Some Conversion Factors

Length

1 m = 39.37 in = 3.281 ft = 1.094 yd

1 m = 10^{15} fm = 10^{10} Å = 10^9 nm

1 km = 0.6214 mi

1 mi = 5280 ft = 1.609 km

1 lightyear = 1 $c \cdot$ y = 9.461×10^{15} m

1 in = 2.540 cm

Volume

1 L = 10^3 cm^3 = 10^{-3} m^3 = 1.057 qt

Time

1 h = 3600 s = 3.6 ks

1 y = 365.24 d = 3.156×10^7 s

Speed

1 km/h = 0.278 m/s = 0.6214 mi/h

1 ft/s = 0.3048 m/s = 0.6818 mi/h

Angle–angular speed

1 rev = 2π rad = 360°

1 rad = 57.30°

1 rev/min = 0.1047 rad/s

Force–pressure

1 N = 10^5 dyn = 0.2248 lb

1 lb = 4.448 N

1 atm = 101.3 kPa = 1.013 bar = 76.00 cmHg = 14.70 lb/in^2

Mass

1 u = $[(10^{-3}\ \text{mol}^{-1})/N_A]$ kg = 1.661×10^{-27} kg

1 tonne = 10^3 kg = 1 Mg

1 slug = 14.59 kg

1 kg weighs about 2.205 lb

Energy–power

1 J = 10^7 erg = 0.7376 ft $\cdot$ lb = 9.869×10^{-3} L $\cdot$ atm

1 kW $\cdot$ h = 3.6 MJ

1 cal = 4.184 J = 4.129×10^{-2} L $\cdot$ atm

1 L $\cdot$ atm = 101.325 J = 24.22 cal

1 eV = 1.602×10^{-19} J

1 Btu = 778 ft $\cdot$ lb = 252 cal = 1054 J

1 horsepower = 550 ft $\cdot$ lb/s = 746 W

Thermal conductivity

1 W/(m $\cdot$ K) = 6.938 Btu $\cdot$ in/(h $\cdot$ ft^2 $\cdot$ °F)

Magnetic field

1 T = 10^4 G

Viscosity

1 Pa $\cdot$ s = 10 poise

Preface

The sixth edition of *Physics for Scientists and Engineers* offers a completely integrated text and media solution that will help students learn most effectively and will enable professors to customize their classrooms so that they teach most efficiently.

The text includes a new strategic problem-solving approach, an integrated Math Tutorial, and new tools to improve conceptual understanding. New Physics Spotlights feature cutting-edge topics that help students relate what they are learning to real-world technologies.

The new online learning management system enables professors to easily customize their classes based on their students' needs and interests by using the new interactive Physics Portal, which includes a complete e-book, student and instructor resources, and a robust online homework system. Interactive Exercises in the Physics Portal give students the opportunity to learn from instant feedback, and give instructors the option to track and grade each step of the process. Because no two physics students or two physics classes are alike, tools to help make each physics experience successful are provided.

KEY FEATURES

NEW!

PROBLEM-SOLVING STRATEGY

The sixth edition features a new problem-solving strategy in which Examples follow a consistent **Picture**, **Solve**, and **Check** format. This format walks students through the steps involved in analyzing the problem, solving the problem, and then checking their answers. Examples often include helpful **Taking It Further** sections which present alternative ways of solving problems, interesting facts, or additional information regarding the concepts presented. Where appropriate, Examples are followed by **Practice Problems** so students can assess their mastery of the concepts.

In this edition, the problem-solving steps are again juxtaposed with the necessary equations so that it's easier for students to see a problem unfold.

After each problem statement, students are asked to **Picture** the problem. Here, the problem is analyzed both conceptually and visually.

In the **Solve** sections, each step of the solution is presented with a written statement in the left-hand column and the corresponding mathematical equations in the right-hand column.

Check reminds students to make sure their results are accurate and reasonable.

Taking It Further suggests a different way to approach an Example or gives additional information relevant to the Example.

A **Practice Problem** often follows the solution of an Example, allowing students to check their understanding. Answers are included at the end of the chapter to provide immediate feedback.

Example 3-4 Rounding a Curve

A car is traveling east at 60 km/h. It rounds a curve, and 5.0 s later it is traveling north at 60 km/h. Find the average acceleration of the car.

PICTURE We can calculate the average acceleration from its definition, $\vec{a}_{av} = \Delta\vec{v}/\Delta t$ To do this, we first calculate $\Delta\vec{v}$, which is the vector that when added to $\vec{v}_i$, results in $\vec{v}_f$.

SOLVE

1. The average acceleration is the change in velocity divided by the elapsed time. To find $\vec{a}_{av}$, we first find the change in velocity: $\vec{a}_{av} = \dfrac{\Delta\vec{v}}{\Delta t}$
2. To find $\Delta\vec{v}$, we first specify $\vec{v}_i$ and $\vec{v}_f$. Draw $\vec{v}_i$ and $\vec{v}_f$ (Figure 3-7*a*), and draw the vector addition diagram (Figure 3-7*b*) corresponding to $\vec{v}_f = \vec{v}_i + \Delta\vec{v}$:
3. The change in velocity is related to the initial and final velocities: $\vec{v}_f = \vec{v}_i + \Delta\vec{v}$
4. Substitute these results to find the average acceleration: $\vec{a}_{av} = \dfrac{\vec{v}_f - \vec{v}_i}{\Delta t} = \dfrac{60\text{ km/h}\,\hat{j} - 60\text{ km/h}\,\hat{i}}{5.0\text{ s}}$
5. Convert 60 km/h to meters per second: $60\,\cancel{\text{km}}/\cancel{\text{h}} \times \dfrac{1\,\cancel{\text{h}}}{3600\text{ s}} \times \dfrac{1000\text{ m}}{1\,\cancel{\text{km}}} = 16.7\text{ m/s}$
6. Express the acceleration in meters per second squared: $\vec{a}_{av} = \dfrac{\vec{v}_f - \vec{v}_i}{\Delta t} = \dfrac{16.7\text{ m/s}\,\hat{j} - 16.7\text{ m/s}\,\hat{i}}{5.0\text{ s}}$ $= \boxed{-3.4\text{ m/s}^2\,\hat{i} + 3.4\text{ m/s}^2\,\hat{j}}$

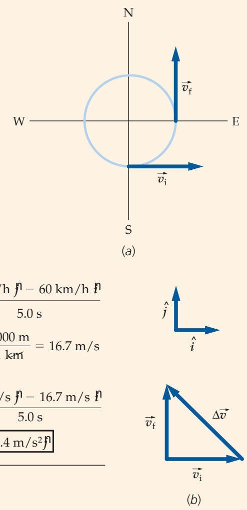

FIGURE 3-7

CHECK The eastward component of the velocity decreases from 60 km/h to zero, so we expect a negative acceleration component in the *x* direction. The northward component of the velocity increases from zero to 60 km/h, so we expect a positive acceleration component in the *y* direction. Our step 6 result meets both of these expectations.

TAKING IT FURTHER Note that the car is accelerating even though its speed remains constant.

PRACTICE PROBLEM 3-1 Find the magnitude and direction of the average acceleration vector.

A boxed **Problem-Solving Strategy** is included in almost every chapter to reinforce the **Picture**, **Solve**, and **Check** format for successfully solving problems.

PROBLEM-SOLVING STRATEGY

Relative Velocity

PICTURE The first step in solving a relative-velocity problem is to identify and label the relevant reference frames. Here, we will call them reference frame A and reference frame B.

SOLVE

1. Using $\vec{v}_{pB} = \vec{v}_{pA} + \vec{v}_{AB}$ (Equation 3-9), relate the velocity of the moving object (particle *p*) relative to frame A to the velocity of the particle relative to frame B.
2. Sketch a vector addition diagram for the equation $\vec{v}_{pB} = \vec{v}_{pA} + \vec{v}_{AB}$. Use the head-to-tail method of vector addition. Include coordinate axes on the sketch.
3. Solve for the desired quantity. Use trigonometry where appropriate.

CHECK Make sure that you solve for the velocity or position of the moving object relative to the proper reference frame.

NEW! INTEGRATED MATH TUTORIAL

This edition has improved mathematical support for students who are taking calculus concurrently with introductory physics or for students who need a math review.

The comprehensive **Math Tutorial**

- reviews basic results of algebra, geometry, trigonometry, and calculus,
- links mathematical concepts to physics concepts in the text,
- provides Examples and Practice Problems so students may check their understanding of mathematical concepts.

Example M-13 **Radioactive Decay of Cobalt-60**

The half-life of cobalt-60 (^{60}Co) is 5.27 y. At $t = 0$ you have a sample of ^{60}Co that has a mass equal to 1.20 mg. At what time t (in years) will 0.400 mg of the sample of ^{60}Co have decayed?

PICTURE When we derived the half-life in exponential decay, we set $N/N_0 = 1/2$. In this example, we are to find the time at which two-thirds of a sample remains, and so the ratio N/N_0 will be 0.667.

SOLVE

1. Express the ratio N/N_0 as an exponential function: $\frac{N}{N_0} = 0.667 = e^{-\lambda t}$
2. Take the reciprocal of both sides: $\frac{N_0}{N} = 1.50 = e^{\lambda t}$
3. Solve for t: $t = \frac{\ln 1.50}{\lambda} = \frac{0.405}{\lambda}$
4. The decay constant is related to the half-life by $\lambda = (\ln 2)/t_{1/2}$ (Equation M-70). Substitute $(\ln 2)/t_{1/2}$ for λ and evaluate the time: $t = \frac{\ln 1.5}{\ln 2} t_{1/2} = \frac{\ln 1.5}{\ln 2} \times 5.27\text{ y} = 3.08\text{ y}$

CHECK It takes 5.27 y for the mass of a sample of ^{60}Co to decrease to 50 percent of its initial mass. Thus, we expect it to take less than 5.27 y for the sample to lose 33.3 percent of its mass. Our step-4 result of 3.08 y is less than 5.27 y, as expected.

PRACTICE PROBLEMS

27. The discharge time constant τ of a capacitor in an RC circuit is the time in which the capacitor discharges to e^{-1} (or 0.368) times its charge at $t = 0$. If $\tau = 1$ s for a capacitor, at what time t (in seconds) will it have discharged to 50.0% of its initial charge?
28. If the coyote population in your state is increasing at a rate of 8.0% a decade and continues increasing at the same rate indefinitely, in how many years will it reach 1.5 times its current level?

M-12 INTEGRAL CALCULUS

Integration can be considered the inverse of differentiation. If a function $f(t)$ is *integrated,* a function $F(t)$ is found for which $f(t)$ is the derivative of $F(t)$ with respect to t.

THE INTEGRAL AS AN AREA UNDER A CURVE; DIMENSIONAL ANALYSIS

The process of finding the area under a curve on the graph illustrates integration. Figure M-27 shows a function $f(t)$. The area of the shaded element is approximately $f_i \Delta t_i$, where f_i is evaluated anywhere in the interval Δt_i. This approximation is highly accurate if Δt_i is very small. The total area under some stretch of the curve is found by summing all the area elements it covers and taking the limit as each Δt_i approaches zero. This limit is called the **integral** of f over t and is written

$$\int f\,dt = \text{area}_i = \lim_{\Delta t_i \to 0} \sum_i f_i \Delta t_i \qquad \text{M-74}$$

The *physical dimensions* of an integral of a function $f(t)$ are found by multiplying the dimensions of the *integrand* (the function being integrated) and the dimensions of the integration variable t. For example, if the integrand is a velocity function

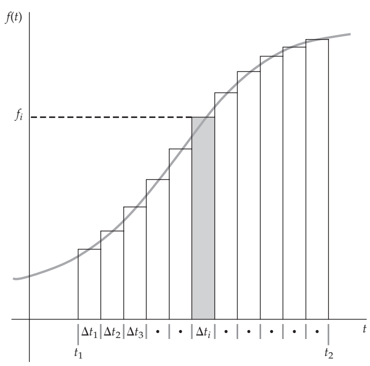

FIGURE M-27 A general function $f(t)$. The area of the shaded element is approximately $f_i \Delta t_i$, where f_i is evaluated anywhere in the interval.

In addition, margin notes allow students to easily see the links between physics concepts in the text and math concepts.

See **Math Tutorial** *for more information on*
Differential Calculus

NEW! PEDAGOGY TO ENSURE CONCEPTUAL UNDERSTANDING

Student-friendly tools have been added to allow for better conceptual understanding of physics.

- New **Conceptual Examples** are introduced, where appropriate, to help students fully understand essential physics concepts. These Examples use the **Picture**, **Solve**, and **Check** strategy so that students not only gain fundamental conceptual understanding but must evaluate their answers.

Example 8-12 **Collisions with Putty** *Conceptual*

Mary has two small balls of equal mass, a ball of plumber's putty and a one of Silly Putty. She throws the ball of plumber's putty at a block suspended by strings shown in Figure 8-20. The ball strikes the block with a "thonk" and falls to the floor. The block subsequently swings to a maximum height *h*. If she had thrown the ball of Silly Putty (instead of the plumber's putty), would the block subsequently have risen to a height greater than *h*? Silly Putty, unlike plumber's putty, is elastic and would bounce back from the block.

PICTURE During impact the change in momentum of the ball–block system is zero. The greater the magnitude of the change in momentum of the ball, the greater, the magnitude of the change in momentum of the block. Does magnitude of the change in momentum of the ball increase more if the ball bounces back than if it does not?

SOLVE

The ball of plumber's putty loses a large fraction of its forward momentum. The ball of Silly Putty would lose all of its forward momentum and then gain momentum in the opposite direction. It would undergo a larger change in momentum than did the ball of plumber's putty.

$\boxed{\text{The block would swing to a greater height after being struck with the ball of Silly Putty than it did after being struck with the ball of plumbers putty.}}$

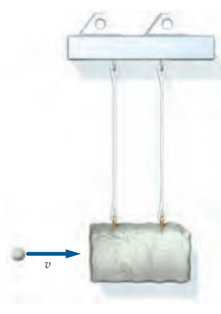

FIGURE 8-20

CHECK The block exerts a backward impulse on the ball of plumber's putty to slow the ball to a stop. The same backward impulse on the ball of Silly Putty would also bring it to a stop, and an additional backward impulse on the ball would give it momentum in the backward direction. Thus, the block exerts the larger backward impulse on the Silly-Putty ball. In accord with Newton's third law, the impulse of a ball on the block is equal and opposite to the impulse of the block on the ball. Thus, the Silly-Putty ball exerts the larger forward impulse on the block, giving the block a larger forward change in momentum.

- New **Concept Checks** enable students to check their conceptual understanding of physics concepts while they read chapters. Answers are located at the end of chapters to provide immediate feedback. Concept Checks are placed near relevant topics so students can immediately reread any material that they do not fully understand.

CONCEPT CHECK 3-1

Figure 3-9 is a motion diagram of the bungee jumper before, during, and after time t_6, when she momentarily come to rest at the lowest point in her descent. During the part of her ascent shown, she is moving upward with increasing speed. Use this diagram to determine the direction of the jumper's acceleration (*a*) at time t_6 and (*b*) at time t_9.

- New **Pitfall Statements**, identified by exclamation points, help students avoid common misconceptions. These statements are placed near the topics that commonly cause confusion, so that students can immediately address any difficulties.

where U_0, the arbitrary constant of integration, is the value of the potential energy at $y = 0$. Because only a change in the potential energy is defined, the actual value of U is not important. For example, if the gravitational potential energy of the Earth–skier system is chosen to be zero when the skier is at the bottom of the hill, its value when the skier is at a height h above that level is mgh. Or we could choose the potential energy to be zero when the skier is at point P halfway down the ski slope, in which case its value at any other point would be mgy, where y is the height of the skier above point P. On the lower half of the slope, the potential energy would then be negative.

! We are free to choose U to be zero at any convenient reference point.

NEW!

PHYSICS SPOTLIGHTS

Physics Spotlights at the end of appropriate chapters discuss current applications of physics and connect applications to concepts described in chapters. These topics range from wind farms to molecular thermometers to pulse detonation engines.

Physics Spotlight

Blowing Warmed Air

Wind farms dot the Danish coast, the plains of the upper Midwest, and hills from California to Vermont. Harnessing the kinetic energy of the wind is nothing new. Windmills have been used to pump water, ventilate mines,[*] and grind grain for centuries.

Today, the most visible wind turbines run electrical generators. These turbines transform kinetic energy into electromagnetic energy. Modern turbines range widely in size, cost, and output. Some are very small, simple machines that cost under \$500/turbine, and put out less than 100 watts of power.[†] Others are complex behemoths that cost over \$2 million and put out as much as 2.5 MW/turbine.[‡] All of these turbines take advantage of a widely available energy source—the wind.

The theory behind the windmill's conversion of kinetic energy to electromagnetic energy is straightforward. The moving air molecules push on the turbine blades, driving their rotational motion. The rotating blades then turn a series of gears. The gears, in turn, step up the rotation rate, and drive the rotation of a generator rotor. The generator sends the electromagnetic energy out along power lines.

But the conversion of the wind's kinetic energy to electromagnetic energy is not 100 percent efficient. The most important thing to remember is that it *cannot* be 100 percent efficient. If turbines converted 100 percent of the kinetic energy of the air into electrical energy, the air would leave the turbines with zero kinetic energy. That is, the turbines would stop the air. If the air were completely stopped by the turbine, it would flow around the turbine, rather than through the turbine.

So the theoretical efficiency of a wind turbine is a trade-off between capturing the kinetic energy of the moving air, and preventing most of the wind from flowing around the turbine. Propeller-style turbines are the most common, and their theoretical efficiency at transforming the kinetic energy of the air into electromagnetic energy varies from 30 percent to 59 percent.[§] (The predicted efficiencies vary because of assumptions made about the way the air behaves as it flows through and around the propellers of the turbine.)

So even the most efficient turbine cannot convert 100 percent of the theoretically available energy. What happens? Upstream from the turbine, the air moves along straight streamlines. After the turbine, the air rotates and is turbulent. The rotational component of the air's movement beyond the turbine takes energy. Some dissipation of energy occurs because of the viscosity of air. When some of the air slows, there is friction between it and the faster moving air flowing by it. The turbine blades heat up, and the air itself heats up.[°] The gears within the turbine also convert kinetic energy into thermal energy through friction. All this thermal energy needs to be accounted for. The blades of the turbine vibrate individually—the energy associated with those vibrations cannot be used. Finally, the turbine uses some of the electricity it generates to run pumps for gear lubrication, and to run the yaw motor that moves the turbine blades into the most favorable position to catch the wind.

In the end, most wind turbines operate at between 10 and 20 percent efficiency.[#] They are still attractive power sources, because of the free fuel. One turbine owner explains, "The bottom line is we did it for our business to help control our future."[**]

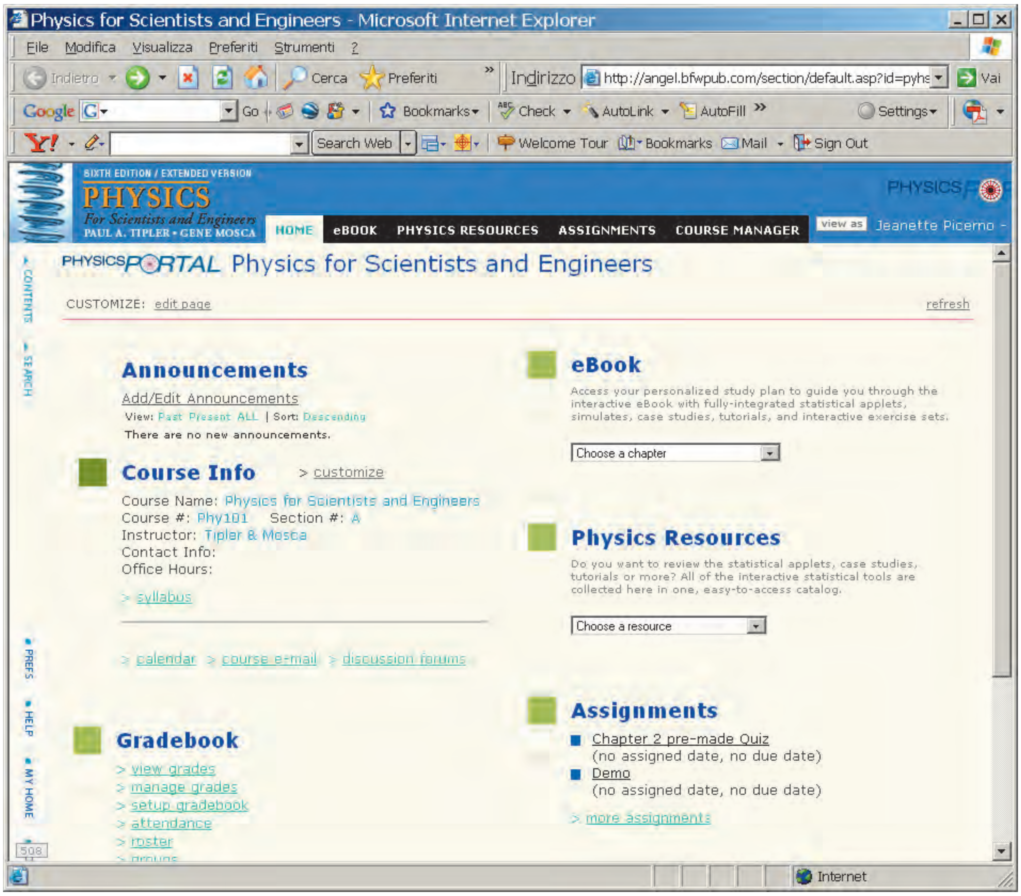
PHYSICS PORTAL

www.whfreeman.com/physicsportal



Physics Portal is a complete learning management system that includes a complete e-book, student and instructor resources, and an online homework system. Physics Portal is designed to enrich any course and enhance students' study.

All Resources in One Place

Physics Portal creates a powerful learning environment. Its three central components—the **Interactive e-Book**, the **Physics Resources** library, and the **Assignment Center** —are conceptually tied to the text and to one another, and are easily accessed by students with a single log-in.

Flexibility for Teachers and Students

From its home page to its text content, Physics Portal is fully customizable. Instructors can customize the home page, set course announcements, annotate the e-book, and edit or create new exercises and tutorials.

Interactive e-Book

The complete text is integrated with the following:

- Conceptual animations
- Interactive exercises
- Video illustrations of key concepts

Study resources include

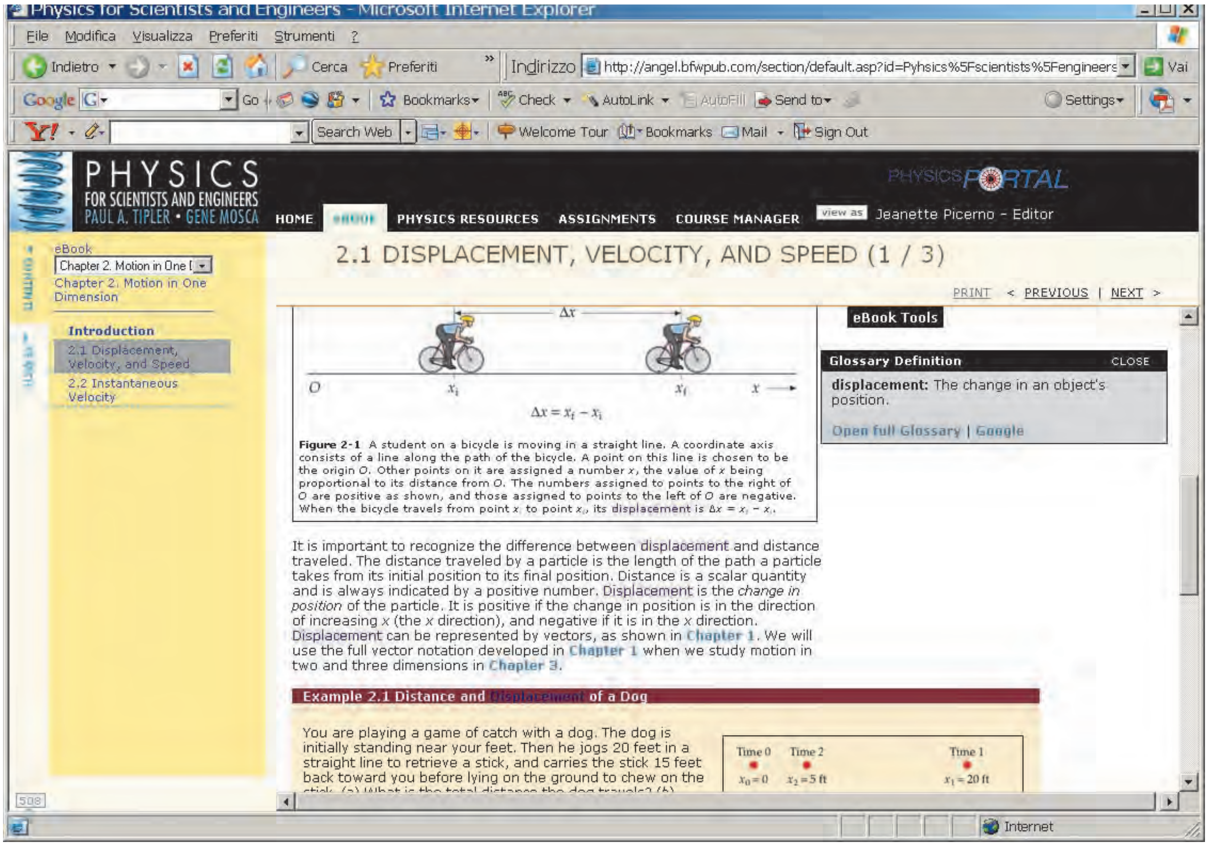
- **Notetaking and highlighting** Student notes can be collectively viewed and printed for a personalized study guide.
- **Bookmarking** for easy navigation and quick return to important locations.
- **Key terms with links** to definitions, Wikipedia, and automated Google Search
- **Full text search** for easy location of *every* resource for each topic

Instructors can customize their students' texts through annotations and supplementary links, providing students with a guide to reading and using the text.

Physics Resources

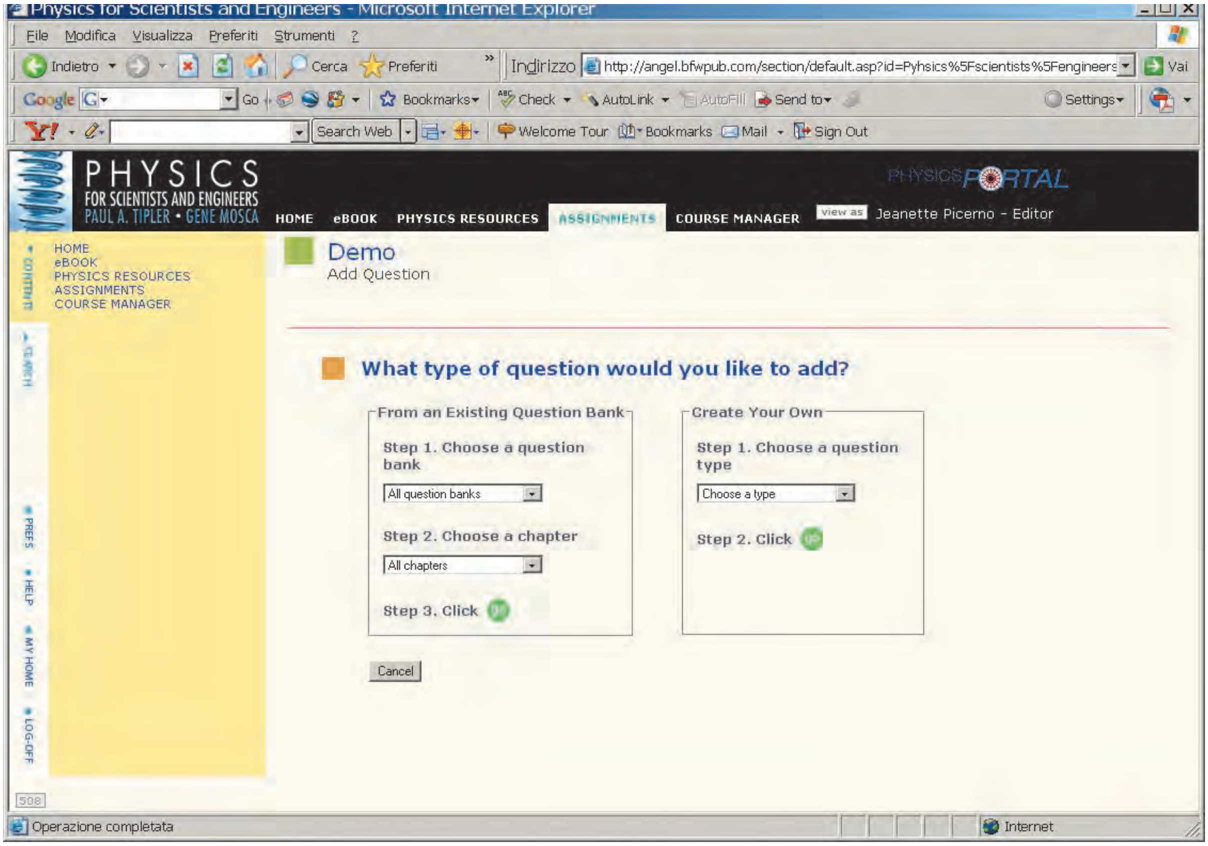
For the student, the wide range of resources focuses on interactivity and conceptual examples, engaging the student and addressing different learning styles.

