadsheet program or graphing calculator, graph B_z versus y when both currents are in the $-x$ direction.

27 •• The current in the wire at $y = -6.0$ cm is in the $-x$ direction and the current in the wire at $y = +6.0$ cm is in the $+x$ direction. Find the magnetic field at the following points on the y axis: (*a*) $y = -3.0$ cm, (*b*) $y = 0$, (*c*) $y = +3.0$ cm, and (*d*) $y = +9.0$ cm.

28 •• **SPREADSHEET** The current in the wire at $y = -6.0$ cm is in the $+x$ direction and the current in the wire at $y = +6.0$ cm is in the $-x$ direction. Using a spreadsheet program or graphing calculator, graph B_z versus y.

29 • Find the magnetic field on the z axis at $z = +8.0$ cm if (*a*) the currents are both in the $-x$ direction and (*b*) the current in the wire at $y = -6.0$ cm is in the $-x$ direction and the current in the wire at $y = +6.0$ cm is in the $+x$ direction.

30 • Find the magnitude of the force per unit length exerted by one wire on the other.

31 • Two long, straight parallel wires 8.6 cm apart carry equal currents. The wires repel each other with a force per unit length of 3.6 nN/m. (*a*) Are the currents parallel or antiparallel? Explain your answer. (*b*) Determine the current in each wire.

32 •• The current in the wire shown in Figure 27-52 is 8.0 A. Find the magnetic field at point P.

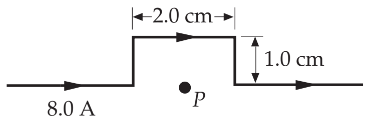

FIGURE 27-52 Problem 32

33 •• As a student technician, you are preparing a lecture demonstration on "magnetic suspension." You have a 16-cm-long straight, rigid wire that will be suspended by flexible conductive lightweight leads above a long, straight wire. Currents that are equal but are in opposite directions will be established in the two wires so the 16-cm wire "floats" a distance h above the long wire with no tension in its suspension leads. If the mass of the 16-cm wire is 14 g and if h (the distance between the central axes of the two wires) is 1.5 mm, what should their common current be? SSM

34 •• Three long, parallel straight wires pass through the vertices of an equilateral triangle that has sides equal to 10 cm, as shown in Figure 27-53. A dot indicates that the direction of the current is out of the page and a cross indicates that the direction of the current is into the page. If each current is 15 A, find (*a*) the magnetic field at the location of the upper wire due to the currents in the two lower wires and (*b*) the force per unit length on the upper wire.

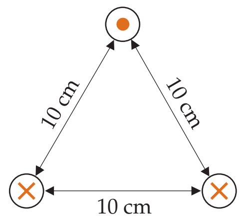

FIGURE 27-53 Problems 34 and 35

35 •• Rework Problem 34 with the current in the lower right corner of Figure 27-53 reversed.

36 •• An infinitely long wire lies along the x axis and carries current I in the $+x$ direction. A second infinitely long wire lies along the y axis and carries current I in the $+y$ direction. At what points in the $z = 0$ plane is the resultant magnetic field zero?

37 •• An infinitely long wire lies along the z axis and carries a current of 20 A in the $+z$ direction. A second infinitely long wire is parallel to the z axis and intersects the x axis at $x = 10.0$ cm.

(*a*) Find the current in the second wire if the magnetic field is zero at (2.0 cm, 0, 0). (*b*) What is the magnetic field at (5.0 cm, 0, 0)? SSM

38 •• Three long parallel wires are at the corners of a square, as shown in Figure 27-54. The wires each carry a current I. Find the magnetic field at the unoccupied corner of the square when (*a*) all the currents are into the page, (*b*) I_1 and I_3 are into the page and I_2 is out, and (*c*) I_1 and I_2 are into the page and I_3 is out. Your answers should be in terms of I and L.

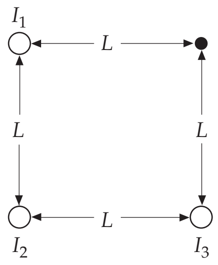

FIGURE 27-54 Problem 38

39 •• Four long, straight parallel wires each carry current I. In a plane perpendicular to the wires, the wires are at the corners of a square of side length a. Find the magnitude of the force per unit length on one of the wires if (*a*) all the currents are in the same direction and (*b*) the currents in the wires at adjacent corners are oppositely directed. SSM

40 •• Five long, straight, current-carrying wires are parallel to the z axis, and each carries a current I in the $+z$ direction. The wires each are a distance R from the z axis. Two of the wires intersect the x axis, one at $x = R$ and the other at $x = -R$. Another wire intersects the y axis at $y = R$. One of the remaining wires intersects the $z = 0$ plane at the point $(R/\sqrt{2}, R/\sqrt{2})$ and the last remaining wire intersects the $z = 0$ plane at the point $(-R/\sqrt{2}, R/\sqrt{2})$. Find the magnetic field on the z axis.

MAGNETIC FIELD DUE TO A CURRENT-CARRYING SOLENOID

41 •• A solenoid that has length 30 cm, radius 1.2 cm, and 300 turns carries a current of 2.6 A. Find the magnitude of the magnetic field on the axis of the solenoid (*a*) at the center of the solenoid and (*b*) at one end of the solenoid. SSM

42 • A solenoid is 2.7 m long, has a radius of 0.85 cm, and has 600 turns. It carries a current I of 2.5 A. What is the magnitude of the magnetic field B inside the solenoid and far from either end?

43 •• A solenoid has n turns per unit length, has a radius R, and carries a current I. Its axis coincides with the z axis—one end at $z = -\frac{1}{2}\ell$ and the other end at $z = +\frac{1}{2}\ell$. Show that the magnitude of the magnetic field at a point on the z axis is given by $B = \frac{1}{2}\mu_0 nI(\cos\theta_1 - \cos\theta_2)$, where the angles are related to the geometry by $\cos\theta_1 = (z + \frac{1}{2}\ell)/\sqrt{(z + \frac{1}{2}\ell)^2 + R^2}$ and $\cos\theta_2 = (z - \frac{1}{2}\ell)/\sqrt{(z - \frac{1}{2}\ell)^2 + R^2}$.

44 ••• In Problem 43, an expression for the magnitude of the magnetic field along the axis of a solenoid is given. For $z \gg \ell$ and $z \gg R$, the angles θ_1 and θ_2 are very small, so the small-angle approximations $\cos\theta \approx 1 - \frac{1}{2}\theta^2$ and $\sin\theta \approx \tan\theta \approx \theta$ are highly accurate. (*a*) Draw a diagram and use it to show that, for these conditions, the angles can be approximated as $\theta_1 \approx R/(z + \frac{1}{2}\ell)$ and $\theta_2 \approx R/(z - \frac{1}{2}\ell)$. (*b*) Using these approximations, show that the magnetic field at points on the z axis where $z \gg \ell$ can be written as $B = \frac{\mu_0}{4\pi}\left(\frac{q_m}{r_2^2} - \frac{q_m}{r_1^2}\right)$ where $r_2 = z - \frac{1}{2}\ell$ is the distance to the near end of the solenoid, $r_1 = z + \frac{1}{2}\ell$ is the distance to the far end, and the quantity q_m is defined by $q_m = nI\pi R^2 = \mu/\ell$, where $\mu = NI\pi R^2$ is the magnitude of the magnetic moment of the solenoid.

USING AMPÈRE'S LAW

45 • A long, straight, thin-walled cylindrical shell of radius R carries a current I parallel to the central axis of the shell. Find the magnetic field (including direction) both inside and outside the shell. SSM

46 • In Figure 27-55, one current is 8.0 A into the page, the other current is 8.0 A out of the page, and each curve is a circular path. (*a*) Find $\oint_C \vec{B} \cdot d\vec{\ell}$ for each path, assuming that each integral is to be evaluated in the counterclockwise direction. (*b*) Which path, if any, can be used to find the combined magnetic field of the currents?

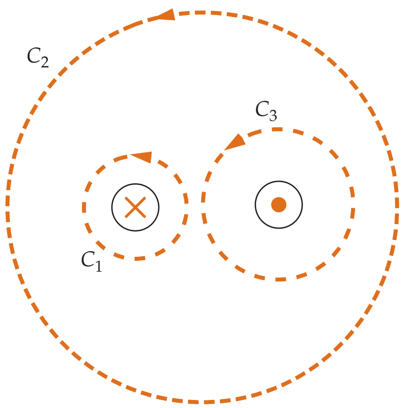

FIGURE 27-55 Problem 46

47 •• Show that a uniform magnetic field that has no fringing field, such as that shown in Figure 27-56, is impossible because it violates Ampère's law. Do this calculation by applying Ampère's law to the rectangular curve shown by the dashed lines. SSM

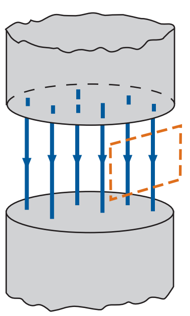

FIGURE 27-56 Problem 47

48 •• SPREADSHEET A coaxial cable consists of a solid conducting cylinder that has a radius equal to 1.00 mm and a conducting cylindrical shell that has an inner radius equal to 2.00 mm and an outer radius equal to 3.00 mm. The solid cylinder carries a current of 15.0 A parallel to the central axis. The cylindrical shell carries a current of 15.0 A in the opposite direction. Assume that the current densities are uniformly distributed in both conductors. (*a*) Using a spreadsheet program or graphing calculator, graph the magnitude of the magnetic field as a function of the radial distance r from the central axis for $0 < R < 3.00$ mm. (*b*) What is the magnitude of the field for $R > 3.00$ mm?

49 •• A long cylindrical shell has an inner radius a and an outer radius b and carries a current I parallel to the central axis. Assume that within the material of the shell the current density is uniformly distributed. Find an expression for the magnitude of the magnetic field for (*a*) $0 < R < a$, (*b*) $a < R < b$, and (*c*) $R > b$. SSM

50 •• Figure 27-57 shows a solenoid that has n turns per unit length and carries a current I. Apply Ampère's law to the rectangular curve shown in the figure to derive an expression for the magnitude of the magnetic field. Assume that inside the solenoid the magnetic field is uniform and parallel with the central axis, and that outside the solenoid there is no magnetic field.

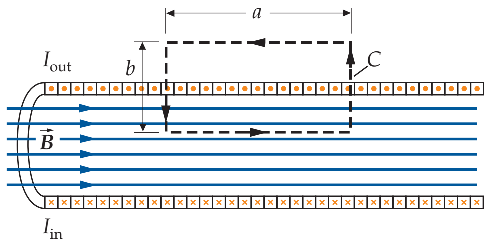

FIGURE 27-57 Problem 50

51 •• A tightly wound 1000-turn toroid has an inner radius of 1.00 cm and an outer radius of 2.00 cm, and carries a current of 1.50 A. The toroid is centered at the origin with the centers of the individual turns in the $z = 0$ plane. In the $z = 0$ plane: (*a*) What is the magnetic field strength at a distance of 1.10 cm from the origin? (*b*) What is the magnetic field strength at a distance of 1.50 cm from the origin? SSM

52 ••• A thin conducting sheet in the $z = 0$ plane carries current in the $-x$ direction (Figure 27-58*a*). The sheet extends indefinitely in all directions and the current is uniformly distributed throughout the sheet. To find the direction of the magnetic field at point P consider the field due only to the currents I_1 and I_2 in the two narrow strips shown. The strips are identical, so $I_1 = I_2$. (*a*) What is the direction of the magnetic field at point P due to just I_1 and I_2? Explain your answer using a sketch. (*b*) What is the direction of the magnetic field at point P due to the *entire* sheet? Explain your answer. (*c*) What is the direction of the field at a point to the right of point P (where $y \neq 0$)? Explain your answer. (*d*) What is the direction of the field at a point below the sheet (where $z < 0$)? Explain your answer using a sketch. (*e*) Apply Ampère's law to the rectangular curve (Figure 27-58*b*) to show that the magnetic field strength at point P is given by $B = \frac{1}{2}\mu_0\lambda$, where $\lambda = dI/dy$ is the current per unit length along the y axis.

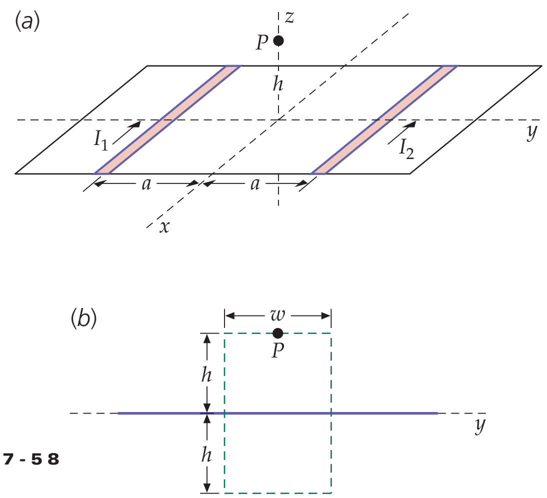

FIGURE 27-58 Problem 52

MAGNETIZATION AND MAGNETIC SUSCEPTIBILITY

53 • A tightly wound solenoid is 20.0 cm long, has 400 turns, and carries a current of 4.00 A so that its axial field is in the $+z$ direction. Find B and B_{app} at the center when (*a*) there is no core in the solenoid and (*b*) there is a soft iron core that has a magnetization of 1.2×10^6 A/m. SSM

54 • A long tungsten-core solenoid carries a current. (*a*) If the core is removed while the current is held constant, does the magnetic field strength in the region inside the solenoid decrease or increase? (*b*) By what percentage does the magnetic field strength in the region inside the solenoid decrease or increase?

55 • As a liquid fills the interior volume of a solenoid that carries a constant current, the magnetic field inside the solenoid *decreases* by 0.0040 percent. Determine the magnetic susceptibility of the liquid.

56 • A long thin solenoid carrying a current of 10 A has 50 turns per centimeter of length. What is the magnetic field strength in the region occupied by the interior of the solenoid when the interior is (*a*) a vacuum, (*b*) filled with aluminum, and (*c*) filled with silver?

57 •• A cylinder of iron, initially unmagnetized, is cooled to 4.00 K. What is the magnetization of the cylinder at that temperature due to the influence of Earth's magnetic field of 0.300 G? Assume a magnetic moment of 2.00 Bohr magnetons per atom. SSM

58 •• A cylinder of silver at a temperature of 77 K has a magnetization equal to 0.075% of its saturation magnetization. Assume a magnetic moment of one Bohr magneton per atom. The density of silver is 1.05×10^4 kg/m^3. (*a*) What value of applied magnetic field parallel to the central axis of the cylinder is required to reach this magnetization? (*b*) What is the magnetic field strength at the center of the cylinder?

59 •• During a solid-state physics lab, you are handed a cylindrically shaped sample of unknown magnetic material. You and your lab partners place the sample in a long solenoid that has n turns per unit length and a current I. The values for magnetic field B

within the material versus nI are given below. Use these values to plot B versus B_{app} and K_m versus nI, where B_{app} is the field due to the current I and K_m is the relative permeability of the sample.

***nI*, A/m**	0	50	100	150	200	500	1000	10 000
***B*, T**	0	0.04	0.67	1.00	1.2	1.4	1.6	1.7

ATOMIC MAGNETIC MOMENTS

60 •• Nickel has a density of 8.70 g/cm^3 and a molar mass of 58.7 g/mol. Nickel's saturation magnetization is 0.610 T. Calculate the magnetic moment of a nickel atom in Bohr magnetons.

61 •• Repeat Problem 60 for cobalt, which has a density of 8.90 g/cm^3, a molar mass of 58.9 g/mol, and a saturation magnetization of 1.79 T.

*PARAMAGNETISM

62 • Show that Curie's law predicts that the magnetic susceptibility of a paramagnetic substance is given by $\chi_m = \mu_0 M_s/(3kT)$.

63 •• In a simple model of paramagnetism, we can consider that some fraction f of the atoms have their magnetic moments aligned with the external magnetic field and that the rest of the atoms are randomly oriented and therefore do not contribute to the magnetic field. (*a*) Use this model and Curie's law to show that at temperature T and external magnetic field B, the fraction of aligned atoms f is given by $\mu B/(3kT)$. (*b*) Calculate this fraction for a sample temperature of 300 K and an external field of 1.00 T. Assume that μ has a value of 1.00 Bohr magneton.

64 •• Assume that the magnetic moment of an aluminum atom is 1.00 Bohr magneton. The density of aluminum is 2.70 g/cm^3 and its molar mass is 27.0 g/mol. (*a*) Calculate the value of the saturation magnetization and the saturation magnetic field for aluminum. (*b*) Use the result of Problem 62 to calculate the magnetic susceptibility at 300 K. (*c*) Explain why the result for Part (*b*) is larger than the value listed in Table 27-1.

65 •• A toroid has N turns, carries a current I, has a mean radius R, and has a cross-sectional radius r, where $r \ll R$ (Figure 27-59). When the toroid is filled with material, it is called a *Rowland ring*. Find B_{app} and B in such a ring, assuming a magnetization that is everywhere parallel to $\vec{B}_{app}$. SSM

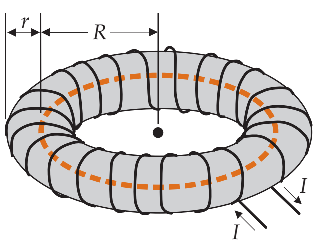

FIGURE 27-59 Problems 65 and 73

66 •• A toroid is filled with liquid oxygen that has a magnetic susceptibility of 4.00×10^{-3}. The toroid has 2000 turns and carries a current of 15.0 A. Its mean radius is 20.0 cm, and the radius of its cross section is 8.00 mm. (*a*) What is the magnetization? (*b*) What is the magnetic field? (*c*) What is the percentage change in the magnetic field produced by the liquid oxygen?

67 •• The centers of the turns of a toroid form a circle with a radius of 14.0 cm. The cross-sectional area of each turn is 3.00 cm^2. It is wound with 5278 turns of fine wire, and the wire carries a current of 4.00 A. The core is filled with a paramagnetic material of magnetic susceptibility 2.90×10^{-4}. (*a*) What is the magnitude of the magnetic field within the substance? (*b*) What is the magnitude of the magnetization? (*c*) What would the magnitude of the magnetic field be if there were no paramagnetic core present?

*FERROMAGNETISM

68 • For annealed iron, the relative permeability K_m has its maximum value of approximately 5500 at $B_{app} = 1.57 \times 10^{-4}$ T. Find the magnitude of the magnetization and magnetic field in annealed iron when K_m is maximum.

69 •• The saturation magnetization for annealed iron occurs when $B_{app} = 0.201$ T. Find the permeability and the relative permeability of annealed iron at saturation. (See Table 27-2.) SSM

70 •• The *coercive force* (which is a misnomer because it is really a magnetic field value) is defined as the applied magnetic field needed to bring the magnetic field back to zero along the hysteresis curve (which is point *c* in Figure 27-44). For a certain permanent bar magnet, the coercive force is known to be 5.53×10^{-2} T. The bar magnet is to be demagnetized by placing it inside a 15.0-cm-long solenoid that has 600 turns. What minimum current is needed in the solenoid to demagnetize the magnet?

71 •• A long thin solenoid has 50 turns/cm and carries a current of 2.00 A. The solenoid is filled with iron and the magnetic field is measured to be 1.72 T. (*a*) Neglecting end effects, what is the magnitude of the applied magnetic field? (*b*) What is the magnetization? (*c*) What is the relative permeability?

72 •• When the current in Problem 71 is 0.200 A, the magnetic field is measured to be 1.58 T. (*a*) Neglecting end effects, what is the applied magnetic field? (*b*) What is the magnetization? (*c*) What is the relative permeability?

73 •• A toroid has N turns, carries a current I, has a mean radius R, and has a cross-sectional radius r, where $r \ll R$ (Figure 27-59). The core of the toroid is filled with iron. When the current is 10.0 A, the magnetic field in the region where the iron is has a magnitude of 1.80 T. (*a*) What is the magnetization? (*b*) Find the values for the relative permeability, the permeability, and the magnetic susceptibility for this iron sample. SSM

74 • The centers of the turns of a toroid form a circle with a radius of 14.0 cm. The cross-sectional area of each turn is 3.00 cm^2. It is wound with 5278 turns of fine wire, and the wire carries a current of 0.200 A. The core is filled with soft iron, which has a relative permeability of 500. What is the magnetic field strength in the core?

75 ••• A long, straight wire that has a radius of 1.00 mm is coated with an insulating ferromagnetic material that has a thickness of 3.00 mm and a relative magnetic permeability of 400. The coated wire is in air and the wire itself is nonmagnetic. The wire carries a current of 40.0 A. (*a*) Find the magnetic field in the region occupied by the inside of the wire as a function of the perpendicular distance, *r*, from the central axis of the wire. (*b*) Find the magnetic field in the region occupied by the inside of the ferromagnetic

material as a function of the perpendicular distance, r, from the central axis of the wire. (c) Find the magnetic field in the region surrounding the wire and coating as a function of the perpendicular distance, r, from the central axis of the wire. (d) What must the magnitudes and directions of the amperian currents be on the surfaces of the ferromagnetic material to account for the magnetic fields observed?

GENERAL PROBLEMS

76 • Find the magnetic field at point P in Figure 27-60.

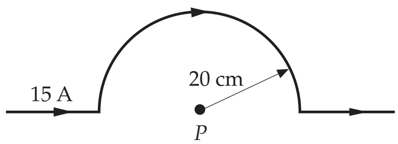

FIGURE 27-60 Problem 76

77 • Using Figure 27-61, find the magnetic field (in terms of the parameters given in the figure) at point P, the common center of the two arcs. SSM

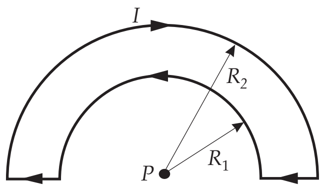

FIGURE 27-61 Problem 77

78 •• A wire of length ℓ is wound into a circular coil of N turns and carries a current I. Show that the magnetic field strength in the region occupied by the center of the coil is given by $\mu_0\pi N^2 I/\ell$.

79 •• A very long wire carrying a current I is bent into the shape shown in Figure 27-62. Find the magnetic field at point P.

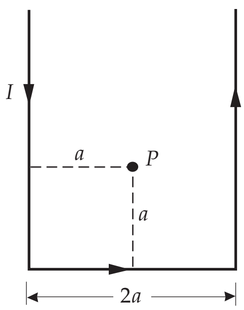

FIGURE 27-62 Problem 79

80 •• A power cable carrying 50 A is 2.0 m below Earth's surface, but the cable's direction and precise position are unknown. Explain how you could locate the cable using a compass. Assume that you are at the equator, where Earth's magnetic field is horizontal and 0.700 G due north.

81 •• A long, straight wire carries a current of 20.0 A, as shown in Figure 27-63. A rectangular coil that has two sides parallel to the straight wire has sides that are 5.00 cm long and 10.0 cm long. The side nearest to the wire is 2.00 cm from the wire. The coil carries a current of 5.00 A. (a) Find the force on each segment of the rectangular coil due to the current in the long, straight wire. (b) What is the net force on the coil? SSM

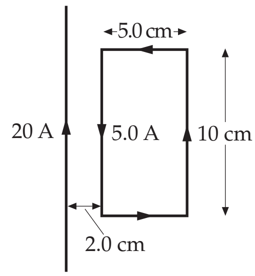

FIGURE 27-63 Problem 81

82 •• The closed loop shown in Figure 27-64 carries a current of 8.0 A in the counterclockwise direction. The radius of the outer arc is 0.60 m and that of the inner arc is 0.40 m. Find the magnetic field at point P.

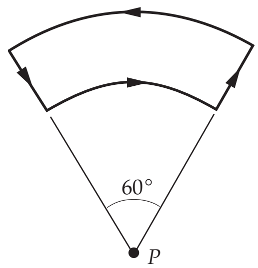

FIGURE 27-64 Problem 82

83 •• A closed circuit consists of two semicircles of radii 40 cm and 20 cm that are connected by straight segments, as shown in Figure 27-65. A current of 3.0 A exists in this circuit and has a clockwise direction. Find the magnetic field at point P.

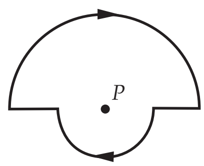

FIGURE 27-65 Problem 83

84 •• A very long, straight wire carries a current of 20.0 A. An electron outside the wire is 1.00 cm from the central axis of the wire and is moving with a speed of 5.00×10^6 m/s. Find the force on the electron when it moves (a) directly away from the wire, (b) parallel to the wire in the direction of the current, and (c) perpendicular to the central axis of wire and tangent to a circle that is coaxial with the wire.

85 •• SPREADSHEET A current of 5.00 A is uniformly distributed over the cross section of a long, straight wire of radius $R_0 = 2.55$ mm. Using a spreadsheet program, graph the magnetic field strength as a function of R (the distance from the central axis of the wire) for $0 \le R \le 10R_0$.

86 •• A 50-turn coil of radius 10.0 cm carries a current of 4.00 A and a concentric 20-turn coil of radius 0.500 cm carries a current of 1.00 A. The planes of the two coils are perpendicular. Find the magnitude of the torque exerted by the large coil on the small coil. (Neglect any variation in magnetic field due to the current in the large coil over the region occupied by the small coil.)

87 •• The magnetic needle of a compass is a uniform rod with a length of 3.00 cm, a radius of 0.850 mm, and a density of $7.96 \times 10^3\ \mathrm{kg/m^3}$. The needle is free to rotate in a horizontal plane, where the horizontal component of Earth's magnetic field is 0.600 G. When disturbed slightly, the compass executes simple harmonic motion about its midpoint with a frequency of 1.40 Hz. (*a*) What is the magnetic dipole moment of the needle? (*b*) What is the magnetization of the needle? (*c*) What is the amperian current on the surface of the needle?

88 •• A relatively inexpensive ammeter, called a *tangent galvanometer*, can be made using Earth's magnetic field. A plane circular coil that has N turns and a radius R is oriented so the magnetic field B_c it produces in the center of the coil is either east or west. A compass is placed at the center of the coil. When there is no current in the coil, assume the compass needle points due north. When there is a current in the coil (I), the compass needle points in the direction of the resultant magnetic field at an angle θ to the north. Show that the current I is related to θ and to the horizontal component of Earth's magnetic field B_e by $I = \dfrac{2RB_e}{\mu_0 N}\tan\theta$.

89 •• Earth's magnetic field is about 0.600 G at the magnetic poles, and is pointed vertically downward at the magnetic pole in the northern hemisphere. If the magnetic field were due to an electric current circulating in a loop at the radius of the inner iron core of Earth (approximately 1300 km), (*a*) what would be the magnitude of the current required? (*b*) What direction would this current have–the same as Earth's spin, or opposite? Explain your answer.

90 •• A long, narrow bar magnet has its magnetic moment $\vec{\mu}$ parallel to its long axis and is suspended at its center—in essence becoming a frictionless compass needle. When the magnet is placed in a magnetic field $\vec{B}$, it lines up with the field. If it is displaced by a small angle and released, show that the magnet will oscillate about its equilibrium position with frequency given by $\dfrac{1}{2\pi}\sqrt{\dfrac{\mu B}{I}}$, where I is the moment of inertia about the point of suspension.

91 •• An infinitely long, straight wire is bent, as shown in Figure 27-66. The circular portion has a radius of 10.0 cm and its center is a distance r from the straight part. Find the value of r such that the magnetic field at the center of the circular portion is zero.

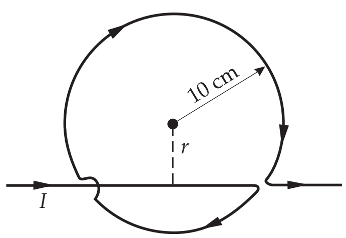

FIGURE 27-66 Problem 91

92 •• (*a*) Find the magnetic field strength at point P on the perpendicular bisector of a wire segment carrying current I, as shown in Figure 27-67. (*b*) Use your result from Part (*a*) to find the magnetic field strength at the center of a regular polygon of N sides. (*c*) Show that when N is very large, your result approaches that for the magnetic field strength at the center of a circle.

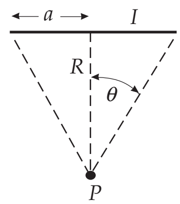

FIGURE 27-67 Problem 92

93 •• The current in a long cylindrical conductor of radius 10 cm varies with distance from the axis of the cylinder according to the relation $I(r) = (50\ \mathrm{A/m})r$. Find the magnetic field at the following perpendicular distances from the wire's central axis: (*a*) 5.0 cm, (*b*) 10 cm, and (*c*) 20 cm.

94 •• Figure 27-68 shows a square loop that has 20-cm-long sides and is in the $z = 0$ plane with its center at the origin. The loop carries a current of 5.0 A. An infinitely long wire that is parallel to the x axis and carries a current of 10 A intersects the z axis at $z = 10$ cm. The directions of the currents are shown in the figure. (*a*) Find the net torque on the loop. (*b*) Find the net force on the loop.

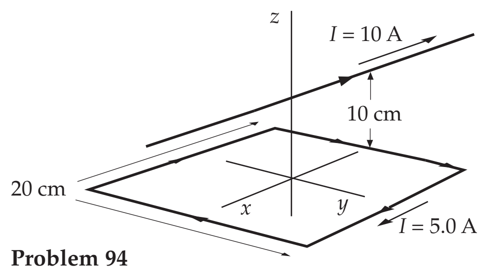

FIGURE 27-68 Problem 94

95 •• A current balance is constructed in the following way: A straight 10.0-cm-long section of wire is placed on top of the pan of an electronic balance (Figure 27-69). This section of wire is connected in series with a power supply and a long straight horizontal section of wire that is parallel to it and positioned directly above it. The distance between the central axes of the two wires is 2.00 cm. The power supply provides a current in the wires. When the power supply is switched on, the reading on the balance increases by 5.00 mg. What is the current in the wire? SSM

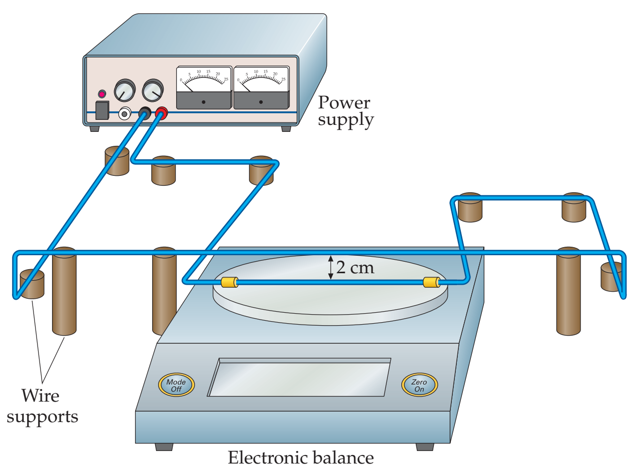

FIGURE 27-69 Problem 95

96 •• Consider the current balance of Problem 95. If the sensitivity of the balance is 0.100 mg, what is the minimum current detectable using this current balance?

97 ••• A nonconducting disk has radius R, carries a uniform surface charge density σ, and rotates with angular speed ω. (*a*) Consider an annular strip that has a radius r, a width dr, and a charge dq. Show that the current (dI) produced by this rotating strip is given by $\omega\sigma r\, dr$. (*b*) Use your result from Part (*a*) to show that the magnetic field strength at the center of the disk is given by the expression $\frac{1}{2}\mu_0\sigma\omega R$. (*c*) Use your result from Part (*a*) to find an expression for the magnetic field strength at a point on the central axis of the disk a distance z from its center. SSM

98 ••• A square loop that has sides of length ℓ lies in the $z = 0$ plane with its center at the origin. The loop carries a current I. (*a*) Derive an expression for the magnetic field strength at any point on the z axis. (*b*) Show that for z much larger than ℓ, your result from Part (*a*) becomes $B \approx \mu\mu_0/(2\pi z^3)$, where μ is the magnitude of the magnetic moment of the loop.

CHAPTER 28

DEMONSTRATION OF INDUCED EMF. WHEN THE MAGNET IS MOVING TOWARD OR AWAY FROM THE COIL, AN EMF IS INDUCED IN THE COIL, AS SHOWN BY THE GALVANOMETER'S DEFLECTION. NO DEFLECTION IS OBSERVED WHEN THE MAGNET IS STATIONARY. *(Richard Megna/Fundamental Photographs.)*

Magnetic Induction

? How do you calculate the magnitude of an induced emf in a coil? (See Example 28-2.)

In the early 1830s, Michael Faraday in England and Joseph Henry in the United States independently discovered that in a *changing* magnetic field a changing magnetic flux through a surface bounded by a closed stationary loop of wire induces a current in the wire. The emfs and currents caused by such changing magnetic fluxes are called **induced emfs** and **induced currents.** The process itself is referred to as **induction.** Faraday and Henry also discovered that in a *static* magnetic field a changing magnetic flux through a surface bounded by a moving loop of wire induces an emf in the wire. An emf caused by the motion of a conductor in a region with a magnetic field is called a **motional emf.**

When you pull the plug of an electric cord from its socket, you sometimes observe a small spark. Before the cord is disconnected, the cord carries a current that produces a magnetic field encircling the current. When the cord is disconnected, the current abruptly ceases and the magnetic field encircling the cord collapses.

This changing magnetic field induces an emf that tends to maintain the original current, resulting in a spark at the points of the disconnect. Once the magnetic field collapses to zero it is no longer changing, and the induced emf is zero.

This chapter will explore the various methods of magnetic induction, all of which can be summarized by a single relation known as Faraday's law. Faraday's law relates the induced emf in a circuit to the rate of change in magnetic flux through the circuit. (The magnetic flux through the circuit refers to the flux of the magnetic field through a surface bounded by the circuit.)

28-1 MAGNETIC FLUX

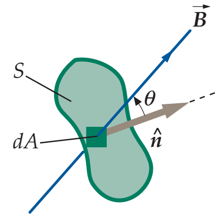

FIGURE 28-1 When $\vec{B}$ makes an angle θ with the normal to the surface S, the flux through the area dA is $\vec{B}\cdot\hat{n}\,dA = B\,dA\cos\theta$, where dA is the area of the surface element.

The flux of any vector field through a surface is calculated in the same way as the flux of an electric field through a surface (Section 22-2). Let dA be an element of area on the surface S, and let $\hat{n}$ be a unit vector normal to the surface element of area dA (Figure 28-1). If $\hat{n}$ is a normal to a surface element, then so is $-\hat{n}$, so there are two directions normal to any surface element, and which of the two directions is selected for the direction of $\hat{n}$ is optional. However, the sign of the flux does depend on the choice for the direction of $\hat{n}$. The magnetic flux ϕ_m through S is

$$\phi_m = \int_S \vec{B}\cdot\hat{n}\,dA = \int_S B_n\,dA \qquad 28\text{-}1$$

MAGNETIC FLUX

The unit of magnetic flux is that of magnetic field strength multiplied by area, namely, the tesla-meter-squared, which is called a **weber** (Wb):

$$1\text{ Wb} = 1\text{ T}\cdot\text{m}^2 \qquad 28\text{-}2$$

Because B is proportional to the number of field lines per unit area, the magnetic flux is proportional to the number of field lines through an element of area.

PRACTICE PROBLEM 28-1
Show that one weber per second is one volt.

If the surface is flat and has an area A, and if $\vec{B}$ is uniform (has the same magnitude and direction) everywhere on the surface, the magnetic flux through the surface is

$$\phi_m = \vec{B}\cdot\hat{n}A = BA\cos\theta = B_nA \qquad 28\text{-}3$$

where θ is the angle between the direction of $\vec{B}$ and the direction of $\hat{n}$. We shall refer to the direction of $\hat{n}$ as the positive normal direction. We are often interested in the flux through a surface bounded by a coil that has several turns of wire. If the coil has N turns, the flux through the surface is N multiplied by the flux through each turn (Figure 28-2). That is,

$$\phi_m = NBA\cos\theta \qquad 28\text{-}4$$

where A is the area of the flat surface bounded by a single turn. (*Note:* Only a closed curve can actually bound a surface. A single turn of a multiturn coil is not closed, so a single turn cannot actually bound a surface. However, if a coil is tightly wound a single turn is almost closed, and A is the area of the flat surface that it almost bounds.)

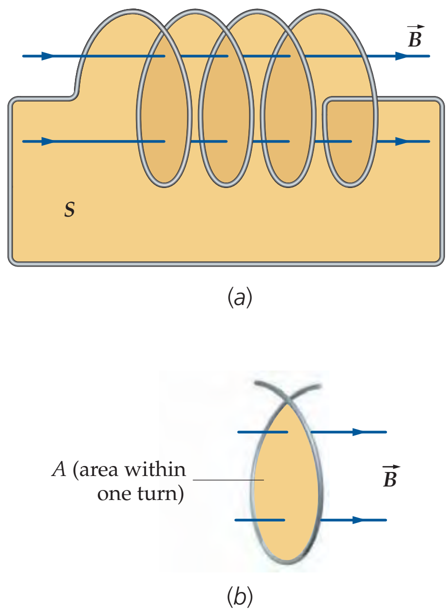

FIGURE 28-2 (*a*) The flux through the surface S bounded by a coil that has N turns is proportional to the number of field lines penetrating the surface. The coil shown has 4 turns. For the two field lines shown, each line penetrates the surface S four times, once for each turn, so the flux through S is four times greater than the flux through the surface "bounded" by a single turn of the coil. The coil shown is not tightly wound so the surface S can be seen better. (*b*) The area A of the flat surface is (almost) bounded by a single turn.

Example 28-1 Flux through a Solenoid

Find the magnetic flux through a solenoid that is 40 cm long, has a radius of 2.5 cm, has 600 turns, and carries a current of 7.5 A.

PICTURE The magnetic field $\vec{B}$ inside this long solenoid is uniform and parallel with the axis of the solenoid. (We are neglecting the end effects.) It is therefore perpendicular to the plane of each loop of the solenoid. Therefore, to find the flux we need to find B inside the solenoid and then multiply B by NA.

SOLVE

1. The magnetic flux is the product of the number of turns, the magnetic field strength, and the area bounded by one turn (Equation 28-4):

$$\phi_m = NBA$$

2. The magnetic field inside the solenoid is given by $B = \mu_0 nI$ (Equation 27-10), where $n = N/\ell$ is the number of turns per unit length:

$$\phi_m = N\mu_0 nIA = N\mu_0 \frac{N}{\ell} IA = \frac{\mu_0 N^2 IA}{\ell}$$

3. Express the area A in terms of its radius:

$$A = \pi r^2$$

4. Substitute the given values to calculate the flux:

$$\phi_m = \frac{\mu_0 N^2 I \pi r^2}{\ell}$$

$$= \frac{(4\pi \times 10^{-7}\,\mathrm{T\cdot m/A})(600)^2(7.5\,\mathrm{A})\pi(0.025\,\mathrm{m})^2}{0.40\,\mathrm{m}}$$

$$= \boxed{1.67 \times 10^{-2}\,\mathrm{Wb}}$$

CHECK The units in line 2 of step 4 work out to $\mathrm{T\cdot m^2}$, and a weber is defined as $1\,\mathrm{T\cdot m^2}$. These are the correct units for magnetic flux.

TAKING IT FURTHER Note that because $\phi_m = NBA$ and B is proportional to the number of turns N, ϕ_m is proportional to N^2.

28-2 INDUCED EMF AND FARADAY'S LAW

Experiments by Faraday, Henry, and others showed that if the magnetic flux through a surface bounded by a wire (a conducting path) changes, an emf equal in magnitude to the rate of change of the flux is induced in the wire. We usually detect the emf by observing a current in the conductor, but the emf around the boundary of the surface exists even if the conducting path does not exist or is incomplete (not closed) and no current exists. In previous chapters, we considered emfs that were localized in a specific part of a circuit, such as between the terminals of a battery. However, induced emfs can be distributed throughout a circuit.

The magnetic flux ϕ_m through a flat surface of area A in a uniform magnetic field $\vec{B}$ is given by $\phi_m = BA\cos\theta$ (Equation 28-3), where θ is the angle between $\vec{B}$ and the normal to the surface. The flux can be changed by increasing or decreasing B, by increasing or decreasing A, or by changing the angle θ. If the magnetic field is due to a permanent magnet, the magnitude of the magnetic field can be increased or decreased by moving a permanent magnet toward or away from the surface. If the magnetic field is due to a current in a circuit, the magnitude of the magnetic field can be increased or decreased by increasing or decreasing the current. The flux through the surface can also be changed by varying the angle θ. To vary θ, we can change either the orientation of the surface or the direction of the magnetic field. In each case, if along the perimeter of the surface there is a conducting path, such as a metal wire, an emf $\mathcal{E}$ is induced along the path that is equal in magnitude to the rate of change of the magnetic flux through the surface. That is,

$$\mathcal{E} = -\frac{d\phi_m}{dt} \qquad 28\text{-}5$$

FARADAY'S LAW

This result is known as **Faraday's law.** The minus sign in Faraday's law has to do with the direction of the induced emf (clockwise or counterclockwise), which is addressed later in this section.