- **Flashcards** Key terms from the text can be studied and used as self-quizzes.
- **Concept Tester—Picture It** Students input values for variables and see resulting graphs based on values.
- **Concept Tester—Solve It** Provides additional questions within interactive animations to help students visualize concepts.
- **Applied Physics Videos** Show physics concepts in real-life scenarios.
- **On-line quizzing** Provides immediate feedback to students and quiz results can be collected for the instructor in a gradebook.



Assignment Center

Homework and Branched-Tutorials for Student Practice and Success



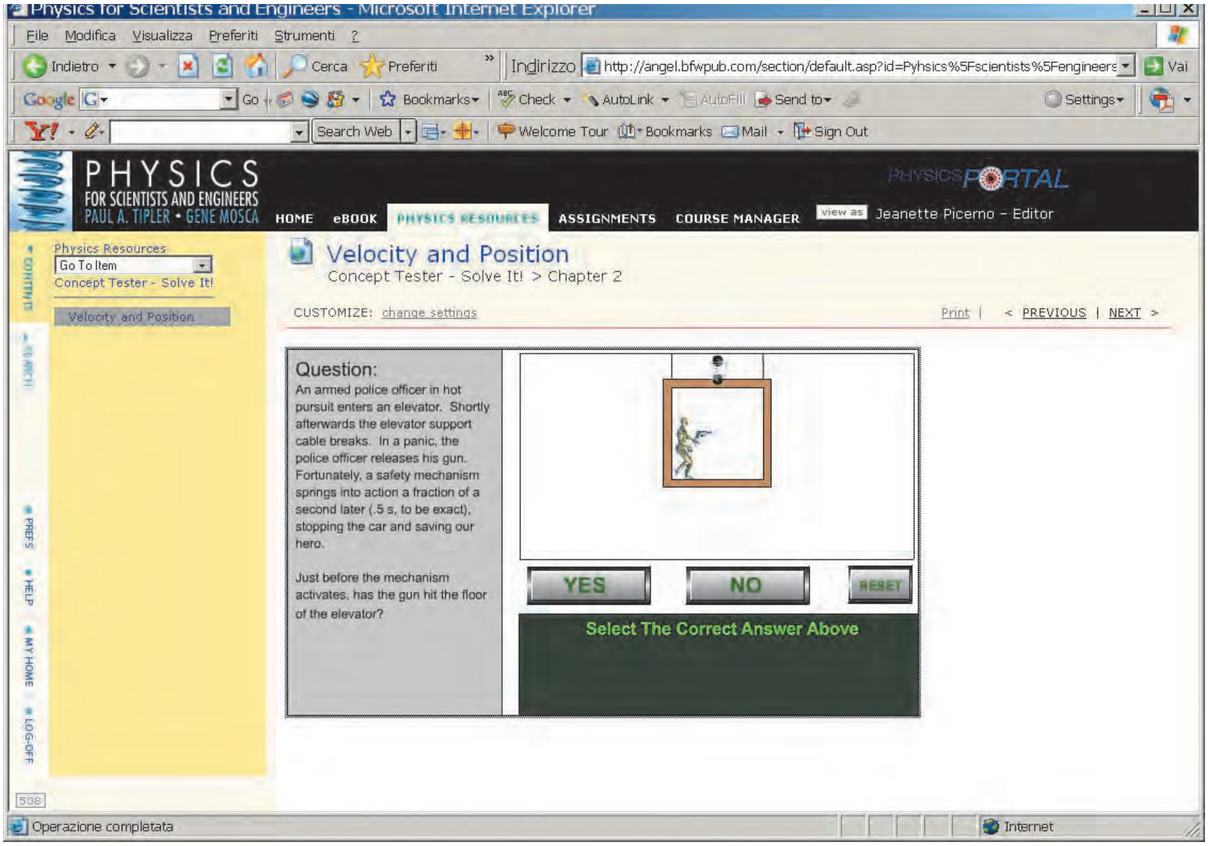
The **Assignment Center** manages and automatically grades homework, quizzes, and guided practice.

- All aspects of **Physics Portal** can be assigned, including e-book sections, simulations, tutorials, and homework problems.
- **Interactive Exercises** break down complex problems into individual steps.
- **Tutorials** offer guidance at each stage to ensure students fully understand the problem-solving process.
- **Video Analysis Exercises** enable students to investigate real-world motion.

Student progress is tracked in a single, easy-to-use gradebook.

- Details tracked include completion, time spent, and type of assistance.
- Instructors can choose grade criteria.
- The gradebook is easily exported into alternative course management systems.

Homework services End-of-chapter problems are available in WebAssign and on Physics Portal.



Integrated | **Easy to Use** | **Customizable**

MEDIA AND PRINT SUPPLEMENTS

FOR THE STUDENT

Student Solutions Manual The new manual, prepared by David Mills, professor emeritus at the College of the Redwoods in California, provides solutions for selected odd-numbered end-of-chapter problems in the textbook and uses the same side-by-side format and level of detail as the Examples in the text.

- **Volume 1** (Chapters 1–20, R) 1-4292-0302-1
- **Volume 2** (Chapters 21–33) 1-4292-0303-X
- **Volume 3** (Chapters 34–41) 1-4292-0301-3

Study Guide The Study Guide provides students with key physical quantities and equations, misconceptions to avoid, questions and practice problems to gain further understanding of physics concepts, and quizzes to test student knowledge of chapters.

- **Volume 1** (Chapters 1–20, R) 0-7167-8467-X
- **Volume 2** (Chapters 21–33) 1-4292-0410-9
- **Volume 3** (Chapters 34–41) 1-4292-0411-7

Physics Portal

- **On-line quizzing** Multiple-choice quizzes are available for each chapter. Students will receive immediate feedback, and the quiz results are collected for the instructor in a grade book.
- **Concept Tester Questions**
- **Flashcards**

FOR THE INSTRUCTOR

Instructor's Resource CD-ROM This multifaceted resource provides instructors with the tools to make their own Web sites and presentations. The CD contains illustrations from the text in .jpg format, Powerpoint Lecture Slides for each chapter of the book, i-clicker questions, a problem conversion guide, and a complete test bank that includes more than 4000 multiple-choice questions.

- **Volume 1** (Chapters 1–20, R) 0-7167-8470-X
- **Volume 2** (Chapters 21–33) 1-4292-0268-8
- **Volume 3** (Chapters 34–41) 1-4292-0267-X

Answer Booklet with Solution CD Resource This book contains answers to all end-of-chapter problems and CD-ROMs of fully worked solutions for all end-of-chapter problems. Solutions are available in editable Word files on the Instructor's CD-ROM and are also available in print.

- **Volume 1** (Chapters 1–20, R) 0-7167-8479-3
- **Volume 2** (Chapters 21–33) 1-4292-0457-5
- **Volume 3** (Chapters 34–41) 1-4292-0461-3

Transparencies 0-7167-8469-6 More than 100 full color acetates of figures and tables from the text are included, with type enlarged for projection.

FLEXIBILITY FOR PHYSICS COURSES

We recognize that not all physics courses are alike, so we provide instructors with the opportunity to create the most effective resource for their students.

Custom-Ready Content and Design

Physics for Scientists and Engineers was written and designed to allow maximum customization. Instructors are invited to create specific volumes (such as a five-volume set), reduce the text's depth by selecting only certain chapters, and add additional material. To make using the textbook easier, W. H. Freeman encourages instructors to inquire about our custom options.

Versions Accomodate Common Course Arrangements

To simplify the review and use of the text, *Physics for Scientists and Engineers* is available in these versions:

Volume 1 *Mechanics/Oscillations and Waves/Thermodynamics* (Chapters 1–20, R) 1-4292-0132-0

Volume 2 *Electricity and Magnetism/Light* (Chapters 21–33) 1-4292-0133-9

Volume 3 *Elementary Modern Physics* (Chapters 34–41) 1-4292-0134-7

Standard Version (Chapters 1-33, R) 1-4292-0124-X

Extended Version (Chapters 1-41, R) 0-7167-8964-7

Acknowledgments

We are grateful to the many instructors, students, colleagues, and friends who have contributed to this edition and to earlier editions.

Anthony J. Buffa, professor emeritus at California Polytechnic State University in California, wrote many new end-of-chapter problems and edited the end-of-chapter problems sections. Laura Runkle wrote the Physics Spotlights. Richard Mickey revised the Math Review of the fifth edition, which is now the Math Tutorial of the sixth edition. David Mills, professor emeritus at the College of the Redwoods in California, extensively revised the Solutions Manual. We received invaluable help in creating text and checking the accuracy of text and problems from the following professors:

Thomas Foster
Southern Illinois University

Karamjeet Arya
San Jose State University

Mirley Bala
Texas A&M University—Corpus Christi

Michael Crivello
San Diego Mesa College

Carlos Delgado
Community College of Southern Nevada

David Faust
Mt. Hood Community College

Robin Jordan
Florida Atlantic University

Jerome Licini
Lehigh University

Dan Lucas
University of Wisconsin

Laura McCullough
University of Wisconsin, Stout

Jeannette Myers
Francis Marion University

Marian Peters

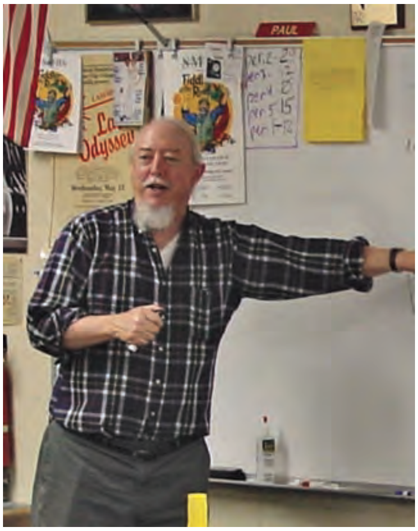
Of course, our work is never done. We hope to receive comments and suggestions from our readers so that we can improve the text and correct any errors. If you believe you have found an error, or have any other comments, suggestions, or questions, send us a note at **asktipler@whfreeman.com**. We will incorporate corrections into the text during subsequent reprinting.

Finally, we would like to thank our friends at W. H. Freeman and Company for their help and encouragement. Susan Brennan, Clancy Marshall, Kharissia Pettus, Georgia Lee Hadler, Susan Wein, Trumbull Rogers, Connie Parks, John Smith, Dena Digilio Betz, Ted Szczepanski, and Liz Geller were extremely generous with their creativity and hard work at every stage of the process.

We are also grateful for the contributions and help of our colleagues Larry Tankersley, John Ertel, Steve Montgomery, and Don Treacy.

About the Authors

Paul Tipler was born in the small farming town of Antigo, Wisconsin, in 1933. He graduated from high school in Oshkosh, Wisconsin, where his father was superintendent of the public schools. He received his B.S. from Purdue University in 1955 and his Ph.D. at the University of Illinois in 1962, where he studied the structure of nuclei. He taught for one year at Wesleyan University in Connecticut while writing his thesis, then moved to Oakland University in Michigan, where he was one of the original members of the physics department, playing a major role in developing the physics curriculum. During the next 20 years, he taught nearly all the physics courses and wrote the first and second editions of his widely used textbooks *Modern Physics* (1969, 1978) and *Physics* (1976, 1982). In 1982, he moved to Berkeley, California, where he now resides, and where he wrote *College Physics* (1987) and the third edition of *Physics* (1991). In addition to physics, his interests include music, hiking, and camping, and he is an accomplished jazz pianist and poker player.



Gene Mosca was born in New York City and grew up on Shelter Island, New York. He studied at Villanova University, the University of Michigan, and the University of Vermont, where he received his Ph.D. in physics. Gene recently retired from his teaching position at the U.S. Naval Academy, where as coordinator of the core physics course he instituted numerous enhancements to both the laboratory and classroom. Proclaimed by Paul Tipler "the best reviewer I ever had," Mosca became his coauthor beginning with the fifth edition of this book.

CHAPTER 1

THE NUMBER OF GRAINS OF SAND ON A BEACH MAY BE TOO GREAT TO COUNT, BUT WE CAN ESTIMATE THE NUMBER BY USING REASONABLE ASSUMPTIONS AND SIMPLE CALCULATIONS. *(Corbis.)*

? How many grains of sand are on your favorite beach? (See Example 1-7.)

Measurement and Vectors

We have always been curious about the world around us. Since the beginnings of recorded thought, we have sought to understand the bewildering diversity of events that we observe—the color of the sky, the change in sound of a passing car, the swaying of a tree in the wind, the rising and setting of the Sun, the flight of a bird or plane. This search for understanding has taken a variety of forms: one is religion, one is art, and one is science. Although the word *science* comes from the Latin verb meaning "to know," science has come to mean not merely knowledge but specifically knowledge of the natural world. Physics attempts to describe the fundamental nature of the universe and how it works. It is the science of matter and energy, space and time.

Like all science, physics is a body of knowledge organized in a specific and rational way. Physicists build, test, and connect models in an effort to describe, explain, and predict reality. This process involves hypotheses, repeatable experiments and observations, and new hypotheses. The end result is a set of fundamental principles and laws that describe the phenomena of the world around us.

These laws and principles apply both to the exotic—such as black holes, dark energy, and particles with names like leptoquarks and bosons—and to everyday life. As you will see, countless questions about our world can be answered with a basic knowledge of physics: Why is the sky blue? How do astronauts float in space? How do CD players work? Why does an oboe sound different from a flute? Why must a helicopter have two rotors? Why do metal objects feel colder than wood objects at the same temperature? How do moving clocks run slow?

In this book, you will learn how to apply the principles of physics to answer these, and many other questions. You will encounter the standard topics of physics, including mechanics, sound, light, heat, electricity, magnetism, atomic physics, and nuclear physics. You will also learn some useful techniques for solving physics problems. In the process, we hope you gain a greater awareness, appreciation, and understanding of the beauty of physics.

In this chapter, we'll begin by addressing some preliminary concepts that you will need throughout your study of physics. We'll briefly examine the nature of physics, establish some basic definitions, introduce systems of units and how to use them, and present an introduction to vector mathematics. We'll also look at the accuracy of measurements, significant figures, and estimations.

1-1 THE NATURE OF PHYSICS

The word physics comes from the Greek word meaning the knowledge of the natural world. It should come as no surprise, therefore, that the earliest recorded efforts to systematically assemble knowledge concerning motion came from ancient Greece. In Aristotle's (384–322 B.C.) system of natural philosophy, explanations of physical phenomena were deduced from assumptions about the world, rather than derived from experimentation. For example, it was a fundamental assumption that every substance had a "natural place" in the universe. Motion was thought to be the result of a substance trying to reach its natural place. Because of the agreement between the deductions of Aristotelian physics and the motions observed throughout the physical universe and the lack of experimentation that could overturn the ancient physical ideas, the Greek view was accepted for nearly two thousand years. It was the Italian scientist Galileo Galilei (1564–1642) whose brilliant experiments on motion established the absolute necessity of experimentation in physics. Within a hundred years, Isaac Newton had generalized the results of Galileo's experiments into his three spectacularly successful laws of motion, and the reign of the natural philosophy of Aristotle was over.

Experimentation during the next two hundred years brought a flood of discoveries—and raised a flood of new questions. Some of these discoveries involved electrical and thermal phenomena, and some involved the expansion and compression of gases. These discoveries and questions inspired the development of new models to explain them. By the end of the nineteenth century, Newton's laws for the motions of mechanical systems had been joined by equally impressive laws from James Maxwell, James Joule, Sadi Carnot, and others to describe electromagnetism and thermodynamics. The subjects that occupied physical scientists through the end of the nineteenth century—mechanics, light, heat, sound, electricity and magnetism—are usually referred to as *classical physics*. Because classical physics is what we need to understand the macroscopic world we live in, it dominates Parts I through V of this text.

The remarkable success of classical physics led many scientists to believe that the description of the physical universe was complete. However, the discovery of X rays by Wilhelm Röntgen in 1895 and of radioactivity by Antoine Becquerel and

Marie and Pierre Curie a few years later seemed to be outside the framework of classical physics. The theory of special relativity proposed by Albert Einstein in 1905 expanded the classical ideas of space and time promoted by Galileo and Newton. In the same year, Einstein suggested that light energy is quantized; that is, that light comes in discrete packets rather than being wavelike and continuous as was thought in classical physics. The generalization of this insight to the quantization of all types of energy is a central idea of quantum mechanics, one that has many amazing and important consequences. The application of special relativity, and particularly quantum theory, to extremely small systems such as atoms, molecules, and nuclei, has led to a detailed understanding of solids, liquids, and gases. This application is often referred to as *modern physics*. Modern physics is the subject of Part VI of this text.

While classical physics is the main subject of this book, from time to time in the earlier parts of the text we will note the relationship between classical and modern physics. For example, when we discuss velocity in Chapter 2, we will take a moment to consider velocities near the speed of light and briefly cross over to the relativistic universe first imagined by Einstein. After discussing the conservation of energy in Chapter 7, we will discuss the quantization of energy and Einstein's famous relation between mass and energy, $E = mc^2$. Four chapters later, in Chapter R, we will study the nature of space and time as revealed by Einstein in 1903.

1-2 UNITS

The laws of physics express relationships among physical quantities. **Physical quantities** are numbers that are obtained by measuring physical phenomena. For example, the length of this book is a physical quantity, as is the amount of time it takes for you to read this sentence and the temperature of the air in your classroom.

Measurement of any physical quantity involves comparing that quantity to some precisely defined standard, or **unit,** of that quantity. For example, to measure the distance between two points, we need a standard unit of distance, such as an inch, a meter, or a kilometer. The statement that a certain distance is 25 meters means that it is 25 times the length of the unit meter. It is important to include the unit, in this case meters, along with the number, 25, when expressing this distance because different units can be used to measure distance. To say that a distance is 25 is meaningless.

! When you use a number to describe a physical quantity, the number must always be accompanied by a unit.

Some of the most basic physical quantities—time, length, and mass—are defined by the processes of measuring them. The length of a pole, for example, is defined to be the number of some unit of length that is required to equal the length of the pole. A physical quantity is often defined using an **operational definition,** a statement that defines a physical quantity by the operation or procedure that should be carried out to measure the physical quantity. Other physical quantities are defined by describing how to calculate them from these fundamental quantities. The speed of an object, for example, is equal to a length divide by a time. Many of the quantities that you will be studying, such as velocity, force, momentum, work, energy, and power, can be expressed in terms of time, length, and mass. Thus, a small number of basic units are sufficient to express all physical quantities. These basic units are called base units, and the choice of base units determines a system of units.

Water clock used to measure time intervals in the thirteenth century. *(The Granger Collection.)*

THE INTERNATIONAL SYSTEM OF UNITS

In physics, it is important to use a consistent set of units. In 1960, an international committee established a set of standards for the scientific community called SI (for *Système International*). There are seven base quantities in the SI system. They are length, mass, time, electric current, thermodynamic temperature, amount of substance, and luminous intensity, and each base quantity has a base unit. The base SI unit of time is the second, the base unit of length is the meter, and the base unit of mass is the kilogram. Later, when you study thermodynamics and electricity, you will need to use the base SI units for temperature (the kelvin, K), for the amount of a substance (the mole, mol), and one for electrical current (the ampere, A). The seventh base SI unit, the candela (cd) for luminous intensity, we shall have no occasion to use in this book. Complete definitions of the SI units are given in Appendix A, along with commonly used units derived from these units.

Cesium fountain clock with developers Steve Jefferts and Dawn Meekhof. *(© 1999 Geoffrey Wheeler.)*

Time The unit of time, the **second** (s), was historically defined in terms of the rotation of Earth and was equal to $(1/60)(1/60)(1/24)$ of the mean solar day. However, scientists have observed that the rate of rotation of Earth is gradually slowing down. The second is now defined in terms of a characteristic frequency associated with the cesium atom. All atoms, after absorbing energy, emit light with frequencies and wavelengths characteristic of the particular element. There is a set of frequencies and wavelengths for each element, with a particular frequency and wavelength associated with each energy transition within the atom. As far as we know, these frequencies remain constant. The second is now defined so that the frequency of the light from a certain transition in cesium is exactly 9 192 631 770 cycles per second.

Length The **meter** (m) is the SI unit of length. Historically, this length was defined as one ten-millionth of the distance between the equator and the North Pole along the meridian through Paris (Figure 1-1). This distance proved to be difficult to measure accurately. So in 1889, the distance between two scratches on a bar made of platinum-iridium alloy held at a specified temperature was adopted as the new standard. In time, the precision of this standard also proved inadequate and other standards were created for the meter. Currently, the meter is determined using the speed of light through empty space, which is defined to be exactly 299 792 458 m/s. The meter, then, is the distance light travels through empty space in 1/(299 729 458) second. By using these definitions, the units of time and length are accessible to laboratories throughout the world.

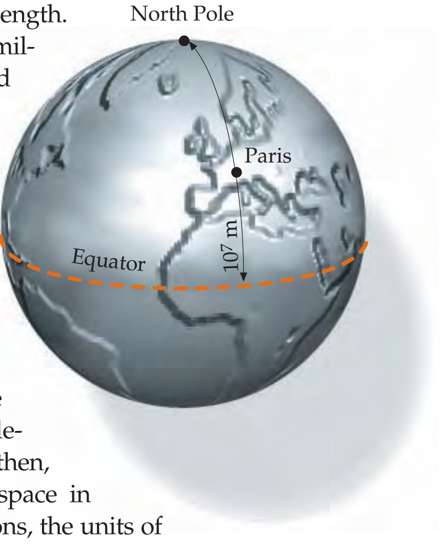


FIGURE 1-1 The meter was originally chosen so that the distance from the equator to the North Pole along the meridian through Paris would be 10 million meters (10 thousand kilometers).

Mass The SI unit of mass, the **kilogram** (kg) was once defined as the mass of one liter of water at 4°C. (A volume of one liter is equal to the volume of a cube 10 cm on an edge.) Like the standards for time and length, the kilogram standard has changed over time. The kilogram is now defined to be the mass of a specific platinum-iridium alloy cylinder. This cylinder, called the *standard body*, is kept at the International Bureau of Weights and Measures in Sèvres, France. A duplicate of the standard body is kept at the National Institute of Standards and Technology (NIST) in Gaithersburg, Maryland. We shall discuss the concept of mass in detail in Chapter 4, where we will see that the weight of an object at a given location is proportional to its mass. Thus, by comparing the weights of different objects of ordinary size with the weight of the standard body, the masses of the objects can be compared with each other.

The standard body is the mass of a specific platinum-iridium alloy cylinder that is kept at the International Bureau of Weights and Measures in Sèvres, France. *(© BIPM; www.bipm.org.)*

Table 1-1 Prefixes for Powers of 10*

Multiple	Prefix	Abbreviation
10^{18}	exa	E
10^{15}	peta	P
10^{12}	tera	T
10^{9}	giga	G
10^{6}	mega	M
10^{3}	kilo	k
10^{2}	hecto	h
10^{1}	deka	da
10^{-1}	deci	d
10^{-2}	centi	c
10^{-3}	milli	m
10^{-6}	micro	μ
10^{-9}	nano	n
10^{-12}	pico	p
10^{-15}	femto	f
10^{-18}	atto	a

* The prefixes hecto (h), deka (da) and deci (d) are not multiples of 10^3 or 10^{-3} and are rarely used. The other prefix that is not a multiple of 10^3 or 10^{-3} is centi (c). The prefixes frequently used in this book are printed in red. Note that all prefix abbreviations for multiples 10^6 and higher are uppercase letters, all others are lowercase letters.

UNIT PREFIXES

Sometimes it is necessary to work with measurements that are much smaller or much larger than the standard SI units. In these situations, we can use other units that are related to the standard SI units by a multiple of ten. Prefixes are used to denote the different powers of ten. For example, the prefix "kilo" means 1000, or 10^3, while the prefix "micro" means 0.000 001, or 10^{-6}. Table 1-1 lists prefixes for common multiples of SI units. These prefixes can be applied to any SI unit; for example, 0.001 second is 1 millisecond (ms) and 1 000 000 watts is 1 megawatt (MW).

PRACTICE PROBLEM 1-1

Use prefixes to describe the following: (*a*) the delay caused by scrambling a cable television broadcast, which is about 0.000 000 3 second and (*b*) the circumference of Earth, which is about 40 000 000 meters.

OTHER SYSTEMS OF UNITS

In addition to SI, other systems of units are sometimes used. One such system is the *cgs system*. The fundamental units of the cgs system are the centimeter for length, the gram for mass, and the second for time. Other cgs units include the dyne (force) and the erg (work or energy).

The system of units with which you are probably most familiar is the U.S. customary system. In this system, the base unit of length is the foot and the base unit of time is the second. Also, a unit of force (the pound-force) rather than mass is considered a base unit. You will see in Chapter 4 that mass is a better choice for a fundamental unit than force, because mass is an intrinsic property of an object, independent of its location. The base U.S. customary units are now defined in terms of the base SI units.

1-3 CONVERSION OF UNITS

Because different systems of units are in use, it is important to know how to covert from one unit to another unit. When physical quantities are added, subtracted, multiplied, or divided in an algebraic equation, the unit can be treated like any other algebraic quantity. For example, suppose you want to find the distance traveled in 3 hours (h) by a car moving at a constant rate of 80 kilometers per hour (km/h). The distance is the product of the speed v and the time t:

$$x = vt = \frac{80\text{ km}}{\cancel{\text{h}}} \times 3\ \cancel{\text{h}} = 240\text{ km}$$

We cancel the unit of time, the hours, just as we would any algebraic quantity to obtain the distance in the proper unit of length, the kilometer. This method of treating units makes it easy to convert from one unit of distance to another. Now, suppose we want to convert the units in our answer from kilometers (km) to miles (mi). First, we need to find the relationship between kilometers and miles, which is 1 mi = 1.609 km (see either the front pages or Appendix A). Then, we divide each side of this equality by 1.609 km to obtain

$$\frac{1\text{ mi}}{1.609\text{ km}} = 1$$

Notice that the relationship is a ratio equal to 1. A ratio such as (1 mi)/(1.609 km) is called a **conversion factor,** which is a ratio equal to 1 and expresses a quantity expressed in some unit or units divided by its equal expressed some different unit or units. Because any quantity can be multiplied by 1 without changing its value, we can multiply the original quantity by the conversion factor to convert the units:

$$240\text{ km} = 240\ \cancel{\text{km}} \times \frac{1\text{ mi}}{1.609\ \cancel{\text{km}}} = 149\text{ mi}$$

By writing out the units explicitly and canceling them, you do not need to think about whether you multiply by 1.609 or divide by 1.609 to change kilometers to miles, because the units tell you whether you have chosen the correct or incorrect factor.

! If the units of the quantity and the conversion factor do not combine to give the desired final units, the conversion has not been properly carried out.

(a)

(b)

(*a*) Laser beam from the Macdonald Observatory used to measure the distance to the moon. The distance can be measured within a few centimeters by measuring the time required for the beam to go to the moon and back after reflecting off a mirror (*b*) placed on the moon by the Apollo 14 astronauts. *(a, McDonald Observatory; b, Bruce Coleman).*

Example 1-1 Using Conversion Factors

Your employer sends you on a trip to a foreign country where the road signs give distances in kilometers and the automobile speedometers are calibrated in kilometers per hour. If you drive 90 km/h, how fast are you going in meters per second and in miles per hour?

PICTURE First we have to find the appropriate conversion factors for hours to seconds and kilometers to meters. We can use the facts that 1000 m = 1 km and 1 h = 60 min = 3600 s. The quantity 90 km/h is multiplied by the conversion factors, so the unwanted units cancel. (Each conversion factor has the value 1, so the value of the speed is not changed.) To convert to miles per hour, we use the conversion factor 1 mi/1.609 km.

SOLVE

1. Multiply 90 km/h by the conversion factors 1 h/3600 s and 1000 m/1 km to convert km to m and h to s:

$$\frac{90\ \cancel{\text{km}}}{\text{h}} \times \frac{1\ \cancel{\text{h}}}{3600\ \text{s}} \times \frac{1000\ \text{m}}{1\ \cancel{\text{km}}} = \boxed{25\ \text{m/s}}$$

2. Multiply 90 km/h by 1 mi/1.609 km:

$$\frac{90\ \cancel{\text{km}}}{\text{h}} \times \frac{1\ \text{mi}}{1.609\ \cancel{\text{km}}} = \boxed{56\ \text{mi/h}}$$

CHECK Notice that the final units in each step are correct. If you had not set up the conversion factors correctly, for example if you multiplied by 1 km/1000 m instead of 1000 m/1 km, the final units would not be correct.

TAKING IT FURTHER Step 1 can be shortened by writing 1 h/3600 s as 1 h/3.6 ks and canceling the prefixes in ks and km. That is,

$$\frac{90\ \text{km}}{\cancel{\text{h}}} \times \frac{1\ \cancel{\text{h}}}{3.6\ \text{ks}} = \boxed{25\ \text{m/s}}$$

Canceling these prefixes is equivalent to dividing the numerator and the denominator by 1000.

You may find it helpful to memorize the conversion results in Example 1-1. These results are

$$25\ \text{m/s} = 90\ \text{km/h} \approx (60\ \text{mi/h})$$

Knowing these values can provide you with a quick way to convert speeds to units you are more familiar with.

(Eunice Harris/Photo Researchers.)