Figure 28-3 shows a single stationary loop of wire in a magnetic field. The flux through the loop is changing because the magnetic field strength on surface S is increasing, so an emf is induced in the loop. Because emf is the work done per unit charge, we know there must be forces exerted on the mobile charges that are doing work on these charges. Magnetic forces can do no work; therefore, we cannot attribute the emf to the work done by magnetic forces. It is electric forces associated with a nonconservative electric field $\vec{E}_{\text{nc}}$ doing the work on the mobile charges. The line integral of this electric field around a complete circuit equals the work done per unit charge, which is equal to the induced emf in the circuit.

The electric fields that we studied in earlier chapters resulted from static electric charges. Such electric fields are conservative, meaning that their circulation about any closed path C is zero. (The circulation of a vector field $\vec{E}$ about a closed path C is defined as $\oint_C \vec{E}\cdot d\vec{\ell}$.) However, the electric field associated with a changing magnetic field is nonconservative. Its circulation about C is equal to the induced emf in the loop of wire. The circulation of the electric field is equal to the negative of the rate of change of the magnetic flux through any surface S bounded by C:

$$\mathcal{E} = \oint_C \vec{E}_{\text{nc}}\cdot d\vec{\ell} = -\frac{d}{dt}\int_S \vec{B}\cdot\hat{n}\,dA = -\frac{d\phi_{\text{m}}}{dt} \qquad 28\text{-}6$$

INDUCED EMF FOR A STATIONARY CIRCUIT IN A CHANGING MAGNETIC FIELD

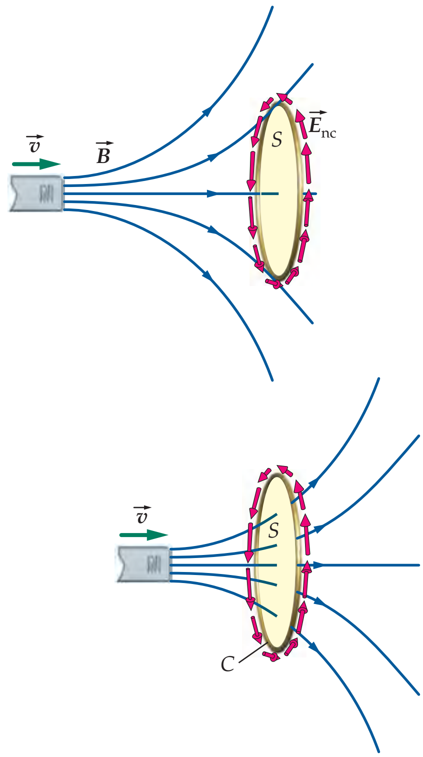

FIGURE 28-3 If the magnetic flux through the stationary wire loop is changing, an emf is induced in the loop. The emf is distributed throughout the loop, which is due to a nonconservative electric field $\vec{E}_{\text{nc}}$ tangent to the wire. The closed path C is within the material of the conducting loop.

Example 28-2 Induced EMF in a Circular Coil I

A uniform magnetic field makes an angle of 30.0° with the axis of a circular coil that has 300 turns and a radius equal to 4.00 cm. The magnitude of the magnetic field increases at a rate of 85.0 T/s while its direction remains fixed. Find the magnitude of the induced emf in the coil.

PICTURE The induced emf equals the number of turns N multiplied by the rate of change of the flux through a single turn. Because $\vec{B}$ is uniform, the flux through each turn is simply $\phi_{\text{m}} = BA\cos\theta$, where $A = \pi r^2$ is the area of the circle bounded by one turn of the coil.

SOLVE

1. The magnitude of the induced emf is given by Faraday's law: $\mathcal{E} = -\dfrac{d\phi_{\text{m}}}{dt}$
2. For a uniform field, the flux is: $\phi_{\text{m}} = N\vec{B}\cdot\hat{n}A = NBA\cos\theta$
3. Substitute this expression for ϕ_{m} and calculate $\mathcal{E}$:

$$\mathcal{E} = -\frac{d\phi_{\text{m}}}{dt} = -\frac{d}{dt}(NBA\cos\theta) = -N\pi r^2\cos\theta\frac{dB}{dt}$$
$$= (300)\pi(0.0400\text{ m})^2\cos 30.0°(85.0\text{ T/s}) = -111\text{ V}$$
$$\mathcal{E} = \boxed{111\text{ V}}$$

CHECK Line 2 of step 3 has units of T·m²/s, where 1 T·m²/s = 1 Wb/s = 1 volt. [Use the formula $\vec{F} = q\vec{v}\times\vec{B}$ as a reminder that 1 N = 1 C·m·T/s, so 1 T = 1 N·s/(C·m).]

PRACTICE PROBLEM 28-2 If the resistance of the coil is 200 Ω, what is the induced current?

Example 28-3 Induced EMF in a Circular Coil II

Try It Yourself

An 80.0-turn coil that has a radius equal to 5.00 cm and a resistance equal to 30.0 Ω sits in a region that has a uniform magnetic field normal to the plane of the coil. At what rate must the magnitude of the magnetic field change to produce a current of 4.00 A in the coil?

PICTURE The number of turns, multiplied by the rate of change of the magnetic flux through a surface bounded by a single turn, is equal to the negative of the induced emf using Faraday's law. The emf in the coil equals IR.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. Write the magnetic flux in terms of B, N, and the radius r, and solve for B.	$\phi_m = NBA = NB\pi r^2$ $B = \dfrac{\phi_m}{N\pi r^2}$
2. Take the time derivative of B.	$\dfrac{dB}{dt} = \dfrac{1}{N\pi r^2}\dfrac{d\phi_m}{dt}$
3. Use Faraday's law to relate the rate of change of the flux to the emf.	$\mathcal{E} = -\dfrac{d\phi_m}{dt}$
4. Calculate the magnitude of the emf in the coil from the current and resistance of the coil.	$\lvert\mathcal{E}\rvert = IR = 120\text{ V}$
5. Substitute numerical values of $\mathcal{E}$, N, and r to calculate $\lvert dB/dt\rvert$.	$\left\lvert\dfrac{dB}{dt}\right\rvert = \dfrac{1}{N\pi r^2}\lvert\mathcal{E}\rvert = \boxed{191\text{ T/s}}$

A sign convention allows us to use the minus sign in Faraday's law to find the direction of the induced emf. According to this convention, the positive tangential direction along the integration path C is related to the direction of the unit normal $\hat{\boldsymbol{n}}$ on the surface S bounded by C by a right-hand rule (Figure 28-4). By placing your right thumb in the direction of $\hat{\boldsymbol{n}}$, the fingers of your hand curl in the positive tangential direction on C. If $d\phi_m/dt$ is positive, then in accord with Faraday's law (Equation 28-6), $\mathcal{E}$ is in the negative tangential direction. (The direction of $\mathcal{E}$ can also be determined via Lenz's law, which is discussed in Section 28-3.)

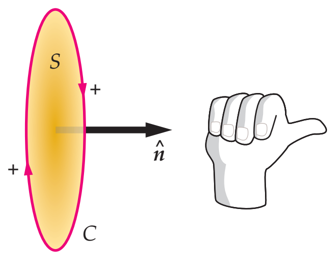

FIGURE 28-4 By placing your right thumb in the direction of $\hat{\boldsymbol{n}}$ on the surface S, the fingers of your hand curl in the positive tangential direction on C.

Example 28-4 Induced Nonconservative Electric Field

A magnetic field $\vec{B}$ is perpendicular to the plane of the page. $\vec{B}$ is uniform throughout a circular region that has a radius R, as shown in Figure 28-5. Outside this region, B equals zero. The direction of $\vec{B}$ remains fixed and the rate of change of B is dB/dt. What are the magnitude and direction of the induced electric field in the plane of the page (*a*) a distance $r < R$ from the center of the circular region and (*b*) a distance $r > R$ from the center, where $B = 0$?

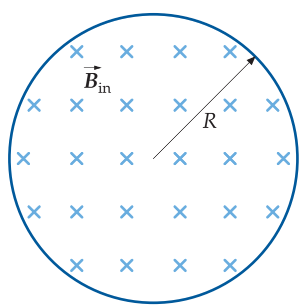

FIGURE 28-5

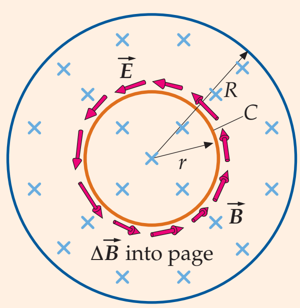

FIGURE 28-6

PICTURE The magnetic field $\vec{B}$ is into the page and uniform over a circular region of radius R, as shown in Figure 28-6. As B increases or decreases, the magnetic flux through a surface bounded by closed curve C also changes, and an emf $\mathcal{E} = \oint_C \vec{E}\cdot d\vec{\ell}$ is induced around C. The induced electric field is found by applying $\oint_C \vec{E}\cdot d\vec{\ell} = -d\phi_m/dt$ (Equation 28-6). To take advantage of the system's symmetry, we choose C to be a circular curve of radius r and then evaluate the line integral. By symmetry, $\vec{E}$ is tangent to circle C and has the same magnitude at any point on the circle. We will assign into the page as the direction of $\hat{n}$. The sign convention then tells us that the positive tangential direction is clockwise. We then calculate the magnetic flux ϕ_m, take its time derivative, and solve for E_t (the tangential component of $\vec{E}$).

SOLVE

(*a*) 1. The $\vec{E}$ and $\vec{B}$ fields are related by Equation 28-6:

$$\oint_C \vec{E} \cdot d\vec{\ell} = -\frac{d\phi_m}{dt}$$

where

$$\phi_m = \int_S \vec{B} \cdot \hat{n}\, dA$$

2. E_t (the tangential component of $\vec{E}$) is found from the line integral for a circle of radius $r < R$. $\vec{E}$ is tangent to the circle and has the same magnitude at all points on the circle:

$$\oint_C \vec{E} \cdot d\vec{\ell} = \oint_C E_t\, d\ell = E_t \oint_C d\ell = E_t 2\pi r$$

3. For $r < R$, $\vec{B}$ is uniform on the flat surface S bounded by the circle C. We choose into the page as the direction of $\hat{n}$. Because $\vec{B}$ is also into the page, the flux through S is simply BA:

$$\phi_m = \int_S \vec{B} \cdot \hat{n}\, dA = \int_S B_n\, dA = B_n \int_S dA = BA = B\pi r^2$$

4. Calculate the time derivative of ϕ_m:

$$\frac{d\phi_m}{dt} = \frac{d}{dt}(B\pi r^2) = \frac{dB}{dt}\pi r^2$$

5. Substitute the step 2 and step 4 results into the step 1 result and solve for E_t:

$$E_t 2\pi r = -\frac{dB}{dt}\pi r^2$$

so

$$E_t = \boxed{-\frac{r}{2}\frac{dB}{dt} \quad r < R}$$

6. For the choice of the direction of $\hat{n}$ in step 3, the positive tangential direction is clockwise:

E_t is negative, so the direction of $\vec{E}$ is $\boxed{\text{counterclockwise}}$.

(*b*) 1. For a circle of radius $r > R$ (the region where the magnetic field is zero), the line integral is the same as before:

$$\oint_C \vec{E} \cdot d\vec{\ell} = E_t 2\pi r$$

2. Because $B = 0$ for $r > R$, the magnetic flux through S is $B\pi R^2$:

$$\phi_m = B\pi R^2$$

3. Apply Faraday's law to find E_t:

$$E_t 2\pi r = -\frac{dB}{dt}\pi R^2$$

so

$$E_t = \boxed{-\frac{R^2}{2r}\frac{dB}{dt} \quad r > R}$$

E_t is negative, so the direction of $\vec{E}$ is $\boxed{\text{counterclockwise}}$.

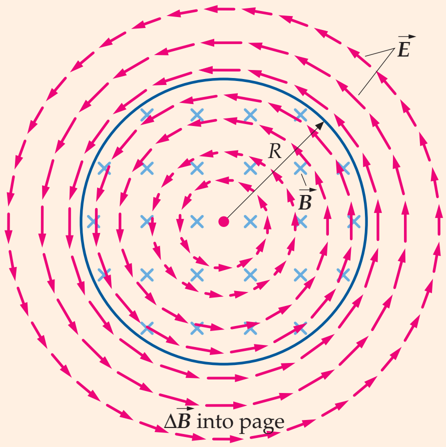

FIGURE 28-7 The magnetic field is into the page and increasing in magnitude. The induced electric field is counterclockwise.

CHECK The positive tangential direction is clockwise. When $d\phi_m/dt$ is positive, E_t is negative. The electric field direction is counterclockwise, as shown in Figure 28-7.

TAKING IT FURTHER Note that the electric field in this example is produced by a changing magnetic field rather than by electric charges. Note also that $\vec{E}$, and thus an emf, exists along any closed curve bounding the area through which the magnetic flux is changing, whether there is a wire or circuit along the curve or there is not.

! Note also that $\vec{E}$, and thus the emf, exists along any closed curve bounding the area through which the magnetic flux is changing, whether there is a wire or circuit along the curve or there is not.

28-3 LENZ'S LAW

The minus sign in Faraday's law has to do with the direction of the induced emf. This can be obtained by applying the sign convention described in the previous section, or by applying a general physical principle known as **Lenz's law:**

> The induced emf is in such a direction as to oppose, or tend to oppose, the change that produces it.
>
> LENZ'S LAW

Note that Lenz's law does not specify just what kind of change causes the induced emf and current. The statement of Lenz's law is purposely left vague to cover a variety of conditions, which we will now illustrate.

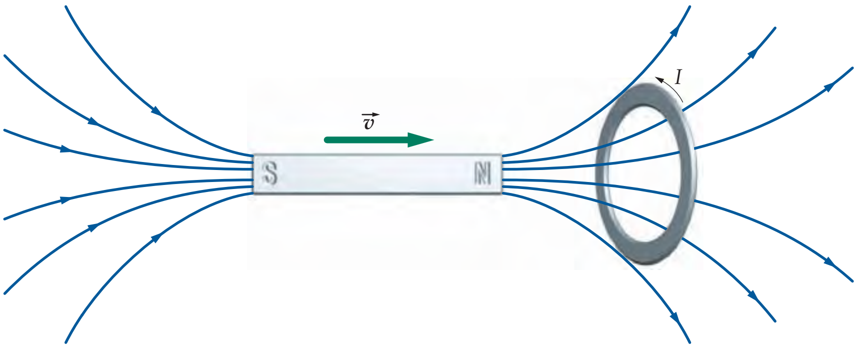

FIGURE 28-8 When the bar magnet is moving to the right, toward the loop, the emf induced in the loop produces an induced current in the direction shown. The magnetic field due to this induced current in the loop produces a magnetic field that exerts a force on the bar magnet opposing its motion to the right.

Figure 28-8 shows a bar magnet moving toward a conducting loop. It is the motion of the bar magnet to the right that induces an emf and current in the loop. Lenz's law tells us that this induced emf and current must be in a direction to oppose the motion of the bar magnet. That is, the current induced in the loop produces a magnetic field of its own, and this magnetic field must exert a force to the left on the approaching bar magnet. Figure 28-9 shows the induced magnetic moment of the current loop when the magnet is moving toward it. The loop acts like a small magnet with its north pole to the left and its south pole to the right. Because like poles repel, the induced magnetic moment of the loop repels the bar magnet; that is, it opposes its motion toward the loop. This result means the direction of the induced current in the loop must be as shown in Figure 28-9.

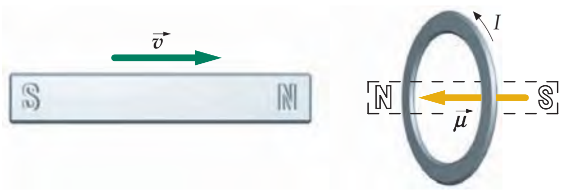

FIGURE 28-9 The magnetic moment of the loop $\vec{\mu}$ (shown in outline as if it were a bar magnet) due to the induced current is such as to oppose the motion of the bar magnet. The bar magnet is moving toward the loop, so the induced magnetic moment repels the bar magnet.

Suppose the induced current in the loop shown in Figure 28-9 was opposite to the direction shown. Then there would be a magnetic force toward the right on the approaching bar magnet, causing the bar magnet to gain speed. This gain in speed would cause an increase in the induced current, which in turn would cause the force on the bar magnet to increase, and so on. This result is too good to be true. Any time we nudge a bar magnet toward a conducting loop it would move toward the loop with ever increasing speed and with no significant effort on our part. Were this situation to occur, it would be a violation of energy conservation. The reality, however, is that energy is conserved, and Lenz's law is consistent with this reality.

An alternative statement of Lenz's law in terms of magnetic flux is frequently of use. This statement is

> When a magnetic flux through a surface changes, the magnetic field due to any induced current produces a flux of its own—through the same surface and opposite in sign to the initial change in flux.
>
> ALTERNATIVE STATEMENT OF LENZ'S LAW

For an example which shows how this alternative statement is applied, see Example 28-5.

Example 28-5 Lenz's Law and Induced Current

Using the alternative statement of Lenz's law, find the direction of the induced current in the loop shown in Figure 28-8.

PICTURE Use the alternative statement of Lenz's law to determine the direction of the magnetic field due to the current induced in the loop. When a magnetic flux through a surface changes, the magnetic field due to any induced current produces a flux of its own—through the same surface and opposite in sign to the initial change in flux. Then use a right-hand rule to determine the direction of the induced current.

SOLVE

1. Draw a sketch of the loop bounding the flat surface S (Figure 28-10). On surface S draw the vector $\Delta\vec{B}_1$, which is the change in the magnetic field $\vec{B}_1$ of the approaching bar magnet on S:

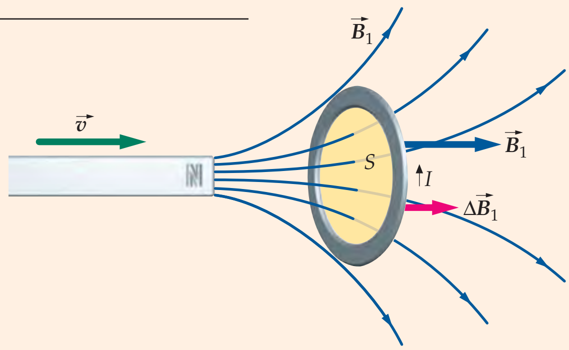

FIGURE 28-10

2. On the sketch draw the vector $\vec{B}_2$, which is the magnetic field of the current induced in the loop (Figure 28-11). Because $\vec{B}_2$ was initially zero, $\vec{B}_2$ is in the same direction as $\Delta\vec{B}_2$. Use the alternative statement of Lenz's law to determine the direction of $\vec{B}_2$. $\vec{B}_2$ and $\Delta\vec{B}_1$ must penetrate S in opposite directions for the change in the flux of $\vec{B}_2$ to be opposite in sign to the change in flux of $\vec{B}_1$:

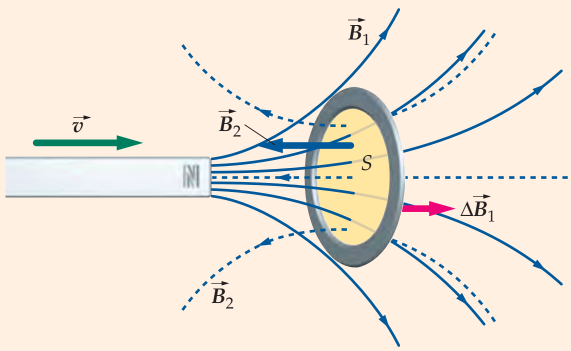

FIGURE 28-11

3. Using the right-hand rule and the direction of $\vec{B}_2$, determine the direction of the current induced in the loop (Figure 28-12):

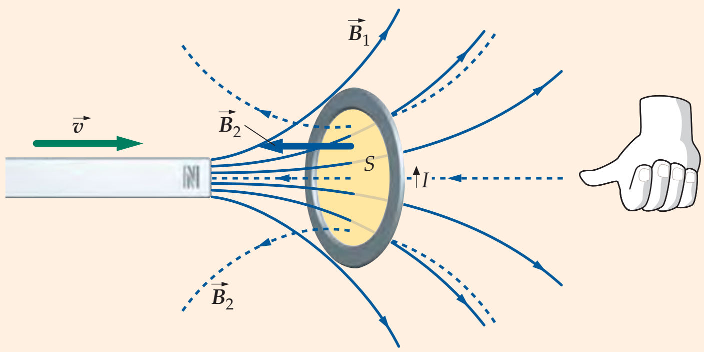

FIGURE 28-12

CHECK The step-3 result gives the same direction as was obtained on page 995 using the initial statement of Lenz's law.

CONCEPT CHECK 28-1

Using the alternative statement of Lenz's law, find the direction of the induced current in the loop shown in Figure 28-8 if the magnet is moving to the left (away from the loop).

In Figure 28-13, the bar magnet is at rest and the loop is moving away from the magnet. The induced current and magnetic moment are shown in the figure. In this case, the bar magnet attracts the loop, thus opposing the motion of the loop as required by Lenz's law.

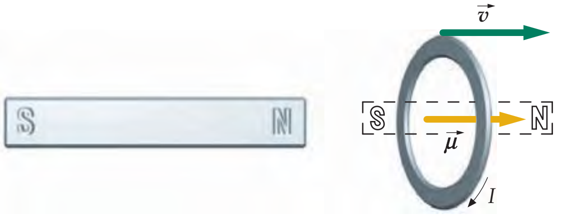

FIGURE 28-13 When the loop is moving away from the stationary bar magnet, the bar magnet attracts the magnetic moment of the loop, again opposing the relative motion.

In Figure 28-14, when the current in circuit 1 is changing, there is a changing flux through circuit 2. Suppose that the switch S in circuit 1 is initially open so that there is no current in the circuit (Figure 28-14*a*). When we close the switch (Figure 28-14*b*), the current in circuit 1 does not instantaneously reach its steady value $\mathcal{E}_1/R_1$ but takes some time to change from zero to that value. During the time the current is increasing, the flux through circuit 2 is changing and a current is induced in circuit 2 in the direction shown. When the current in circuit 1 reaches its steady value, the flux through circuit 2 is no longer changing, so there is no longer an induced current in circuit 2. An induced current in circuit 2 in the opposite direction appears briefly when the switch in circuit 1 is opened (Figure 28-14*c*) and the current in circuit 1 is decreasing to zero. It is important to understand that there is an induced emf *only while the flux is changing*. The emf does not depend on the magnitude of the flux itself, but only on its rate of change. If there is a large steady flux through a circuit, there is no induced emf.

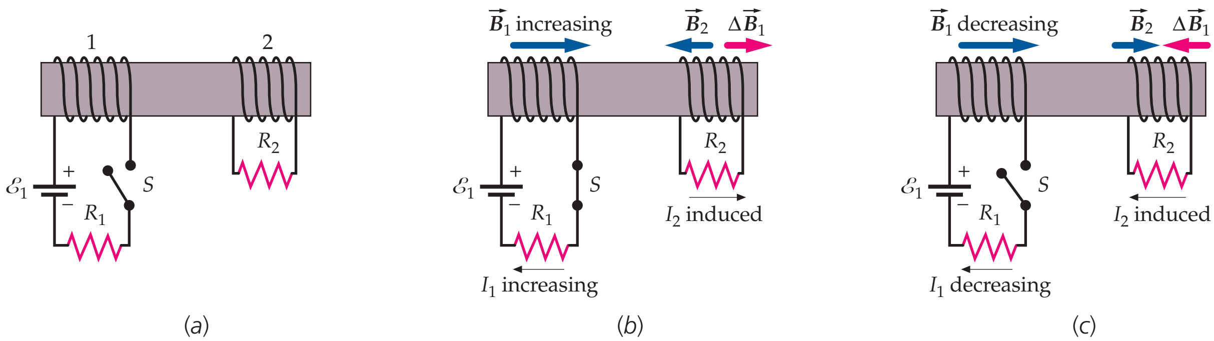

FIGURE 28-14 (*a*) Two adjacent circuits. (*b*) Just after the switch is closed, I_1 is increasing in the direction shown. The changing flux through circuit 2 induces the current I_2. The flux through circuit 2 due to I_2 opposes the change in flux due to I_1. (*c*) As the switch is opened, I_1 decreases and the flux through circuit 2 changes. The induced current I_2 then tends to maintain the flux through circuit 2.

For our next example, we consider the single isolated circuit shown in Figure 28-15. If there is a current in the circuit, there is a magnetic flux through the coil due to its own current. If the current is changing, the flux through the coil is changing and there is an induced emf in the circuit while the flux is changing. This *self-induced emf* opposes the change in the current. It is therefore called a **back emf.** Because of this self-induced emf, the current in a circuit cannot jump instantaneously from zero to some finite value or from some finite value to zero. Henry first noticed this effect when he experimented with a circuit consisting of many turns of a wire like that in Figure 28-15. This arrangement gives a large flux through the circuit for even a small current. Joseph Henry noticed a spark across the switch when he tried to break the circuit. Such a spark is due to the large induced emf that occurs when the current varies rapidly, as during the opening of the switch. In this case, the induced emf is directed so as to maintain the original current. The large induced emf produces a large potential difference across the switch as it is opened. The electric field between the contacts of the switch is large enough to produce dielectric breakdown in the surrounding air. When dielectric breakdown occurs, the air conducts electric current in the form of a spark.

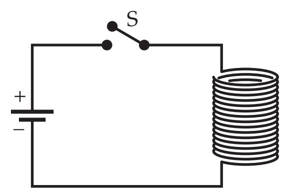

FIGURE 28-15 The coil that has many turns of wire yields a large flux for a given current in the circuit. Thus, when the current changes, there is a large emf induced in the coil opposing the change.

Example 28-6 Lenz's Law and a Moving Coil

A rectangular coil has $N = 80$ turns and each turn has a width $a = 20.0$ cm and a length $b = 30.0$ cm. Half the coil is located in a region that has a magnetic field of magnitude $B = 0.800$ T directed into the page (Figure 28-16). The resistance R of the coil is 30.0 Ω. Find the magnitude and direction of the induced current if the coil is moved with a speed of 2.00 m/s (*a*) to the right, (*b*) up the page, and (*c*) down the page.

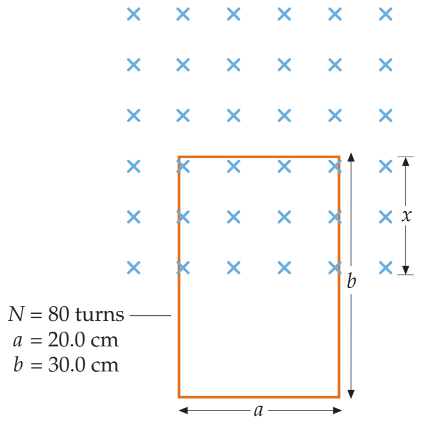

FIGURE 28-16

PICTURE The induced current equals the induced emf divided by the resistance. We can calculate the emf induced in the circuit as the coil moves by calculating the rate of change of the flux through the coil. The direction of the induced current is found from Lenz's law.

SOLVE

(*a*) 1. The induced current equals the emf divided by the resistance:

$$I = \frac{\mathcal{E}}{R}$$

2. The induced emf and the magnetic flux are related by Faraday's law:

$$\mathcal{E} = -\frac{d\phi_m}{dt}$$

3. The flux through the surface bounded by the coil is N multiplied by the flux through each turn of the coil. We choose into the page as the direction of $\hat{\boldsymbol{n}}$. The flux through the surface S bounded by a single turn is Bax:

$$\phi_m = N\vec{B}\cdot\hat{n}A = N[Bax - (0)a(b - x)] = NBax$$

4. When the coil is moving to the right (or to the left), x does not change and the flux does not change (until the coil leaves the region of the magnetic field). The current is therefore zero:

$$\mathcal{E} = -\frac{d\phi_m}{dt} = 0$$

so

$$I = \boxed{0}$$

(*b*) 1. Compute the rate of change of the flux when the coil is moving up the page. In this case x is increasing, so dx/dt is positive:

$$\frac{d\phi_m}{dt} = \frac{d}{dt}(NBax) = NBa\frac{dx}{dt}$$

2. The derivative dx/dt is equal to the speed of the coil.

$$|I| = \frac{|\mathcal{E}|}{R} = \frac{NBa|dx/dt|}{R} = \frac{(80)(0.800\text{ T})(0.200\text{ m})(2.00\text{ m/s})}{30.0\ \Omega} = 0.853\text{ A}$$

3. As the coil moves up the page, the flux of $\vec{B}$ through S is increasing. The induced current must produce a magnetic field whose flux through S decreases as x increases. That would be a magnetic field whose dot product with $\hat{\boldsymbol{n}}$ is negative. Such a magnetic field is directed out of the page on S. To produce a magnetic field in this direction the induced current must be counterclockwise:

$$\boxed{I = 0.853\text{ A, counterclockwise}}$$

(*c*) As the coil moves down the page, the flux of $\vec{B}$ through S is decreasing. The induced current must produce a magnetic field whose flux through S increases as x decreases. That would be a magnetic field whose dot product with $\hat{\boldsymbol{n}}$ is positive. Such a magnetic field is directed into the page on S. To produce a magnetic field in this direction the induced current must be clockwise:

$$\boxed{I = 0.853\text{ A, clockwise}}$$

CHECK In Part (*b*) the motion up the page causes the current to be induced, so the direction of the induced current must result in a force opposing the upward motion. Applying $\vec{F} = I\vec{L} \times \vec{B}$ (Equation 26-4) to the upper section of the loop gives a force down the page if the current in the loop is counterclockwise. This is in agreement with our Part (*b*) result.

TAKING IT FURTHER In this example the magnetic field is static, so no nonconservative electric field exists. Thus, the emf is not the work done by a nonconservative electric field. The cause of this emf is examined in the next section.

28-4 MOTIONAL EMF

The emf induced in a conductor due to its motion in a region in which there exists a magnetic field is called motional emf. More generally,

> Motional emf is any emf induced by the motion of a conductor in a region in which there exists a magnetic field.
>
> DEFINITION—MOTIONAL EMF

Example 28-7 Total Charge through a Flipped Coil

A small coil of N turns has its plane perpendicular to a uniform static magnetic field $\vec{B}$, as shown in Figure 28-17. The coil is connected to a current integrator (C.I.), which is a device used to measure the total charge passing through the coil. Find the charge passing through the coil if the coil is rotated through 180° about the axis shown.

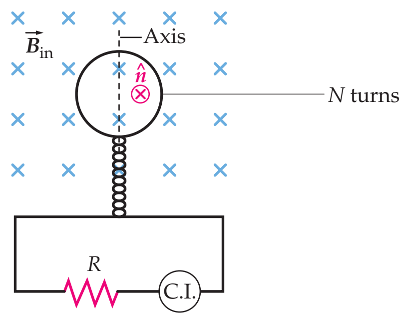

FIGURE 28-17

PICTURE When the coil in Figure 28-17 is rotated, the magnetic flux through the coil changes, causing an induced emf $\mathcal{E}$. The emf in turn causes a current $I = \mathcal{E}/R$, where R is the total resistance of the circuit. Because $I = dq/dt$, we can find the charge Q passing through the integrator by integrating I; that is, $Q = \int I\,dt$.

SOLVE

1. The increment of charge dq equals the current I multiplied by the increment of time dt:

$$dq = I\,dt$$

2. The emf $\mathcal{E}$ is related to I by Ohm's law:

$$\mathcal{E} = RI$$

so

$$\mathcal{E}\,dt = RI\,dt$$

3. The emf is related to the flux ϕ_m by Faraday's law:

$$\mathcal{E} = -\frac{d\phi_m}{dt}$$

or

$$\mathcal{E}\,dt = -d\phi_m$$

4. Substitute $-d\phi_m$ for $\mathcal{E}\,dt$ and dq for $I\,dt$ in the step 2 result and solve for dq:

$$-d\phi_m = R\,dq$$

so

$$dq = -\frac{1}{R}\,d\phi_m$$

5. Integrate to find the total charge Q:

$$Q = \int_0^Q dq = -\frac{1}{R}\int_{\phi_{mi}}^{\phi_{mf}} d\phi_m = -\frac{1}{R}(\phi_{mf} - \phi_{mi}) = -\frac{\Delta\phi_m}{R}$$

6. The flux through the coil is $\phi_m = n\vec{B}\cdot\hat{n}A$, where $\hat{n}$ is the normal to the flat surface bounded by the coil (Figure 28-18). The normal initially is directed into the page. When the coil rotates, so does the surface and its normal. Find the change in ϕ_m when the coil rotates 180°:

$$\Delta\phi_m = \phi_{mf} - \phi_{mi} = N\vec{B}\cdot\hat{n}_f A - N\vec{B}\cdot\hat{n}_i A$$

$$= NA(\vec{B}\cdot\hat{n}_f - \vec{B}\cdot\hat{n}_i) = NA[(-B) - (+B)] = -2NBA$$

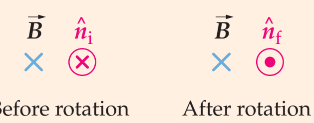

FIGURE 28-18

7. Combining the results from the previous two steps yields Q:

$$Q = \boxed{\frac{2NBA}{R}}$$

TAKING IT FURTHER Note that the charge Q does not depend on whether or not the coil is rotated slowly or quickly—all that matters is the change in the magnetic flux through the coil. A coil used in this way is called a *flip coil*. It is used to measure magnetic fields. For example, if the current integrator (C.I.) measures a total charge Q passing through the coil when it is flipped, the magnetic field strength is given by $B = RQ/(2NA)$, which can be obtained directly from the step-7 result.

PRACTICE PROBLEM 28-3 A flip coil has 40 turns, a radius of 3.00 cm, and a resistance of 16.0 Ω, and the plane of the coil is initially perpendicular to a static, uniform 0.500-T magnetic field. If the coil is rotated 90° about an axis perpendicular to the magnetic field, how much charge passes through the coil?

Figure 28-19 shows a thin conducting rod sliding to the right along conducting rails that are connected by a resistor. A uniform magnetic field $\vec{B}$ is directed into the page.

Consider the magnetic flux through the flat surface S bounded by the circuit. Let the normal $\hat{n}$ to the surface be into the page. As the rod moves to the right, the surface S increases, as does the magnetic flux through S. Thus, an emf is induced in the circuit. Let ℓ be the separation of the rails and x be the distance from the left end of the rails to the rod. The area of surface S is then ℓx, and the magnetic flux through S is

$$\phi_m = \vec{B} \cdot \hat{n} A = B_n A = B\ell x$$

Taking the time derivative of both sides gives

$$\frac{d\phi_m}{dt} = B\ell\frac{dx}{dt} = B\ell v$$

where $v = dx/dt$ is the speed of the rod. The emf induced in this circuit is therefore

$$\mathcal{E} = -\frac{d\phi_m}{dt} = -B\ell v$$

where the negative sign tells us that the emf is in the negative tangential direction. Put your right thumb in the direction of $\hat{n}$ (into the page) and your fingers will curl in the positive tangential direction (clockwise). Thus, the induced emf is counterclockwise.

We can check this result (the direction of the induced emf) using Lenz's law. It is the motion of the rod to the right that produces the induced current, so the magnetic force on this rod due to the induced current must be to the left. The magnetic force on a current-carrying conductor is given by $I\vec{L} \times \vec{B}$ (Equation 26-4), where $\vec{L}$ is in the direction of the current. If $\vec{L}$ is up the page and $\vec{B}$ is into the page, the force is to the left, which affirms our previous result (that the induced emf is counterclockwise). If the rod is given some initial velocity $\vec{v}$ to the right and is then released, the force due to the induced current slows the rod until it stops. To maintain the motion of the rod, an external force pushing the rod to the right must be maintained.

A second check on the direction of the induced emf and current is implemented by considering the direction of the magnetic force on the charge carriers moving to the right with the rod. The charge carriers move rightward with the same velocity $\vec{v}$ as the rod, so the charge carriers experience a magnetic force $\vec{F} = q\vec{v} \times \vec{B}$. If q is positive that force is upward, which means the induced emf is counterclockwise.

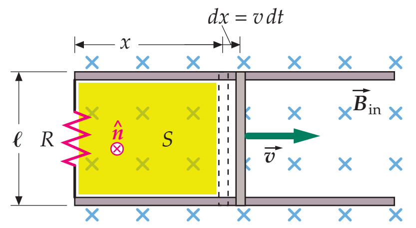

FIGURE 28-19 A conducting rod sliding on conducting rails in a magnetic field. As the rod moves to the right, the area of the surface S increases, so the magnetic flux through S into the paper increases. An emf of magnitude $B\ell v$ is induced in the circuit, inducing a counterclockwise current that produces flux through the surface S directed out of the paper opposing the change in flux due to the motion of the rod.

$$|\mathcal{E}| = B\ell v \tag{28-7}$$

MAGNITUDE OF EMF FOR A ROD MOVING PERPENDICULAR TO BOTH THE LENGTH OF THE ROD AND $\vec{B}$

(If the magnetic field is not normal to the plane of the circuit, the B in Equation 28-7 should be replaced with the component of B normal to the plane of the circuit.)

Figure 28-20 shows a positive charge carrier in a conducting rod that is moving at constant speed through a uniform magnetic field directed into the paper. Because the charge carrier is moving horizontally with the rod, there is an upward magnetic force on the charge carrier of magnitude qvB. Responding to that force, the charge carriers in the rod move upward, producing a net positive charge at the top of the rod and leaving a net negative charge at the bottom of the rod. The charge carriers continue to move upward until the electric field $\vec{E}_{\parallel}$ produced by the separated charges exerts a downward force of magnitude $qE_{\parallel}$ on the separated charges, which balances the upward magnetic force qvB. In equilibrium, the magnitude of this electric field in the rod is

$$E_{\parallel} = vB$$

The direction of this electric field is parallel to the rod, directed downward. The associated potential difference across the length ℓ of the rod is

$$\Delta V = E_{\parallel}\ell = vB\ell$$

with the potential being higher at the top. That is, when there is no current through the rod, the potential difference across the length of the rod equals $vB\ell$ (the motional emf). When there is a current I through the rod, the potential difference is

$$\Delta V = vB\ell - Ir \qquad 28\text{-}8$$

where r is the resistance of the rod.

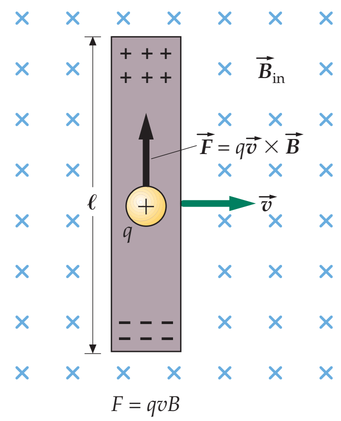

FIGURE 28-20 A positive charge carrier in a conducting rod that is moving through a magnetic field experiences a magnetic force that has an upward component. Some of these charge carriers move to the top of the rod, leaving the bottom of the rod negative. The charge separation produces a downward electric field of magnitude $E_{\parallel} = vB$ in the rod. Thus, the potential at the top of the rod is greater than the potential at the bottom of the rod by $E_{\parallel}\ell = vB\ell$.

PRACTICE PROBLEM 28-4

A rod 40 cm long moves at 12 m/s in a plane perpendicular to a magnetic field of 0.30 T. The rod's velocity is perpendicular to its length. Find the emf induced in the rod.

Example 28-8 A U-Shaped Conductor and a Sliding Rod *Try It Yourself*

Using Figure 28-19, let $B = 0.600$ T, $v = 8.00$ m/s, $\ell = 15.0$ cm, and $R = 25.0\ \Omega$; assume that the resistances of the rod and the rails are negligible. Find (*a*) the induced emf in the circuit, (*b*) the current in the circuit, (*c*) the force needed to move the rod with constant velocity, and (*d*) the power dissipated in the resistor.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. Calculate the induced emf from Equation 28-7.	$\mathcal{E} = Bv\ell = \boxed{0.720\text{ V}}$
2. Find the current from Ohm's law.	$I = \dfrac{\mathcal{E}}{R} = \boxed{28.8\text{ mA}}$
3. The force needed to move the rod with constant velocity is equal and opposite to the force exerted by the magnetic field on the rod, which has the magnitude $IB\ell$ (Equation 26-4). Calculate the magnitude of this force.	$F = IB\ell = \boxed{2.59\text{ mN}}$
4. Find the power dissipated in the resistor.	$P = I^2R = \boxed{20.7\text{ mW}}$

CHECK Using $P = Fv$, we confirm that the power is 20.7 mW.

TAKING IT FURTHER The potential at the top of the rod is greater than the potential at the bottom of the rod by the emf.

Example 28-9 Magnetic Drag

A rod that has a mass m slides on frictionless conducting rails in a region that has a static uniform magnetic field $\vec{B}$ directed into the page (Figure 28-21). An external agent is pushing the rod, maintaining its motion to the right at constant speed v_0. At time $t = 0$, the agent abruptly stops pushing and the rod continues forward while being slowed by the magnetic force. Find the speed v of the rod as a function of time.

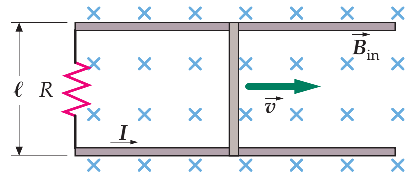

FIGURE 28-21

PICTURE The speed of the rod changes because a magnetic force acts on the induced current. The motion of the rod through a magnetic field induces an emf $\mathcal{E} = B\ell v$ and, therefore, a current in the rod, $I = \mathcal{E}/R$. This result causes a magnetic force to act on the rod, $F = I\ell B$ (Equation 26-4). With the force known, we apply Newton's second law to find the speed as a function of time. Take the $+x$ direction as being to the right.