1-4 DIMENSIONS OF PHYSICAL QUANTITIES

Recall that a physical quantity includes both a number and a unit. The unit tells the standard that is used for the measurement and the number gives the comparison of the quantity to the standard. To tell *what* you are measuring, however, you need to state the *dimension* of the physical quantity. Length, time, and mass are all dimensions. The distance d between two objects has dimensions of length. We express this relation as $[d] = \text{L}$, where $[d]$ represents the dimension of the distance d and L represents the dimension of length. All dimensions are represented by upper-case roman (nonitalic) letters. The letters T and M represent the dimensions of time and mass, respectively. The dimensions of a number of quantities can be written in terms of these fundamental dimensions. For example, the area A of a surface is found by multiplying one length by another. Because area is the product of two lengths, it is said to have the dimensions of length multiplied by length, or length squared, written $[A] = \text{L}^2$. In this equation, $[A]$ represents the dimension of the quantity A and L represents the dimension of length. Speed has the dimensions of length divided by time, or L/T. The dimensions of other quantities such as force or energy are written in terms of the fundamental quantities of length, time, and mass. Adding or subtracting two physical quantities makes sense only if the quantities have the same dimensions. For example, we cannot add an area to a speed to obtain a meaningful sum. For the equation

$$A = B + C$$

the quantities A, B, and C must all have the same dimensions. The addition of B and C also requires that these quantities be in the same units. For example, if B is an area of 500 in.^{2} and C is 4 ft^2, we must either convert B into square feet or C into square inches in order to find the sum of the two areas.

You can often find mistakes in a calculation by checking the dimensions or units of the quantities in your result. Suppose, for example, that you mistakenly use the formula $A = 2\pi r$ for the area of a circle. You can see immediately that this cannot be correct because $2\pi r$ has dimensions of length whereas area must have dimensions of length squared.

! Evaluating the dimensions of an expression will tell you only if the dimensions are correct, not whether the entire expression is correct. While expressing the area of a circle, for instance, dimensional analysis will not tell you the correct expression is πr^2 or $2\pi r^2$. (The correct expression is πr^2.)

Example 1-2 Dimensions of Pressure

The pressure P in a fluid in motion depends on its density ρ and its speed v. Find a simple combination of density and speed that gives the correct dimensions of pressure.

PICTURE Using Table 1-2, we can see that pressure has the dimensions $M/(LT^2)$, density is M/L^3, and speed is L/T. In addition, both the dimensions of pressure and density have mass in the numerator, whereas the dimensions of speed do not contain mass. Therefore, the expression must involve multiplying or dividing dimensions of density and dimensions of speed to obtain the unit of mass in the dimensions of pressure. To find out the exact relationship, we can start by dividing the dimensions of pressure by those of density, and then evaluate the result with respect to the dimensions for speed.

SOLVE

1. Divide the dimensions of pressure by those of density to obtain an expression with no M in it:

$$\frac{[P]}{[\rho]} = \frac{M/LT^2}{M/L^3} = \frac{L^2}{T^2}$$

2. By inspection, we note that the result has dimensions of v^2. The dimensions of pressure are thus the same as the dimensions of density multiplied by speed squared:

$$[P] = [\rho][v^2] = \frac{M}{L^3} \times \left(\frac{L}{T}\right)^2 = \frac{M}{L^3} \times \frac{L^2}{T^2} = \boxed{\frac{M}{LT^2}}$$

CHECK Divide the dimensions of pressure by the dimensions of speed squared and the result is the dimensions of density $[P]/[v^2] = (M/LT^2)/(L^2/T^2) = M/L^3 = [\rho]$.

1-5 SIGNIFICANT FIGURES AND ORDER OF MAGNITUDE

Many of the numbers in science are the result of measurement and are therefore known only to within a degree of experimental uncertainty. The magnitude of the uncertainty, which depends on both the skill of the experimenter and the apparatus used, often can only be estimated. A rough indication of the uncertainty in a measurement is inferred by the number of digits used. For example, if a tag on a table in a furniture store states that a table is 2.50 m long, it is saying that its length is close to, but not exactly, 2.50 m. The rightmost digit, the 0, is uncertain. If we use a tape measure with millimeter markings and measured the table length carefully, we might estimate that we could measure the length to ±0.6 mm of its true length. We would indicate this precision when giving the length by using four digits, such as 2.503 m. A reliably known digit (other than a zero used to locate the decimal point) is called a **significant figure.** The

Table 1-2 Dimensions of Physical Quantities

Quantity	Symbol	Dimension
Area	A	L^2
Volume	V	L^3
Speed	v	L/T
Acceleration	a	L/T^2
Force	F	ML/T^2
Pressure (F/A)	p	M/LT^2
Density (M/V)	ρ	M/L^3
Energy	E	ML^2/T^2
Power (E/T)	P	ML^2/T^3

number 2.50 has three significant figures; 2.503 m has four. The number 0.00130 has three significant figures. (The first three zeroes are not significant figures but are merely markers to locate the decimal point.) The number 2300. has four significant figures, but the number 2300 (the same as 2300. but without the decimal point) could have as few as two or as many as four significant figures. The number of significant figures in numbers with trailing zeros and no decimal point is ambiguous.

Suppose, for example, that you measure the area of a circular playing field by pacing off the radius and using the formula for the area of a circle, $A = \pi r^2$. If you estimate the radius to be 8 m and use a 10-digit calculator to compute the area, you obtain $\pi(8 \text{ m})^2 = 201.0619298 \text{ m}^2$. The digits after the decimal point give a false indication of the accuracy with which you know the area. To determine the appropriate numbers of significant figures for calculations involving multiplication and division, you can follow this general rule:

> When multiplying or dividing quantities, the number of significant figures in the final answer is no greater than that in the quantity with the fewest significant figures.

In the previous example, the radius is known to only one significant figure, so the area is also known only to one significant figure, or 200 m^2. This number indicates that the area is likely somewhere between 150 m^2 and 250 m^2.

The accuracy of the sum or difference of measurements is only as good as the accuracy of the *least* accurate of the measurements. A general rule is

> When adding or subtracting quantities, the number of decimal places in the answer should match that of the term with the smallest number of decimal places.

CONCEPT CHECK 1-1

How many significant figures does the number 0.010457 have?

! Exact values have an unlimited number of significant figures. For example, a value determined by counting, such as 2 tables, has no uncertainty and is an exact value. In addition, the conversion factor 1 m/100 cm is an exact value because 1 m *is* exactly equal to 100 cm.

! When you work with numbers that have uncertainties, you should be careful not to include more digits than the certainty of measurement warrants.

Example 1-3 Significant Figures

Subtract 1.040 from 1.21342.

PICTURE The first number, 1.040, has only three significant figures beyond the decimal point, whereas the second, 1.21342, has five. According to the rule stated for the addition and subtraction of numbers, the difference can have only three figures beyond the decimal point.

SOLVE

Sum the numbers, keeping only three digits beyond the decimal point: $1.21342 - 1.040 = 0.173\cancel{42} = \boxed{0.173}$

CHECK The answer cannot be more accurate than the least accurate number or 1.040. The answer has the same number of significant figures beyond the decimal point as 1.040.

TAKING IT FURTHER In this example, the given numbers have four and six significant figures, but the difference has only three significant figures. Most examples and exercises in this book will be done with data to two, three, or occasionally four significant figures.

PRACTICE PROBLEM 1-2 Apply the appropriate rule for significant figures to calculate the following: (*a*) 1.58×0.03, (*b*) $1.4 + 2.53$, (*c*) $2.456 - 2.453$

SCIENTIFIC NOTATION

When we work with very large or very small numbers we can show significant figures more easily by using scientific notation. In this notation, the number is written as a product of a number between 1 and 10 and a power of 10, such as 10^2 (= 100) or 10^3 (= 1000). For example, the number 12 000 000 is written 1.2×10^7; the distance from Earth to the Sun, which is about 150 000 000 000 m, is written 1.5×10^{11} m. We have assumed that none of the trailing zeros in this number are significant. If two of the trailing zeros were significant we could express this unambiguously by writing the number as 1.500×10^{11} m. The number 11 in 10^{11} is called the exponent. For numbers smaller than 1, the exponent is negative. For example, $0.1 = 10^{-1}$, and $0.0001 = 10^{-4}$. The diameter of a virus, which is about 0.000 000 01 m, is written 1×10^{-8} m. Notice that by writing numbers in this form, you can easily identify the number of significant figures. For example, 1.5×10^{11} m contains two significant figures (1 and 5).

See **Math Tutorial** *for more information on* **Exponents**

PRACTICE PROBLEM 1-3

Apply the appropriate rule for significant figures to calculate $2.34 \times 10^2 + 4.93$.

Use the following Problem-Solving Strategy to do calculations with numbers in scientific notation.

PROBLEM-SOLVING STRATEGY

Scientific Notation

PICTURE If the numbers involved in a calculation are very large or very small, you may want to rewrite these numbers in scientific notation. This notation often makes it easier for you to determine the number of significant figures that a number has and makes it easier for you to perform calculations.

SOLVE Use these items to solve problems that involve scientific notation.

1. When numbers in scientific notation are multiplied, the exponents are added; when numbers in scientific notation are divided, the exponents are subtracted.

   Example: $10^2 \times 10^3 = 100 \times 1{,}000 = 100\,000 = 10^5$

   Example: $\dfrac{10^2}{10^3} = \dfrac{100}{1000} = \dfrac{1}{10} = 10^{-1}$

2. In scientific notation, 10^0 is defined to be 1. To see why, suppose we divide 1000 by 1000.

   Example: $\dfrac{1000}{1000} = \dfrac{10^3}{10^3} = 10^{3-3} = 10^0 = 1$

3. Be careful when adding or subtracting numbers written in scientific notation when their exponents do not match.

   Example: $(1.200 \times 10^2) + (8 \times 10^{-1}) = 120.0 + 0.8 = 120.8$

4. To find the sum without converting both numbers into ordinary decimal form, rewrite either of the numbers so that its power of 10 is the same as that of the other.

   Example: $(1200 \times 10^{-1}) + (8 \times 10^{-1}) = 1208 \times 10^{-1} = 120.8$

5. When raising a power to another power, the exponents are multiplied.

   Example: $(10^2)^4 = 10^2 \times 10^2 \times 10^2 \times 10^2 = 10^8$

CHECK Make sure that when you convert numbers smaller than one into scientific notation, the exponent is negative. You should also remember when exponents are added, subtracted, or multiplied, because performing the wrong operation can cause your answer to be inaccurate by powers of 10.

TAKING IT FURTHER During a calculation, avoid entering intermediate results via keyboard entry. Instead store these results in the calculator memory. If you must enter intermediate results via the keyboard, key in one or two additional (non significant) digits, called *guard digits*. This practice serves to minimize round-off errors.

! All exponents are dimensionless and have no units.

Example 1-4 How Much Water?

A liter (L) is the volume of a cube that is 10 cm by 10 cm by 10 cm. If you drink 1 L (exact) of water, how much volume in cubic centimeters and in cubic meters would it occupy in your stomach?

PICTURE The volume V of a cube of edge length ℓ is ℓ^3. The volume in cubic centimeters is found directly from $\ell = 10$ cm. To find the volume in cubic meters, convert cm^3 to m^3 using the conversion factor 1 cm $= 10^{-2}$ m.

SOLVE

1. Calculate the volume in cm^3:

$$V = \ell^3 = (10\text{ cm})^3 = 1000\text{ cm}^3 = \boxed{10^3\text{ cm}^3}$$

2. Convert to m^3:

$$10^3\text{ cm}^3 = 10^3\text{ cm}^3 \times \left(\frac{10^{-2}\text{ m}}{1\text{ cm}}\right)^3$$

Notice that the conversion factor (which equals 1) can be raised to the third power without changing its value, enabling us to cancel units.

$$= 10^3\text{ cm}^3 \times \frac{10^{-6}\text{ m}^3}{1\text{ cm}^3} = \boxed{10^{-3}\text{ m}^3}$$

CHECK Notice that the answers are in cubic centimeters and cubic meters. These answers are consistent with volume having dimensions of length cubed. Also note that the physical quantity 10^3 is greater than the physical quantity 10^{-3}, which is consistent with a meter being larger than a centimeter.

Example 1-5 Counting Atoms

In 12.0 g of carbon, there are $N_A = 6.02 \times 10^{23}$ carbon atoms (Avogadro's number). If you could count 1 atom per second, how long would it take to count the atoms in 1.00 g of carbon? Express your answer in years.

PICTURE We need to find the total number of atoms to be counted, N, and then use the fact that the number counted equals the counting rate R multiplied by the time t.

SOLVE

1. The time is related to the total number of atoms N, and the rate of counting $R = 1$ atom/s:

$$N = Rt$$

2. Find the number of carbon atoms in 1.00 g:

$$N = \frac{6.02 \times 10^{23}\text{ atoms}}{12.0\text{ g}} = 5.02 \times 10^{22}\text{ atoms}$$

3. Calculate the number of seconds it takes to count these at 1 per second:

$$t = \frac{N}{R} = \frac{5.02 \times 10^{22}\text{ atoms}}{1\text{ atom/s}} = 5.02 \times 10^{22}\text{ s}$$

4. Calculate the number n of seconds in a year:

$$n = \frac{365\,\cancel{\text{d}}}{1.00\text{ y}} \times \frac{24\,\cancel{\text{h}}}{1\,\cancel{\text{d}}} \times \frac{3600\text{ s}}{1\,\cancel{\text{h}}} = 3.15 \times 10^7\text{ s/y}$$

5. Use the conversion factor 3.15×10^7 s/y (a handy quantity to remember) to convert the answer in step 3 to years:

$$t = 5.02 \times 10^{22}\text{ s} \times \frac{1.00\text{ y}}{3.15 \times 10^7\text{ s}}$$

$$= \frac{5.02}{3.15} \times 10^{22-7}\text{ y} = \boxed{1.59 \times 10^{15}\text{ y}}$$

CHECK The answer can be checked by estimation. If you need approximately 10^{22} seconds to count the number of atoms in a gram of carbon and there are approximately 10^7 seconds in a year, then you would need $10^{22}/10^7 = 10^{15}$ y.

TAKING IT FURTHER The time required is about 100 000 times the current known value for the age of the universe.

PRACTICE PROBLEM 1-4 How long would it take for 5 billion (5×10^9) people to count the atoms in 1 g of carbon?

Table 1-3 The Universe by Orders of Magnitude

Size or Distance	(m)
Proton	10^{-15}

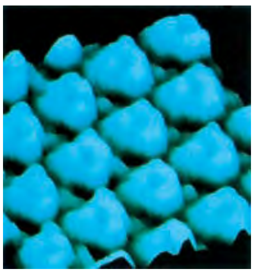
Age of universe	10^{18}

ORDER OF MAGNITUDE

In doing rough calculations, we sometimes round off a number to the nearest power of 10. Such a number is called an **order of magnitude.** For example, the height of an ant might be 8×10^{-4} m or approximately 10^{-3} m. We would say that the order of magnitude of an ant's height is 10^{-3} m. Similarly, though the typical height h of most people is about 2 m, we might round that off further and say that $h \sim 10^{0}$ m, where the symbol $\sim$ means "is the order of magnitude of." By saying $h \sim 10^{0}$ m we do not mean that a typical height is really 1 m but that it is closer to 1 m than to 10 m or to 10^{-1} m. We might say that a human being is three orders of magnitude taller than an ant, meaning that the ratio of heights is about 1000 to 1. An order of magnitude does not provide any digits that are reliably known, so it has no significant figures. Table 1-3 gives some order-of-magnitude values for a variety of sizes, masses, and time intervals encountered in physics.

In many cases, the order of magnitude of a quantity can be estimated using plausible assumptions and simple calculations. The physicist Enrico Fermi was a master at using order-of-magnitude estimations to generate answers for questions that seemed impossible to calculate because of lack of information. Problems like these are often called **Fermi questions.** The following examples are Fermi questions.



Benzene molecules of the order of 10^{-10} m in diameter as seen in a scanning electron microscope. *(IBM Research, Almaden Research Center.)*

The diameter of the Andromeda galaxy is of the order of 10^{21} m. *(Smithsonian Institution.)*

Distances familiar in our everyday world. The height of the woman is of the order of 10^{0} m and that of the mountain is of the order of 10^{4} m. *(Kent and Donnan Dannon/Photo Researchers.)*

Example 1-6 Burning Rubber

What thickness of rubber tread is worn off the tire of your automobile as it travels 1 km (0.6 mi)?

PICTURE Let's assume the tread thickness of a new tire is 1 cm. This estimation may be off by a factor of two or so, but 1 mm is certainly too small and 10 cm is too large. Because tires have to be replaced after about 60 000 km (about 37 000 mi), we will also assume that the tread is completely worn off after 60 000 km. In other words, the rate of wear is 1 cm of tire per 60 000 km of travel.

(Corbis.)

SOLVE

Use 1 cm wear per 60 000 km travel to compute the thickness worn after 1 km of travel:

$$\frac{1\text{ cm wear}}{60\,000\text{ km travel}} = \frac{1.7 \times 10^{-5}\text{ cm wear}}{1\text{ km travel}}$$

$$\approx \boxed{2 \times 10^{-7}\text{ m wear per km of travel}}$$

CHECK If you multiply 1.7×10^{-5} cm/km by 60 000 km, you will get approximately 1 cm, which is the thickness of tread on a new tire.

TAKING IT FURTHER Atoms have diameters equal to about 2×10^{-10} m. Thus, the thickness worn off for each kilometer of travel is about 1000 atomic diameters thick.

Example 1-7 How Many Grains

Context-Rich

You have been placed on detention for falling asleep in class. Your teacher says you can get off detention early by estimating the number of grains of sand on a beach. You decide to give it your best shot.

PICTURE First, you make some assumptions about the size of the beach and the size of each grain of sand. Let's assume the beach is about 500 m long, 100 m wide, and 3 m deep. Searching the Internet, you learn that the diameter of a grain varies from 0.04 mm to 2 mm. You assume that each grain is a 1-mm-diameter sphere. Let's also assume that the grains are so tightly packed that the volume of the space between the grains is negligible compared to the volume of the sand itself.

(Corbis.)

SOLVE

1. The volume V_B of the beach is equal to the number N of grains times the volume V_G of a single grain:

   $$V_B = NV_G$$

2. Using the formula for the volume of a sphere, find the volume of a single grain of sand:

   $$V_G = \frac{4}{3}\pi R^3$$

3. Solve for the number of grains. The numbers in our assumptions are specified to only one significant figure, so the answer will be expressed with one significant figure:

   $$V_B = NV_G = N\frac{4}{3}\pi R^3$$

   so

   $$N = \frac{3V_B}{4\pi R^3} = \frac{3(500\text{ m})(100\text{ m})(3\text{ m})}{4\pi(0.5 \times 10^{-3}\text{ m})^3} = 2.9 \times 10^{14} \approx \boxed{3 \times 10^{14}}$$

CHECK To check the answer, divide the volume of the beach by the number of grains the beach holds. The result is $1.5 \times 10^5\text{ m}^3/3 \times 10^{14}$ grains $= 5 \times 10^{-10}\text{ m}^3$/grain. This result is the estimated volume of one grain of sand or $4/[3\pi(5 \times 10^{-4}\text{ m})^3]$.

TAKING IT FURTHER The volume of the space between grains can be found by first filling a one-liter container with dry sand, and then slowly pouring water into the container until the sand is saturated with water. If we assume that one-tenth of a liter of water is needed to fully saturate the sand in the container, the actual volume of the sand in the one-liter container is only nine-tenths of a liter. Our estimate of the number of grains on the beach is too high. Taking into account that the sand actually occupies only, say, 90 percent of the volume of its container, the number of grains on the beach would be only 90 percent of the value obtained in step 3 of our solution.

PRACTICE PROBLEM 1-5 How many grains of sand are on a 2-km stretch of beach that is 500 m wide? *Hint: Assume that the sand is* 3.00 m *deep and the diameter of one grain of sand is* 1.00 mm.

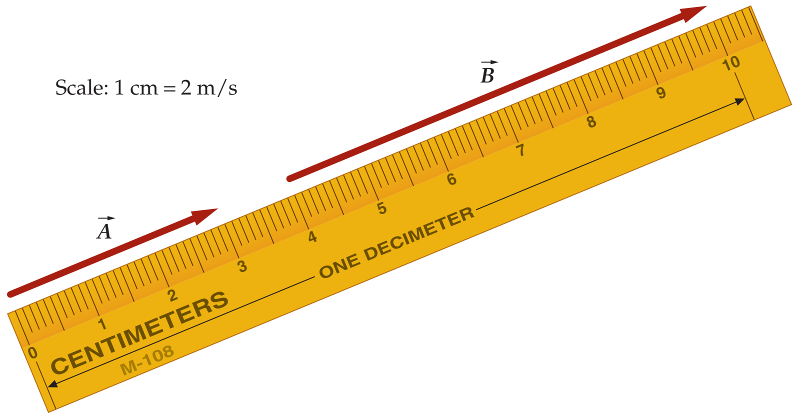


FIGURE 1-2 Velocity vectors $\vec{A}$ and $\vec{B}$ have magnitudes of 6 m/s and 12 m/s, respectively. The arrows representing them are drawn using the scale 1 cm = 2 m/s, so the arrows are drawn 3 and 6 cm long.

1-6 VECTORS

If an object moves in a straight line, we can describe its motion by describing how far or how fast it moves, and whether it moves to the left or right of the origin. But when we look at the motion of an object that is moving in two or three dimensions, we need more than just plus and minus signs to indicate direction. Quantities that have magnitude and direction, such as velocity, acceleration, and force, are called **vectors.** Quantities with magnitude but no associated direction, such as speed, mass, volume, and time, are called **scalars.**

We represent a vector graphically using an arrow. The length of the arrow, drawn to scale, indicates the magnitude of the vector quantity. The direction of the arrow indicates the direction of the vector quantity. Figure 1-2, for example, shows a graphical representation of two velocity vectors. One velocity vector has twice the magnitude of the other. We denote vectors by italic letters with an overhead arrow, $\vec{A}$. The magnitude of $\vec{A}$ is written $|\vec{A}|$, $\|\vec{A}\|$, or simply A. For the vectors in Figure 1-2, $A = |\vec{A}| = 6$ m/s and $B = |\vec{B}| = 12$ m/s.

! While working with vectors, you should always include an arrow over the letter to indicate a vector quantity. The letter without the arrow represents only the magnitude of the vector quantity. Note that the magnitude of a vector is never negative.

1-7 GENERAL PROPERTIES OF VECTORS

Like scalar quantities, vector quantities can be added, subtracted, and multiplied. However, manipulating vectors algebraically requires taking into account their direction. In this section, we will examine some of the general properties of vectors and how to work with them (multiplication of two vectors will be discussed in Chapters 6 and 9). Throughout most of the discussion, we will consider displacement vectors—vectors that represent change of position—because they are the most basic of vectors. However, keep in mind that the properties apply to all vectors, not just displacement vectors.

BASIC DEFINITIONS

If an object moves from location A to location B, we can represent its **displacement** with an arrow pointing from A to B, as shown in Figure 1-3*a*. The length of the arrow represents the distance, or magnitude, between the two locations. The direction of the arrow represents the direction from A to B. A displacement vector is a directed straight-line segment from the initial location to the final location that represents the change in position of an object. It does not necessarily represent the

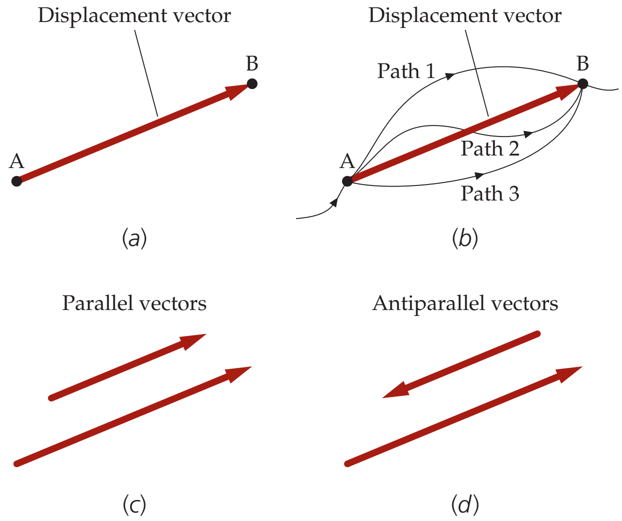

FIGURE 1-3 (*a*) shows a displacement vector from a point A to a point B; (*b*) shows the same displacement vector with three different paths between the two points; (*c*) shows the same displacement vector next to a second displacement vector that is parallel but a different length; (*d*) shows the same displacement vector next to a vector that is antiparallel (the head and tail are reversed) and a different length.

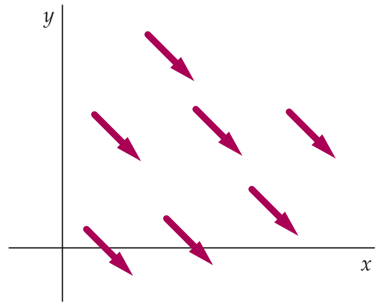

FIGURE 1-4 Vectors are equal if their magnitudes and directions are the same. All vectors in this figure are equal.

actual path the object takes. For example, in Figure 1-3*b*, the same displacement vector corresponds to all three paths between points A and B.

If two displacement vectors have the same direction, as shown in Figure 1-3*c*, they are **parallel.** If they have opposite directions, as shown in Figure 1-3*d*, they are **antiparallel.** If two vectors have *both* the same magnitude and the same direction, they are said to be equal. Graphically, this means that they have the same length and are parallel to each other. A vector can be drawn at different locations as long as it is drawn with the correct magnitude (length) and in the correct direction. Thus, all the vectors in Figure 1-4 are equal. In addition, vectors do not depend on the *coordinate system* used to represent them (except for position vectors, which are introduced in Chapter 3). Two or three mutually perpendicular coordinate axes form a coordinate system.

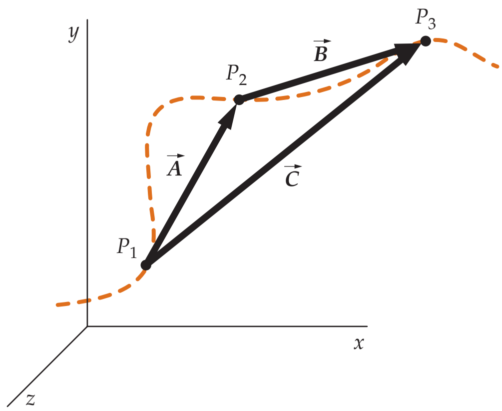

FIGURE 1-5

ADDITION AND SUBTRACTION OF VECTORS

Suppose you decide to take a hike along a trail through a forest. Figure 1-5 shows your path as you move from point P_1 to a second point P_2 and then to a third point P_3. The vector $\vec{A}$ represents your displacement from P_1 to P_2, while $\vec{B}$ represents your displacement from P_2 to P_3. Note that these displacement vectors depend only on the endpoints and not on the actual path taken. Your *net* displacement from P_1 to P_3, is a new vector, labeled $\vec{C}$ in the figure, and is called the sum of the two successive displacements $\vec{A}$ and $\vec{B}$:

$$\vec{C} = \vec{A} + \vec{B} \tag{1-1}$$

The sum of two vectors is called the sum, **vector sum,** or **resultant.**

The plus sign in Equation 1-1 refers to a process called *vector addition.* We find the sum using a geometric process that takes into account both the magnitudes and the directions of the quantities. To add two displacement vectors graphically, we draw the second vector $\vec{B}$ with its tail $\vec{B}$ at the head of the first vector $\vec{A}$ (Figure 1-6). The resultant vector is then drawn from the tail of the first to the head of the second. This method of adding vectors is called the **head-to-tail method.**

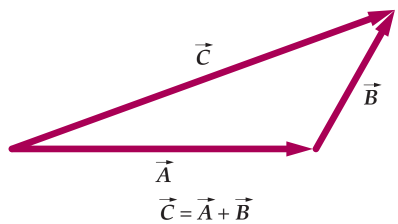

FIGURE 1-6 Head-to-tail method of vector addition.

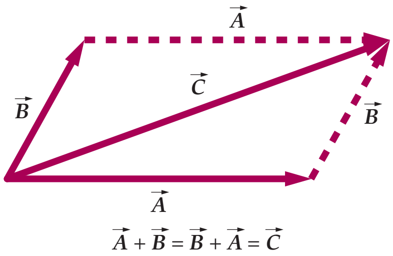

FIGURE 1-7 Parallelogram method of vector addition.

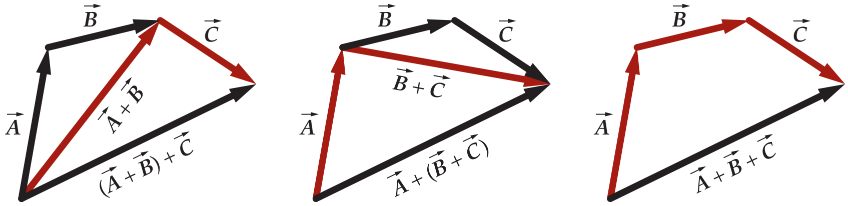

FIGURE 1-8 Vector addition is associative. That is, $(\vec{A} + \vec{B}) + \vec{C} = \vec{A} + (\vec{B} + \vec{C})$.

An equivalent way of adding vectors, called the **parallelogram method,** involves drawing $\vec{B}$ so that it is tail-to-tail with $\vec{A}$ (Figure 1-7). A diagonal of the parallelogram formed by $\vec{A}$ and $\vec{B}$ then equals $\vec{C}$ as shown (Figure 1-7). As you can see in the figure, it makes no difference in which order we add two vectors; that is, $\vec{A} + \vec{B} = \vec{B} + \vec{A}$. Therefore, vector addition obeys the commutative law.