SOLVE

1. Apply Newton's second law to the rod:

$$F_x = ma_x = m\frac{dv}{dt}$$

2. The force exerted on the rod is the magnetic force (Equation 26-4), which is proportional to the current and in the $-x$ direction, as shown in Figure 28-21:

$$F_x = -I\ell B$$

3. The current equals the motional emf divided by the resistance of the rod:

$$I = \frac{\mathcal{E}}{R} = \frac{B\ell v}{R}$$

4. Combining these results, we find the x component of the magnetic force exerted on the rod:

$$F_x = -IB\ell = -\frac{B\ell v}{R}B\ell = -\frac{B^2\ell^2 v}{R}$$

5. Newton's second law then gives:

$$-\frac{B^2\ell^2 v}{R} = m\frac{dv}{dt}$$

6. Separate the variables, then integrate the velocity from v_0 to v_f and the time from 0 to t_f:

$$\frac{dv}{v} = -\frac{B^2\ell^2}{mR}dt$$

$$\int_{v_0}^{v_f}\frac{dv}{v} = -\frac{B^2\ell^2}{mR}\int_0^{t_f}dt$$

$$\ln\frac{v_f}{v_0} = -\frac{B^2\ell^2}{mR}t_f$$

7. Let $v = v_f$ and $t = t_f$, then solve for v:

$$v = \boxed{v_0 e^{-t/\tau} \quad \text{where } \tau = \frac{mR}{B^2\ell^2}}$$

CHECK The kinetic energy of the rod is transformed into thermal energy in the resistor. To conserve energy the kinetic energy of the rod must decrease, which means its speed must decrease. The step 7 result is in agreement with the conservation of energy.

TAKING IT FURTHER If the force were constant, the rod's speed would decrease linearly with time. However, because the force is proportional to the rod's speed, as found in step 4, the force is large initially but the force decreases as the speed decreases. In principle, the rod never stops moving. Even so, the rod travels only a finite distance.

GENERATORS AND MOTORS

Most electrical energy used today is produced by electric generators in the form of alternating current (ac). A simple **generator** of alternating current is a coil rotating in a uniform magnetic field as shown in Figure 28-22. The ends of the coil are connected to rings called slip rings that rotate with the coil. Electrical contact is made with the coil by stationary graphite brushes in contact with the rings.

When the normal to the plane of the coil $\hat{n}$ makes an angle θ with a uniform magnetic field $\vec{B}$, as shown in the figure, the magnetic flux through the coil is

$$\phi_{\mathrm{m}} = NBA\cos\theta \qquad 28\text{-}9$$

where N is the number of turns in the coil and A is the area of the flat surface bounded by the coil. When the coil is mechanically rotated, the flux through it will change, and an emf will be induced in the coil according to Faraday's law. If the initial angle between $\hat{n}$ and $\vec{B}$ is zero, then the angle at some later time t is given by

$$\theta = \omega t$$

where ω is the angular frequency of rotation. Substituting this expression for θ into Equation 28-9, we obtain

$$\phi_{\mathrm{m}} = NBA\cos\omega t = NBA\cos 2\pi f t$$

The emf in the coil will then be

$$\mathcal{E} = -\frac{d\phi_{\mathrm{m}}}{dt} = -NBA\frac{d}{dt}\cos\omega t = \omega NBA\sin\omega t \qquad 28\text{-}10$$

This can be written

$$\mathcal{E} = \mathcal{E}_{\max}\sin\omega t$$

where

$$\mathcal{E}_{\max} = \omega NBA$$

is the maximum value of the emf. We can thus produce a sinusoidal emf in a coil by rotating it with constant frequency in a magnetic field. In this source of emf, the mechanical energy of the rotating coil is converted into electric energy. The mechanical energy usually comes from a waterfall or a steam turbine. Although practical generators are considerably more complicated, they work on the same principle that an alternating emf is produced in a coil rotating in a magnetic field, and they are designed so that the emf produced is sinusoidal.

The same coil in a magnetic field that can be used to generate an alternating emf can also be used as an ac **motor.** Instead of mechanically rotating the coil to generate an emf, we apply an alternating current to the coil from another ac generator as shown in Figure 28-23. (In circuit diagrams, an ac generator is represented by the symbol ⏦.) A current loop in a magnetic field experiences a torque that tends to rotate the loop such that its magnetic moment $\vec{\mu}$ points in the direction of $\vec{B}$ and the plane of the loop is perpendicular to $\vec{B}$. If direct current were supplied to the coil in Figure 28-23, the torque on the coil would change directions when the coil rotates past its equilibrium position, which is when the plane of the coil is vertical in the figure. The coil would then oscillate about its equilibrium position, eventually coming to rest there with its plane vertical. However, if the direction of the current is reversed just as the coil passes the vertical position, the torque does not change direction but continues to rotate the coil in the same direction. As the coil rotates in the magnetic field, a back emf is generated that tends to oppose the current. When the motor is first turned on, there is no back emf and the current is very large, being limited only by the resistance in the circuit. As the motor begins to rotate, the back emf increases and the current decreases.

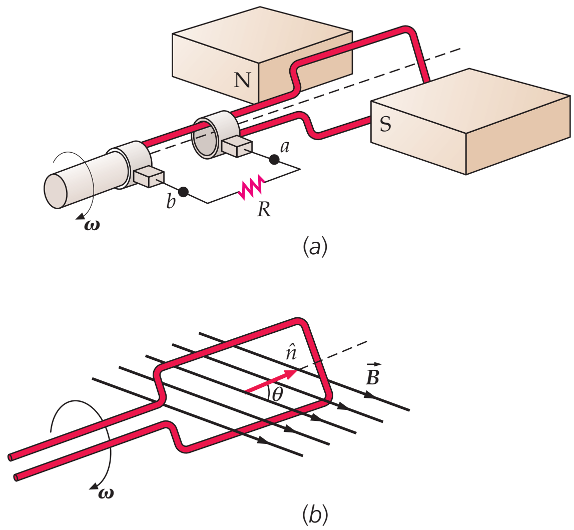

FIGURE 28-22 (*a*) An ac generator. A coil rotating with constant angular speed ω in a magnetic field $\vec{B}$ generates a sinusoidal emf. Energy from a waterfall or a steam turbine is used to rotate the coil to produce electrical energy. The emf is supplied to an external circuit by the brushes in contact with the rings. (*b*) At this instant, the normal to the plane of the coil makes an angle θ with the magnetic field and the flux is equal to $BA\sin\theta$.

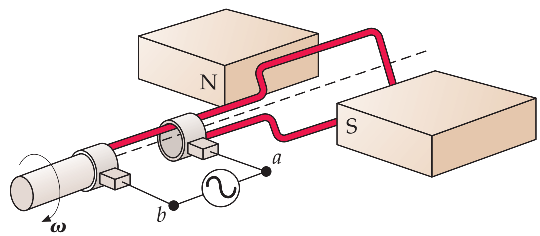

FIGURE 28-23 When alternating current is supplied to the coil of Figure 28-22, the coil becomes a motor. As the coil rotates, a back emf is generated, limiting the current.

PRACTICE PROBLEM 28-5

A 250-turn coil has an area per turn of 3.0 cm^2. If it rotates at 60 rev/s in a 0.40-T magnetic field at 60 Hz, what is the maximum emf in the coil?

CONCEPT CHECK 28-2

When a generator delivers electric energy to a circuit, where does the energy come from?

28-5 EDDY CURRENTS

In the examples we have discussed, currents were induced in thin wires or rods. However, a changing flux often induces circulating currents, which are called *eddy currents*, in a piece of bulk metal like the core of a transformer. The heat produced by such current constitutes a power loss in the transformer. Consider a conducting slab between the pole faces of an electromagnet (Figure 28-24). If the magnetic field $\vec{B}$ between the pole faces is changing with time (as it will if the current in the magnet windings is alternating current), the flux through any closed loop in the slab, such as through the curve C indicated in the figure, will change. Consequently, there will be an induced emf around C. Because path C is in a conductor, the emf will drive currents in the conductor.

The existence of eddy currents can be demonstrated by pulling a copper or aluminum sheet through the region between the poles of a strong permanent magnet (Figure 28-25). Part of the area enclosed by curve C in the figure is in the magnetic field, and part of the area enclosed by curve C is outside the magnetic field. As the sheet is pulled to the right, the flux through this curve decreases (assuming that into the paper is the positive normal direction). A clockwise emf is induced around this curve. This emf drives a current that is directed upward in the region between the pole faces, and the magnetic field exerts a force on this current to the left opposing motion of the sheet. You can feel this drag force on the sheet if you pull a conducting sheet rapidly through a region that has a strong magnetic field.

Eddy currents are frequently undesirable because power is lost due to Joule heating by the current, and this dissipated energy must be transferred to the environment. The power loss can be reduced by increasing the resistance of the possible paths for the eddy currents, as shown in Figure 28-26*a*. Here the conducting slab is laminated; that is, the conducting slab is made up of small strips glued together. Because insulating glue separates the strips, the eddy currents are essentially confined to the individual strips. The large eddy-current loops are broken up, and the power loss is greatly reduced. Similarly, if there are cuts in the sheet, as shown in Figure 28-26*b*, the eddy currents are lessened and the magnetic force is greatly reduced.

Eddy currents are not always undesirable. For example, eddy currents are often used to damp unwanted oscillations. With no damping present, sensitive mechanical balance scales that are used to measure small masses might oscillate back and forth around their equilibrium reading many times. Such scales are usually designed so that a small sheet of aluminum (or some other metal) moves between the poles of a permanent magnet as the scales oscillate. The resulting eddy currents dampen the oscillations so that equilibrium is quickly reached. Eddy currents also play a role in the magnetic braking systems of some rapid transit cars. A large electromagnet is positioned in the vehicle over the rails. If the magnet is energized by a current in its windings, eddy currents are induced in the rails by the motion of the magnet and the magnetic forces provide a drag force on the magnet that slows the car.

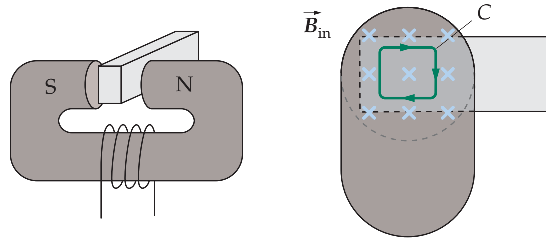

FIGURE 28-24 Eddy currents. When the magnetic field through a metal slab is changing, an emf is induced in any closed loop in the metal, such as loop C. The induced emfs drive currents, which are called eddy currents.

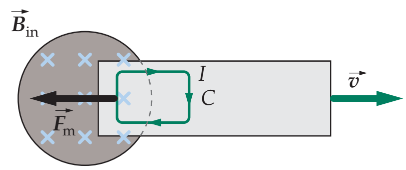

FIGURE 28-25 Demonstration of eddy currents. When the metal sheet is pulled to the right, there is a magnetic force to the left on the induced current opposing the motion.

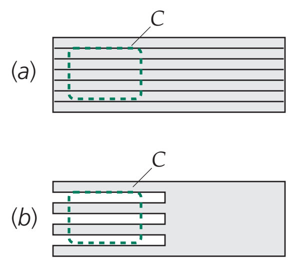

FIGURE 28-26 Disrupting the conduction paths in the metal slab can reduce the eddy current. (*a*) If the slab is constructed from strips of metal glued together, the insulating glue between the slabs increases the resistance of the closed loop C. (*b*) Slots cut into the metal slab also reduce the eddy current.

28-6 INDUCTANCE

SELF-INDUCTANCE

Consider a coil carrying a current I. The current in the coil produces a magnetic field $\vec{B}$ that varies from point to point, but at each point in space the value of B is proportional to I. The magnetic flux of $\vec{B}$ through the coil is therefore also proportional to I:

$$\phi_{\text{m}} = LI \qquad \text{28-11}$$

DEFINITION—SELF-INDUCTANCE

where L, the proportionality constant, is called the self-inductance of the coil. The self-inductance depends on the geometric shape of the coil. The SI unit of inductance is the **henry** (H). From Equation 28-11, we can see that the unit of inductance equals the unit of flux divided by the unit of current:

$$1\ \text{H} = 1\ \text{Wb/A} = 1\ \text{T}\cdot\text{m}^2/\text{A}$$

In principle, the self-inductance of any coil or circuit can be calculated by assuming a current I, calculating $\vec{B}$ at every point on a surface bounded by the coil, calculating the flux ϕ_m, and using $L = \phi_m/I$. In actual practice, the calculation is often very challenging. However, the self-inductance of a long, tightly wound solenoid can be calculated directly. The magnetic flux through a long, thin solenoid is given by NBA, where $B = \mu_0 nI$, N is the number of turns, n is the number of turns per unit length, I is the current and A is the area per turn. Thus, the magnetic flux through the coil is

$$\phi_m = NBA = \mu_0 N(\mu_0 nI)A = \frac{\mu_0 N^2 IA}{\ell} = \mu_0 n^2 IA\ell \qquad \text{28-12}$$

where ℓ is the length of the solenoid. As expected, the flux is proportional to the current. The proportionality constant is the self-inductance L:

$$L = \frac{\phi_m}{I} = \mu_0 n^2 A\ell \qquad \text{28-13}$$

SELF-INDUCTANCE OF A LONG SOLENOID

The self-inductance of a long solenoid is proportional to the square of the number of turns per unit length n and to the volume $A\ell$. Thus, like capacitance, self-inductance depends only on geometric factors.* From the dimensions of Equation 28-13, we can see that μ_0 can be expressed in henrys per meter:

$$\mu_0 = 4\pi \times 10^{-7}\ \text{H/m}$$

Example 28-10 Self-Inductance of a Solenoid

Find the self-inductance of a solenoid of length 10.0 cm, area 5.00 cm^2, and 100 turns.

PICTURE We can calculate the self-inductance in henrys from Equation 28-13.

SOLVE

1. L is given by Equation 28-13: $L = \mu_0 n^2 A\ell$
2. Convert the given quantities to SI units:
   $\ell = 10.0\ \text{cm} = 0.100\ \text{m}$
   $A = 5.00\ \text{cm}^2 = 5.00 \times 10^{-4}\ \text{m}^2$
   $n = N/\ell = (100\ \text{turns})/(0.100\ \text{m}) = 1000\ \text{turns/m}$
   $\mu_0 = 4\pi \times 10^{-7}\ \text{H/m}$
3. Substitute the given quantities:
   $$L = \mu_0 n^2 A\ell = (4\pi \times 10^{-7}\ \text{H/m})(1000\ \text{turns/m})^2(5.00 \times 10^{-4}\ \text{m}^2)(0.100\ \text{m}) = \boxed{6.28 \times 10^{-5}\ \text{H}}$$

CHECK The inductance of a solenoid that does not have a soft iron core is expected to be a small fraction of a henry. That is the case for the solenoid in this example.

* If the inductor has a material in the core, the self-inductance also depends on the properties of the material.

When the current in a circuit is changing, the magnetic flux due to the current is also changing, so an emf is induced in the circuit. Because the self-inductance L of a circuit is constant, the rate of change of the flux is related to the rate of change of the current by

$$\frac{d\phi_{\mathrm{m}}}{dt} = \frac{d(LI)}{dt} = L\frac{dI}{dt}$$

According to Faraday's law, we have

$$\mathcal{E} = -\frac{d\phi_{\mathrm{m}}}{dt} = -L\frac{dI}{dt} \qquad \text{28-14}$$

SELF–INDUCED EMF

Thus, the self-induced emf is proportional to the rate of change of the current. Because of the negative sign in Equation 28-14, the self-induced emf is often called a back emf. A coil or solenoid that has enough turns to have a significant self-inductance is called an **inductor.** In circuits, it is denoted by the symbol . Typically, the self-inductance of the rest of the circuit is negligible in comparison to the self-inductance of a coil or solenoid. The potential difference across an inductor is given by

$$\Delta V = \mathcal{E} - Ir = -L\frac{dI}{dt} - Ir \qquad \text{28-15}$$

POTENTIAL DIFFERENCE ACROSS AN INDUCTOR

where r is the internal resistance of the inductor.* For an ideal inductor, $r = 0$.

PRACTICE PROBLEM 28-6

At what rate must the current in the solenoid of Example 28-10 change in order to induce a back emf of 20.0 V?

MUTUAL INDUCTANCE

When two or more circuits are close to each other, as in Figure 28-27, the magnetic flux through one circuit depends not only on the current in that circuit but also on the current in the nearby circuits. Let I_1 be the current in circuit 1, on the left in Figure 28-27, and let I_2 be the current in circuit 2, on the right. The magnetic field $\vec{B}$ at surface S_2 is the superposition of $\vec{B}_1$ due to I_1 and $\vec{B}_2$ due to I_2, where B_1 is proportional to I_1 and B_2 is proportional to I_2. We can therefore write the flux of $\vec{B}_1$ through circuit 2, $\phi_{\mathrm{m}12}$, as

$$\phi_{\mathrm{m}12} = M_{12}I_1 \qquad \text{28-16}a$$

DEFINITION—MUTUAL INDUCTANCE

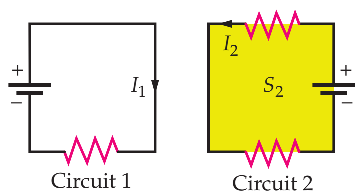

FIGURE 28-27 Two adjacent circuits. The magnetic field on S_2 is partly due to current I_1 and partly due to current I_2. The flux through S_2 is the sum of two terms, one proportional to I_1 and the other to I_2.

where M_{12} is called the **mutual inductance** of the two circuits. The mutual inductance depends on the geometrical arrangement of the two circuits. For instance, if the circuits are far apart, the flux of $\vec{B}_1$ through circuit 2 will be small and the mutual inductance will be small. (The net flux $\phi_{\mathrm{m}2}$ of $\vec{B} = \vec{B}_1 + \vec{B}_2$ through circuit 2 is given by $\phi_{\mathrm{m}2} = \phi_{\mathrm{m}12} + \phi_{\mathrm{m}22}$.) An equation similar to Equation 28-16a can be written for the flux of $\vec{B}_2$ through circuit 1:

$$\phi_{\mathrm{m}21} = M_{21}I_2 \qquad \text{28-16}b$$

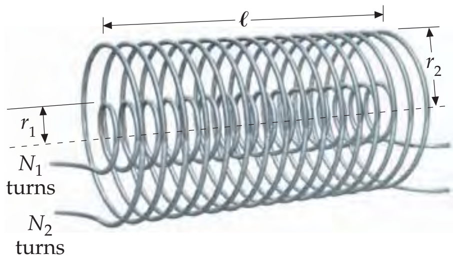
We can calculate the mutual inductance for two tightly wound coaxial solenoids like the solenoids shown in Figure 28-28. Let ℓ be the length of both solenoids, and let the inner solenoid have N_1 turns and radius r_1 and the outer solenoid have N_2 turns and radius r_2. We will first calculate the mutual inductance M_{12} by assuming that the inner solenoid carries a current I_1 and finding the magnetic flux $\phi_{\mathrm{m}2}$ due to this current through the outer solenoid.

* If the inductor has an iron core, the internal resistance includes properties of the core.

The magnetic field $\vec{B}_1$ due to the current in the inner solenoid is uniform in the space inside the inner solenoid and has magnitude

$$B_1 = \mu_0(N_1/\ell)I_1 = \mu_0 n_1 I_1 \quad r < r_1 \qquad \text{28-17}$$

and outside the inner solenoid this magnetic field B_1 is essentially zero. The flux of $\vec{B}_1$ through the outer solenoid is therefore



(a)

$$\phi_{m2} = N_2 B_1(\pi r_1^2) = n_2 \ell B_1(\pi r_1^2) = \mu_0 n_2 n_1 \ell(\pi r_1^2) I_1$$

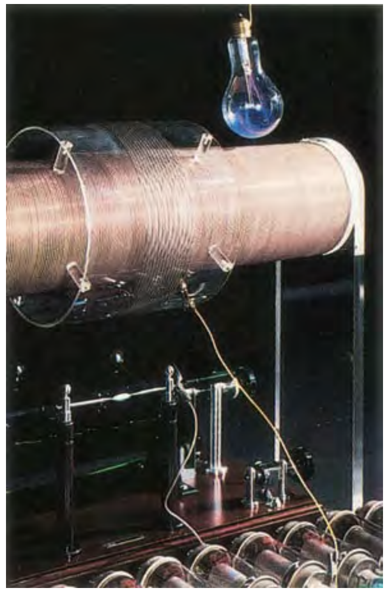
Note that the area used to compute the flux through the outer solenoid is not the area of the surface bounded by a loop of that solenoid, πr_2^2, but rather is the area of the surface bounded by a loop of the inner solenoid, πr_1^2. This is because the magnetic field due to the inner solenoid is zero outside the inner solenoid. The mutual inductance M_{12} is thus

$$M_{12} = \frac{\phi_{m12}}{I_1} = \mu_0 n_2 n_1 \ell \pi r_1^2 \qquad \text{28-18}$$

PRACTICE PROBLEM 28-7

Calculate the mutual inductance M_{21} of the coaxial solenoids of Figure 28-28 by finding the flux through the inner solenoid due to a current I_2 in the outer solenoid.

Note the result of Practice Problem 28-7 reveals that $M_{12} = M_{21}$. It can be shown that this is a general result. Therefore in the future we will drop the subscripts for mutual inductance and simply write M.



(b)

FIGURE 28-28 (*a*) A long, narrow solenoid inside a second solenoid of the same length. A current in either solenoid produces a magnetic flux in the other. (*b*) A tesla coil illustrating the geometry of the wires in Figure 28-28*a*. Such a device functions as a transformer.* Here, low-voltage alternating current in the outer winding is transformed into a higher-voltage alternating current in the inner winding. The emf induced in the inner coil by the field of the charging current in the outer coil is high enough to light the bulb above the coils. *((b) © Michael Holford, Collection of the Science Museum, London.)*

28-7 MAGNETIC ENERGY

An inductor stores magnetic energy, just as a capacitor stores electrical energy. Consider the circuit shown in Figure 28-29, which consists of an ideal inductor that has an inductance L and a resistor that has a resistance R in series with an ideal battery that has emf $\mathcal{E}_0$ and a switch S. We assume that R and L are the resistance and inductance of the entire circuit. The switch is initially open, so no current exists in the circuit. A short time after the switch is closed, there are a current I in the circuit, a potential difference $-IR$ across the resistor, and a potential difference $-L\,dI/dt$ across the inductor. (For an ideal inductor, the difference in potential across the inductor equals the back emf, which was given in Equation 28-14.) Applying Kirchhoff's loop rule to this circuit gives

$$\mathcal{E}_0 - IR - L\frac{dI}{dt} = 0 \qquad \text{28-19}$$

If we multiply each term by the current I and rearrange, we obtain

$$\mathcal{E}_0 I = I^2 R + LI\frac{dI}{dt} \qquad \text{28-20}$$

The term $\mathcal{E}_0 I$ is the rate at which electrical potential energy is supplied by the battery. The term I^2R is the rate at which potential energy is delivered to the resistor. (It is also the rate at which potential energy is dissipated by the resistance in the circuit.) The term $LI\,dI/dt$ is the rate at which potential energy is delivered to the inductor, so if U_m is the energy stored in the inductor, then

$$\frac{dU_m}{dt} = LI\frac{dI}{dt}$$

which implies

$$dU_m = LI\,dI$$

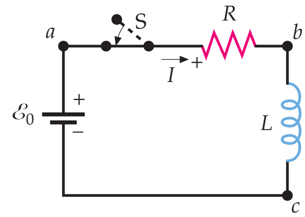


FIGURE 28-29 Just after the switch S is closed in this circuit, the current begins to increase and a back emf of magnitude $L\,dI/dt$ is induced in the inductor. The potential drop across the resistor IR plus the potential drop across the inductor ($L\,dI/dt$) equals the emf of the battery ($\mathcal{E}_0$).

* The transformer is discussed in Chapter 29.

Integrating this equation, we obtain

$$U_m = \frac{1}{2}LI^2 + C$$

where C is a constant of integration. To evaluate C, we set U_m equal to zero when I is equal to zero. The energy stored in an inductor carrying a current I is thus given by

$$U_m = \frac{1}{2}LI^2 \tag{28-21}$$

ENERGY STORED IN AN INDUCTOR

When a current is produced in an inductor, a magnetic field is created in the region in and around the inductor coil. We can think of the energy stored in an inductor as energy stored in this magnetic field. For the special case of a long, thin solenoid, the magnetic field strength is zero except for the region inside the inductor, where it is given by

$$B = \mu_0 n I$$

The self-inductance of a long, thin solenoid is given by Equation 28-13:

$$L = \mu_0 n^2 A\ell$$

where A is the cross-sectional area and ℓ is the length. Substituting $B/(\mu_0 n)$ for I and $\mu_0 n^2 A\ell$ for L in Equation 28-21, we obtain

$$U_m = \frac{1}{2}LI^2 = \frac{1}{2}\mu_0 n^2 A\ell\left(\frac{B}{\mu_0 n}\right)^2 = \frac{B^2}{2\mu_0}A\ell$$

The quantity $A\ell$ is the volume of the space within the solenoid containing the magnetic field. The energy per unit volume is the **magnetic energy density** u_m:

$$u_m = \frac{B^2}{2\mu_0} \tag{28-22}$$

MAGNETIC ENERGY DENSITY

Although we derived this expression by considering the special case of the magnetic field in a long solenoid, it is a general result. Whenever a magnetic field exists in space, the magnetic energy per unit volume is given by Equation 28-22. Note the similarity to the energy density in a region where there is an electric field (Equation 24-9):

$$u_e = \frac{1}{2}\epsilon_0 E^2$$

Example 28-11 Electromagnetic Energy Density

A certain region of space has a uniform magnetic field of 0.0200 T and a uniform electric field of 2.50×10^6 N/C. Find (*a*) the total electromagnetic energy density in the region, and (*b*) the energy in a cubical box of edge length $\ell = 12.0$ cm.

PICTURE The total energy density u is the sum of the electrical and magnetic energy densities, $u = u_e + u_m$. The energy in a volume $\mathcal{V}$ is given by $U = u\mathcal{V}$.

SOLVE

(*a*) 1. Calculate the electrical energy density:

$$u_e = \frac{1}{2}\epsilon_0 E^2$$
$$= \frac{1}{2}(8.85 \times 10^{-12}\ \mathrm{C^2/N\cdot m^2})(2.50 \times 10^6\ \mathrm{N/C})^2$$
$$= 27.7\ \mathrm{J/m^3}$$

2. Calculate the magnetic energy density: $u_m = \dfrac{B^2}{2\mu_0} = \dfrac{(0.0200\text{ T})^2}{2(4\pi \times 10^{-7}\text{ N/A}^2)} = 159\text{ J/m}^3$

3. The total energy density is the sum of the above two contributions: $u = u_e + u_m = 27.7\text{ J/m}^3 + 159\text{ J/m}^3 = \boxed{187\text{ J/m}^3}$

(*b*) The total energy in the box is $U = u\mathcal{V}$, where $\mathcal{V} = \ell^3$ is the volume of the box: $U = u\mathcal{V} = u\ell^3 = (187\text{ J/m}^3)(0.120\text{ m})^3 = \boxed{0.323\text{ J}}$

*28-8 *RL* CIRCUITS

A circuit containing a resistor and an inductor, such as that shown in Figure 28-29, is called an ***RL* circuit.** Because all circuits have resistance and self-inductance at room temperature, the analysis of an *RL* circuit can be applied to some extent to all circuits.*

For the circuit shown in Figure 28-29, application of Kirchhoff's loop rule gave us

$$\mathcal{E}_0 - IR - L\frac{dI}{dt} = 0 \qquad 28\text{-}19$$

Let us look at some general features of this equation. First, the sum $IR + L\,dI/dt$ equals the emf of the battery, which is constant. Immediately after we close the switch in the circuit, the current is still zero, so IR is zero, and $L\,dI/dt$ equals the emf of the battery, $\mathcal{E}_0$. Setting $I = 0$ in Equation 28-19, we get

$$\left.\frac{dI}{dt}\right|_{I=0} = \frac{\mathcal{E}_0}{L} \qquad 28\text{-}23$$

As the current increases, IR increases and dI/dt decreases. Note that the current cannot abruptly jump from zero to some final value as it would if the inductance L were zero. When the inductance L is greater than zero dI/dt is finite, and therefore the current must be continuous in time. After a short time, the current has reached a positive value I, and the rate of change of the current is

$$\frac{dI}{dt} = \frac{\mathcal{E}_0 - IR}{L}$$

At this time the current is still increasing, but its rate of increase is less than it was at $t = 0$. The final value I_f of the current can be obtained by setting dI/dt equal to zero in Equation 28-19:

$$I_f = \frac{\mathcal{E}_0}{R} \qquad 28\text{-}24$$

Figure 28-30 shows the current in this circuit as a function of time. This figure is the same as that for the charge on a capacitor as a function of time when the capacitor is being charged in an *RC* circuit (Figure 25-45).

Equation 28-19 is of the same form as Equation 25-38 for the charging of a capacitor—and can be solved in the same way (by separating variables and integrating). The result is

$$I = \frac{\mathcal{E}_0}{R}(1 - e^{-(R/L)t}) = I_f(1 - e^{-t/\tau}) \qquad 28\text{-}25$$

where $I_f = \mathcal{E}_0/R$ is the current as $t \to \infty$, and

$$\tau = \frac{L}{R} \qquad 28\text{-}26$$

is the **time constant** of the circuit. The larger the self-inductance L or the smaller the resistance R, the longer it takes for the current to reach any specified fraction of its final current I_f.

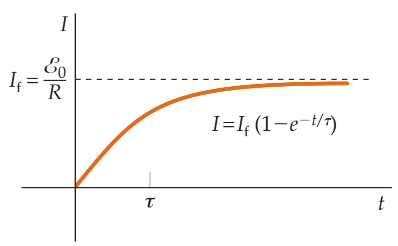

FIGURE 28-30 Current versus time in an *RL* circuit. At a time $t = \tau = L/R$, the current is at 63 percent of its maximum value $\mathcal{E}_0/R$.

* All circuits also have some capacitance between parts of the circuits at different potentials. We will consider the effects of capacitance in Chapter 29 when we study ac circuits. Here we will neglect capacitance to simplify the analysis and to focus on the effects of inductance.

Example 28-12 Energizing a Coil

A coil that has a self-inductance equal to 5.00 mH and a resistance equal to 15.0 Ω is placed across the terminals of a 12.0-V battery that has a negligible internal resistance. (*a*) What is the final current? (*b*) What is the time constant? (*c*) How many time constants does it take for the current to reach 99.0 percent of its final value?

PICTURE The final current is the current when $dI/dt = 0$. The current as a function of time is given by Equation 28-25, $I = I_f(1 - e^{-t/\tau})$, where $\tau = L/R$.

SOLVE

(*a*) Using Equation 28-19, set dI/dt equal to zero to find the final current, I_f:

$$\mathcal{E}_0 - IR - L\frac{dI}{dt} = 0$$

$$\mathcal{E}_0 - I_f R - 0 = 0$$

$$I_f = \frac{\mathcal{E}_0}{R} = \frac{12.0\ \text{V}}{15.0\ \Omega} = \boxed{0.800\ \text{A}}$$

(*b*) Calculate the time constant τ.

$$\tau = \frac{L}{R} = \frac{5.00 \times 10^{-3}\text{H}}{15.0\ \Omega} = \boxed{333\ \mu\text{s}}$$

(*c*) Use Equation 28-25 and calculate the time t for $I = 0.990 I_f$:

$$I = I_f(1 - e^{-t/\tau}),$$

so

$$e^{-t/\tau} = \left(1 - \frac{I}{I_f}\right)$$

Taking the logarithm of both sides gives

$$-\frac{t}{\tau} = \ln\left(1 - \frac{I}{I_f}\right)$$

Thus,

$$t = -\tau \ln\left(1 - \frac{I}{I_f}\right) = -\tau \ln(1 - 0.990)$$

$$= -\tau \ln(0.010) = \tau \ln 100 = \boxed{4.61\tau}$$

CHECK In five time constants, the current is within one percent of its final value. This is consistent with the results of Example 25-18 where we found that after five time constants the charge on a discharging capacitor was less that one percent of its initial charge.

PRACTICE PROBLEM 28-8

How much energy is stored in this inductor when the final current has been attained?

In Figure 28-31, the circuit has a make-before-break switch (shown in Figure 28-32) that allows us to remove the battery from the circuit without interrupting the current through the inductor. The resistor R_1 protects the battery so that the battery is not shorted when the switch is thrown. If the switch throw is in position e, the battery, the inductor, and the two resistors are connected in series and the current builds up in the circuit as just discussed, except that the total resistance is now $R_1 + R$ and the final current is $\mathcal{E}_0/(R + R_1)$. Suppose that the throw has been in position e for a long time, so that the current remains at its final value, which we will call I_0. At time $t = 0$, we rapidly move the throw from position e to position f. With the throw at f, the current is zero in the branch with the battery and R_1. We now have a closed single-loop circuit (loop $abcdfa$) that has a resistor and an inductor carrying an initial current I_0. Applying Kirchoff's loop rule to this circuit gives

$$-IR - L\frac{dI}{dt} = 0$$

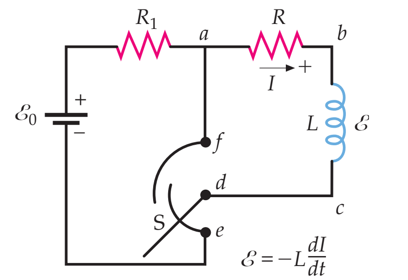

FIGURE 28-31 An RL circuit that has a make-before-break switch so that the battery can be removed from the circuit without interrupting the current through the inductor. The current in the inductor reaches its steady-state value with the switch pole in position e. The pole is then rapidly moved to position f.

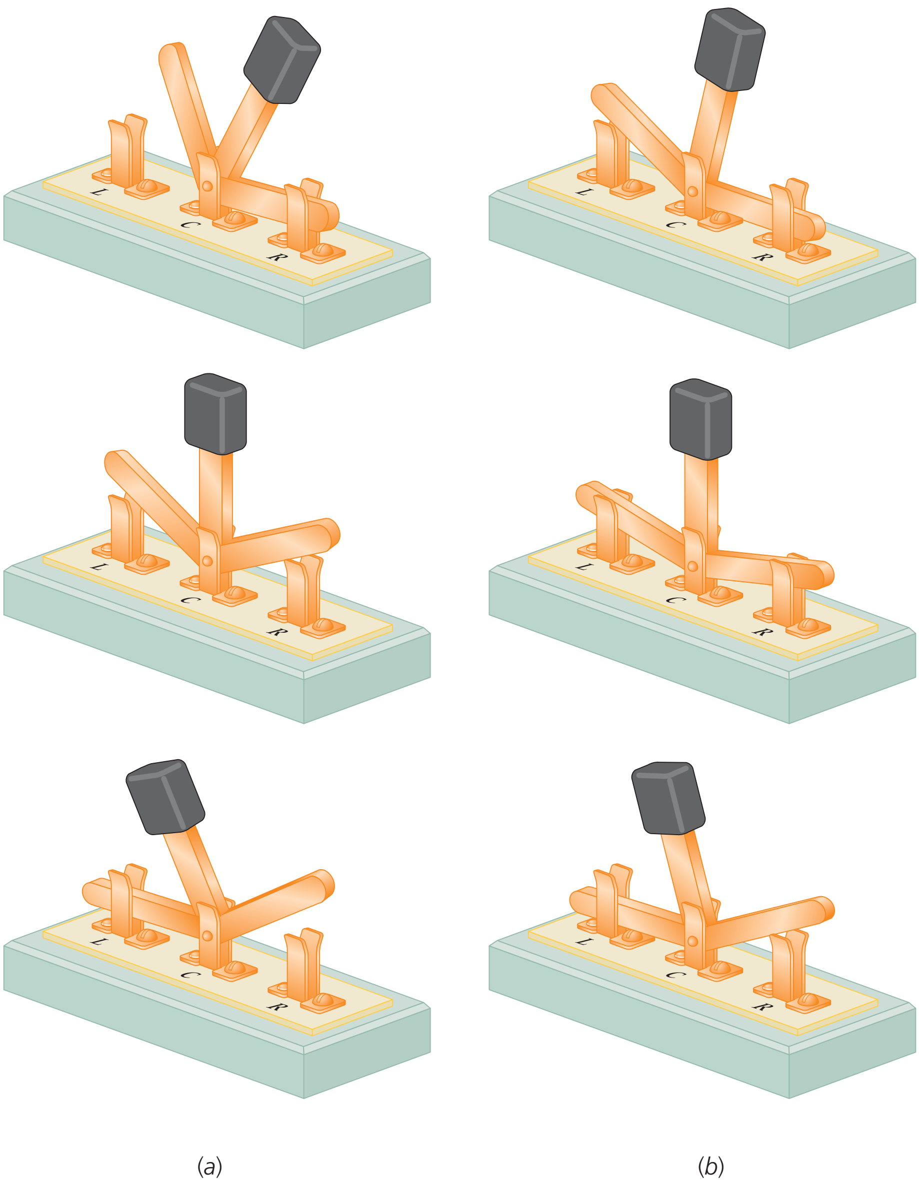

FIGURE 28-32 (*a*) The standard single-pole, double-throw switch is a break-before-make switch. That is, it breaks the first contact before making the second contact. (*b*) In a make-before-break, single-pole, double-throw switch, the throw makes the second contact before breaking the first contact. With the throw in the middle position, the throw is simultaneously in electrical contact with contacts L and R.

Rearranging this equation to separate the variables I and t gives

$$\frac{dI}{I} = -\frac{R}{L}\,dt \qquad \text{28-27}$$

(Equation 28-27 is of the same form as Equation 25-34 for the discharge of a capacitor.) Integrating and then solving for I gives

$$I = I_0 e^{-t/\tau} \qquad \text{28-28}$$

where $\tau = L/R$ is the time constant. Figure 28-33 shows the current as a function of time.

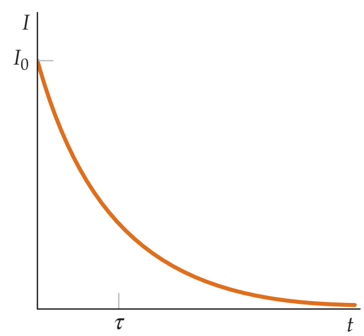

FIGURE 28-33 Current versus time for the circuit in Figure 28-31. The current decreases exponentially with time.

PRACTICE PROBLEM 28-9

What is the time constant of a closed single-loop circuit that has a resistance equal to 85 Ω and an inductance equal to 6.0 mH?

Example 28-13 Energy Dissipated

Find the total energy dissipated in the resistor R, as shown in Figure 28-31, when the current in the circuit decreases from its initial value of I_0 to 0.

PICTURE The rate of energy dissipation is equal to I^2R.

SOLVE

1. The rate of energy dissipation is I^2R: $$\frac{dU}{dt} = I^2R$$
2. The total energy U dissipated in the resistor is the integral of $P\,dt$ from $t = 0$ to $t = \infty$: $$U = \int_0^\infty I^2R\,dt$$
3. The current I is given by Equation 28-28: $$I = I_0e^{-(R/L)t}$$
4. Substitute this current into the integral: $$U = \int_0^\infty I^2R\,dt = \int_0^\infty I_0^2e^{-2(R/L)t}R\,dt = I_0^2R\int_0^\infty e^{-2(R/L)t}\,dt$$
5. The integration can be done by substituting $x = 2Rt/L$: $$U = I_0^2R\frac{e^{-2(R/L)t}}{-2(R/L)}\bigg|_0^\infty = I_0^2R\frac{-L}{2R}(0-1) = \boxed{\frac{1}{2}LI_0^2}$$

CHECK The total amount of energy dissipated equals the energy $\frac{1}{2}LI_0^2$ originally stored in the inductor. (The energy stored in an inductor is $\frac{1}{2}LI^2$ (Equation 28-21.)

Example 28-14 Initial Currents and Final Currents

For the circuit shown in Figure 28-34, find the currents I_1, I_2, and I_3 (*a*) immediately after switch S is closed and (*b*) a long time after switch S has been closed. After the switch has been closed for a long time the switch is opened. Immediately after the switch is opened (*c*) find the three currents and (*d*) find the potential drop across the 20-Ω resistor. (*e*) Find all three currents a long time after switch S was opened.

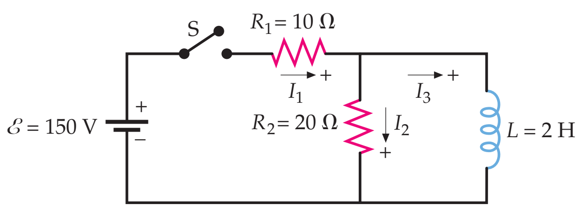

FIGURE 28-34

PICTURE (*a*) We simplify our calculations by using the fact that the current in an inductor cannot change abruptly. Thus, because the current in the inductor is zero before the switch is closed, the current in the inductor must be zero just after the switch is closed. (*b*) When the current reaches its final value dI/dt equals zero, so there is no potential drop across the inductor. The inductor thus acts like a short circuit; that is, the inductor acts like a wire with zero resistance. (*c*) Immediately after the switch is opened, the current in the inductor is the same as it was just before the switch was opened. (*d*) A long time after the switch is opened, all the currents must be zero.