To add more than two vectors—for example, $\vec{A}$, $\vec{B}$, and $\vec{C}$—we first add two vectors (Figure 1-8), and then add the third vector to the vector sum of the first two. The order in which the vectors are grouped before adding does not matter; that is $(\vec{A} + \vec{B}) + \vec{C} = \vec{A} + (\vec{B} + \vec{C})$. This reveals that like the addition of ordinary numbers, vector addition is associative.

If vectors $\vec{A}$ and $\vec{B}$ are equal in magnitude and opposite in direction, then the vector $\vec{C} = \vec{A} + \vec{B}$ is a vector with a magnitude of zero. This can be shown by using the head-to-tail method of vector addition to graphically construct the sum $\vec{A} + \vec{B}$. Any vector with a magnitude of zero is called the zero vector $\vec{0}$. The direction of a vector with zero magnitude has no meaning, so in this book we will not use vector notation for the zero vector. That is, we will use 0 rather than $\vec{0}$ to denote the zero vector. If $\vec{A} + \vec{B} = 0$, then $\vec{B}$ is said to be the negative of $\vec{A}$ and vice versa. Note that $\vec{B}$ is the negative of $\vec{A}$ if $\vec{B}$ has the same magnitude as $\vec{A}$ but is in the opposite direction. The negative of $\vec{A}$ is written $-\vec{A}$, so if $\vec{A} + \vec{B} = 0$, then $\vec{B} = -\vec{A}$ (Figure 1-9).

To subtract vector $\vec{B}$ from vector $\vec{A}$, add the negative of $\vec{B}$ to $\vec{A}$. The result is $\vec{C} = \vec{A} - \vec{B} = \vec{A} + (-\vec{B})$ (Figure 1-10*a*). An alternative method of subtracting $\vec{B}$ from $\vec{A}$ is to add $\vec{B}$ to both sides of the equation $\vec{C} = \vec{A} + (-\vec{B})$ to obtain $\vec{B} + \vec{C} = \vec{A}$, and then graphically add $\vec{B}$ and $\vec{C}$ to get $\vec{A}$ using the head-to-tail method. This is accomplished by first drawing $\vec{A}$ and $\vec{B}$ tail-to-tail (Figure 1-10*b*), and then drawing $\vec{C}$ from the head of $\vec{B}$ to the head of $\vec{A}$.

! C does not equal $A + B$ unless $\vec{A}$ and $\vec{B}$ are in the same direction. That is, $\vec{C} = \vec{A} + \vec{B}$ does not imply that $C = A + B$.

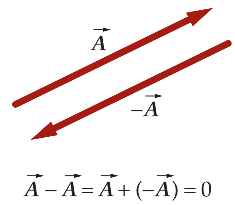

FIGURE 1-9

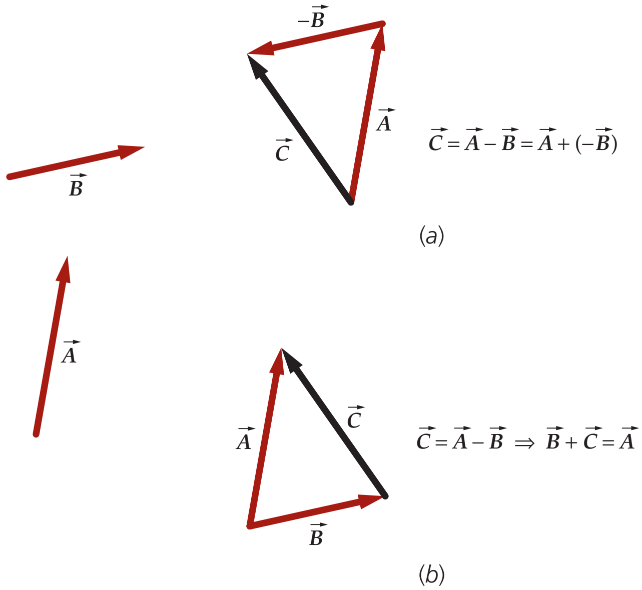

FIGURE 1-10 Alternative ways of subtracting vectors. Let $\vec{C} = \vec{A} - \vec{B}$. (*a*) To obtain $\vec{C}$, we add $-\vec{B}$ to $\vec{A}$. (*b*) To obtain $\vec{C}$, we first draw $\vec{A}$ and $\vec{B}$ with their tails together. Then, $\vec{C}$ is the vector we add to $\vec{B}$ to get $\vec{A}$.

Example 1-8 Your Displacement — Conceptual

You walk 3.00 km due east and then 4.00 km due north. Determine your resultant displacement by adding these two displacement vectors graphically.

PICTURE Your displacement is the vector from your initial position to your final position. You can add the two individual displacement vectors graphically to find the resultant displacement. To accurately draw the resultant, you must use a scale such as 1 cm on the drawing = 1 km on the ground.

SOLVE

1. Let $\vec{A}$ and $\vec{B}$ represent displacements of 3.00 km due east and 4.00 km due north, respectively, and let $\vec{C} = \vec{A} + \vec{B}$. Draw $\vec{A}$ and $\vec{B}$ with the tail of $\vec{B}$ at the head of $\vec{A}$, and with $\vec{C}$ drawn from the tail of $\vec{A}$ to the head of $\vec{B}$ (Figure 1-11). Use the scale 1 cm = 1 km. Include axes indicating the directions north and east.
2. Determine the magnitude and direction of $\vec{C}$ using your diagram, the scale 1 cm = 1 km, and a protractor.

The arrow representing $\vec{C}$ has a length of 5.00 cm, so the magnitude of $\vec{C}$ is 5.00 km. The direction of $\vec{C}$ is approximately 53° north of east.

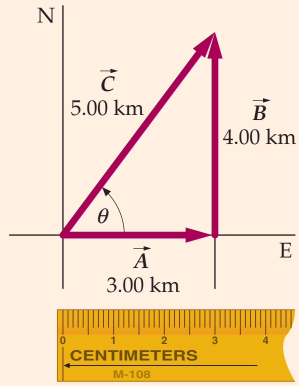

FIGURE 1-11

CHECK The distance traveled is 3.00 km + 4.00 km = 7.00 km and the magnitude of the net displacement is 5 km. This is consistent with the adage "the shortest distance between two points is a straight line." Also, if you go 3 km east and 4 km north, you should expect to be somewhat more than 45° north of east from your starting point.

TAKING IT FURTHER A vector is described by its magnitude and its direction. Your resultant displacement is therefore a vector of length 5.00 km in a direction approximately 53° north of east.

MULTIPLYING A VECTOR BY A SCALAR

The expression $3\vec{A}$, where $\vec{A}$ is an arbitrary vector, represents the sum $\vec{A} + \vec{A} + \vec{A}$. That is, $\vec{A} + \vec{A} + \vec{A} = 3\vec{A}$. (In like manner, $(-\vec{A}) + (-\vec{A}) + (-\vec{A}) = 3(-\vec{A}) = -3\vec{A}$.) More generally, the vector $\vec{A}$ multiplied by a scalar s is the vector $\vec{B} = s\vec{A}$, where $\vec{B}$ has magnitude $|s|A$. $\vec{B}$ is in the same direction as $\vec{A}$ if s is positive and is in the opposite direction if s is negative. The dimensions of $s\vec{A}$ are those of s multiplied by those of A. (In addition, to divide $\vec{A}$ by a scalar s, you multiply $\vec{A}$ by $1/s$.)

COMPONENTS OF VECTORS

We can add or subtract vectors algebraically by first breaking down the vectors into their components. The **component** of a vector in a given direction is the projection of the vector onto an axis in that direction. We can find the components of a vector by drawing perpendicular lines from the ends of the vector to the axis, as shown in Figure 1-12. The process of finding the x, y, and z components of a

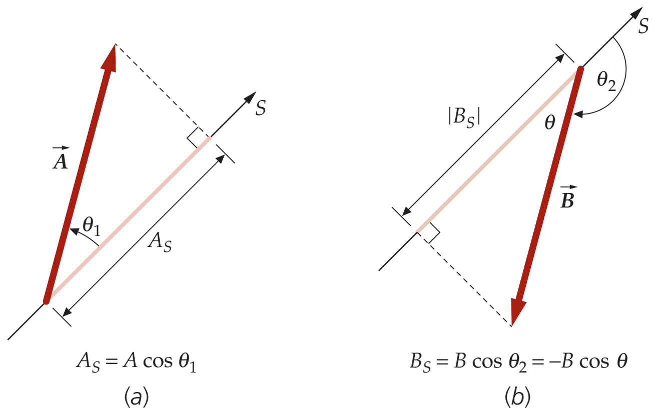

FIGURE 1-12 The component of a vector in a specified direction is equal to the magnitude of the vector times the cosine of the angle between the direction of the vector and the specified direction. The component of the vector $\vec{A}$ in the $+S$ direction is A_S, and A_S is positive. The component of the vector $\vec{B}$ in the $+S$ direction is B_S, and B_S is negative.

vector is called **resolving the vector** into its components. The components of a vector along the x, y, and z directions, illustrated in Figure 1-13 for a vector in the xy plane, are called the rectangular (or Cartesian) components. Note that the components of a vector *do* depend on the coordinate system used, although the vector itself does not.

We can use right-triangle geometry to find the rectangular components of a vector. If θ is the angle measured counterclockwise* from the $+x$ direction to the direction of $\vec{A}$ (see Figure 1-13), then

$$A_x = A\cos\theta \qquad \text{1-2}$$

x COMPONENT OF A VECTOR

and

$$A_y = A\sin\theta \qquad \text{1-3}$$

y COMPONENT OF A VECTOR

where A is the magnitude of $\vec{A}$.

If we know A_x and A_y we can find the angle θ from

$$\tan\theta = \frac{A_y}{A_x} \qquad \theta = \tan^{-1}\frac{A_y}{A_x} \qquad \text{1-4}$$

and the magnitude A from the Pythagorean theorem:

$$A = \sqrt{A_x^2 + A_y^2} \qquad \text{1-5}a$$

In three dimensions,

$$A = \sqrt{A_x^2 + A_y^2 + A_z^2} \qquad \text{1-5}b$$

Components can be positive or negative. The x component of a vector is positive if the x coordinate of an ant as it walks from the tail to the head of the vector increases. Thus, if $\vec{A}$ points in the positive x direction, then A_x is positive, and if $\vec{A}$ points in the negative x direction, then A_x is negative.

It is important to note that in Equation 1-4, the inverse tangent function is multiple valued. This issue is clarified in Example 1-9.

PRACTICE PROBLEM 1-6

A car travels 20.0 km in a direction 30.0° north of west. Let east be the $+x$ direction and north be the $+y$ direction, as in Figure 1-14. Find the x and y components of the displacement vector of the car.

Once we have resolved a vector into its components, we can manipulate the individual components. Consider two vectors $\vec{A}$ and $\vec{B}$ that lie in the xy plane. The rectangular components of each vector and those of the sum $\vec{C} = \vec{A} + \vec{B}$ are shown in Figure 1-15. We see that the rectangular components of each vector and those of the sum $\vec{C} = \vec{A} + \vec{B}$ are equivalent to the two component equations

$$C_x = A_x + B_x \qquad \text{1-6}a$$

and

$$C_y = A_y + B_y \qquad \text{1-6}b$$

In other words, the sum of the x components equals the x component of the resultant, and the sum of the y components equals the y component of the resultant. The angle and magnitude of the resultant vector can be found using Equations 1-4 and 1-5a, respectively.

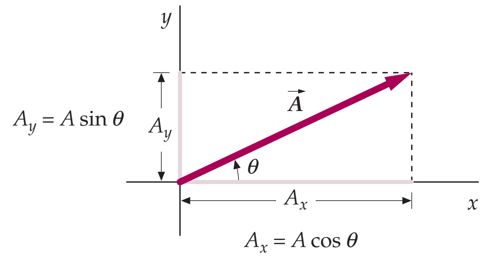

FIGURE 1-13 The rectangular components of a vector. θ is the angle between the direction of the vector and the $+x$ direction. The angle is positive if it is measured counterclockwise from the $+x$ direction, as shown.

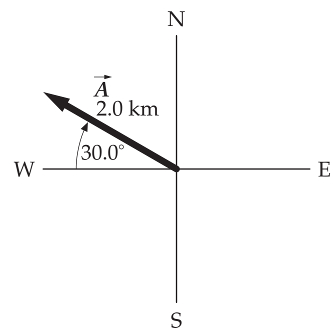

FIGURE 1-14

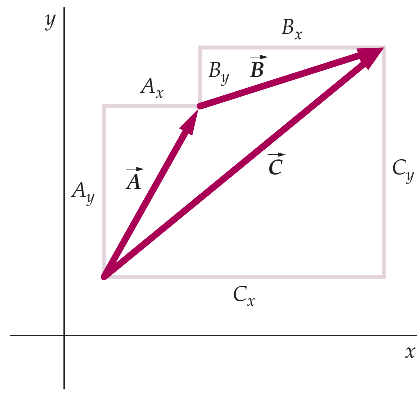

FIGURE 1-15

* This assumes the $+y$ direction is 90° counterclockwise from the $+x$ direction.

Example 1-9 A Treasure Map *Context-Rich*

You are working at a tropical resort, and are setting up a treasure hunt activity for the guests. You've been given a map and told to follow its directions in order to bury a "treasure" at a specific location. You don't want to waste time walking around the island, because you want to finish early and go surfing. The directions are to walk 3.00 km headed 60.0° north of due east and then 4.00 km headed 40.0° north of due west. Where should you head and how far must you walk to get the job done quickly? Find your answer (*a*) graphically and (*b*) using components.

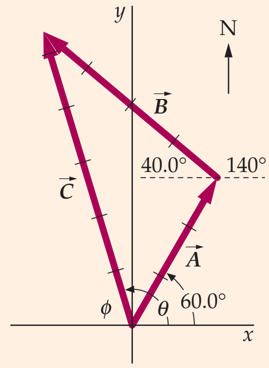

FIGURE 1-16

PICTURE In both cases you need to find your resultant displacement. In Part (*a*), use the head-to-tail method of vector addition and solve for the resultant vector graphically. You can do this by drawing each of the displacements to scale and then measuring the resultant displacement directly from your sketch. For Part (*b*), you will need to resolve the vectors into their individual components and then use the components to find the resultant displacement.

SOLVE

(*a*) 1. Draw a vector-addition diagram to scale (Figure 1-16). First draw coordinate axes, with the $+x$ direction toward the east and the $+y$ direction toward the north. Next, starting at the origin draw the first displacement vector $\vec{A}$ 3.00 cm long at 60.0° north of east. Beginning at the head of $\vec{A}$, draw the second vector $\vec{B}$ 4.00 cm long at 40.0° north of west. (You will need a protractor to measure the angles.) Then draw the resultant vector $\vec{C}$ from the tail of $\vec{A}$ to the head of $\vec{B}$:

2. Measure the length of $\vec{C}$. Using a protractor, measure the angle between the direction of $\vec{C}$ and the $+x$ direction:

$\vec{C}$ is about 5.40 cm long. Thus, the magnitude of the resultant displacement is $\boxed{5.40\text{ km}}$. The angle ϕ made between $\vec{C}$ and due west is about 73.2°. Therefore, you should walk 5.40 km headed $\boxed{73.2°\text{ north of west}}$.

(*b*) 1. To solve using components, let $\vec{A}$ denote the first displacement and choose the $+x$ direction toward the east and the $+y$ direction toward the north. Compute A_x and A_y from Equations 1-2 and 1-3:

$$A_x = (3.00\text{ km})\cos 60° = 1.50\text{ km}$$
$$A_y = (3.00\text{ km})\sin 60° = 2.60\text{ km}$$

2. Similarly, compute the components of the second displacement $\vec{B}$. The angle between the direction of $\vec{B}$ and the $+x$ direction is $180.0° - 40.0° = 140°$:

$$B_x = (4.00\text{ km})\cos 140° = -3.06\text{ km}$$
$$B_y = (4.00\text{ km})\sin 140° = +2.57\text{ km}$$

3. The components of the resultant displacement $\vec{C} = \vec{A} + \vec{B}$ are found by addition:

$$C_x = A_x + B_x = 1.50\text{ km} - 3.06\text{ km} = -1.56\text{ km}$$
$$C_y = A_y + B_y = 2.60\text{ km} + 2.57\text{ km} = 5.17\text{ km}$$

4. The Pythagorean theorem gives the magnitude of $\vec{C}$:

$$C^2 = C_x^2 + C_y^2 = (-1.56\text{ km})^2 + (5.17\text{ km})^2 = 29.2\text{ km}^2$$
$$C = \sqrt{29.2\text{ km}^2} = \boxed{5.40\text{ km}}$$

5. The ratio of C_y to C_x equals the tangent of the angle θ between $\vec{C}$ and the positive x direction. Be careful, the value you are seeking may be 180° larger than the value returned by your calculator for the inverse tangent:

$$\tan\theta = \frac{C_y}{C_x} \quad \text{so}$$
$$\theta = \tan^{-1}\frac{5.17\text{ km}}{-1.56\text{ km}} = \tan^{-1}(-3.31)$$
$$= \text{either } -73.2° \quad \text{or} \quad (-73.2° + 180°)$$
$$= \text{either } -73.2° \quad \text{or} \quad +107°$$

6. Because C_y is positive and C_x is negative we know to select the value for θ in the second quadrant:

$$\theta = \boxed{107°\text{ counterclockwise from east}}$$
$$\phi = \boxed{73.2°\text{ north of west}}$$

CHECK Step 4 of Part (*b*) gives the magnitude as 5.40 km and step 6 gives the direction as 73.2° north of west. This agrees with the results in Part (*a*) within the accuracy of our measurement.

TAKING IT FURTHER To specify a vector, you need to specify either the magnitude *and* direction, or both components. In this example, the magnitude and direction was specifically asked for.

UNIT VECTORS

A **unit vector** is a *dimensionless* vector with magnitude exactly equal to 1. The vector $\hat{A} = \vec{A}/A$ is an example of a unit vector that points in the direction of $\vec{A}$. The circumflex, or hat, denotes that it is a unit vector. Unit vectors that point in the positive x, y, and z directions are convenient for expressing vectors in terms of their rectangular components. These unit vectors are usually written $\hat{i}$, $\hat{j}$, and $\hat{k}$, respectively. For example, the vector $A_x\hat{i}$ has magnitude $|A_x|$ and points in the $+x$ direction if A_x is positive (or the $-x$ direction if A_x is negative). A general vector $\vec{A}$ can be written as the sum of three vectors, each of which is parallel to a coordinate axis (Figure 1-17):

$$\vec{A} = A_x\hat{i} + A_y\hat{j} + A_z\hat{k} \qquad \text{1-7}$$

The addition of two vectors $\vec{A}$ and $\vec{B}$ can be written in terms of unit vectors as

$$\begin{aligned}\vec{A} + \vec{B} &= (A_x\hat{i} + A_y\hat{j} + A_z\hat{k}) + (B_x\hat{i} + B_y\hat{j} + B_z\hat{k}) \\ &= (A_x + B_x)\hat{i} + (A_y + B_y)\hat{j} + (A_z + B_z)\hat{k} \qquad \text{1-8}\end{aligned}$$

The general properties of vectors are summarized in Table 1-4.

PRACTICE PROBLEM 1-7

Given vectors $\vec{A} = (4.00\text{ m})\hat{i} + (3.00\text{ m})\hat{j}$ and $\vec{B} = (2.00\text{ m})\hat{i} - (3.00\text{ m})\hat{j}$ find (*a*) A, (*b*) B, (*c*) $\vec{A} + \vec{B}$, and (*d*) $\vec{A} - \vec{B}$.

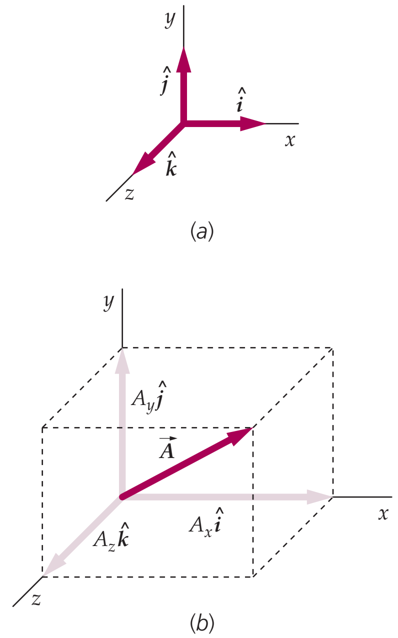

FIGURE 1-17 (*a*) The unit vectors $\hat{i}$, $\hat{j}$, and $\hat{k}$ in a rectangular coordinate system. (*b*) The vector $\vec{A}$ in terms of the unit vectors: $\vec{A} = A_x\hat{i} + A_y\hat{j} + A_z\hat{k}$.

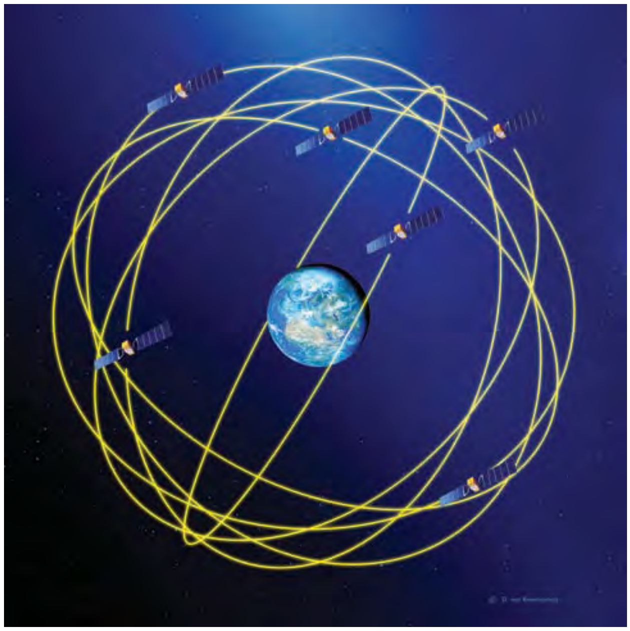
Table 1-4 Properties of Vectors

Property	Explanation	Figure	Component Representation
Equality	$\vec{A} = \vec{B}$ if $\lvert\vec{A}\rvert = \lvert\vec{B}\rvert$ and their directions are the same		$A_x = B_x$ $A_y = B_y$ $A_z = B_z$
Addition	$\vec{C} = \vec{A} + \vec{B}$		$C_x = A_x + B_x$ $C_y = A_y + B_y$ $C_z = A_z + B_z$
Negative of a vector	$\vec{A} = -\vec{B}$ if $\lvert\vec{B}\rvert = \lvert\vec{A}\rvert$ and their directions are opposite		$A_x = -B_x$ $A_y = -B_y$ $A_z = -B_z$
Subtraction	$\vec{C} = \vec{A} - \vec{B}$		$C_x = A_x - B_x$ $C_y = A_y - B_y$ $C_z = A_z - B_z$
Multiplication by a scalar	$\vec{B} = s\vec{A}$ has magnitude $\lvert\vec{B}\rvert = \lvert s\rvert\lvert\vec{A}\rvert$ and has the same direction as $\vec{A}$ if s is positive or $-\vec{A}$ if s is negative		$B_x = sA_x$ $B_y = sA_y$ $B_z = sA_z$

Physics Spotlight

The 2005 Leap Second



The global positioning system (GPS) requires that there be 24 satellites in primary service at least 70 percent of the time. Each primary satellite has an orbital period of 1/2 a sidereal day (1 sidereal day = ~23 h 56 min) and an orbital radius about 4 times the radius of Earth. There are 6 equally spaced orbital planes, each of which is inclined 55° with respect to the equatorial plane of Earth, and each of these planes contains 4 primary satellites. In addition, there are several other GPS satellites that serve as in-orbit spares in the event that one or more of the primary satellites fails. At the time of this writing (May 2006) there are 29 operational satellites in orbit. *(Detlev Van Ravenswaay/Photo Researchers.)*

The calendar year 2005 was longer—by exactly one second, known officially as a "leap second." This adjustment was necessary to synchronize two systems of keeping time, one based on Earth's rotation and the other based on a select group of atomic clocks.

Throughout history, timekeeping has been related to the position of the Sun in the sky, a factor determined by Earth's rotation on its axis and around the Sun. This astronomical time, now called Universal Time (UT1), assumed that the rate of Earth's rotation was uniform. But as more accurate methods of measurement were developed, it became evident that there were slight irregularities in the rotation rate of Earth. This meant that there would also be some variability in the scientific standard unit for time, the second, as long as its definition—$(1/60)(1/60)(1/24)$ of a mean solar day—depended on astronomical time.

In 1955 the National Physical Laboratory in Britain developed the first cesium atomic clock, a device of far greater accuracy than any clock formerly in existence. Timekeeping could now be independent of astronomical observations, and a much more precise definition of the second could be given based on the frequency of radiation emitted in the transition between two energy levels of the cesium-133 atom. However, the more familiar UT1 continues to be of importance for systems such as navigation and astronomy. Thus it is important that atomic time and UT1 be synchronized.

According to the National Physical Laboratory, UK, "The solution adopted [for synchronization] was to construct an atomic time scale called Coordinated Universal Time … (UTC) as the basis of international timekeeping. It combines all the regularity of atomic time with most of the convenience of UT1, and many countries have adopted it as the legal basis for time."* The International Bureau of Weights and Measures in Sèvres, France, takes data from select time laboratories around the world, including the U.S. Naval Observatory in Washington, DC, to provide the international standard UTC.

When slight differences accrue between UTC and UT1 because Earth's rotation varies slightly (usually slowing) over time, a leap second is added to close the gap. The concept is similar to the way that leap years are used to correct the calendar. A year is not exactly 365 days, but rather 365.242 days. To account for this, an extra day is added to the calendar every four years and designated February 29.

Since 1972 when the world shifted to atomic timekeeping, 23 leap seconds have been added to UTC. By international agreement, a leap second is added whenever the difference between UT1 and UTC approaches 0.9 seconds. The International Earth Rotation and Reference Systems (IERS) Service, through its center at the Paris Observatory, announces the need for a leap second months in advance.

In a year without any leap second, the last second of the year would be 23:59:59 UTC on December 31, while the first second of the new year would be 00:00:00 UTC on January 1 of the new year. But for 2005 a leap second was added at 23:59:59 UTC on December 31, so that atomic clocks read 23:59:60 UTC before changing to all zeros.

Summary

TOPIC	RELEVANT EQUATIONS AND REMARKS
1. Units	**Physical quantities** are numbers that are obtained by taking measurements of physical objects. Operational definitions specify operations or procedures that, if followed, define physical quantities. The magnitude of a physical quantity is expressed as a number times a unit.
2. Base Units	The base units in the SI system are the meter (m), the second (s), the kilogram (kg), the kelvin (K), the ampere (A), the mole (mol), and the candela (cd). The unit(s) of every physical quantity can be expressed in terms of these base units.
3. Units in Equations	Units in equations are treated just like any other algebraic quantity.
4. Conversion	**Conversion factors,** which are always equal to 1, provide a convenient method for converting from one kind of unit to another.
5. Dimensions	The terms of an equation must have the same dimensions.
6. Scientific Notation	For convenience, very small and very large numbers are generally written as a number between 1 and 10 times a power of 10.
7. Exponents	
Multiplication	When multiplying two numbers, the exponents are added.
Division	When dividing two numbers, the exponents are subtracted.
Raising to a power	When a number containing an exponent is itself raised to a power, the exponents are multiplied.
8. Significant Figures	
Multiplication and division	The number of significant figures in the result of multiplication or division is *no greater than* the least number of significant figures in any of the numbers.
Addition and subtraction	The result of addition or subtraction of two numbers has no significant figures beyond the last decimal place where both of the numbers being added or subracted have significant figures.
9. Order of Magnitude	A number rounded to the nearest power of 10 is called an order of magnitude. The order of magnitude of a quantity can often be estimated using plausible assumptions and simple calculations.
10. Vectors	
Definition	Vectors are quantities that have both magnitude and direction. Vectors add like displacements.
Components	The component of a vector in a direction in space is the projection of the vector on an axis in that direction. If $\vec{A}$ makes an angle θ with the positive x direction, its x and y components are $A_x = A\cos\theta$ 1-2 $A_y = A\sin\theta$ 1-3
Magnitude	$A = \sqrt{A_x^2 + A_y^2}$ 1-5*a*
Adding vectors graphically	Two vectors may be added graphically by drawing them with the tail of the second arrow at the head of the first arrow. The arrow representing the resultant vector is drawn from the tail of the first vector to the head of the second.
Adding vectors using components	If $\vec{C} = \vec{A} + \vec{B}$, then $C_x = A_x + B_x$ 1-6*a* and $C_y = A_y + B_y$ 1-6*b*
Unit vectors	A vector $\vec{A}$ can be written in terms of unit vectors $\hat{i}$, $\hat{j}$, and $\hat{k}$, which are dimensionless, have unit magnitude and lie along the x, y, and z axes, respectively $\vec{A} = A_x\hat{i} + A_y\hat{j} + A_z\hat{k}$ 1-7

Answers to Concept Checks

Answers to Practice Problems

1-1 (*a*) 300 ns; (*b*) 40 Mm

1-2 (*a*) 0.05, (*b*) 3.9, (*c*) 0.003

1-3 2.39×10^2

1-4 3.2×10^5 y

1-5 $\approx 6 \times 10^{15}$

1-6 $A_x = -17.3$ km, $A_y = 10.0$ km

1-7 (*a*) $A = 5.00$ m, (*b*) $B = 3.61$ m, (*c*) $\vec{A} + \vec{B} = (6.00\text{ m})\hat{i}$, (*d*) $\vec{A} - \vec{B} = (2.00\text{ m})\hat{i} + (6.00\text{ m})\hat{j}$

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeroes and no decimal points.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging, for advanced students
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • Which of the following *is not* one of the base quantities in the SI system? (*a*) mass, (*b*) length, (*c*) energy, (*d*) time, (*e*) All of the above are base quantities. SSM

2 • In doing a calculation, you end up with m/s in the numerator and m/s^2 in the denominator. What are your final units? (*a*) m^2/s^3, (*b*) 1/s, (*c*) s^3/m^2, (*d*) s, (*e*) m/s

3 • The prefix giga means (*a*) 10^3, (*b*) 10^6, (*c*) 10^9, (*d*) 10^{12}, (*e*) 10^{15}.