SOLVE

(*a*) 1. The switch is just closed. The current through the inductor is zero, just as it was before the switch was closed. Apply the junction rule to relate I_1 and I_2:
$$I_3 = \boxed{0}$$
$$I_1 = I_2 + I_3$$
so
$$I_1 = I_2$$

2. The current in the left loop is obtained by applying the loop rule to the loop on the left:
$$\mathcal{E} - I_1R_1 - I_1R_2 = 0$$
so
$$I_1 = I_2 = \frac{\mathcal{E}}{R_1 + R_2} = \frac{150\text{ V}}{10\ \Omega + 20\ \Omega} = \boxed{5.0\text{ A}}$$

(*b*) 1. After a long time, the currents are steady and the inductor acts like a short circuit, so the potential drop across R_2 is zero. Apply the loop rule to the loop on the right and solve for I_2:
$$-L\frac{dI_3}{dt} + I_2R_2 = 0$$
$$0 + I_2R_2 = 0 \quad\Rightarrow\quad I_2 = \boxed{0}$$

2. Apply the loop rule to the loop on the left and solve for I_1:

$$\mathcal{E} - I_1R_1 - I_2R_2 = 0$$
$$\mathcal{E} - I_1R_1 - 0 = 0$$

so

$$I_1 = \frac{\mathcal{E}}{R_1} = \frac{150\text{ V}}{10\ \Omega} = \boxed{15\text{ A}}$$

3. Apply the junction rule and solve for I_3:

$$I_1 = I_2 + I_3$$
$$15\text{ A} = 0 + I_3$$

so

$$I_3 = \boxed{15\text{ A}}$$

(*c*) When the switch is reopened, I_1 *"instantaneously"* becomes zero. The current I_3 in the inductor changes continuously, so at that "instant" $I_3 = 15$ A. Apply the junction rule and solve for I_2:

$$I_3 = \boxed{15\text{ A}}$$
$$I_1 = I_2 + I_3$$

so

$$I_2 = I_1 - I_3 = 0 - 15\text{ A} = \boxed{-15\text{ A}}$$

(*d*) Apply Ohm's law to find the potential drop across R_2:

$$V = I_2R_2 = (15\text{ A})(20\ \Omega) = \boxed{300\text{ V}}$$

(*e*) A long time after the switch is opened, all the currents must equal zero.

$$I_1 = I_2 = I_3 = \boxed{0}$$

TAKING IT FURTHER Were you surprised to find the potential drop across R_2 in Part (*d*) to be larger than the emf of the battery? This potential drop is equal to the emf of the inductor.

PRACTICE PROBLEM 28-10 Suppose $R_2 = 200\ \Omega$ and the switch has been closed for a long time. What is the potential drop across R_2 immediately after the switch is then opened?

28-9 MAGNETIC PROPERTIES OF SUPERCONDUCTORS

A superconductor has a resistivity equal to zero below a critical temperature T_c, which varies from material to material. In the presence of a magnetic field $\vec{B}$, the critical temperature is lower than the critical temperature is when there is no magnetic field. As the magnetic field increases, the critical temperature decreases. If the magnetic field strength is greater than some critical field strength B_c, superconductivity does not exist at any temperature.

*MEISSNER EFFECT

As a superconductor in a region that has a magnetic field is cooled below its critical temperature, the magnetic field in the region within the superconducting material becomes zero (Figure 28-35). This effect was discovered by Walter Meissner and Robert Ochsenfeld in 1933 and is now known as the **Meissner effect.** The magnetic field becomes zero because superconducting currents induced on the surface of the superconductor produce a

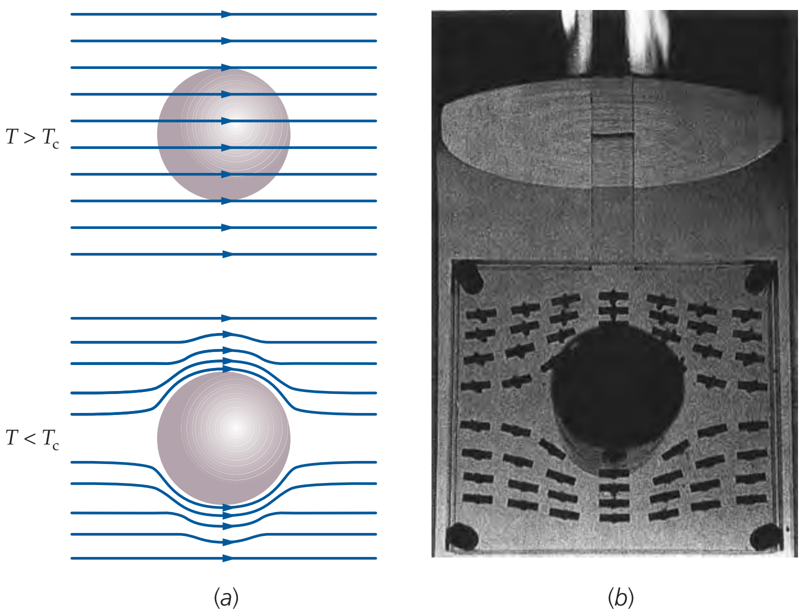

FIGURE 28-35 (*a*) The Meissner effect in a superconducting solid sphere cooled in a constant applied magnetic field. As the temperature drops below the critical temperature T_c, the magnetic field inside the sphere becomes zero. (*b*) Demonstration of the Meissner effect. A superconducting tin cylinder is situated with its axis perpendicular to a horizontal magnetic field. The directions of the field lines are indicated by weakly magnetized compass needles mounted in a Lucite sandwich so that they are free to turn. *(A. Leitner/Rensselaer Polytechnic Institute.)*

second magnetic field that cancels out the applied one. The magnetic levitation (see the photo) results from the repulsion between the permanent magnet producing the applied field and the magnetic field produced by the currents induced in the superconductor.

Only certain superconductors, called **type I superconductors,** exhibit the complete Meissner effect. Figure 28-36*a* shows a plot of the magnetization M multiplied by μ_0 versus the applied magnetic field B_{app} for a type I superconductor. For a magnetic field less than the critical field strength B_{c}, the magnetic field $\mu_0 M$ induced in the superconductor is equal and opposite to the applied magnetic field. The values of B_{c} for type I superconductors are always too small for such materials to be useful in the coils of a superconducting magnet.

Other materials, known as **type II superconductors,** have a magnetization curve similar to that in Figure 28-36*b*. Such materials are usually alloys or metals that have large resistivities in the normal state. Type II superconductors exhibit the electrical properties of superconductors, except for the Meissner effect, up to the critical field B_{c2}, which may be several hundred times the typical values of critical fields for type I superconductors. For example, the alloy Nb_3Ge has a critical field $B_{\text{c2}} = 34$ T. Such materials can be used for high-field superconducting magnets. Below the critical field B_{c1}, the behavior of a type II superconductor is the same as that of a type I superconductor.

The disk is a superconductor. The magnetic levitation results from the repulsion between the permanent magnet producing the applied field and the magnetic field produced by the currents induced in the superconductor. *(© Palmer/Kane, Inc./CORBIS.)*

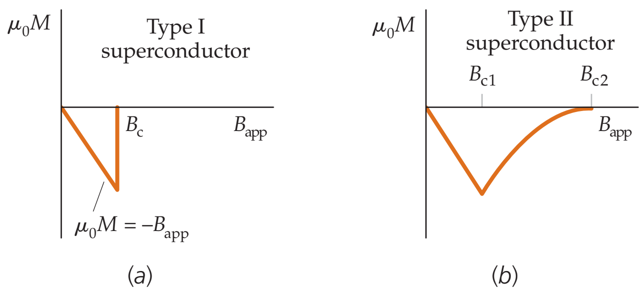

FIGURE 28-36 Plots of μ_0 multiplied by the magnetization M versus applied magnetic field for type I and type II superconductors. (*a*) In a type I superconductor, the resultant magnetic field is zero below a critical applied field B_{c} because the field due to induced currents on the surface of the superconductor exactly cancels the applied field. Above the critical field, the material is a normal conductor and the magnetization is too small to be seen on this scale. (*b*) In a type II superconductor, the magnetic field starts to penetrate the superconductor at a field B_{c1}, but the material remains superconducting up to a field B_{c2}, after which the material becomes a normal conductor.

*FLUX QUANTIZATION

Consider a superconducting ring that has an area A and carries a current. A magnetic flux $\phi_{\text{m}} = B_{\text{n}}A$ can exist through the flat surface S bounded by the ring due to the current in the ring and due also perhaps to other currents external to the ring. According to Equation 28-6, if the flux of the magnetic field through S changes, an electric field will be induced in the ring whose circulation is proportional to the rate of change of the flux. But no electric field can exist in a superconducting ring because the ring has no resistance and a finite electric field would drive an infinite current. The flux through S is thus fixed and cannot change.

Another effect, which results from the quantum-mechanical treatment of superconductivity, is that the total flux through surface S is quantized and is given by

$$\phi_{\text{m}} = n\frac{h}{2e} \qquad n = 1, 2, 3, \ldots \tag{28-29}$$

The smallest unit of flux, called a **fluxon,** is

$$\phi_0 = \frac{h}{2e} = 2.0678 \times 10^{-15}\ \text{T}\cdot\text{m}^2 \tag{28-30}$$

Physics Spotlight

The Promise of Superconductors

The researcher is filling tubes with high-temperature superconducting powder in order to make wire. *(Courtesy of Department of Energy.)*

In 1986, a pair of IBM researchers tested a metal oxide—a ceramic—and found it was superconductive at 23 K.* Researchers worldwide then began testing different ceramics for superconductivity. By early 1987, a high-temperature superconductor (HTS) ceramic had been found. It is superconducting at 90 K—warm enough to be cooled by liquid nitrogen rather than liquid helium.† Superconducting ceramics were also found that could carry very large currents. The popular press assumed that room-temperature superconductors would be discovered. Books written in the late 1980s discussed the possibilities of superconductor-assisted levitating trains, superconductor-enabled computers, transfer of power over long distances without large losses due to resistance, and even superconductor-assisted satellite lasers.‡, #

Unfortunately, room-temperature superconductors have not been reliably observed. Furthermore, high-temperature ceramic superconductors are difficult to work with.° They are brittle and cannot be connected easily to wires, so several ways of depositing the superconducting ceramics on other surfaces had to be invented. In addition, if the boundaries between the tiny ceramic grains are not properly oriented or if the layers are too thick, the ceramic is not superconductive.§

These difficulties have, however, slowly been overcome. HTS are now used in a growing number of applications. Superconducting quantum interference detectors, or SQUIDs, use interruptions¶ in superconductivity to detect extremely small amounts of energy. They are used in extraordinarily sensitive metal detectors,** light detectors,†† and even to detect magnetic fields in the nervous systems of newborns.‡‡ HTS have been tested in short lengths of electrical cable that have been nitrogen-cooled and carry large currents## and in fine superconducting wires.°°

Superconductors become resistive conductors when they carry large currents, which can be advantageous for long-distance power distribution systems. When short circuits occur in electrical circuits, the current rapidly increases unless the circuit is protected by a fuse or circuit breaker. Without the protections, the large currents can damage equipment and cause fires. Superconducting current limiters are being developed§§ to protect electrical distribution networks from those excessively large currents.¶¶

In 2001, Japanese researchers discovered that magnesium diboride, MgB_2, is superconductive at 39 K, much warmer than any other metallic superconductor. Unlike other metallic superconductors, it can be cooled by liquid neon instead of the more costly liquid helium. Because MgB_2 is a metallic alloy, it is easily made into wire.*** Pure MgB_2 does develop resistance at a lower critical current than other metallic superconductors, so it is not currently used for high-current applications.††† Researchers are studying the additions of small amounts of other elements to improve the characteristics of MgB_2.‡‡‡

Summary

1. Faraday's law and Lenz's law are fundamental laws of physics.
2. Self-inductance is a property of a circuit element that relates the flux through the element to the current.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Magnetic Flux ϕ_m		
General definition	$\phi_m = \int_S \vec{B} \cdot \hat{n}\, dA$	28-1
Uniform field, flat surface bounded by coil of N turns	$\phi_m = NBA\cos\theta$ where A is the area of the flat surface bounded by a single turn.	28-4
Units	$1\text{ Wb} = 1\text{ T}\cdot\text{m}^2$	28-2
Due to current in a circuit	$\phi_m = LI$	28-11
Due to current in two circuits	$\phi_{m1} = L_1I_1 + MI_2$ $\phi_{m2} = L_2I_2 + MI_1$	28-16
2. EMF		
Faraday's law (includes both induction and motional emf)	$\mathcal{E} = -\frac{d\phi_m}{dt}$	28-5
Induction (time-varying magnetic field, C stationary)	$\mathcal{E} = \oint_C \vec{E} \cdot d\vec{\ell}$	28-6
Rod moving perpendicular to both its length and $\vec{B}$	$\lvert\mathcal{E}\rvert = vB\ell$	28-7
Self-induced (back emf)	$\mathcal{E} = -L\frac{dI}{dt}$	28-14
3. Faraday's Law	$\mathcal{E} = -\frac{d\phi_m}{dt}$	28-5
4. Lenz's Law	The induced emf and induced current are in such a direction as to oppose, or tend to oppose, the change that produces them.	
Alternative statement	When a magnetic flux through a surface changes, the magnetic field due to any induced current produces a flux of its own—through the same surface and opposite in sign to the change in flux.	
5. Inductance		
Self-inductance	$L = \frac{\phi_m}{I}$	28-11
Self-inductance of a solenoid	$L = \mu_0 n^2 A\ell$	28-13

TOPIC	RELEVANT EQUATIONS AND REMARKS	
Mutual inductance	$M = \frac{\phi_{m21}}{I_1} = \frac{\phi_{m12}}{I_2}$	28-18
Units and constants	$1\ \text{H} = 1\ \text{Wb/A} = 1\ \text{T}\cdot\text{m}^2/\text{A}$ $\mu_0 = 4\pi \times 10^{-7}\ \text{H/m}$	
6. Magnetic Energy		
Energy stored in an inductor	$U_m = \frac{1}{2}LI^2$	28-21
Energy density in a magnetic field	$u_m = \frac{B^2}{2\mu_0}$	28-22
***7. *RL* Circuits**		
Potential difference across an inductor	$\Delta V = \mathcal{E} - Ir = -L\frac{dI}{dt} - Ir$ where r is the internal resistance of the inductor. For an ideal inductor $r = 0$.	28-15
Energizing an inductor with a battery	In a single-loop circuit consisting of a resistor that has a resistance R, an inductor that has a self-inductance L, and a battery that has an emf $\mathcal{E}_0$, the current does not reach its maximum value I_f instantaneously, but rather takes some time to build up. If the current is initially zero, its value at some later time t is given by $I = \frac{\mathcal{E}_0}{R}(1 - e^{-t/\tau}) = I_f(1 - e^{-t/\tau})$	28-25
Time constant τ	$\tau = \frac{L}{R}$	28-26
De-energizing an inductor	In a single-loop circuit consisting of a resistor that has a resistance R and an inductor that has a self-inductance L, the current does not drop to zero through a resistor instantaneously, but rather takes some time to decrease. If the current is initially I_0, its value at some later time t is given by $I = I_0 e^{-t/\tau}$	28-28

Answers to Concept Checks

28-1 Opposite to the direction shown in Figure 28-12.

28-2 The external agent turning the coil does work on the coil. The energy comes from the external agent.

Answers to Practice Problems

28-2	0.555 A
28-3	3.53 mC
28-4	1.4 V
28-5	11 V
28-6	3.18×10^5 A/s
28-7	$M_{12} = \mu_0 n_2 n_1 \ell \pi r_1^2$
28-8	$U_m = \frac{1}{2}LI_f^2 = 1.60 \times 10^{-3}$ J
28-9	71 μs
28-10	3.0 kV

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • (*a*) The magnetic equator is a line on the surface of Earth on which Earth's magnetic field is horizontal. At the magnetic equator, how would you orient a flat sheet of paper so as to create the maximum magnitude of magnetic flux through it? (*b*) How about the minimum magnitude of magnetic flux? SSM

2 • At one of Earth's magnetic poles, how would you orient a flat sheet of paper so as to create the maximum magnitude of magnetic flux through it?

3 • Show that the following combination of SI units is equivalent to the volt: $\mathrm{T \cdot m^2/s}$. SSM

4 • Show that the following combination of SI units is equivalent to the ohm: $\mathrm{Wb/(A \cdot s)}$

5 • A current is induced in a conducting loop that lies in a horizontal plane, and the induced current is clockwise when viewed from above. Which of the following statements could be true? (*a*) A constant magnetic field is directed vertically downward. (*b*) A constant magnetic field is directed vertically upward. (*c*) A magnetic field whose magnitude is increasing is directed vertically downward. (*d*) A magnetic field whose magnitude is decreasing is directed vertically downward. (*e*) A magnetic field whose magnitude is decreasing is directed vertically upward. SSM

6 • Give the direction of the induced current in the circuit, shown on the right in Figure 28-37, when the resistance in the circuit on the left is suddenly (*a*) increased and (*b*) decreased. Explain your answer.

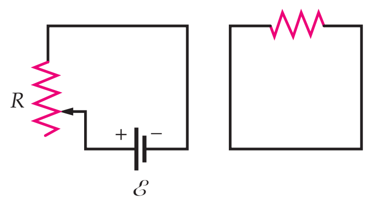

FIGURE 28-37 Problem 6

7 • The planes of the two circular loops in Figure 28-38 are parallel. As viewed from the left, a counterclockwise current exists in loop A. If the magnitude of the current in loop A is increasing, what is the direction of the current induced in loop B? Do the loops attract or repel each other? Explain your answer. SSM

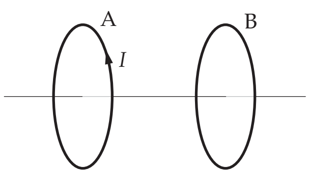

FIGURE 28-38 Problem 7

8 • A bar magnet moves with constant velocity along the axis of a loop, as shown in Figure 28-39. (*a*) Make a graph of the magnetic flux through the loop as a function of time. Indicate on the graph when the magnet is halfway through the loop by designating this time t_1. Choose the direction of the normal to the flat surface bounded by the loop to be to the right. (*b*) Make a graph of the induced current in the loop as a function of time. Choose the positive direction for the current to be clockwise as viewed from the left.

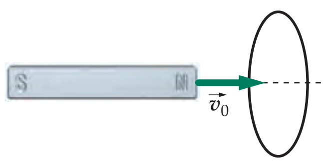

FIGURE 28-39 Problem 8

9 • A bar magnet is mounted on the end of a coiled spring and is oscillating in simple harmonic motion along the axis of a loop, as shown in Figure 28-40. The magnet is in its equilibrium position when its midpoint is in the plane of the loop. (*a*) Make a graph of the magnetic flux through the loop as a function of time. Indicate when the magnet is halfway through the loop by designating these times t_1 and t_2. (*b*) Make a graph of the induced current in the loop as a function of time, choosing the current to be positive when it is clockwise as viewed from above.

FIGURE 28-40 Problem 9

10 • A pendulum is fabricated from a thin, flat piece of aluminum. At the bottom of its arc, it passes between the poles of a strong permanent magnet. In Figure 28-41*a*, the metal sheet is continuous, whereas in Figure 28-41*b*, there are slots in the sheet. When released from the same angle, the pendulum that has slots swings back and forth many times, but the pendulum that does not have slots stops swinging after no more than one complete oscillation. Explain why.

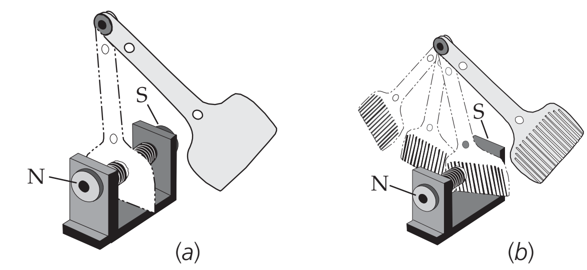

FIGURE 28-41 Problem 10 *(Courtesy of PASCO Scientific Co.)*

11 • A bar magnet is dropped inside a long, vertical tube. If the tube is made of metal, the magnet quickly approaches a terminal speed, but if the tube is made of cardboard, the magnet falls with constant acceleration. Explain why the magnet falls differently in the metal tube than it does in the cardboard tube.

12 • A small square wire loop lies in the plane of this page, and a constant magnetic field is directed into the page. The loop is moving to the right, which is the $+x$ direction. Find the direction of the induced current, if any, in the loop if (*a*) the magnetic field is uniform, (*b*) the magnetic field strength increases as x increases, and (*c*) the magnetic field strength decreases as x increases.

13 • If the current in an inductor doubles, the energy stored in the inductor will (*a*) remain the same, (*b*) double, (*c*) quadruple, (*d*) halve.