4 • The prefix mega means (*a*) 10^{-9}, (*b*) 10^{-6}, (*c*) 10^{-3}, (*d*) 10^6, (*e*) 10^9.

5 • Show that there are 30.48 cm per foot. How many centimeters are there in one mile? SSM

6 • The number 0.000 513 0 has ______ significant figures. (*a*) one, (*b*) three, (*c*) four, (*d*) seven, (*e*) eight

7 • The number 23.0040 has ______ significant figures. (*a*) two, (*b*) three, (*c*) four, (*d*) five, (*e*) six

8 • Force has dimensions of mass times acceleration. Acceleration has dimensions of speed divided by time. Pressure is defined as force divided by area. What are the dimensions of pressure? Express pressure in terms of the SI base units kilogram, meter, and second.

9 • True or false: Two quantities must have the same dimensions in order to be multiplied.

10 • A vector has a negative x component and a positive y component. Its angle measured counterclockwise from the positive x axis is (*a*) between zero and 90 degrees, (*b*) between 90 and 180 degrees, (*c*) more than 180 degrees.

11 • A vector $\vec{A}$ points in the $+x$ direction. Show graphically at least three choices for a vector $\vec{B}$ such that $\vec{B} + \vec{A}$ points in the $+y$ direction. SSM

12 • A vector $\vec{A}$ points in the $+y$ direction. Show graphically at least three choices for a vector $\vec{B}$ such that $\vec{B} - \vec{A}$ points in the $+x$ direction.

13 • Is it possible for three equal-magnitude vectors to add to zero? If so, sketch a graphical answer. If not, explain why not. SSM

ESTIMATION AND APPROXIMATION

14 • The angle subtended by the moon's diameter at a point on Earth is about 0.524° (Figure 1-18). Use this information and the fact that the moon is about 384 Mm away to find the diameter of the moon. *Hint: The angle can be determined from the diameter of the moon and the distance to the moon.*

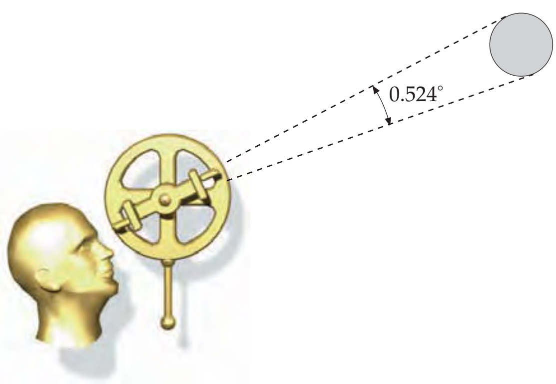

FIGURE 1-18 Problem 14

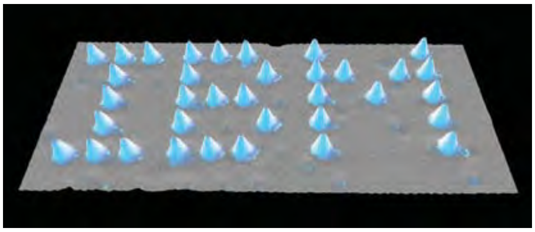
15 • **Biological Application** Some good estimates about the human body can be made if it is assumed that we are made mostly of water. The mass of a water molecule is 29.9×10^{-27} kg. If the mass of a person is 60 kg, estimate the number of water molecules in that person. SSM

16 •• **ENGINEERING APPLICATION** In 1989, IBM scientists moved atoms with a scanning tunneling microscope (STM). One of the first STM images seen by the general public was of the letters IBM spelled with xenon atoms on a nickel surface. The letters IBM were 15 xenon atoms across. If the space between the centers of adjacent xenon atoms is 5 nm (5×10^{-9} m), estimate how many times "IBM" could be written across this 8.5-inch page.



(By permission of IBM Reasearch, Almaden Research Center.)

17 •• There is an environmental debate over the use of cloth versus disposable diapers. (*a*) If we assume that between birth and 2.5 y of age, a child uses 3 diapers per day, estimate the total number of disposable diapers used in the United States per year. (*b*) Estimate the total landfill volume due to these diapers, assuming that 1000 kg of waste fills about 1 m^3 of landfill volume. (*c*) How many square miles of landfill area at an average height of 10 m is needed for the disposal of diapers each year?

18 •• (*a*) Estimate the number of gallons of gasoline used per day by automobiles in the United States and the total amount of money spent on it. (*b*) If 19.4 gal of gasoline can be made from one barrel of crude oil, estimate the total number of barrels of oil imported into the United States per year to make gasoline. How many barrels per day is this?

19 •• **ENGINEERING APPLICATION** A megabyte (MB) is a unit of computer memory storage. A CD has a storage capacity of 700 MB and can store approximately 70 min of high-quality music. (*a*) If a typical song is 5 min long, how many megabytes are required for each song? (*b*) If a page of printed text takes approximately 5 kilobytes, estimate the number of novels that could be saved on a CD. SSM

UNITS

20 • Express the following quantities using the prefixes listed in Table 1-1 and the unit abbreviations listed in the table Abbreviations for Units. For example, 10 000 meters = 10 km. (*a*) 1 000 000 watts, (*b*) 0.002 gram, (*c*) 3×10^{-6} meter, (*d*) 30 000 seconds

21 • Write each of the following without using prefixes: (*a*) 40 μW, (*b*) 4 ns, (*c*) 3 MW, (*d*) 25 km.

22 • Write the following (which are not SI units) using prefixes (but not their abbreviations). For example, 10^3 meters = 1 kilometer: (*a*) 10^{-12} boo, (*b*) 10^9 low, (*c*) 10^{-6} phone, (*d*) 10^{-18} boy, (*e*) 10^6 phone, (*f*) 10^{-9} goat, (*g*) 10^{12} bull.

23 •• In the following equations, the distance x is in meters, the time t is in seconds, and the velocity v is in meters per second. What are the SI units of the constants C_1 and C_2? (*a*) $x = C_1 + C_2 t$, (*b*) $x = \frac{1}{2}C_1 t^2$, (*c*) $v^2 = 2C_1 x$, (*d*) $x = C_1 \cos C_2 t$, (*e*) $v^2 = 2C_1 v - (C_2 x)^2$ SSM

24 •• If x is in feet, t is in milliseconds, and v is in feet per second, what are the units of the constants C_1 and C_2 in each part of Problem 23?

CONVERSION OF UNITS

25 • **MULTISTEP** From the original definition of the meter in terms of the distance along a meridian from the equator to the North Pole, find in meters (*a*) the circumference of Earth and (*b*) the radius of Earth. (*c*) Convert your answers for (*a*) and (*b*) from meters into miles.

26 • The speed of sound in air is 343 m/s. What is the speed of a supersonic plane that travels at twice the speed of sound? Give your answer in kilometers per hour and miles per hour.

27 • A basketball player is 6 ft $10\frac{1}{2}$ in tall. What is his height in centimeters?

28 • Complete the following: (*a*) 100 km/h = ______ mi/h, (*b*) 60 cm = ______ in., (*c*) 100 yd = ______ m.

29 • The main span of the Golden Gate Bridge is 4200 ft. Express this distance in kilometers.

30 • Find the conversion factor to convert from miles per hour into kilometers per hour.

31 • Complete the following: (*a*) 1.296×10^5 km/h^2 = ______ km/(h·s), (*b*) 1.296×10^5 km/h^2 = ______ m/s^2, (*c*) 60 mi/h = ______ ft/s, (*d*) 60 mi/h = ______ m/s.

32 • There are 640 acres in a square mile. How many square meters are there in one acre?

33 •• **CONTEXT-RICH** You are a delivery person for the Fresh Aqua Spring Water Company. Your truck carries 4 pallets. Each pallet carries 60 cases of water. Each case of water has 24 one-liter bottles. The dolly you use to carry the water into the stores has a weight limit of 250 lb. (*a*) If a milliliter of water has a mass of 1 g, and a kilogram has a weight of 2.2 lb, what is the weight, in pounds, of all the water in your truck? (*b*) How many full cases of water can you carry on the cart? SSM

34 •• A right circular cylinder has a diameter of 6.8 in. and a height of 2 ft. What is the volume of the cylinder in (*a*) cubic feet, (*b*) cubic meters, (*c*) liters?

35 •• In the following, x is in meters, t is in seconds, v is in meters per second, and the acceleration a is in meters per second squared. Find the SI units of each combination: (*a*) v^2/x, (*b*) $\sqrt{x/a}$, (*c*) $\frac{1}{2}at^2$. SSM

DIMENSIONS OF PHYSICAL QUANTITIES

36 • What are the dimensions of the constants in each part of Problem 23?

37 • The law of radioactive decay is $N(t) = N_0 e^{-\lambda t}$, where N_0 is the number of radioactive nuclei at $t = 0$, $N(t)$ is the number remaining at time t, and λ is a quantity known as the decay constant. What is the dimension of λ?

38 •• The SI unit of force, the kilogram-meter per second squared (kg·m/s^2) is called the newton (N). Find the dimensions and the SI units of the constant G in Newton's law of gravitation $F = Gm_1m_2/r^2$.

39 •• The magnitude of the force (F) that a spring exerts when it is stretched a distance x from its unstressed length is governed by Hooke's law, $F = kx$. (*a*) What are the dimensions of the *force constant*, k? (*b*) What are the dimensions and SI units of the quantity kx^2?

40 •• Show that the product of mass, acceleration, and speed has the dimensions of power.

41 •• The momentum of an object is the product of its velocity and mass. Show that momentum has the dimensions of force multiplied by time. SSM

42 •• What combination of force and one other physical quantity has the dimensions of power?

43 •• When an object falls through air, there is a drag force that depends on the product of the cross sectional area of the object and the square of its velocity, that is, $F_{air} = CAv^2$, where C is a constant. Determine the dimensions of C. SSM

44 •• Kepler's third law relates the period of a planet to its orbital radius r, the constant G in Newton's law of gravitation ($F = Gm_1m_2/r^2$), and the mass of the Sun M_s. What combination of these factors gives the correct dimensions for the period of a planet?

SCIENTIFIC NOTATION AND SIGNIFICANT FIGURES

45 • Express as a decimal number without using powers of 10 notation: (*a*) 3×10^4, (*b*) 6.2×10^{-3}, (*c*) 4×10^{-6}, (*d*) 2.17×10^5. SSM

46 • Write the following in scientific notation: (*a*) 1 345 100 m = ______ km, (*b*) 12 340. kW = ______ MW, (*c*) 54.32 ps = ______ s, (*d*) 3.0 m = ______ mm.

47 • Calculate the following, round off to the correct number of significant figures, and express your result in scientific notation: (*a*) $(1.14)(9.99 \times 10^4)$, (*b*) $(2.78 \times 10^{-8}) - (5.31 \times 10^{-9})$, (*c*) $12\pi/(4.56 \times 10^{-3})$, (*d*) $27.6 + (5.99 \times 10^2)$. SSM

48 • Calculate the following, round off to the correct number of significant figures, and express your result in scientific notation: (*a*) $(200.9)(569.3)$, (*b*) $(0.000\,000\,513)(62.3 \times 10^7)$, (*c*) $28\,401 + (5.78 \times 10^4)$, (*d*) $63.25/(4.17 \times 10^{-3})$.

49 • **BIOLOGICAL APPLICATION** A cell membrane has a thickness of 7.0 nm. How many cell membranes would it take to make a stack 1.0 in. high? SSM

50 •• **ENGINEERING APPLICATION** A circular hole of radius 8.470×10^{-1} cm must be cut into the front panel of a display unit. The *tolerance* is 1.0×10^{-3} cm, which means the actual hole cannot differ by more than this quantity from the desired radius. If the actual hole is larger than the desired radius by the allowed tolerance, what is the difference between the actual area and the desired area of the hole?

51 •• **ENGINEERING APPLICATION** A square peg must be made to fit through a square hole. If you have a square peg that has an edge length of 42.9 mm, and the square hole has an edge length of 43.2 mm, (*a*) what is the area of the space available when the peg is in the hole? (*b*) If the peg is made rectangular by removing 0.10 mm of material from one side, what is the area available now? SSM

VECTORS AND THEIR PROPERTIES

52 • **MULTISTEP** A vector that is 7.0 units long and a vector that is 5.5 units long are added. Their sum is a vector 10.0 units long. (*a*) Show graphically at least one way that the vectors can be added. (*b*) Using your sketch in Part (*a*), determine the angle between the original two vectors.

53 • Determine the x and y components of the following three vectors in the xy plane. (*a*) A 10-m displacement vector that makes an angle of 30° clockwise from the $+y$ direction. (*b*) A 25-m/s velocity vector that makes an angle of 40° counterclockwise from the $-x$ direction. (*c*) A 40-lb force vector that makes an angle of 120° counterclockwise from the $-y$ direction. SSM

54 • Rewrite the following vectors in terms of their magnitude and angle (counterclockwise from the $+x$ direction). (*a*) A displacement vector with an x component of +8.5 m and a y component of −5.5 m (*b*) A velocity vector with an x component of −75 m/s and a y component of +35 m/s (*c*) A force vector with a magnitude of 50 lb that is in the third quadrant with an x component whose magnitude is 40 lb.

55 • **CONCEPTUAL** You walk 100 m in a straight line on a horizontal plane. If this walk took you 50 m east, what are your possible north or south movements? What are the possible angles that your walk made with respect to due east?

56 • **ESTIMATION** The final destination of your journey is 300 m due east of your starting point. The first leg of this journey is the walk described in Problem 55, and the second leg in also a walk along a single straight-line path. Estimate graphically the length and heading for the second leg of your journey.

57 •• Given the following vectors: $\vec{A} = 3.4\hat{i} + 4.7\hat{j}$, $\vec{B} = (-7.7)\hat{i} + 3.2\hat{j}$, and $\vec{C} = 5.4\hat{i} + (-9.1)\hat{j}$. (*a*) Find the vector $\vec{D}$, in unit vector notation, such that $\vec{D} + 2\vec{A} - 3\vec{C} + 4\vec{B} = 0$. (*b*) Express your answer in Part (*a*) in terms of magnitude and angle with the $+x$ direction.

58 •• Given the following force vectors: $\vec{A}$ is 25 lb at an angle of 30° clockwise from the $+x$ axis, and $\vec{B}$ is 42 lb at an angle of 50° clockwise from the $+y$ axis. (*a*) Make a sketch and visually estimate the magnitude and angle of the vector $\vec{C}$ such that $2\vec{A} + \vec{C} - \vec{B}$ results in a vector with a magnitude of 35 lb pointing in the $+x$ direction. (*b*) Repeat the calculation in Part (*a*) using the method of components and compare your result to the estimate in (*a*).

59 •• Calculate the unit vector (in terms of $\hat{i}$, and $\hat{j}$) in the direction opposite to the direction of each of vectors $\vec{A}$, $\vec{B}$ and $\vec{C}$ in Problem 57. SSM

60 •• Unit vectors $\hat{i}$ and $\hat{j}$ are directed east and north, respectively. Calculate the unit vector (in terms of $\hat{i}$ and $\hat{j}$) in the following directions. (*a*) northeast, (*b*) 70° clockwise from the $-y$ axis, (*c*) southwest.

GENERAL PROBLEMS

61 • The Apollo trips to the moon in the 1960s and 1970s typically took 3 days to travel the Earth–moon distance once they left Earth orbit. Estimate the spacecraft's average speed in kilometers per hour, miles per hour, and meters per second. SSM

62 • On many of the roads in Canada the speed limit is 100 km/h. What is this speed limit in miles per hour?

63 • If you could count $1.00 per second, how many years would it take to count 1.00 billion dollars?

64 • (*a*) The speed of light in vacuum is 186 000 mi/s = 3.00×10^8 m/s. Use this fact to find the number of kilometers in a mile. (*b*) The weight of 1.00 ft^3 of water is 62.4 lb, and 1.00 ft = 30.5 cm. Use this information and the fact that 1.00 cm^3 of water has a mass of 1.00 g to find the weight in pounds of a 1.00-kg mass.

65 • The mass of one uranium atom is 4.0×10^{-26} kg. How many uranium atoms are there in 8.0 g of pure uranium?

66 •• During a thunderstorm, a total of 1.4 in. of rain falls. How much water falls on one acre of land? (1 mi^2 = 640 acres.) Express your answer in (*a*) cubic inches, (*b*) cubic feet, (*c*) cubic meters, and (*d*) kilograms. Note that the density of water is 1000 kg/m^3.

67 •• An iron nucleus has a radius of 5.4×10^{-15} m and a mass of 9.3×10^{-26} kg. (*a*) What is its mass per unit volume in kg/m^3? (*b*) If Earth had the same mass per unit volume, what would be its radius? (The mass of Earth is 5.98×10^{24} kg.)

68 •• **ENGINEERING APPLICATION** The Canadian Norman Wells Oil Pipeline extends from Norman Wells, Northwest Territories, to Zama, Alberta. The 8.68×10^5-m-long pipeline has an inside diameter of 12 in. and can be supplied with oil at 35 L/s. (*a*) What is the volume of oil in the pipeline if it is full at some instant in time? (*b*) How long would it take to fill the pipeline with oil if it is initially empty?

69 •• The astronomical unit (AU) is defined as the mean center-to-center distance from Earth to the Sun, namely 1.496×10^{11} m. The parsec is the radius of a circle for which a central angle of 1 s intercepts an arc of length 1 AU. The light-year is the distance that light travels in 1 y. (*a*) How many parsecs are there in one astronomical unit? (*b*) How many meters are in a parsec? (*c*) How many meters in a light-year? (*d*) How many astronomical units in a light-year? (*e*) How many light-years in a parsec?

70 •• If the average density of the universe is at least 6×10^{-27} kg/m^3, then the universe will eventually stop expanding and begin contracting. (*a*) How many electrons are needed in each cubic meter to produce the critical density? (*b*) How many protons per cubic meter would produce the critical density? ($m_e = 9.11 \times 10^{-31}$ kg; $m_p = 1.67 \times 10^{-27}$ kg.)

71 ••• **CONTEXT-RICH, ENGINEERING APPLICATION, SPREADSHEET** You are an astronaut doing physics experiments on the moon. You are interested in the experimental relationship between distance fallen, y, and time elapsed, t, of falling objects dropped from rest. You have taken some data for a falling penny, which is represented in the table below.

(*a*) y (m)	10	20	30	40	50
(*b*) t (s)	3.5	5.2	6.0	7.3	7.9

You expect that a general relationship between distance y and time t is $y = Bt^C$, where B and C are constants to be determined experimentally. To accomplish this, create a log-log plot of the data: (*a*) graph $\log(y)$ vs. $\log(t)$, with $\log(y)$ the ordinate variable and $\log(t)$ the abscissa variable. (*b*) Show that if you take the log of each side of your expected relationship, you get $\log(y) = \log(B) + C\log(t)$. (*c*) By comparing this linear relationship to the graph of the data, estimate the values of B and C. (*d*) If you drop a penny, how long should it take to fall 1.0 m? (*e*) In the next chapter, we will show that the expected relationship between y and t is $y = \frac{1}{2}at^2$, where a is the acceleration of the object. What is the acceleration of objects dropped on the moon? SSM

72 ••• **SPREADSHEET** A particular company's stock prices vary with the market and with the company's type of business, and can be very unpredictable, but people often try to look for mathematical patterns where they may not belong. Corning is a materials-engineering company located in upstate New York. Below is a table of the price of Corning stock on August 3, for every 5 years from 1981 to 2001. Assume that the price follows a power law: price (in \$) $= Bt^C$ where t is expressed in years. (*a*) Evaluate the constants B and C (see methods suggested for the previous problem). (*b*) According to the power law, what should the price of Corning stock have been on August 3, 2000? (It was actually \$82.83!)

(*a*) Price (dollars)	2.10	4.19	9.14	10.82	16.85
(*b*) Years since 1980	1	6	11	16	21

73 ••• **ENGINEERING APPLICATION** The Super-Kamiokande neutrino detector in Japan is a large transparent cylinder filled with ultra-pure water. The height of the cylinder is 41.4 m and the diameter is 39.3 m. Calculate the mass of the water in the cylinder. Does this match the claim posted on the official Super-K Web site that the detector uses 50,000 tons of water? SSM

74 ••• **CONTEXT-RICH** You and a friend are out hiking across a large flat plain and decide to determine the height of a distant mountain peak, and also the horizontal distance from you to the peak (Figure 1-19). In order to do this, you stand in one spot and determine that the sightline to the top of the peak is inclined at 7.5° above the horizontal. You also make note of the heading to the peak at that point: 13° east of north. You stand at the original position, and your friend hikes due west for 1.5 km. He then sights the peak and determines that its sightline has a heading of 15° east of north. How far is the mountain from your position, and how high is its summit above your position?

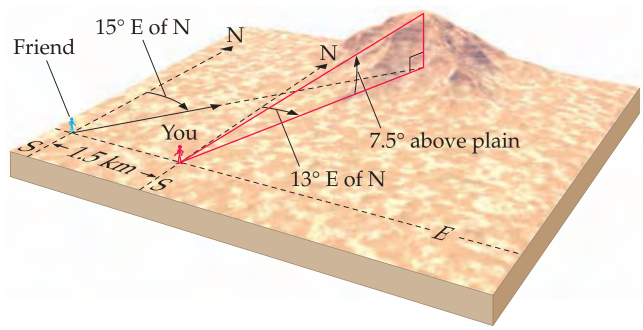


FIGURE 1-19 Problem 74

75 ••• **SPREADSHEET** The table below gives the periods T and orbit radii r for the motions of four satellites orbiting a dense, heavy asteroid. (*a*) These data can be fitted by the formula $T = Cr^n$. Find the values of the constants C and n. (*b*) A fifth satellite is discovered to have a period of 6.20 y. Find the radius for the orbit of this satellite, which fits the same formula.

(*a*) Period T, y	0.44	1.61	3.88	7.89
(*b*) Radius r, Gm	0.088	0.208	0.374	0.600

76 ••• **MULTISTEP** The period T of a simple pendulum depends on the length L of the pendulum and the acceleration of gravity g (dimensions L/T^2). (*a*) Find a simple combination of L and g that has the dimensions of time. (*b*) Check the dependence of the period T on the length L by measuring the period (time for a complete swing back and forth) of a pendulum for two different values of L. (*c*) The correct formula relating T to L and g involves a constant that is a multiple of π, and cannot be obtained by the dimensional analysis of Part (*a*). It can be found by experiment as in Part (*b*) if g is known. Using the value $g = 9.81$ m/s^2 and your experimental results from Part (*b*), find the formula relating T to L and g.

77 ••• A sled at rest is suddenly pulled in three horizontal directions at the same time but it goes nowhere. Paul pulls to the northeast with a force of 50 lb. Johnny pulls at an angle of 35° south of due west with a force of 65 lb. Connie pulls with a force to be determined. (*a*) Express the boys' two forces in terms of the usual unit vectors. (b) Determine the third force (from Connie), expressing it first in component form and then as a magnitude and angle (direction).

78 ••• You spot a plane that is 1.50 km north, 2.5 km east, and at an altitude 5.0 km above your position. (*a*) How far from you is the plane? (*b*) At what angle from due north (in the horizontal plane) are you looking? (*c*) Determine the plane's position vector (from your location) in terms of the unit vectors, letting $\hat{i}$ be toward the east direction, $\hat{j}$ be toward the north direction, and $\hat{k}$ be in vertically upward. (*d*) At what elevation angle (above the horizontal plane of Earth) is the airplane?

PART I **MECHANICS**

CHAPTER 2

MOTION IN ONE DIMENSION IS MOTION ALONG A STRAIGHT LINE LIKE THAT OF A CAR ON A STRAIGHT ROAD. THIS DRIVER ENCOUNTERS STOPLIGHTS AND DIFFERENT SPEED LIMITS ON HER COMMUTE ALONG A STRAIGHT HIGHWAY TO SCHOOL. *(Medio Images/Getty Images.)*

? How can she estimate her arrival time? (See Example 2-3.)

Motion in One Dimension

Imagine a car speeding down a highway. There are a number of ways in which you could describe the car's motion to someone else. For example, you could describe the change in the car's position as it travels from one point to another, how fast the car is moving and the direction in which it travels, and whether the car is speeding up or slowing down as it moves. These basic descriptors of motion—known as displacement, velocity, and acceleration—are an essential part of physics. In fact, the attempt to describe the motion of objects gave birth to physics more than 400 years ago.

The study of motion, and the related concepts of force and mass, is called **mechanics.** We begin our investigation into motion by examining **kinematics,** the branch of mechanics that deals with the characteristics of motion. You will need to understand kinematics to understand the rest of this book. Motion permeates all of physics, and an understanding of kinematics is needed to understand how force and mass effect motion. Starting in Chapter 4, we look at **dynamics,** which relates motion, force, and mass.

We study the simplest case of kinematics in this chapter — motion along a straight line. We will develop the models and tools you will need to describe motion in one dimension, and introduce the precise definitions of words commonly used to describe motion, such as displacement, speed, velocity, and acceleration. We will also look at the special case of straight-line motion when acceleration is constant. Finally, we consider the ways in which integration can be used to describe motion. In this chapter, moving objects are restricted to motion along a straight line. To describe such motion, it is not necessary to use the full vector notation developed in Chapter 1. A + or − sign are all that is needed to specify direction along a straight line.

2-1 DISPLACEMENT, VELOCITY, AND SPEED

(*Bettmann/Corbis.*)

In a horse race, the winner is the horse whose nose first crosses the finish line. One could argue that all that really matters during the race is the motion of that single point on the horse, and that the size, shape, and motion of the rest of the horse is unimportant. In physics, this type of simplification turns out to be useful for examining the motion of other objects as well. We can often describe the motion of an object by describing the motion of a single point of the object. For example, as a car moves in a straight line along a road, you could describe the motion of the car by examining the motion of a single point on the side of the car. An object that can be represented in this idealized manner is called a **particle.** In kinematics, any object can be considered a particle as long as we are not interested in its size, shape, or internal motion. For example, we can consider cars, trains, and rockets particles. Earth and other planets can also be thought of as particles as they move around the Sun. Even people and galaxies can be treated as particles.

POSITION AND DISPLACEMENT

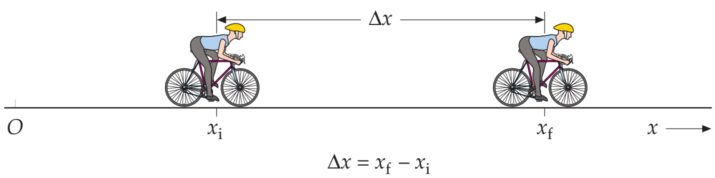

FIGURE 2-1 A student on a bicycle is moving in a straight line. A coordinate axis consists of a line along the path of the bicycle. A point on this line is chosen to be the origin O. Other points on it are assigned a number x, the value of x being proportional to its distance from O. The numbers assigned to points to the right of O are positive as shown, and those assigned to points to the left of O are negative. When the bicycle travels from point x_i to point x_f, its displacement is $\Delta x = x_f - x_i$.

To describe the motion of a particle, we need to be able to describe the **position** of the particle and how that position changes as the particle moves. For one-dimensional motion, we often choose the x axis as the line along which the motion takes place. For example, Figure 2-1 shows a student on a bicycle at position x_i at time t_i. At a later time, t_f, the student is at position x_f. The change in the student's position, $x_f - x_i$, is called a **displacement.** We use the Greek letter Δ (uppercase delta) to indicate the change in a quantity; thus, the change in x can be written as

$$\Delta x = x_f - x_i \tag{2-1}$$

DEFINITION—DISPLACEMENT

It is important to recognize the difference between displacement and distance traveled. The distance traveled by a particle is the length of the path a particle takes from its initial position to its final position. Distance is a scalar quantity and is always indicated by a positive number. Displacement is the *change in position* of the particle. It is positive if the change in position is in the direction of increasing x (the $+x$ direction), and negative if it is in the $-x$ direction. Displacement can be represented by vectors, as shown in Chapter 1. We will use the full vector notation developed in Chapter 1 when we study motion in two and three dimensions in Chapter 3.

! The notation Δx (read "delta x") stands for a single quantity that is the change in x. Δx is not a product of Δ and x any more than cos θ is a product of cos and θ. By convention, the change in a quantity is always its final value minus its initial value.

Example 2-1 Distance and Displacement of a Dog

You are playing a game of catch with a dog. The dog is initially standing near your feet. Then he jogs 20 feet in a straight line to retrieve a stick, and carries the stick 15 feet back toward you before lying on the ground to chew on the stick. (*a*) What is the total distance the dog travels? (*b*) What is the net displacement of the dog? (*c*) Show that the net displacement for the trip is the sum of the sequential displacements that make up the trip.

PICTURE The total distance, s, is determined by summing the individual distances the dog travels. The displacement is the dog's final position minus the dog's initial position. The dog leaves your side at time 0, gets the stick at time 1, and lies down to chew it at time 2.

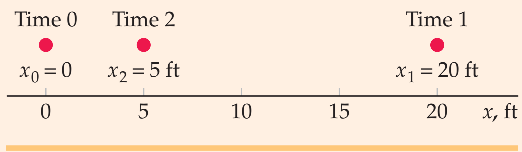

FIGURE 2-2 The red dots represent the dog's position at different times.

SOLVE

(*a*) 1. Make a diagram of the motion (Figure 2-2). Include a coordinate axis:

2. Calculate the total distance traveled:

$$s_{02} = s_{01} + s_{12} = (20 \text{ ft}) + (15 \text{ ft}) = \boxed{35} \text{ ft}$$

(The subscripts indicate the time intervals, where s_{01} is the distance traveled during the interval from time 0 to time 1, and so forth.)

(*b*) The net displacement is found from its definition, $\Delta x = x_f - x_i$, where $x_i = x_0 = 0$ is the dog's initial position. Five feet from the initial position or $x_f = x_2 = 5$ ft is the dog's final position:

$$\Delta x_{02} = x_2 - x_0 = 5 \text{ ft} - 0 \text{ ft} = \boxed{5 \text{ ft}}$$

where Δx_{02} is the displacement during the interval from time 0 to time 2.

(*c*) The net displacement is also found by adding the displacement for the first leg to the displacement for the second leg.

$$\Delta x_{01} = x_1 - x_0 = 20 \text{ ft} - 0 \text{ ft} = 20 \text{ ft}$$

$$\Delta x_{12} = x_2 - x_1 = 5 \text{ ft} - 20 \text{ ft} = -15 \text{ ft}$$

adding, we obtain

$$\Delta x_{01} + \Delta x_{12} = (x_1 - x_0) + (x_2 - x_1) = x_2 - x_0 = \Delta x_{02}$$

so

$$\Delta x_{02} = \Delta x_{01} + \Delta x_{12} = 20 \text{ ft} - 15 \text{ ft} = \boxed{5 \text{ ft}}$$

CHECK The magnitude of the displacement for any part of the trip is never greater than the total distance traveled for that part. The magnitude of the Part (*b*) result (5 ft) is less than the Part (*a*) result (35 ft), so the Part (*b*) result is plausible.

TAKING IT FURTHER The total distance traveled for a trip is always equal to the sum of the distances traveled for the individual legs of the trip. The total or net displacement for a trip is always equal to the sum of the displacements for the individual legs of the trip.

AVERAGE VELOCITY AND SPEED

We often are interested in the speed something is moving. The **average speed** of a particle is the total distance traveled by the particle divided by the total time from start to finish:

$$\text{Average speed} = \frac{\text{total distance}}{\text{total time}} = \frac{s}{\Delta t} \qquad \text{2-2}$$

DEFINITION—AVERAGE SPEED

Because the total distance and total time are both always positive, the average speed is always positive.

Although speed is a useful idea, it does not reveal anything about the direction of motion because neither the total distance nor the total time has an associated direction. A more useful quantity is one that describes both how fast and in what direction an object moves. The term used to describe this quantity is *velocity*. The **average velocity,** $v_{\mathrm{av}\,x}$, of a particle is defined as the ratio of the displacement Δx to the time interval Δt:

$$v_{\mathrm{av}\,x} = \frac{\Delta x}{\Delta t} = \frac{x_{\mathrm{f}} - x_{\mathrm{i}}}{t_{\mathrm{f}} - t_{\mathrm{i}}} \qquad (\text{so } \Delta x = v_{\mathrm{av}\,x}\,\Delta t) \qquad \text{2-3}$$

DEFINITION—AVERAGE VELOCITY

Like displacement, average velocity is a quantity that may be positive or negative. A positive value indicates the displacement is in the $+x$ direction. A negative value indicates the displacement is in the $-x$ direction. The dimensions of velocity are L/T and the SI unit of velocity is meters per second (m/s). Other common units include kilometers per hour (km/h), feet per second (ft/s), and miles per hour (mi/h).

Figure 2-3 is a graph of a particle's position as a function of time. Each point represents the position x of a particle at a particular time t. A straight line connects points P_1 and P_2 and forms the hypotenuse of the triangle having sides $\Delta x = x_2 - x_1$ and $\Delta t = t_2 - t_1$. Notice that the ratio $\Delta x/\Delta t$ is the line's **slope,** which gives us a geometric interpretation of average velocity:

The average velocity for the interval between $t = t_1$ and $t = t_2$ is the slope of the straight line connecting the points (t_1, x_1) and (t_2, x_2) on an x versus t graph.

GEOMETRIC INTERPRETATION OF AVERAGE VELOCITY

See **Math Tutorial** *for more information on*

Linear Equations

Notice that the average velocity depends on the time interval on which it is based. In Figure 2-3, for example, the smaller time interval indicated by t_2' and P_2' gives a larger average velocity, as shown by the greater steepness of the line connecting points P_1 and P_2'.

! The definitions of average speed and average velocity are the most basic of the kinematic parameters. You will need to know these definitions and the definitions that appear later in this chapter to effectively solve kinematics problems.

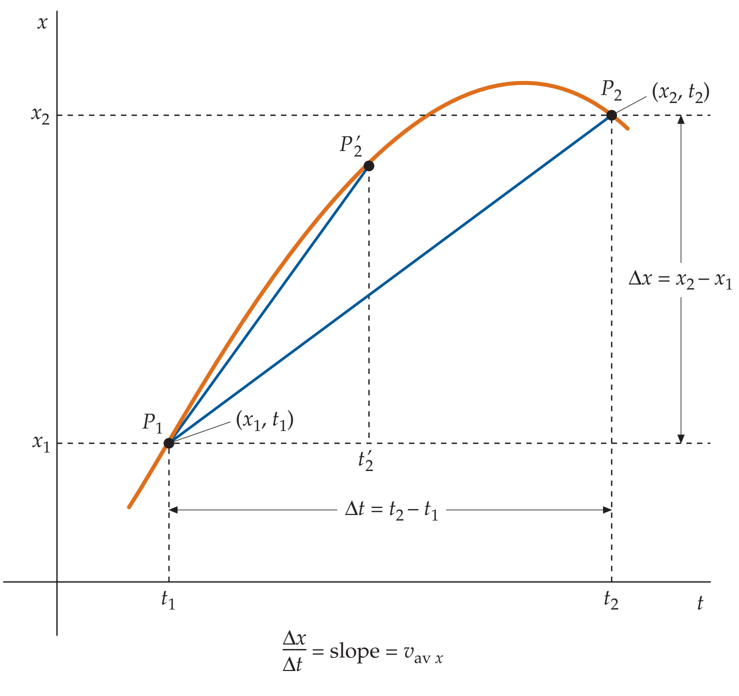

FIGURE 2-3 Graph of x versus t for a particle moving in one dimension. Each point on the curve represents the position x at a particular time t. We have drawn a straight line through points (x_1, t_1) and (x_2, t_2). The displacement $\Delta x = x_2 - x_1$ and the time interval $\Delta t = t_2 - t_1$ between these points are indicated. The straight line between P_1 and P_2 is the hypotenuse of the triangle having sides Δx and Δt, and the ratio $\Delta x/\Delta t$ is its slope. In geometric terms, the slope is a measure of the line's steepness.

Example 2-2 Average Speed and Velocity of the Dog

The dog that you were playing catch with in Example 2-1 jogged 20.0 ft away from you in 1.0 s to retrieve the stick and ambled back 15.0 ft in 1.5 s (Figure 2-4). Calculate (*a*) the dog's average speed, and (*b*) the dog's average velocity for the total trip.

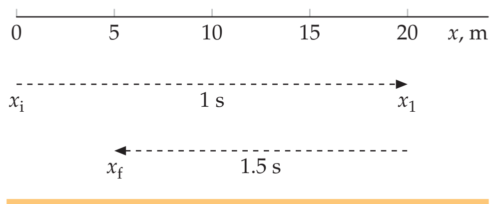

FIGURE 2-4

PICTURE We can solve this problem using the definitions of average speed and average velocity, noting that average *speed* is the total *distance* divided by the total time Δt, whereas the average *velocity* is the net *displacement* divided by Δt:

SOLVE

(*a*) 1. The dog's average speed equals the total distance divided by the total time:
$$\text{Average speed} = \frac{s}{\Delta t}$$

2. Calculate the total distance traveled and the total time:
$$s = s_1 + s_2 = 20.0\text{ ft} + 15.0\text{ ft} = 35.0\text{ ft}$$
$$\Delta t = (t_1 - t_i) + (t_f - t_2) = 1.0\text{ s} + 1.5\text{ s} = 2.5\text{ s}$$

3. Use s and Δt to find the dog's average speed:
$$\text{Average speed} = \frac{35.0\text{ ft}}{2.5\text{ s}} = \boxed{14\text{ ft/s}}$$

(*b*) 1. The dog's average velocity is the ratio of the net displacement Δx to the time interval Δt:
$$v_{\text{av }x} = \frac{\Delta x}{\Delta t}$$

2. The dog's net displacement is $x_f - x_i$, where $x_i = 0.0$ ft is the initial position of the dog and $x_f = 5.0$ ft is the dog's final position:
$$\Delta x = x_f - x_i = 5.0\text{ ft} - 0.0\text{ ft} = 5.0\text{ ft}$$

3. Use Δx and Δt to find the dog's average velocity:
$$v_{\text{av }x} = \frac{\Delta x}{\Delta t} = \frac{5.0\text{ ft}}{2.5\text{ s}} = \boxed{2.0\text{ ft/s}}$$

CHECK An Internet search reveals a greyhound can have an average speed of approximately 66 ft/s (45 mi/h), so our dog should easily be able to jog 14 ft/s (9.5 mi/h). A Part (*a*) result greater than 66 ft/s would not be plausible.

TAKING IT FURTHER Note that the dog's speed is greater than the dog's average velocity because the total distance traveled is greater than the magnitude of the total displacement. Also, note that the total displacement is the sum of the individual displacements. That is, $\Delta x = \Delta x_1 + \Delta x_2 = (20.0\text{ ft}) + (-15.0\text{ ft}) = 5.0$ ft, which is the Part (*b*), step 2 result.

Example 2-3 Driving to School

It normally takes you 10 min to travel 5.0 mi to school along a straight road. You leave home 15 min before class begins. Delays caused by a broken traffic light slow down traffic to 20 mi/h for the first 2.0 mi of the trip. Will you be late for class?

PICTURE You need to find the total time that it will take you to travel to class. To do so, you must find the time $\Delta t_{2\text{ mi}}$ that you will be driving at 20 mi/h, and the time $\Delta t_{3\text{ mi}}$ for the remainder of the trip, during which you are driving at your usual velocity.

SOLVE

1. The total time equals the time to travel the first 2.0 mi plus the time to travel the remaining 3.0 mi:
$$\Delta t_{\text{tot}} = \Delta t_{2\text{ mi}} + \Delta t_{3\text{ mi}}$$

2. Using $\Delta x = v_{\text{av }x}\,\Delta t$, solve for the time taken to travel 2.0 mi at 20 mi/h:
$$\Delta t_{2\text{ mi}} = \frac{\Delta x_1}{v_{\text{av }x}} = \frac{2.0\text{ mi}}{20\text{ mi/h}} = 0.10\text{ h} = 6.0\text{ min}$$

3. Using $\Delta x = v_{\text{av }x}\,\Delta t$, relate the time taken to travel 3 mi at the usual velocity:
$$\Delta t_{3\text{ mi}} = \frac{\Delta x_2}{v_{\text{av }x}} = \frac{3.0\text{ mi}}{v_{\text{usual }x}}$$

4. Using $\Delta x = v_{\text{av }x}\,\Delta t$, solve for $v_{\text{usual }x}$, the velocity needed for you to travel the 5.0 mi in 10 min:
$$v_{\text{usual }x} = \frac{\Delta x_{\text{tot}}}{\Delta t_{\text{usual}}} = \frac{5.0\text{ mi}}{10\text{ min}} = 0.50\text{ mi/min}$$

5. Using the results from steps 3 and 4, solve for $\Delta t_{3\text{ mi}}$: $\Delta t_{3\text{ mi}} = \dfrac{\Delta x_2}{v_{\text{usual }x}} = \dfrac{3.0\text{ mi}}{0.50\text{ mi/min}} = 6.0\text{ min}$

6. Solve for the total time: $\Delta t_{\text{tot}} = \Delta t_{2\text{ mi}} + \Delta t_{3\text{ mi}} = 12\text{ min}$

7. The trip takes 12 min with the delay, compared to the usual 10 min. Because you wisely allowed yourself 15 min for the trip, $\boxed{\textit{you will not be late for class}}$.

CHECK Note that 20 mi/h = 20 mi/60 min = 1.0 mi/3.0 min. Traveling the entire 5.0 miles at one mile every three minutes, it would take 15 minutes for the trip to school. You allowed yourself 15 minutes for the trip, so you would get there on time even if you traveled at the slow speed of 20 mi/h for the entire 5.0 miles.

Example 2-4 A Train-Hopping Bird

Two trains 60 km apart approach each other on parallel tracks, each moving at 15 km/h. A bird flies back and forth between the trains at 20 km/h until the trains pass each other. How far does the bird fly?

PICTURE In this problem, you are asked to find the total distance flown by the bird. You are given the bird's speed, the trains' speeds, and the initial distance between the trains. At first glance, it might seem like you should find and sum the distances flown by the bird each time it moves from one train to the other. However, a much simpler approach is to use the facts that the time t the bird is flying is the time taken for the trains to meet. The total distance flown is the bird's speed multiplied by the time the bird is flying. Therefore, we can approach this problem by first writing an equation for the quantity to be found, the total distance s flown by the bird.

SOLVE

1. The total distance s_{bird} traveled by the bird equals its speed times the time of flight:

$$s_{\text{bird}} = (\text{average speed})_{\text{bird}} \times t = (\text{speed})_{\text{av bird}} \times t$$

2. The time t that the bird is in the air is the time taken for one of the trains to travel half the initial distance D separating the trains. (Because the trains are traveling at the same speed, each train travels half of the 60 km, which is 30 km, before they meet.):

$$\tfrac{1}{2}D = (\text{speed})_{\text{av train}} \times t$$

so

$$t = \frac{D}{2(\text{speed})_{\text{av train}}}$$

3. Substitute the step-2 result for the time into the step-1 result. The initial separation of the two trains is $D = 60$ km. The total distance traveled by the bird is therefore:

$$s_{\text{bird}} = (\text{speed})_{\text{av bird}}\, t = (\text{speed})_{\text{av bird}} \frac{D}{2(\text{speed})_{\text{av train}}}$$

$$= 20\text{ km/h}\,\frac{60\text{ km}}{2\,(15\text{ km/h})} = \boxed{40\text{ km}}$$

CHECK The speed of each train is three-fourths the speed of the bird, so the distance traveled by one of the trains will be three-fourths the distance the bird travels. Each train travels 30 km. Because 30 km is three-fourths of 40 km, our result of 40 km for the distance the bird travels is very plausible.

INSTANTANEOUS VELOCITY AND SPEED

Suppose your average velocity for a long trip was 60 km/h. Because this value is an average, it does not convey any information about how your velocity changed during the trip. For example, there may have been some parts of the journey where you were stopped at a traffic light and other parts where you went faster to make up time. To learn more about the details of your motion, we have to look at the velocity at any given instant during the trip. On first consideration, defining the velocity of a particle at a single instant might seem impossible. At a given instant, a particle is at a single point. If it is at a single point, how can it be moving? If it is not moving, how can it have a velocity? This age-old paradox is resolved when we realize that observing and defining motion requires that we look at the position of the object at more than one instant of time. For example, consider the graph of position versus time in Figure 2-5. As we consider successively shorter time intervals beginning at t_P, the average velocity for the interval approaches the slope of the tangent at t_P. We define the slope of this tangent as the **instantaneous velocity,** $v_x(t)$, at t_P. This tangent is the limit of the ratio $\Delta x/\Delta t$ as Δt, and therefore Δx, approaches zero. So we can say:

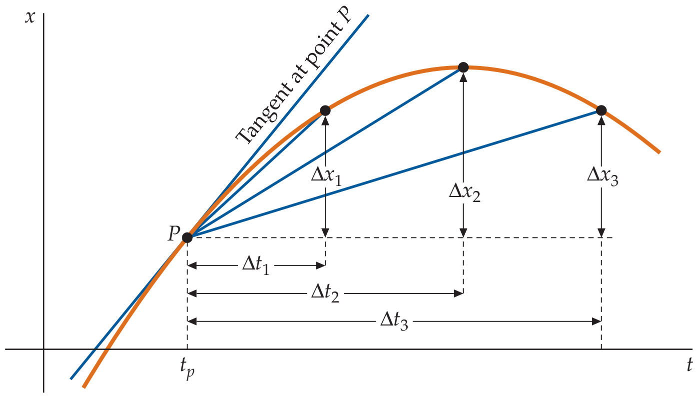

FIGURE 2-5 Graph of x versus t. Note the sequence of successively smaller time intervals, $\Delta t_3, \Delta t_2, \Delta t_1, \ldots$. The average velocity of each interval is the slope of the straight line for that interval. As the time intervals become smaller, these slopes approach the slope of the tangent to the curve at point t_P. The slope of this tangent line is defined as the instantaneous velocity at time t_P.

The instantaneous velocity v_x is the limit of the ratio $\Delta x/\Delta t$ as Δt approaches zero.

$$v_x(t) = \lim_{\Delta t \to 0} \frac{\Delta x}{\Delta t}$$

= slope of the line tangent to the x-versus-t curve 2-4

DEFINITION—INSTANTANEOUS VELOCITY

In calculus, this limit is called the **derivative** of x with respect to t and is written dx/dt. Using this notation, Equation 2-4 becomes:

$$v_x(t) = \lim_{\Delta t \to 0} \frac{\Delta x}{\Delta t} = \frac{dx}{dt} \qquad 2\text{-}5$$

See* Math Tutorial *for more information on

Differential Calculus

A line's slope may be positive, negative, or zero; consequently, instantaneous velocity (in one-dimensional motion) may be positive (x increasing), negative (x decreasing), or zero (no motion). For an object moving with constant velocity, the object's instantaneous velocity is equal to its average velocity. The position versus time graph of this motion (Figure 2-6) will be a straight line whose slope equals the velocity.

The instantaneous velocity is a vector, and the magnitude of the instantaneous velocity is the **instantaneous speed.** Throughout the rest of the text, we shall use "velocity" in place of "instantaneous velocity" and "speed" in place of "instantaneous speed," except when emphasis or clarity is better served by the use of the adjective "instantaneous."

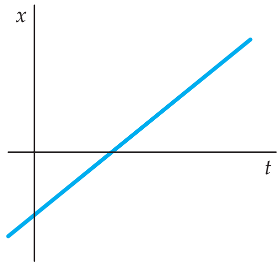

FIGURE 2-6 The position-versus-time graph for a particle moving at constant velocity.

Example 2-5 Position of a Particle as a Function of Time *Try It Yourself*

The position of a particle as a function of time is given by the curve shown in Figure 2-7. Find the instantaneous velocity at time $t = 1.8$ s. When is the velocity greatest? When is it zero? Is it ever negative?

PICTURE In Figure 2-7, we have sketched the line tangent to the curve at $t = 1.8$ s. The tangent line's slope is the instantaneous velocity of the particle at the given time. You can measure the slope of the tangent line directly off this figure.

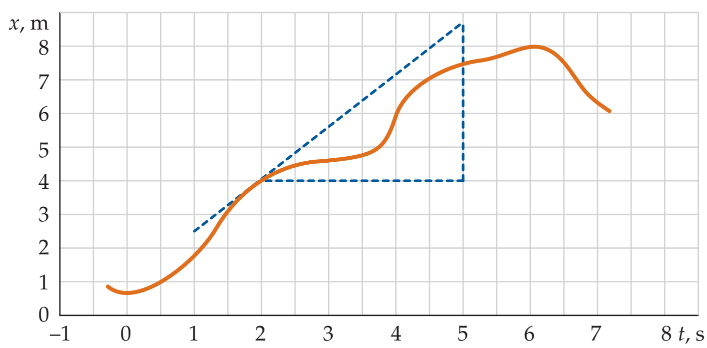

FIGURE 2-7

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. Find the values x_1 and x_2 for the points on the tangent line at times $t_1 = 2.0$ s and $t_2 = 5.0$ s.	$x_1 \approx 4.0\text{ m}$, $x_2 \approx 8.5\text{ m}$
2. Compute the slope of the tangent line from these values. This slope equals the instantaneous velocity at $t = 2.0$ s.	$v_x = \text{slope} \approx \dfrac{8.5\text{ m} - 4.0\text{ m}}{5.0\text{ s} - 2.0\text{ s}} = \boxed{1.5\text{ m/s}}$
3. From the figure, the tangent line is steepest, and, therefore, the slope is greatest at about $t = 4.0$ s. The velocity is $\boxed{\text{greatest at } t \approx 4.0\text{ s}}$. The slope and the velocity both are $\boxed{\text{zero at } t = 0.0 \text{ and } t = 6.0\text{ s}}$ and are $\boxed{\text{negative for } t < 0.0 \text{ and } t > 6.0\text{ s}}$.	

CHECK The position of the particle changes from about 1.8 m at 1.0 s to 4.0 m at 2.0 s, so the average velocity for the interval from 1.0 s to 2.0 s is 2.2 m/s. This is the same order of magnitude as the value for the instantaneous velocity at 1.8 s, so the step-2 result is plausible.

PRACTICE PROBLEM 2-1 Estimate the average velocity of this particle between $t = 2.0$ s and $t = 5.0$ s.

Example 2-6 A Stone Dropped from a Cliff

The position of a stone dropped from a cliff is described approximately by $x = 5t^2$, where x is in meters and t is in seconds. The $+x$ direction is downwards and the origin is at the top of the cliff. Find the velocity of the stone during its fall as a function of time t.

PICTURE We can compute the velocity at some time t by computing the derivative dx/dt directly from the definition in Equation 2-4. The corresponding curve giving x versus t is shown in Figure 2-8. Tangent lines are drawn at times t_1, t_2, and t_3. The slopes of these tangent lines increase steadily with increasing time, indicating that the instantaneous velocity increases steadily with time.

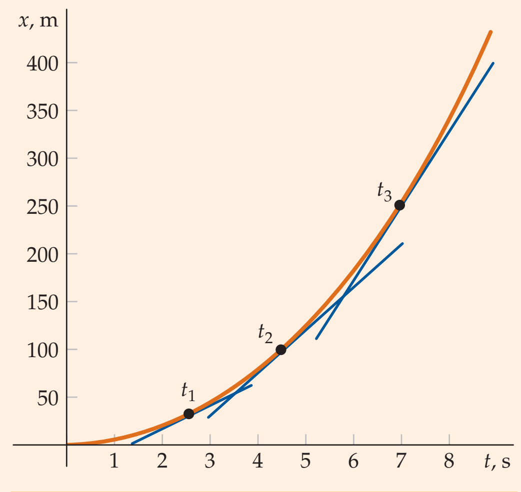

FIGURE 2-8

SOLVE

1. By definition the instantaneous velocity is	$v_x(t) = \lim\limits_{\Delta t \to 0} \dfrac{\Delta x}{\Delta t} = \lim\limits_{\Delta t \to 0} \dfrac{x(t + \Delta t) - x(t)}{\Delta t}$
2. We compute the displacement Δx from the position function $x(t)$:	$x(t) = 5t^2$
3. At a later time $t + \Delta t$, the position is $x(t + \Delta t)$, given by:	$x(t + \Delta t) = 5(t + \Delta t)^2 = 5[t^2 + 2t\,\Delta t + (\Delta t)^2] = 5t^2 + 10t\,\Delta t + 5(\Delta t)^2$
4. The displacement for this time interval is thus:	$\Delta x = x(t + \Delta t) - x(t) = [5t^2 + 10t\,\Delta t + 5(\Delta t)^2] - 5t^2 = 10t\,\Delta t + 5(\Delta t)^2$
5. Divide Δx by Δt to find the average velocity for this time interval:	$v_{\text{av}\,x} = \dfrac{\Delta x}{\Delta t} = \dfrac{10t\,\Delta t + 5(\Delta t)^2}{\Delta t} = 10t + 5\,\Delta t$
6. As we consider shorter and shorter time intervals, Δt approaches zero and the second term $5\Delta t$ approaches zero, though the first term, $10t$, remains unchanged:	$v_x(t) = \lim\limits_{\Delta t \to 0} \dfrac{\Delta x}{\Delta t} = \lim\limits_{\Delta t \to 0} (10t + 5\,\Delta t) = \boxed{10t}$ where v_x is in m/s and t is in s.

CHECK The stone starts at rest and goes faster and faster as it moves in the positive direction. Our result for the velocity, $v_x = 10t$, is zero at $t = 0$ and gets larger as t increases. Thus, $v_x = 10t$ is a plausible result.

TAKING IT FURTHER If we had set $\Delta t = 0$ in steps 4 and 5, the displacement would be $\Delta x = 0$, in which case the ratio $\Delta x/\Delta t$ would be undefined. Instead, we leave Δt as a variable until the final step, when the limit $\Delta t \to 0$ is well defined.

To find derivatives quickly, we use rules based on the limiting process above (see Appendix Table A-4). A particularly useful rule is

$$\text{If} \quad x = Ct^n, \quad \text{then} \quad \frac{dx}{dt} = Cnt^{n-1} \tag{2-6}$$

where C and n are any constants. Using this rule in Example 2-6, we have $x = 5t^2$ and $v_x = dx/dt = 10t$, in agreement with our previous results.

2-2 ACCELERATION

When you step on your car's gas pedal or brake, you expect your velocity to change. An object whose velocity changes is said to be accelerating. **Acceleration** is the rate of change of velocity with respect to time. The **average acceleration,** $a_{\text{av}\,x}$, for a particular time interval Δt is defined as the change in velocity, $\Delta \boldsymbol{v}$, divided by that time interval:

$$a_{\text{av}\,x} = \frac{\Delta v_x}{\Delta t} = \frac{v_{\text{f}\,x} - v_{\text{i}\,x}}{t_\text{f} - t_\text{i}} \qquad (\text{so } \Delta v_x = a_{\text{av}\,x}\,\Delta t) \tag{2-7}$$

DEFINITION—AVERAGE ACCELERATION

Notice that acceleration has the dimensions of velocity (L/T) divided by time (T), which is the same as length divided by time squared (L/T^2). The SI unit is meters per second squared, m/s^2. Furthermore, like displacement and velocity, acceleration is a vector quantity. For one-dimensional motion, we can use $+$ and $-$ to indicate the direction of the acceleration. Equation 2-7 tells us that for $a_{\text{av}\,x}$ to be positive, Δv_x must be positive, and for $a_{\text{av}\,x}$ to be negative, Δv_x must be negative.

Instantaneous acceleration is the limit of the ratio $\Delta v_x/\Delta t$ as Δt approaches zero. On a plot of velocity versus time, the instantaneous acceleration at time t is the slope of the line tangent to the curve at that time:

$$a_x = \lim_{\Delta t \to 0} \frac{\Delta v_x}{\Delta t}$$

$$= \text{slope of the line tangent to the } v\text{-versus-}t \text{ curve} \tag{2-8}$$

DEFINITION—INSTANTANEOUS ACCELERATION

! Deceleration does not mean the acceleration is negative. Deceleration does mean that v_x and a_x have opposite signs.

Thus, acceleration is the derivative of velocity v_x with respect to time, dv_x/dt. Because velocity is the derivative of the position x with respect to t, acceleration is the second derivative of x with respect to t, d^2x/dt^2. We can see the reason for this notation when we write the acceleration as dv_x/dt and replace v_x with dx/dt:

$$a_x = \frac{dv_x}{dt} = \frac{d(dx/dt)}{dt} = \frac{d^2x}{dt^2} \tag{2-9}$$

Notice that when the time interval becomes extremely small, the average acceleration and the instantaneous acceleration become equal. Therefore, we will use the word acceleration to mean "instantaneous acceleration."

It is important to note that the sign of an object's acceleration does not tell you whether the object is speeding up or slowing down. To determine this, you need to compare the signs of both the velocity and the acceleration of the object. If v_x and a_x are both positive, v_x is positive and becoming more positive so the speed is increasing. If v_x and a_x are both negative, v_x is negative and becoming more negative so the speed is again increasing. When v_x and a_x have opposite signs, the object is slowing down. If v_x is positive and a_x is negative, v_x is positive but is becoming less positive

CONCEPT CHECK 2-1

You are following the car in front of you at high speed when the driver of the car in front of you brakes hard, bringing his car to a stop to avoid running over a huge pothole. Three tenths of a second after you see the brake lights on the lead car flash, you too brake hard. Assume that the two cars are initially traveling at the same speed, and that once both cars are braking hard, they lose speed at the same rate. Does the distance between the two cars remain constant while the two cars are both braking hard?

so the speed is decreasing. If v_x is negative and a_x is positive, v_x is negative but is becoming less negative so the speed is again decreasing. In summary, if v_x and a_x have the same sign, the speed is increasing; if v_x and a_x have opposite signs, the speed is decreasing. When an object is slowing down, we sometimes say it is decelerating.

If acceleration remains zero, there is no change in velocity over time—velocity is constant. In this case, the plot of x versus t is a straight line. If acceleration is nonzero and constant, as in Example 2-13 , then velocity varies linearly with time and x varies quadratically with time.

Example 2-7 A Fast Cat

A cheetah can accelerate from 0 to 96 km/h (60 mi/h) in 2.0 s, whereas a Corvette requires 4.5 s. Compute the average accelerations for the cheetah and Corvette and compare them with the free-fall acceleration, $g = 9.81\ \text{m/s}^2$.

(Gunther Ziesler/Peter Arnold.)

PICTURE Because we are given the initial and final velocities, as well as the change in time for both the cat and the car, we can simply use Equation 2-7 to find the acceleration for each object.

SOLVE

1. Convert 96 km/h into a velocity of m/s:

$$96\ \frac{\cancel{\text{km}}}{\cancel{\text{h}}}\left(\frac{1\ \cancel{\text{h}}}{3600\ \text{s}}\right)\left(\frac{1000\ \text{m}}{1\ \cancel{\text{km}}}\right) = 26.7\ \text{m/s}$$

2. Find the average acceleration from the information given:

$$\text{cat}\quad a_{\text{av}\,x} = \frac{\Delta v_x}{\Delta t} = \frac{26.7\ \text{m/s} - 0}{2.0\ \text{s}} = 13.3\ \text{m/s}^2 = \boxed{13\ \text{m/s}^2}$$

$$\text{car}\quad a_{\text{av}\,x} = \frac{\Delta v_x}{\Delta t} = \frac{26.7\ \text{m/s} - 0}{4.5\ \text{s}} = 5.93\ \text{m/s}^2 = \boxed{5.9\ \text{m/s}^2}$$

3. To compare the result with the acceleration due to gravity, multiply each by the conversion factor $1g/9.81\ \text{m/s}^2$:

$$\text{cat}\quad 13.3\ \text{m/s}^2 \times \frac{1g}{9.81\ \text{m/s}^2} = 1.36g = \boxed{1.4g}$$

$$\text{car}\quad 5.93\ \text{m/s}^2 \times \frac{1g}{9.81\ \text{m/s}^2} = 0.604g = \boxed{0.60g}$$

CHECK Because the car takes slightly more than twice as long as the cheetah to accelerate to the same velocity, it makes sense that the car's acceleration is slightly less than half that of the cat's.

TAKING IT FURTHER To reduce round-off errors, calculations are carried out using values with at least three digits even though the answers are reported using only two significant digits. These extra digits used in the calculations are called *guard digits.*

PRACTICE PROBLEM 2-2 A car is traveling at 45 km/h at time $t = 0$. It accelerates at a constant rate of 10 km/(h·s). (*a*) How fast is it traveling at $t = 2.0$ s? (*b*) At what time is the car traveling at 70 km/h?

Example 2-8 Velocity and Acceleration as Functions of Time

The position of a particle is given by $x = Ct^3$, where C is a constant. Find the dimensions of C. In addition, find both the velocity and the acceleration as functions of time.

PICTURE We can find the velocity by applying $dx/dt = Cnt^{n-1}$ (Equation 2-6) to the position of the particle, where n in this case equals 3. Then, we repeat the process to find the time derivative of velocity.

SOLVE

1. The dimensions of x and t are L and T, respectively:

$$C = \frac{x}{t^3} \Rightarrow [C] = \frac{[x]}{[t]^3} = \boxed{\frac{\text{L}}{\text{T}^3}}$$

2. We find the velocity by applying $dx/dt = Cnt^{n-1}$ (Equation 2-6):

$$x = Ct^n = Ct^3$$

$$v_x = \frac{dx}{dt} = Cnt^{n-1} = C3t^{3-1} = \boxed{3Ct^2}$$

3. The time derivative of velocity gives the acceleration: $a = \dfrac{dv_x}{dt} = Cnt^{n-1} = 3C(2)(t^{2-1}) = \boxed{6Ct}$

CHECK We can check the dimensions of our answers. For velocity, $[v_x] = [C][t^2] = (\mathrm{L/T^3})(\mathrm{T^2}) = \mathrm{L/T}$. For acceleration, $[a_x] = [C][t] = (\mathrm{L/T^3})(\mathrm{T}) = \mathrm{L/T^2}$.

PRACTICE PROBLEM 2-3 If a car starts from rest at $x = 0$ with constant acceleration a_x, its velocity v_x depends on a_x and the distance traveled x. Which of the following equations has the correct dimensions and therefore could possibly be an equation relating x, a_x, and v_x?

(*a*) $v_x = 2a_x x$ (*b*) $v_x^2 = 2a_x/x$ (*c*) $v_x = 2a_x x^2$ (*d*) $v_x^2 = 2a_x x$

MOTION DIAGRAMS

In studying physics, you will often wish to estimate the direction of the acceleration vector from a description of the motion. Motion diagrams can help. In a motion diagram the moving object is drawn at a sequence of equally spaced time intervals. For example, suppose you are on a trampoline and, following a high bounce, you are falling back toward the trampoline. As you descend, you keep going faster and faster. A motion diagram of this motion is shown in Figure 2-9*a*. The dots represent your position at equally spaced time intervals, so the space between successive dots increases as your speed increases. The numbers placed next to the dots are there to indicate the progression of time and an arrow representing your velocity is drawn next to each dot. The direction of each arrow represents the direction of your velocity at that instant, and the length of the arrow represents how fast you are going. Your acceleration vector* is in the direction that your velocity vector is changing—which is downward. In general, if the velocity arrows get longer as time progresses, then the acceleration is in the same direction of the velocity. On the other hand, if the velocity arrows get shorter as time progresses (Figure 2-9*b*), the acceleration is in the direction opposite to that of the velocity. Figure 2-9*b* is a motion diagram of your motion as you rise toward the ceiling following a bounce on the trampoline.

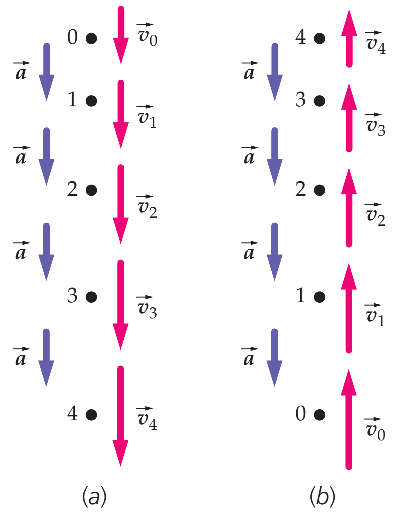

FIGURE 2-9 Motion diagrams. The time intervals between successive dots are identical. (*a*) The velocity vector is increasing, so the acceleration is in the direction of the velocity vector. (*b*) The velocity vector is decreasing, so the acceleration is in the direction opposite to that of the velocity vector.

2-3 MOTION WITH CONSTANT ACCELERATION

The motion of a particle that has nearly constant acceleration is found in nature. For example, near Earth's surface all unsupported objects fall vertically with nearly constant acceleration (provided air resistance is negligible). Other examples of near constant acceleration might include a plane accelerating along a runway for takeoff, and the motion of a car braking for a red light or speeding up at a green light. For a moving particle, the final velocity v_x equals the initial velocity plus the change in velocity, and the change in velocity equals the average acceleration multiplied by the time. That is,

$$v_x = v_{0x} + \Delta v = v_{0x} + a_{\mathrm{av}\,x}\,\Delta t \qquad 2\text{-}10$$

If a particle has constant acceleration a_x, it follows that the instantaneous acceleration and the average acceleration are equal. That is,

$$a_x = a_{\mathrm{av}\,x} \qquad (a_x \text{ is constant}) \qquad 2\text{-}11$$

Because situations involving nearly constant acceleration are common, we can use the equations for acceleration and velocity to derive a special set of **kinematic equations** for problems involving one-dimensional motion at constant acceleration.

* The velocity vector and the acceleration vector were introduced in Chapter 1 and are further developed in Chapter 3.

DERIVING THE CONSTANT-ACCELERATION KINEMATIC EQUATIONS

Suppose a particle moving with constant acceleration a_x has a velocity v_{0x} at time $t_0 = 0$, and v_x at some later time t. Combining Equations 2-10 and 2-11, we have

$$v_x = v_{0x} + a_x t \qquad (a_x \text{ is constant}) \tag{2-12}$$

CONSTANT ACCELERATION: $v_x(t)$

A v_x-versus-t plot (Figure 2-10) of this equation is a straight line. The line's slope is the acceleration a_x.

To obtain an equation for the position x as a function of time, we first look at the special case of motion with a constant velocity $v_x = v_{0x}$ (Figure 2-11). The change in position Δx during an interval of time Δt is

$$\Delta x = v_{0x}\,\Delta t \qquad (a_x = 0)$$

The area of the shaded rectangle under the v_x-versus-t curve (Figure 2-11*a*) is its height v_{0x} times its width Δt, so the area under the curve is the displacement Δx. If v_{0x} is negative (Figure 2-11*b*), both the displacement Δx and the area under the curve are negative. We normally think of area as a quantity that cannot be negative. However, in this context that is not the case. If v_{0x} is negative, the "height" of the curve is negative and the "area under the curve" is the negative quantity $v_{0x}\,\Delta t$.

The geometric interpretation of the displacement as the area under the v_x-versus-t curve is true not only for constant velocity, but it is true in general, as illustrated in Figure 2-12. To show that this statement is true, we first divide the time interval into numerous small intervals, Δt_1, Δt_2, and so on. Then, we draw a set of rectangles as shown. The area of the rectangle corresponding to the ith time interval Δt_i (shaded in the figure) is $v_i\,\Delta t_i$, which is approximately equal

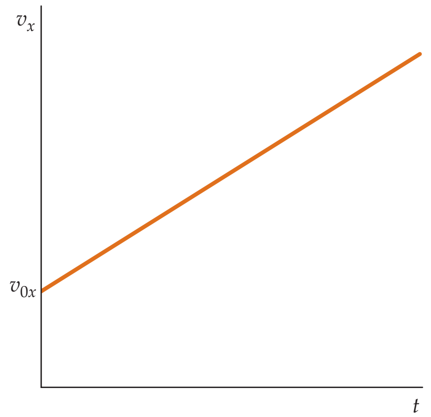

FIGURE 2-10 Graph of velocity versus time for constant acceleration.

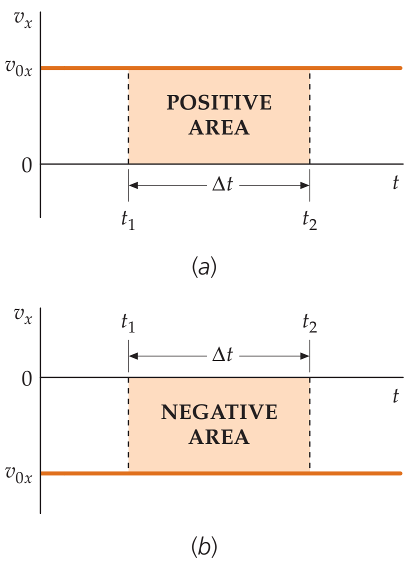

FIGURE 2-11 Motion with constant velocity.

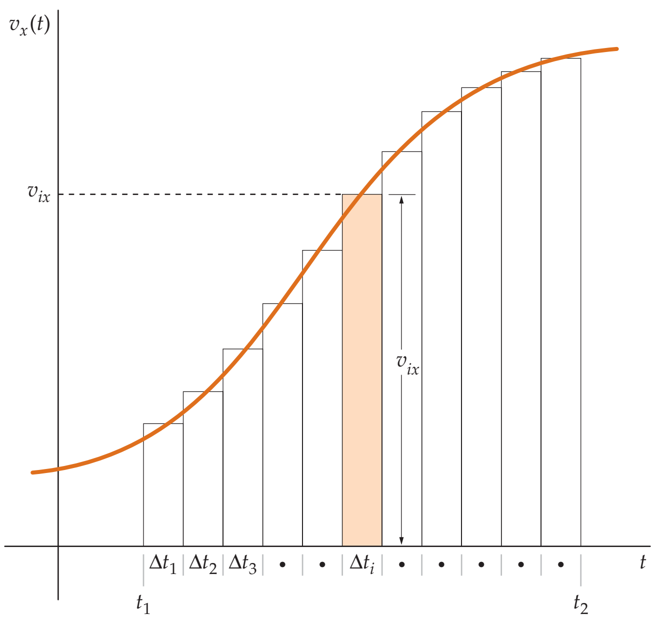

FIGURE 2-12 Graph of a general $v_x(t)$-versus-t curve. The total displacement from t_1 to t_2 is the area under the curve for this interval, which can be approximated by summing the areas of the rectangles.

to the displacement Δx_i during the interval Δt_i. The sum of the rectangular areas is therefore approximately the sum of the displacements during the time intervals and is approximately equal to the total displacement from time t_1 to t_2. We can make the approximation as accurate as we wish by putting enough rectangles under the curve, each rectangle having a sufficiently small value for Δt. For the limit of smaller and smaller time intervals (and more and more rectangles), the resulting sum approaches the area under the curve, which in turn equals the displacement. The displacement Δx is thus the area under the v_x-versus-t curve.

For motion with constant acceleration (Figure 2-13*a*), Δx is equal to the area of the shaded region. This region is divided into a rectangle and a triangle of areas $v_{1x}\,\Delta t$ and $\frac{1}{2}a_x(\Delta t)^2$, respectively, where $\Delta t = t_2 - t_1$. It follows that

$$\Delta x = v_{1x}\,\Delta t + \tfrac{1}{2}a_x(\Delta t)^2 \qquad 2\text{-}13$$

If we set $t_1 = 0$ and $t_2 = t$, then Equation 2-13 becomes

$$x - x_0 = v_{0x}t + \tfrac{1}{2}a_x t^2 \qquad 2\text{-}14$$

CONSTANT ACCELERATION: $x(t)$

where x_0 and v_{0x} are the position and velocity at time $t = 0$, and $x = x(t)$ is the position at time t. The first term on the right, $v_{0x}t$, is the displacement that would occur if a_x were zero, and the second term, $\frac{1}{2}a_x t^2$, is the additional displacement due to the constant acceleration.

We next use Equations 2-12 and 2-14 to obtain two additional kinematic equations for constant acceleration. Solving Equation 2-12 for t, and substituting for t, in Equation 2-14 gives

$$\Delta x = v_{0x}\frac{v_x - v_{0x}}{a_x} + \frac{1}{2}a_x\left(\frac{v_x - v_{0x}}{a_x}\right)^2$$

Multiplying both sides by $2a_x$ we obtain

$$2a_x\,\Delta x = 2v_{0x}(v_x - v_{0x}) + (v_x - v_{0x})^2$$

Simplifying and rearranging terms gives

$$v_x^2 = v_{0x}^2 + 2a_x\,\Delta x \qquad 2\text{-}15$$

CONSTANT ACCELERATION: $v_x(x)$

The definition of average velocity (Equation 2-3) is:

$$\Delta x = v_{\text{av}\,x}\,\Delta t$$

where $v_{\text{av}\,x}\,\Delta t$ is the area under the horizontal line at height $v_{\text{av}\,x}$ in Figure 2-13*b* and Δx is the area under the v_x versus t curve in Figure 2-13*a*. We can see that if $v_{\text{av}\,x} = \frac{1}{2}(v_{1x} + v_{2x})$, the area under the line at height v_{av} in Figure 2-13*a* and the area under the v_x versus t curve in Figure 2-13*b* will be equal. Thus,

$$v_{\text{av}\,x} = \tfrac{1}{2}(v_{1x} + v_{2x}) \qquad 2\text{-}16$$

CONSTANT ACCELERATION: $v_{\text{av}\,x}$ AND v_x

For motion with constant acceleration, the average velocity is the mean of the initial and final velocities.

For an example of an instance where Equation 2-16 is not applicable, consider the motion of a runner during a 10.0-km run that takes 40.0 min to complete. The

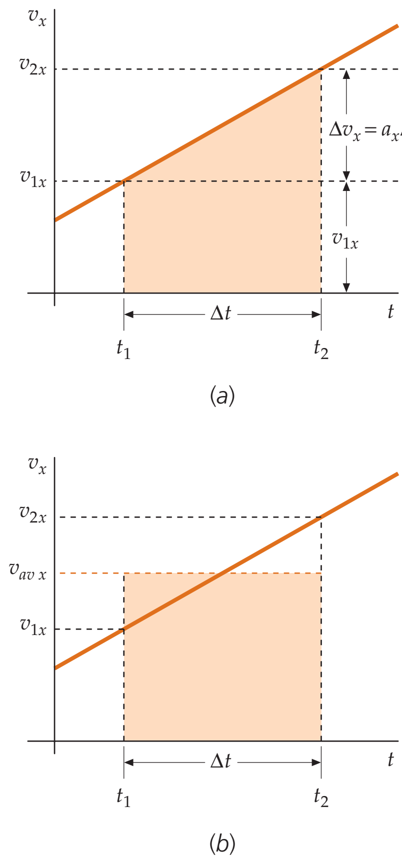

FIGURE 2-13 Motion with constant acceleration.

"It goes from zero to 60 in about 3 seconds." (*© Sydney Harris.*)

! Equation 2-16 is applicable only for time intervals during which the acceleration remains constant.

average velocity for the run is 0.250 km/min, which we compute using the definition of average velocity ($v_{\text{av }x} = \Delta x/\Delta t$). The runner starts from rest ($v_{1x} = 0$), and during the first one or two seconds his velocity increases rapidly, reaching a constant value v_{2x} that is sustained for the remainder of the run. The value of v_{2x} is just slightly greater than 0.250 km/min, so Equation 2-16 gives a value of about 0.125 km/min for the average velocity, a value almost 50% below the value given by the definition of average velocity. Equation 2-16 is not applicable because the acceleration does not remain constant for the entire run.

Equations 2-12, 2-14, 2-15, and 2-16 can be used to solve kinematics problems involving one-dimensional motion with constant acceleration. The choice of which equation or equations to use for a particular problem depends on what information you are given in the problem and what you are asked to find. Equation 2-15 is useful, for example, if we want to find the final velocity of a ball dropped from rest at some height x and we are not interested in the time the fall takes.

A falling apple captured by strobe photography at 60 flashes per second. The acceleration of the apple is indicated by the widening of the spaces between the images. *(Estate of Harold E. Edgerton/Palm Press.)*

USING THE CONSTANT-ACCELERATION KINEMATIC EQUATIONS

Review the Problem-Solving Strategy for solving problems using kinematic equations. Then, examine the examples involving one-dimensional motion with constant acceleration that follow.

PROBLEM-SOLVING STRATEGY

1-D Motion with Constant Acceleration

PICTURE Determine if a problem is asking you to find the time, distance, velocity, or acceleration for an object.

SOLVE Use the following steps to solve problems that involve one-dimensional motion and constant acceleration.

1. Draw a figure showing the particle in its initial and final positions. Include a coordinate axis and label the initial and final coordinates of the position. Indicate the + and − directions for the axis. Label the initial and final velocities, and label the acceleration.
2. Select one of the constant-acceleration kinematic equations (Equations 2-12, 2-14, 2-15, and 2-16). Substitute the given values into the selected equation and, if possible, solve for the desired value.
3. If necessary, select another of the constant-acceleration kinematic equations, substitute the given values into it, and solve for the desired value.

CHECK You should make sure that your answers are dimensionally consistent and the units of the answers are correct. In addition, check to make sure the magnitudes and signs of your answers agree with your expectations.

Problems with one object We will begin by looking at several examples that involve the motion of a single object.

Example 2-9 A Car's Stopping Distance

On a highway at night you see a stalled vehicle and brake your car to a stop. As you brake, the velocity of your car decreases at a constant rate of (5.0 m/s)/s. What is the car's stopping distance if your initial velocity is (*a*) 15 m/s (about 34 mi/h) or (*b*) 30 m/s?

PICTURE Use the Problem-Solving Strategy that precedes this example. The car is drawn as a dot to indicate a particle. We choose the direction of motion as $+x$ direction, and we choose the initial position $x_0 = 0$. The initial velocity is $v_{0x} = +15$ m/s and the final velocity $v_x = 0$. Because the velocity is decreasing, the acceleration is negative. It is $a_x = -5.0$ m/s². We seek the distance traveled, which is the magnitude of the displacement Δx. We are neither given nor asked for the time, so $v_x^2 = v_{0x}^2 + 2a_x\,\Delta x$ (Equation 2-15) will provide a one-step solution.

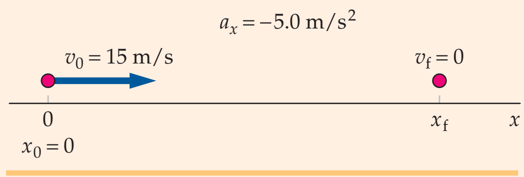

FIGURE 2-14

SOLVE

(*a*) 1. Draw the car (as a small dot) in its initial and final positions (Figure 2-14). Include a coordinate axis and label the drawing with the kinematic parameters.

2. Using Equation 2-15, calculate the displacement Δx:

$$v_x^2 = v_{0x}^2 + 2a_x\,\Delta x$$
$$0 = (15\text{ m/s})^2 + 2(-5.0\text{ m/s}^2)\Delta x$$
$$\Delta x = 22.5\text{ m} = \boxed{23\text{ m}}$$

(*b*) Substitute an initial speed of 30 m/s into the expression for Δx obtained in Part (*a*) (see Figure 2-14):

$$v_x^2 = v_{0x}^2 + 2a_x\,\Delta x$$
$$0 = (30\text{ m/s})^2 + 2(-5.0\text{ m/s}^2)\Delta x$$
$$\Delta x = \boxed{90\text{ m}}$$

CHECK The car's velocity decreases by 5.0 m/s each second. If its initial velocity is 15 m/s, it would take 3.0 s for it to come to rest. During the 3.0 s, it has an average velocity of half 15 m/s, so it would travel $\frac{1}{2}(15\text{ m/s})(3.0\text{ s}) = 23$ m. This confirms our Part (*a*) result. Our Part (*b*) result can be confirmed in the same manner.

Example 2-10 Stopping Distance *Try It Yourself*

In the situation described in Example 2-9, (*a*) how much time does it take for the car to stop if its initial velocity is 30 m/s, and (*b*) how far does the car travel in the last second?

PICTURE Use the Problem-Solving Strategy that precedes Example 2-9. (*a*) In this part of the problem, you are asked to find the time it takes the car to stop. You are given the initial velocity $v_{0x} = 30$ m/s. From Example 2-9, you know the car has an acceleration $a_x = -5.0$ m/s². A relationship between time, velocity, and acceleration is given by Equation 2-12. (*b*) Because the car's velocity decreases by 5.0 m/s each second, the velocity 1.0 s before the car stops must be 5.0 m/s. Find the average velocity during the last second and use that to find the distance traveled.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
(*a*) 1. Draw the car (as a small dot) in its initial and final positions (Figure 2-15). Include a coordinate axis and label the drawing with the kinematic parameters.	
2. Use Equation 2-12 to find the total stopping time Δt.	$\Delta t = \boxed{6.0\text{ s}}$
(*b*) 1. Draw the car (as a small dot) in its initial and final positions (Figure 2-16). Include a coordinate axis.	
2. Find the average velocity during the last second from $v_{\text{av}\,x} = \frac{1}{2}(v_{\text{i}\,x} + v_{\text{f}\,x})$.	$v_{\text{av}\,x} = 2.5$ m/s
3. Compute the distance traveled from $\Delta x = v_{\text{av}\,x}\,\Delta t$.	$\Delta x = v_{\text{av}\,x}\,\Delta t = \boxed{2.5\text{ m}}$

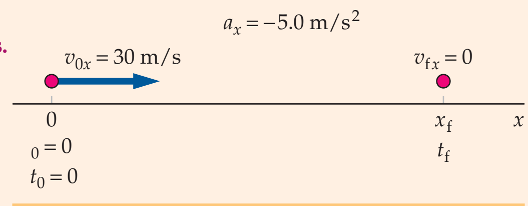

FIGURE 2-15

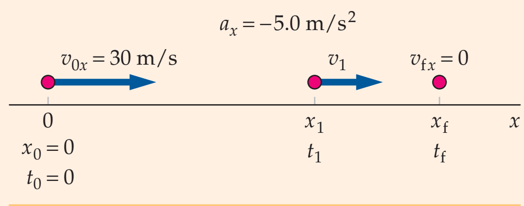

FIGURE 2-16

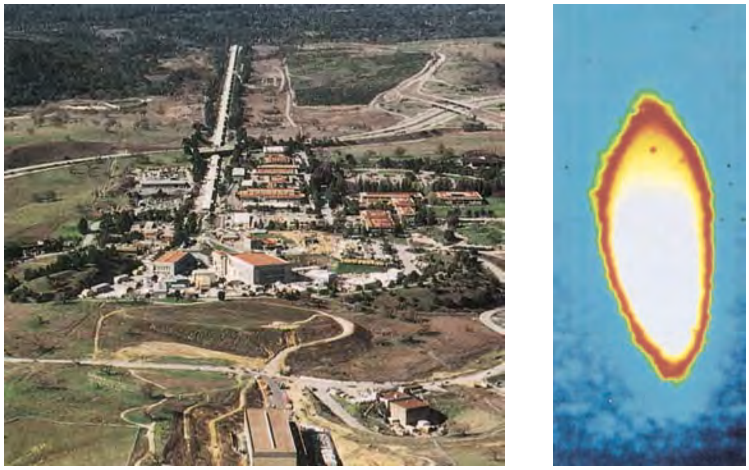
CHECK We would not expect the car to travel very far during the last second because it is moving relatively slowly. The Part (*b*) result of 2.5 m is a plausible result.

Example 2-11 A Traveling Electron

Try It Yourself

An electron in a cathode-ray tube accelerates from rest with a constant acceleration of $5.33 \times 10^{12}\ \mathrm{m/s^2}$ for $0.150\ \mu\mathrm{s}$ ($1\ \mu\mathrm{s} = 10^{-6}\ \mathrm{s}$). The electron then drifts with constant velocity for $0.200\ \mu\mathrm{s}$. Finally, it slows to a stop with an acceleration of $-2.67 \times 10^{13}\ \mathrm{m/s^2}$. How far does the electron travel?



The two-mile-long linear accelerator at Stanford University used to accelerate electrons and positrons in a straight line to nearly the speed of light. Cross section of the accelerator's electron beam as shown on a video monitor. *(Stanford Limear Accelerator, U.S. Department of Energy.)*

PICTURE The equations for constant acceleration do not apply to the full duration of the electron's motion because the acceleration changes twice during that time. However, we can divide the electron's motion into three intervals, each with a different constant acceleration, and use the final position and velocity for the first interval as the initial conditions for the second interval, and the final position and velocity for the second interval as the initial conditions for the third. Apply the Problem-Solving Strategy that precedes Example 2-9 to each of the three constant-acceleration intervals. We will choose the origin to be at the electron's starting position, and the $+x$ direction to be the direction of motion.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps

1. Draw the electron in its initial and final positions for each constant-acceleration interval (Figure 2-17). Include a coordinate axis and label the drawing with the kinematic parameters.

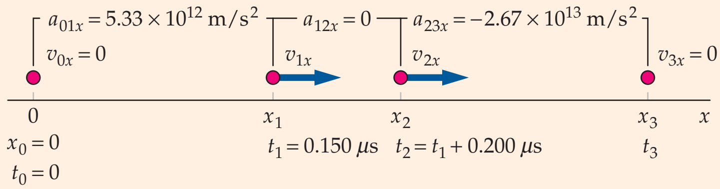


FIGURE 2-17

2. Set $v_{0x} = 0$ (because the electron starts from rest), use Equations 2-12 and 2-14 to find position x_1 and velocity v_{1x} at the end of the first 0.150-μs interval.
3. The acceleration is zero during the second interval, so the velocity remains constant.
4. The velocity remains constant during the second interval, so the displacement Δx_{12} equals the velocity v_{1x} multiplied by $0.200\ \mu\mathrm{s}$.
5. To find the displacement for the third interval, use Equation 2-15 with $v_{3x} = 0$.

Answers

$x_1 = 6.00\ \mathrm{cm}$, $v_{1x} = 8.00 \times 10^5\ \mathrm{m/s}$

$v_{2x} = v_{1x} = 8.00 \times 10^5\ \mathrm{m/s}$

$\Delta x_{12} = 16.0\ \mathrm{cm}$, so $x_2 = 22.0\ \mathrm{cm}$

$\Delta x_{23} = 1.20\ \mathrm{cm}$, so $x_3 = \boxed{23.2\ \mathrm{cm}}$

CHECK The average velocities are large, but the time intervals are small. Thus, the distances traveled are modest as we might expect.

Sometimes valuable insight can be gained about the motion of an object by asserting that the constant-acceleration formulas still apply even when the acceleration is not constant. The results are then estimates and not exact calculations. This is the case in the following example.

Example 2-12 The Crash Test

Context-Rich

In a crash test that you are performing, a car traveling 100 km/h (about 62 mi/h) hits an immovable concrete wall. What is the acceleration of the car during the crash?

(© 1994 General Motors Corporation, all rights reserved GM Archives.)

PICTURE In this example, different parts of the vehicle will have different accelerations as the car crumples to a halt. The front bumper stops virtually instantly while the rear bumper stops some time later. We will solve for the acceleration of a part of the car that is in the passenger compartment and out of the crumple zone. A bolt holding the driver's seat belt to the floor is such a part. We do not really expect the acceleration of this bolt to be constant. We need additional information to solve this problem–either the stopping distance or the stopping time. We can estimate the stopping distance using common sense. Upon impact, the center of the car will certainly move forward less than half the length of the car. We will choose 0.75 m as a reasonable estimate of the distance the center of the car will move during the crash. Because the problem neither asks for nor provides the time, we will use the equation $v_x^2 = v_{0x}^2 + 2a_x\,\Delta x$.

SOLVE

1. Draw the bolt (as a small circle) at the center of the car at its initial and final positions (Figure 2-18). Include a coordinate axis and label the drawing with the kinematic parameters.

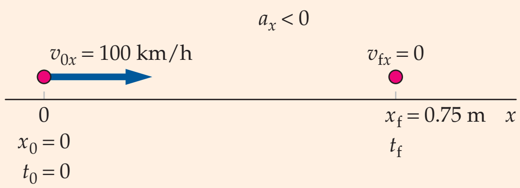

FIGURE 2-18

2. Convert the velocity from km/h to m/s.

$$(100\ \cancel{\text{km}}/\cancel{\text{h}}) \times \left(\frac{1\ \cancel{\text{h}}}{60\ \cancel{\text{min}}}\right) \times \left(\frac{1\ \cancel{\text{min}}}{60\ \text{s}}\right) \times \left(\frac{1000\ \text{m}}{1\ \cancel{\text{km}}}\right) = 27.8\ \text{m/s}$$

3. Using $v_x^2 = v_{0x}^2 + 2a_x\,\Delta x$, solve for the acceleration:

$$v_x^2 = v_{0x}^2 + 2a_x\,\Delta x$$

so

$$a_x = \frac{v_x^2 - v_{0x}^2}{2\Delta x} = \frac{0^2 - (27.8\ \text{m/s})^2}{2(0.75\ \text{m})}$$

4. Complete the calculation of the acceleration:

$$a_x = -\frac{(27.8\ \text{m/s})^2}{1.5\ \text{m}} = -514\ \text{m/s}^2 \approx \boxed{-500\ \text{m/s}^2}$$

CHECK The magnitude of the acceleration is about 50 times greater than the acceleration caused by the car breaking hard on a dry concrete road. The result is plausible because a large acceleration is expected for a high-speed head-on crash into an immovable object.

PRACTICE PROBLEM 2-4 Estimate the stopping time of the car.

Free-Fall Many practical problems deal with objects in free-fall, that is, objects that fall freely under the influence of gravity only. All objects in free-fall with the same initial velocity move identically. As shown in Figure 2-19, an apple and a feather, simultaneously released from rest in a large vacuum chamber, fall with identical motions. Thus, we know that the apple and the feather fall with the same acceleration. The magnitude of this acceleration, designated by g, has the approximate value $a = g \approx 9.81\ \text{m/s}^2 = 32.2\ \text{ft/s}^2$. If downward is designated as the $+y$ direction, then $a_y = +g$; if upward is designated as the $+y$ direction, then $a_y = -g$.

FIGURE 2-19 In a vacuum the apple and the feather, released simultaneously from rest, fall with identical motion. *(James Sugar/Black Star.)*

! Because g is the *magnitude* of the acceleration, g is *always* positive.

Example 2-13 The Flying Cap

Upon graduation, a joyful physics student throws her cap straight upward with an initial speed of 14.7 m/s. Given that its acceleration has a magnitude of 9.81 m/s² and is directed downward (we neglect air resistance), (*a*) how long does it take for the cap to reach its highest point? (*b*) What is the distance to the highest point? (*c*) Assuming the cap is caught at the same height from which it was released, what is the total time the cap is in flight?

PICTURE When the cap is at its highest point, its instantaneous velocity is zero. (When a problem specifies that an object is "at its highest point," translate this condition into the mathematical condition $v_y = 0$.)

SOLVE

(*a*) 1. Make a sketch of the cap in its initial position and again at its highest point (Figure 2-20). Include a coordinate axis and label the origin and the two specified positions of the cap.

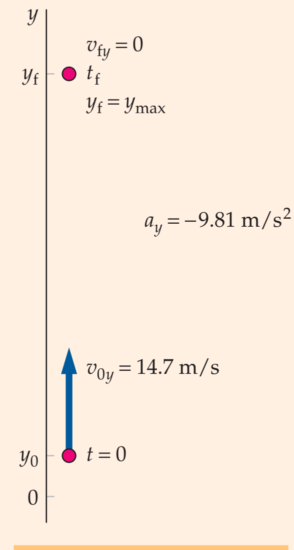

FIGURE 2-20

2. The time is related to the velocity and acceleration:

$$v_y = v_{0y} + a_y t$$

3. Set $v_y = 0$ and solve for t:

$$t = \frac{0 - v_{0y}}{a_y} = \frac{-14.7\ \text{m/s}}{-9.81\ \text{m/s}^2} = \boxed{1.50\ \text{s}}$$

(*b*) We can find the displacement from the time t and the average velocity:

$$\Delta y = v_{\text{av}\,y} t = \tfrac{1}{2}(v_{0y} + v_y)\Delta t$$
$$= \tfrac{1}{2}(14.7\ \text{m/s} + 0)(1.50\ \text{s}) = \boxed{11.0\ \text{m}}$$

(*c*) 1. Set $y = y_0$ in Equation 2-14 and solve for t:

$$\Delta y = v_{0_y} t + \tfrac{1}{2} a_y t^2$$
$$0 = (v_{0_y} + \tfrac{1}{2} a_y t)t$$

2. There are two solutions for t when $y = y_0$. The first corresponds to the time at which the cap is released, the second to the time at which the cap is caught:

$$t = 0 \qquad \text{(first solution)}$$
$$t = -\frac{2v_{0y}}{a_y} = -\frac{2(14.7\ \text{m/s})}{-9.81\ \text{m/s}^2} = \boxed{3.00\ \text{s}}$$
(second solution)

CHECK On the way up, the cap loses speed at the rate of 9.81 m/s each second. Because its initial speed is 14.7 m/s, we expect it rise for more than 1.00 s, but less than 2.00 s. Thus, a rise time of 1.50 s is quite plausible.

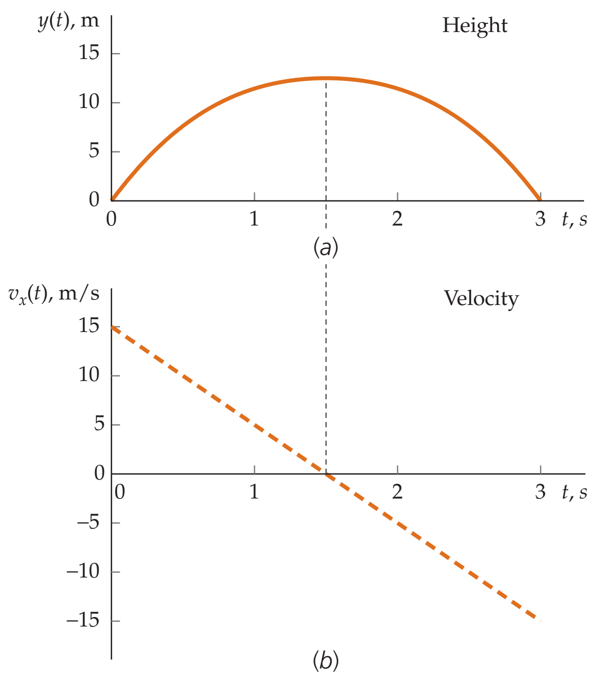

FIGURE 2-21 The height and velocity graphs are drawn one above the other so that both the height and the velocity can be observed at each instant of time.

TAKING IT FURTHER On the plot of velocity versus time (Figure 2-21*b*) note that the slope is the same at all times, including the instant that $v_y = 0$. The slope is equal to the instantaneous acceleration, which is a constant -9.81 m/s². On the plot of height versus time (Figure 2-21*a*), note that the rise time equals the fall time. In reality, the cap will not have a constant acceleration because air resistance has a significant effect on a light object like a cap. If air resistance is not negligible, the fall time will exceed the rise time.

PRACTICE PROBLEM 2-5 Find $y_{max} - y_0$ using Equation 2-15. Find the velocity of the cap when it returns to its starting point.

PRACTICE PROBLEM 2-6 What is the velocity of the cap at the following points in time? (*a*) 0.100 s before it reaches its highest point; (*b*) 0.100 s after it reaches its highest point. (*c*) Compute $\Delta v_y / \Delta t$ for this 0.200-s-long time interval.

Problems with two objects We now give some examples of problems involving two objects moving with constant acceleration.

Example 2-14 Catching a Speeding Car

A car is speeding at a constant 25 m/s (= 90 km/h ≈ 56 mi/h) in a school zone. A police car starts from rest just as the speeder passes by it and accelerates at a constant rate of 5.0 m/s². (*a*) When does the police car catch the speeding car? (*b*) How fast is the police car traveling when it catches up with the speeder?

PICTURE To determine when the two cars will be at the same position, we write the positions of the speeder x_S and of the police car x_P as functions of time and solve for the time t_c when $x_S = x_P$. Once we determine when the police car will catch up to the speeder, we can determine the velocity of the police car when it catches up to the speeder using the equation $v_x = a_x t$.

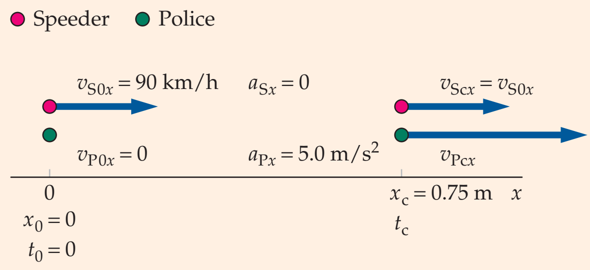

FIGURE 2-22 The speeder and the police car have the same position at $t = 0$ and again at $t = t_c$.

SOLVE

(*a*) 1. Draw the two cars at their initial positions (at $t = 0$) and again at their final positions (at $t = t_c$) (Figure 2-22). Include a coordinate axis and label the drawing with the kinematic parameters.

2. Write the position functions for the speeder and the police car:

$$x_S = v_{Sx}t \quad \text{and} \quad x_P = \tfrac{1}{2}a_{Px}t^2$$

3. Set $x_S = x_P$ and solve for the time t_c, for $t_c > 0$:

$$v_{Sx}t_c = \tfrac{1}{2}a_{Px}t_c^2 \Rightarrow v_{Sx} = \tfrac{1}{2}a_{Px}t_c \qquad t_c \neq 0$$

$$t_c = \frac{2v_{Sx}}{a_{Px}} = \frac{2(25\text{ m/s})}{5.0\text{ m/s}^2} = \boxed{10\text{ s}}$$

(*b*) The velocity of the police car is given by $v_x = v_{0x} + a_x t$, with $v_{0x} = 0$:

$$v_{Px} = a_{Px}t_c = (5.0\text{ m/s}^2)(10\text{ s}) = \boxed{50\text{ m/s}}$$

CHECK Notice that the final velocity of the police car in (*b*) is exactly twice that of the speeder. Because the two cars covered the same distance in the same time, they must have had the same average velocity. The speeder's average velocity, of course, is 25 m/s. For the police car to start from rest, maintain a constant acceleration, and have an average velocity of 25 m/s, it must reach a final velocity of 50 m/s.

PRACTICE PROBLEM 2-7 How far have the cars traveled when the police car catches the speeder?

Example 2-15 The Police Car — *Try It Yourself*

How fast is the police car in Example 2-14 traveling when it is 25 m behind the speeding car?

PICTURE The speed is given by $v_P = a_x t_1$, where t_1 is the time at which $x_S - x_P = 25$ m.

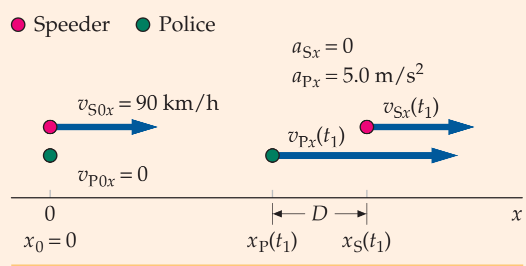

FIGURE 2-23

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps

1. Sketch an x-versus-t graph showing the positions of the two cars (Figure 2-23). On this graph identify the distance $D = x_S - x_P$ between the two cars at a given instant.

Answers

2. Using the equations for x_P and x_S from Example 2-14, solve for t_1 when $x_S - x_P = 25$ m. We expect two solutions, one shortly after the start time and one shortly before the speeder is caught. — $t_1 = (5 \pm \sqrt{15})$ s
3. Use $v_{P1} = a_{Px}t_1$ to compute the speed of the police car when $x_S - x_P = 25$ m. — $v_{P1} = \boxed{5.64\ \text{m/s}}$ and $\boxed{44.4\ \text{m/s}}$

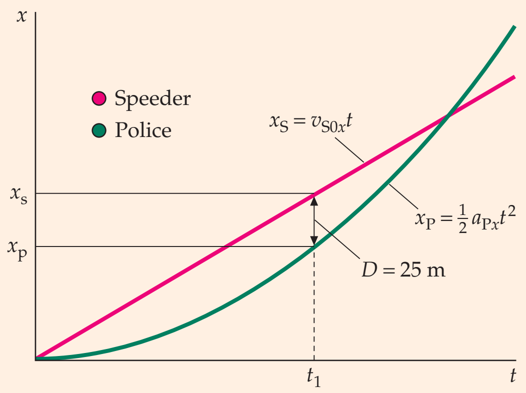

FIGURE 2-24

CHECK We see from Figure 2-24 that the distance between the cars starts at zero, increases to a maximum value, and then decreases. We would expect two speeds for a given separation distance.

TAKING IT FURTHER The separation at any time is $D = x_S - x_P = v_{Sx}t - \frac{1}{2}a_{Px}t^2$. At maximum separation, which occurs at $t = 5.0$ s, $dD/dt = 0$. At equal time intervals before and after $t = 5.0$ s, the separations are equal.

Example 2-16 A Moving Elevator

While standing in an elevator, you see a screw fall from the ceiling. The ceiling is 3.0 m above the floor. How long does it take the screw to hit the floor if the elevator is moving upward and gaining speed at a constant rate of 4.0 m/s² at the instant the screw leaves the ceiling?

PICTURE When the screw hits the floor, the positions of the screw and the floor are equal. Equate the these positions and solve for the time.

SOLVE

1. Draw a diagram showing the initial and final positions of the screw and the elevator floor (Figure 2-25). Include a coordinate axis and label the drawing with the kinematic parameters. The screw and the floor have the same initial velocity, but different accelerations. Choose the origin to be the initial position of the floor, and designate "upward" as the positive y direction. The screw hits the floor at time t_f:

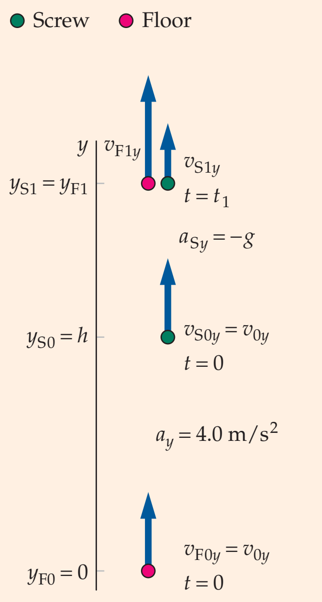

FIGURE 2-25 The y axis is fixed to the building.

2. Write equations specifying the *position* y_F of the elevator floor and the *position* y_S of the screw as functions of time. The screw and the elevator have the same initial velocity v_{0y}:

$$y_F - y_{F0} = v_{F0y}t + \tfrac{1}{2}a_{Fy}t^2$$
$$y_F - 0 = v_{0y}t + \tfrac{1}{2}a_{Fy}t^2$$
$$y_S - y_{S0} = v_{S0y}t + \tfrac{1}{2}a_{Sy}t^2$$
$$y_S - h = v_{0y}t + \tfrac{1}{2}(-g)t^2$$

3. Equate the expressions for y_S and y_F at $t = t_f$ and simplify:

$$y_S = y_F$$
$$h + v_{0y}t_f - \tfrac{1}{2}gt_f^2 = v_{0y}t_f + \tfrac{1}{2}a_{Fy}t_f^2$$
$$h - \tfrac{1}{2}gt_f^2 = \tfrac{1}{2}a_{Fy}t_f^2$$

4. Solve for the time and substitute the given values:

$$h = \tfrac{1}{2}(a_F + g)t_f^2 \quad \text{so}$$
$$t_f = \sqrt{\frac{2h}{a_F + g}} = \sqrt{\frac{2(3.0\ \text{m})}{4.0\ \text{m/s}^2 + 9.81\ \text{m/s}^2}} = 0.659\ \text{s} = \boxed{0.66\ \text{s}}$$

CHECK If the elevator was stationary, the distance the screw falls is given by $h = \frac{1}{2}gt_f^2$. With $h = 3.0$ m, the resulting fall time would be $t_f = 0.78$ s. Because of the elevator's upward acceleration, we would expect it to take less than 0.78 s for the screw to hit the floor. Our 0.66-s result meets this expectation.

Example 2-17 The Moving Elevator — *Try It Yourself*

Consider the elevator and screw in Example 2-16. Assume the velocity of the elevator is 16 m/s upward when the screw separates from the ceiling. (*a*) How far does the elevator rise while the screw is in freefall? What is the displacement of the screw during freefall? (*b*) What are the velocity of the screw and the velocity of the elevator at impact?

PICTURE The time of flight of the screw is obtained in the solution of Example 2-16. Use this time to solve Parts (*a*) and (*b*).

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
(*a*) 1. Using Equation 2-13, find the distance the floor rises between $t = 0$ and $t = t_f$, where t_f is calculated in step-4 of Example 2-16.	$\Delta y_F = v_{Fi}t_f + \frac{1}{2}a_F t_t^2 = \boxed{11.4\text{ m}}$
2. Between $t = 0$ and $t = t_f$, the displacement of the screw is less then that of the floor by 3.0 m.	$\Delta y_S = \boxed{+8.4\text{ m}}$
(*b*) Using $v_y = v_{0y} + a_y t$ (Equation 2-12), find the velocities of the screw and of the floor at impact.	$v_{Sy} = v_{Siy} - gt_f = \boxed{9.5\text{ m/s}}$ $v_{Fy} = v_{Fiy} + a_{Fy}t_f = \boxed{19\text{ m/s}}$

CHECK The Part (*b*) results (velocity of the screw and the velocity of the floor at impact) are both positive indicating both velocities are directed upward. For impact to occur, the floor must be moving upward faster then the screw so it can catch up with the screw. This result is consistent with our Part (*b*) results.

TAKING IT FURTHER The screw strikes the floor 8.4 m above its position when it leaves the ceiling. At impact, the velocity of the screw relative to the building is positive (upward). Relative to the building, the screw is still rising when it and the floor come in contact.

2-4 INTEGRATION

In this section, we use integral calculus to derive the equations of motion. A concise treatment of calculus can be found in the Math Tutorial.

To find the velocity from a given acceleration, we note that the velocity is the function $v_x(t)$ whose time derivative is the acceleration $a_x(t)$:

$$\frac{dv_x(t)}{dt} = a_x(t)$$

If the acceleration is constant, the velocity is that function of time which, when differentiated, equals this constant. One such function is

$$v_x = a_x t \qquad a_x \text{ is constant}$$

More generally, we can add any constant to $a_x t$ without changing the time derivative. Calling this constant c, we have

$$v_x = a_x t + c$$

When $t = 0$, $v_x = c$. Thus, c is the velocity v_{0x} at time $t = 0$.

Similarly, the position function $x(t)$ is that function whose derivative is the velocity:

$$\frac{dx}{dt} = v_x = v_{0x} + a_x t$$

We can treat each term separately. The function whose derivative is the constant v_{0x} is $v_{0x}t$ plus any constant. The function whose derivative is $a_x t$ is $\frac{1}{2}at^2$ plus any constant. Writing x_0 for the combined arbitrary constants, we have

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

When $t = 0$, $x = x_0$. Thus, x_0 is the position at time $t = 0$.

Whenever we find a function from its derivative, we must include an arbitrary constant in the general form of the function. Because we go through the integration process twice to find $x(t)$ from the acceleration, two constants arise. These constants are usually determined from the velocity and position at some given time, which is usually chosen to be $t = 0$. They are therefore called the **initial conditions.** A common problem, called the **initial-value problem,** takes the form "given $a_x(t)$ and the initial values of x and v_x, find $x(t)$." This problem is particularly important in physics because the acceleration of a particle is determined by the forces acting on it. Thus, if we know the forces acting on a particle and the position and velocity of the particle at some particular time, we can find its position and velocity at all other times.

A function $F(t)$ whose derivative (with respect to t) equals the function $f(t)$ is called the **antiderivative** of $f(t)$. (Because $v_x = dx/dt$ and $a_x = dv_x/dt$, x is the antiderivative of v_x and v_x is the antiderivative of a_x.) Finding the antiderivative of a function is related to the problem of finding the area under a curve.

In deriving Equation 2-14 it was shown that the change in position Δx is equal to the area under the velocity-versus-time curve. To show this (see Figure 2-12), we first divided the time interval into numerous small intervals, Δt_1, Δt_2, and so on. Then, we drew a set of rectangles as shown. The area of the rectangle corresponding to the ith time interval Δt_i (shaded in the figure) is $v_{ix}\,\Delta t_i$, which is approximately equal to the displacement Δx_i during the interval Δt_i. The sum of the rectangular areas is therefore approximately the sum of the displacements during the time intervals and is approximately equal to the total displacement from time t_1 to t_2. Mathematically, we write this as

$$\Delta x \approx \sum_i v_{ix}\,\Delta t_i$$

For the limit of smaller and smaller time intervals (and more and more rectangles), the resulting sum approaches the area under the curve, which in turn equals the displacement. The limit of the sum as Δt approaches zero (and the number of rectangles approaches infinity) is called an **integral** and is written

$$\Delta x = x(t_2) - x(t_1) = \lim_{\Delta t \to 0}\left(\sum_i v_{ix}\,\Delta t_i\right) = \int_{t_1}^{t_2} v_x\,dt \qquad \text{2-17}$$

See **Math Tutorial** *for more information on* **Integrals**

It is helpful to think of the integral sign $\int$ as an elongated S indicating a sum. The limits t_1 and t_2 indicate the initial and final values of the integration variable t.

The process of computing an integral is called **integration.** In Equation 2-17, v_x is the derivative of x, and x is the antiderivative of v_x. This is an example of the fundamental theorem of calculus, whose formulation in the seventeenth century greatly accelerated the mathematical development of physics. If

$$f(t) = \frac{dF(t)}{dt}, \quad \text{then} \quad F(t_2) - F(t_1) = \int_{t_1}^{t_2} f(t)\,dt \qquad \text{2-18}$$

FUNDAMENTAL THEOREM OF CALCULUS

The antiderivative of a function is also called the indefinite integral of the function and is written without limits on the integral sign, as in

$$x = \int v_x \, dt$$

Finding the function x from its derivative v_x (that is, finding the antiderivative) is also called integration. For example, if $v_x = v_{0x}$, a constant, then

$$x = \int v_{0x} \, dt = v_{0x} t + x_0$$

where x_0 is the arbitrary constant of integration. We can find a general rule for the integration of a power of t from Equation 2-6, which gives the general rule for the derivative of a power. The result is

$$\int t^n \, dt = \frac{t^{n+1}}{n+1} + C, \quad n \neq -1 \qquad \text{2-19}$$

where C is an arbitrary constant. This equation can be checked by differentiating the right side using the rule of Equation 2-6. (For the special case $n = -1$, $\int t^{-1} dt = \ln t + C$, where $\ln t$ is the natural logarithm of t.)

Because $a_x = dv_x/dt$, the change in velocity for some time interval can similarly be interpreted as the area under the a_x-versus-t curve for that interval. This change is written

$$\Delta v_x = \lim_{\Delta t \to 0} \left(\sum_i a_{ix} \, \Delta t_i \right) = \int_{t_1}^{t_2} a_x \, dt \qquad \text{2-20}$$

We can now derive the constant-acceleration equations by computing the indefinite integrals of the acceleration and velocity. If a_x is constant, we have

$$v_x = \int a_x dt = a_x \int dt = v_{0x} + a_x t \qquad \text{2-21}$$

where we have expressed the product of a_x and the constant of integration as v_{0x}. Integrating again, and writing x_0 for the constant of integration, gives

$$x = \int (v_{0x} + a_x t) dt = x_0 + v_{0x} t + \tfrac{1}{2} a_x t^2 \qquad \text{2-22}$$

It is instructive to derive Equations 2-21 and 2-22 using definite integrals instead of indefinite ones. For constant acceleration, Equation 2-20, with $t_1 = 0$, gives

$$v_x(t_2) - v_x(0) = a_x \int_0^{t_2} dt = a_x(t_2 - 0)$$

where the time t_2 is arbitrary. Because it is arbitrary, we can set $t_2 = t$ to obtain

$$v_x = v_{0x} + a_x t$$

where $v_x = v_x(t)$ and $v_{0x} = v_x(0)$. To derive Equation 2-22, we substitute $v_{0x} + a_x t$ for v_x in Equation 2-17 with $t_1 = 0$. This gives

$$x(t_2) - x(0) = \int_0^{t_2} (v_{0x} + a_x t) dt$$

This integral is equal to the area under the v_x-versus-t curve (Figure 2-26). Evaluating the integral and solving for x gives

$$x(t_2) - x(0) = \int_0^{t_2} (v_{0x} + a_x t) dt = v_{0x} t + \tfrac{1}{2} a_x t^2 \Big|_0^{t_2} = v_{0x} t_2 + \tfrac{1}{2} a_x t_2^2$$

where t_2 is arbitrary. Setting $t_2 = t$, we obtain

$$x = x_0 + v_{0x} t + \tfrac{1}{2} a_x t^2$$

where $x = x(t)$ and $x_0 = x(0)$.

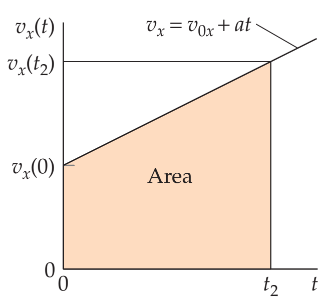

FIGURE 2-26 The area under the v_x-versus-t curve equals the displacement $\Delta x = x(t_2) - x(0)$.

The definition of average velocity is $\Delta x = v_{\text{av}\,x}\,\Delta t$ (Equation 2-3). In addition, $\Delta x = \int_{t_1}^{t_2} v_x\,dt$ (Equation 2-17). Equating the right sides of these equations and solving for $v_{\text{av}\,x}$ gives

$$v_{\text{av}\,x} = \frac{1}{\Delta t}\int_{t_1}^{t_2} v_x\,dt \qquad \text{2-23}$$

ALTERNATIVE DEFINITION OF AVERAGE VELOCITY

where $\Delta t = t_2 - t_1$. Equation 2-23 is mathematically equivalent to the definition of average velocity, so either equation can serve as a definition of average velocity.

Example 2-18 A Coasting Boat

A Shelter Island ferryboat moves with constant velocity $v_{0x} = 8.0$ m/s for 60 s. It then shuts off its engines and coasts. Its coasting velocity is given by $v_x = v_{0x}t_1^2/t^2$, where $t_1 = 60$ s. What is the displacement of the boat for the interval $0 < t < \infty$?

(Gene Mosca.)

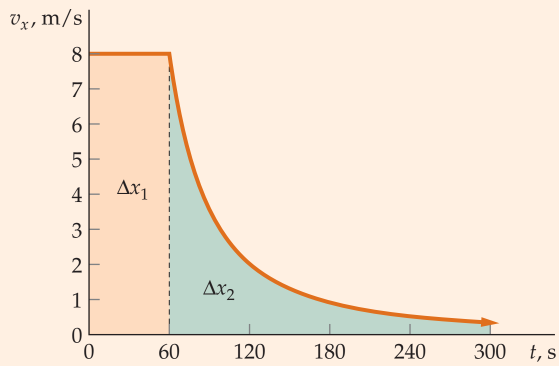

FIGURE 2-27

PICTURE The velocity function for the boat is shown in Figure 2-27. The total displacement is calculated as the sum of the displacement Δx_1 during the interval $0 < t < t_1 = 60$ s and the displacement Δx_2 during the interval $t_1 < t < \infty$.

SOLVE

1. The velocity of the boat is constant during the first 60 s; thus the displacement is simply the velocity times the elapsed time:

$$\Delta x_1 = v_{0x}\,\Delta t = v_{0x}t_1 = (8.0\text{ m/s})(60\text{ s}) = 480\text{ m}$$

2. The remaining displacement is given by the integral of the velocity from $t = t_1$ to $t = \infty$. We use Equation 2-17 to calculate the integral:

$$\Delta x_2 = \int_{t_1}^{\infty} v_x\,dt = \int_{t_1}^{\infty}\frac{v_{0x}t_1^2}{t^2}\,dt = v_{0x}t_1^2\int_{t_1}^{\infty} t^{-2}\,dt$$

$$= v_{0x}t_1^2\left.\frac{t^{-1}}{-1}\right|_{t_1}^{\infty} = -v_{0x}t_1^2\left(\frac{1}{\infty} - \frac{1}{t_1}\right)$$

$$= -(0 - v_0t_1) = (8\text{ m/s})(60\text{ s}) = 480\text{ m}$$

3. The total displacement is the sum of the displacements found above:

$$\