14 • Two solenoids are equal in length and radius, and the cores of both are identical cylinders of iron. However, solenoid A has three times the number of turns per unit length as solenoid B. (*a*) Which solenoid has the larger self-inductance? (*b*) What is the ratio of the self-inductance of solenoid A to the self-inductance of solenoid B?

15 • True or false:

(*a*) The induced emf in a circuit is equal to the negative of the magnetic flux through the circuit.
(*b*) There can be a nonzero induced emf at an instant when the flux through the circuit is equal to zero.
(*c*) The self-inductance of a solenoid is proportional to the rate of change of the current in the solenoid.
(*d*) The magnetic energy density at some point in space is proportional to the square of the magnitude of the magnetic field at that point.
(*e*) The inductance of a solenoid is proportional to the current in it. SSM

ESTIMATION AND APPROXIMATION

16 • **CONTEXT-RICH** Your baseball teammates, having just studied this chapter, are concerned about generating enough voltage to shock them while swinging aluminum bats at fastballs. Estimate the maximum possible motional emf measured between the ends of an aluminum baseball bat during a swing. Do you think your team should switch to wooden bats to avoid electrocution?

17 • Compare the energy density stored in Earth's electric field near its surface to that stored in Earth's magnetic field near its surface.

18 •• A physics teacher does the following emf demonstration. She has two students hold a long wire connected to a voltmeter. The wire is held slack, so that it sags with a large arc in it. When she says, "Start," the students begin rotating the wire as if they were playing jump rope. The students stand 3.0 m apart, and the sag in the wire is about 1.5 m. The motional emf from the "jump rope" is then measured on the voltmeter. (*a*) Estimate a reasonable value for the maximum angular speed at which the students can rotate the wire. (*b*) From this, estimate the maximum motional emf in the wire. *Hint: What field is involved in creating the induced emf?*

19 •• (*a*) Estimate the maximum possible motional emf between the wingtips of a typical commercial airliner in flight. (*b*) Estimate the magnitude of the electric field between the wingtips.

MAGNETIC FLUX

20 • A uniform magnetic field of magnitude 0.200 T is in the $+x$ direction. A square coil that has 5.00-cm-long sides has a single turn and makes an angle θ with the z axis, as shown in Figure 28-42. Find the magnetic flux through the coil when θ is (*a*) 0°, (*b*) 30°, (*c*) 60°, and (*d*) 90°.

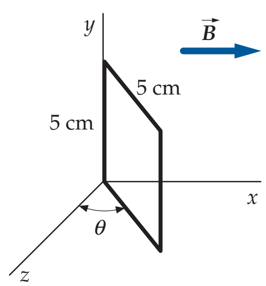

FIGURE 28-42 Problem 20

21 • A circular coil has 25 turns and a radius of 5.0 cm. It is at the equator, where Earth's magnetic field is 0.70 G, north. The axis of the coil is the line that passes through the center of the coil and is perpendicular to the plane of the coil. Find the magnetic flux through the coil when the axis of the coil is (*a*) vertical, (*b*) horizontal with the axis pointing north, (*c*) horizontal with the axis pointing east, and (*d*) horizontal with the axis making an angle of 30° with north. SSM

22 • A magnetic field of 1.2 T is perpendicular to the plane of a 14-turn square coil with sides 5.0 cm long. (*a*) Find the magnetic flux through the coil. (*b*) Find the magnetic flux through the coil if the magnetic field makes an angle of 60° with the normal to the plane of the coil.

23 • A uniform magnetic field $\vec{B}$ is perpendicular to the base of a hemisphere of radius R. Calculate the magnetic flux (in terms of B and R) through the spherical surface of the hemisphere.

24 • Find the magnetic flux through a 400-turn solenoid that has a length equal to 25.0 cm, has a radius equal to 1.00 cm, and carries a current of 3.00 A.

25 • Find the magnetic flux through a 800-turn solenoid that has a length equal to 30.0 cm, has a radius equal to 1.00 cm, and carries a current of 2.00 A.

26 •• A circular coil has 15.0 turns, has a radius of 4.00 cm, and is in a uniform magnetic field of 4.00 kG in the $+x$ direction. Find the flux through the coil when the unit normal to the plane of the coil is (*a*) $\hat{i}$, (*b*) $\hat{j}$, (*c*) $(\hat{i}+\hat{j})/\sqrt{2}$, (*d*) $\hat{k}$, and (*e*) $0.60\hat{i}+0.80\hat{j}$.

27 •• A long solenoid has n turns per unit length, has a radius R_1, and carries a current I. A circular coil with radius R_2 and with N total turns is coaxial with the solenoid and equidistant from its ends. (*a*) Find the magnetic flux through the coil if $R_2 > R_1$. (*b*) Find the magnetic flux through the coil if $R_2 < R_1$. SSM

28 ••• (*a*) Compute the magnetic flux through the rectangular loop shown in Figure 28-43. (*b*) Evaluate your answer for $a = 5.0$ cm, $b = 10$ cm, $d = 2.0$ cm, and $I = 20$ A.

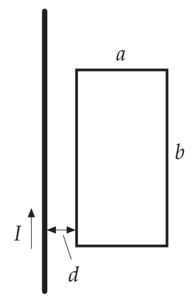

FIGURE 28-43 Problem 28

29 ••• A long, cylindrical conductor with a radius R and a length L carries a current I. Find the magnetic flux per unit length through the area indicated in Figure 28-44.

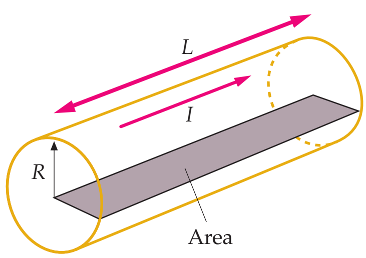

FIGURE 28-44 Problem 29

INDUCED EMF AND FARADAY'S LAW

30 • The flux through a loop is given by $\phi_m = (0.10t^2 - 0.40t)$, where ϕ_m is in webers and t is in seconds. (*a*) Find the induced emf as a function of time. (*b*) Find both ϕ_m and $\mathcal{E}$ at $t = 0$, $t = 2.0$ s, $t = 4.0$ s, and $t = 6.0$ s.

31 • The flux through a loop is given by $\phi_m = (0.10t^2 - 0.40t)$, where ϕ_m is in webers and t is in seconds. (*a*) Sketch graphs of magnetic flux and induced emf as a function of time. (*b*) At what time(s) is the flux minimum? What is the induced emf at that (those) time(s)? (*c*) At what time(s) is the flux zero? What is (are) the induced emf(s) at those time(s)?

32 • A solenoid that has a length equal to 25.0 cm, a radius equal to 0.800 cm, and 400 turns is in a region where a magnetic field of 600 G exists and makes an angle of 50° with the axis of the solenoid. (*a*) Find the magnetic flux through the solenoid. (*b*) Find the magnitude of the average emf induced in the solenoid if the magnetic field is reduced to zero in 1.40 s.

33 •• A 100-turn circular coil has a diameter of 2.00 cm and a resistance of 50.0 Ω, and the two ends of the coil are connected together. The plane of the coil is perpendicular to a uniform magnetic field of magnitude 1.00 T. The direction of the field is reversed. (*a*) Find the total charge that passes through a cross section of the wire. If the reversal takes 0.100 s, find (*b*) the average current and (*c*) the average emf during the reversal. SSM

34 •• At the equator, a 1000-turn coil that has a cross-sectional area of 300 cm² and a resistance of 15.0 Ω is aligned so that its plane is perpendicular to Earth's magnetic field of 0.700 G. (*a*) If the coil is flipped over in 0.350 s, what is the average induced current in it during the 0.350 s? (*b*) How much charge flows through a cross section of the coil wire during the 0.350 s?

35 •• **ENGINEERING APPLICATION** A *current integrator* measures the current as a function of time and integrates (adds) the current to find the total charge passing through it. (Because $I = dq/dt$, the integrator calculates the integral of the current or $Q = \int I\,dt$.) A circular coil that has 300 turns and a radius equal to 5.00 cm is connected to such an instrument. The total resistance of the circuit is 20.0 Ω. The plane of the coil is originally aligned perpendicular to Earth's magnetic field at some point. When the coil is rotated through 90° about an axis that is in the plane of the coil a charge of 9.40 μC passes through the current integrator. Calculate the magnitude of Earth's magnetic field at that point.

MOTIONAL EMF

36 • A 30.0-cm-long rod moves steady at 8.00 m/s in a plane that is perpendicular to a magnetic field of 500 G. The velocity of the rod is perpendicular to its length. Find (*a*) the magnetic force on an electron in the rod, (*b*) the electrostatic field in the rod, and (*c*) the potential difference between the ends of the rod.

37 • A 30.0-cm-long rod moves in a plane that is perpendicular to a magnetic field of 500 G. The velocity of the rod is perpendicular to its length. Find the speed of the rod if the potential difference between the ends is 6.00 V.

38 •• In Figure 28-45, let the magnetic field strength be 0.80 T, the rod speed be 10 m/s, the rod length be 20 cm, and the resistance of the resistor be 2.0 Ω. (The resistance of the rod and rails are negligible.) Find (*a*) the induced emf in the circuit, (*b*) the induced current in the circuit (including direction), and (*c*) the force needed to move the rod with constant speed (assuming negligible friction). Find (*d*) the power delivered by the force found in Part (*c*) and (*e*) the rate of Joule heating in the resistor.

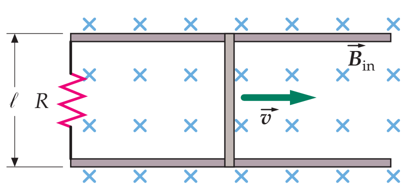

FIGURE 28-45 Problem 38

39 •• A 10-cm by 5.0-cm rectangular loop (Figure 28-46) that has a resistance equal to 2.5 Ω moves at a constant speed of 2.4 cm/s through a region that has a uniform 1.7-T magnetic field directed out of the page as shown. The front of the loop enters the field region at time $t = 0$. (*a*) Graph the flux through the loop as a function of time. (*b*) Graph the induced emf and the current in the loop as functions of time. Neglect any self-inductance of the loop and construct your graphs to include the interval $0 \le t \le 16$ s.

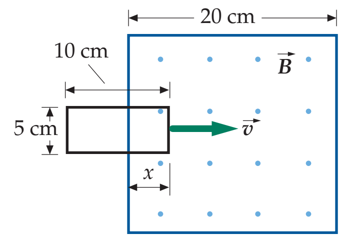

FIGURE 28-46 Problem 39

40 •• A uniform 1.2-T magnetic field is in the $+z$ direction. A conducting rod of length 15 cm lies parallel to the y axis and oscillates in the x direction with displacement given by $x = (2.0\text{ cm})\cos(120\pi t)$, where 120π has units of rad/s. (*a*) Find an expression for potential difference between the ends of the rod as a function of time? (*b*) What is the maximum potential difference between the ends the rod?

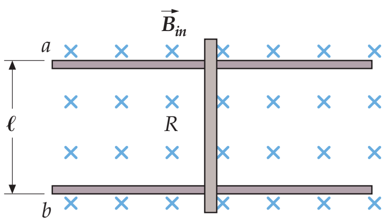

FIGURE 28-47 Problem 41

41 •• In Figure 28-47, the rod has a mass m, and a resistance R. The rails are horizontal, frictionless, and have negligible resistances. The distance between the rails is ℓ. An ideal battery that has an emf $\mathcal{E}$ is connected between points a and b so that the current in the rod is downward. The rod is released from rest at $t = 0$. (*a*) Derive an expression for the force on the rod as a function of the speed. (*b*) Show that the speed of the rod approaches a terminal speed and find an expression for the terminal speed. (*c*) What is the current when the rod is moving at its terminal speed? SSM

42 • A uniform magnetic field is established perpendicular to the plane of a loop that has a radius equal to 5.00 cm and a resistance equal to 0.400 Ω. The magnitude of the field is increasing at a rate of 40.0 mT/s. Find (*a*) the magnitude of the induced emf in the loop, (*b*) the induced current in the loop, and (*c*) the rate of Joule heating in the loop.

43 •• In Figure 28-48, a conducting rod that has a mass m and a negligible resistance is free to slide without friction along two parallel frictionless rails that have negligible resistances separated by a distance ℓ and connected by a resistance R. The rails are attached to a long inclined plane that makes an angle θ with the horizontal. There is a magnetic field directed upward as shown. (*a*) Show that there is a retarding force directed up the incline given by $F = (B^2\ell^2 v\cos^2\theta)/R$. (*b*) Show that the terminal speed of the rod is $v_t = mgR\sin\theta/(B^2\ell^2\cos^2\theta)$

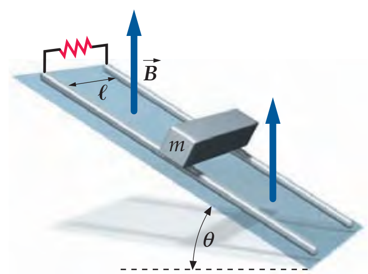

FIGURE 28-48 Problem 43

44 ••• A conducting rod of length ℓ rotates at constant angular speed ω about one end, in a plane perpendicular to a uniform magnetic field B (Figure 28-49). (*a*) Show that the potential difference between the ends of the rod is $\frac{1}{2}B\omega\ell^2$. (*b*) Let the angle θ between the rotating rod and the dashed line be given by $\theta = \omega t$. Show that the area of the pie-shaped region swept out by the rod during time t is $\frac{1}{2}\ell^2\theta$. (*d*) Compute the flux ϕ_m through that area, and apply $\mathcal{E} = -d\phi_m/dt$ (Faraday's law) to show that the motional emf is given by $\frac{1}{2}B\,\omega\ell^2$.

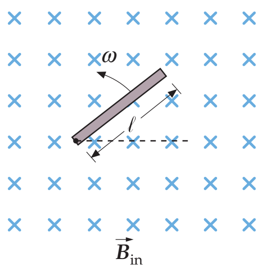

FIGURE 28-49 Problem 44

GENERATORS AND MOTORS

45 • A 2.00-cm by 1.50-cm rectangular coil has 300 turns and rotates in a region that has magnetic field of 0.400 T. (*a*) What is the maximum emf generated when the coil rotates at 60 rev/s? (*b*) What must its angular speed be to generate a maximum emf of 110 V? SSM

46 • The coil of Problem 45 rotates at 60 rev/s in a magnetic field. If the maximum emf generated by the coil is 24 V, ,what is the magnitude of the magnetic field?

INDUCTANCE

47 • When the current in an 8.00-H coil is equal to 3.00 A and is increasing at 200 A/s, find (*a*) the magnetic flux through the coil and (*b*) the induced emf in the coil.

48 •• A 300-turn solenoid has a radius equal to 2.00 cm and a length equal to 25.0 cm; a 1000-turn solenoid has a radius equal to 5.00 cm and is also 25.0 cm long. The two solenoids are coaxial, with one nested completely inside the other. What is their mutual inductance?

49 •• An insulated wire that has a resistance of 18.0 Ω/m and a length of 9.00 m will be used to construct a resistor. First, the wire is bent in half and then the doubled wire is wound on a cylindrical form (Figure 28-50) to create a 25.0-cm-long helix that has a diameter equal to 2.00 cm. Find both the resistance and the inductance of this wire-wound resistor. SSM

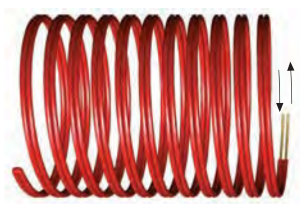

FIGURE 28-50 Problem 49

50 •• You are given a length ℓ of wire that has radius a and are told to wind it into an inductor in the shape of a helix that has a circular cross section of radius r. The windings are to be as close together as possible without overlapping. Show that the self-inductance of this inductor is $L = \frac{1}{4}\mu_0 r\ell/a$.

51 • Using the result of Problem 50, calculate the self-inductance of an inductor wound from 10 cm of wire that has a diameter of 1.0 mm into a coil that has a radius of 0.25 cm.

52 ••• In Figure 28-51, circuit 2 has a total resistance of 300 Ω. After switch *S* is closed, the current in Circuit 1 increases—reaching a value of 5.00 A after a long time. A charge of 200 μC passes through the galvanometer in Circuit 2 during the time that the current in Circuit 1 is increasing. What is the mutual inductance between the two coils?

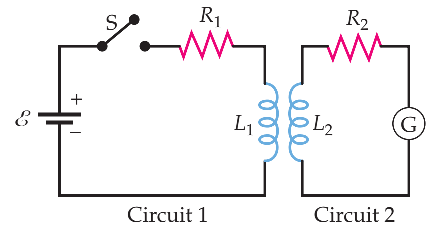

FIGURE 28-51 Problem 52

53 ••• Show that the inductance of a toroid of rectangular cross section, as shown in Figure 28-52, is given by $L = \dfrac{\mu_0 N^2 H \ln(b/a)}{2\pi}$, where N is the total number of turns, a is the inside radius, b is the outside radius, and H is the height of the toroid. SSM

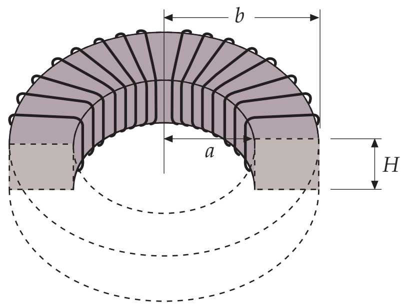

FIGURE 28-52 Problem 53

MAGNETIC ENERGY

54 • A coil that has a self-inductance of 2.00 H and a resistance of 12.0 Ω is connected to an ideal 24.0-V battery. (*a*) What is the steady-state current? (*b*) How much energy is stored in the inductor when the steady-state current is established?

55 • In a plane electromagnetic wave, the magnitudes of the electric fields and magnetic fields are related by $E = cB$, where $c = 1/\sqrt{\epsilon_0\mu_0}$ is the speed of light. Show that when $E = cB$ the electric and the magnetic energy densities are equal. SSM

56 •• A 2000-turn solenoid has a cross-sectional area equal to 4.0 cm^2 and a length equal to 30 cm. The solenoid carries a current of 4.0 A. (*a*) Calculate the magnetic energy stored in the solenoid using $U = \frac{1}{2}LI^2$, where $L = \mu_0 n^2 A\ell$. (*b*) Divide your answer in Part (*a*) by the volume of the region inside the solenoid to find the magnetic energy per unit volume in the solenoid. (*c*) Check your Part (*b*) result by computing the magnetic energy density from $u_m = B^2/(2\mu_0)$ where $B = \mu_0 nI$.

57 •• A long cylindrical wire has a radius equal to 2.0 cm and carries a current of 80 A uniformly distributed over its cross-sectional area. Find the magnetic energy per unit length within the wire.

58 •• A toroid that has a mean radius equal to 25.0 cm and circular loops with radii equal to 2.00 cm is wound with a superconducting wire. The wire has a length equal to 1000 m and carries a current of 400 A. (*a*) What is the number of turns of the wire? (*b*) What is the magnetic field strength and magnetic energy density at the mean radius? (*c*) Estimate the total energy stored in this toroid by assuming that the energy density is uniformly distributed in the region inside the toroid.

*RL CIRCUITS

59 • A circuit consists of a coil that has a resistance equal to 8.00 Ω and a self-inductance equal to 4.00 mH, an open switch, and an ideal 100-V battery—all connected in series. At $t = 0$ the switch is closed. Find the current and its rate of change at times (*a*) $t = 0$, (*b*) $t = 0.100$ ms, (*c*) $t = 0.500$ ms, and (*d*) $t = 1.00$ ms. SSM

60 • In the circuit shown in Figure 28-53, the throw of the make-before-break switch has been at contact *a* for a long time and the current in the 1.00 mH coil is equal to 2.00 A. At $t = 0$ the throw is quickly moved to contact *b*. The total resistance $R + r$ of the coil and the resistor is 10.0 Ω. Find the current when (*a*) $t = 0.500$ ms and (*b*) $t = 10.0$ ms.

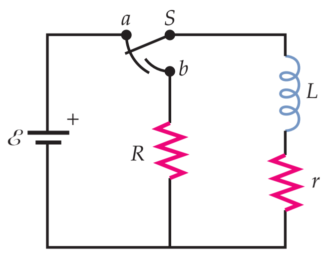

FIGURE 28-53 Problem 60

61 •• In the circuit shown in Figure 28-54, let $\mathcal{E}_0 = 12.0$ V, $R = 3.00\ \Omega$, and $L = 0.600$ H. The switch, which was initially open, is closed at time $t = 0$. At time $t = 0.500$ s, find (*a*) the rate at which the battery supplies energy, (*b*) the rate of Joule heating in the resistor, and (*c*) the rate at which energy is being stored in the inductor. SSM
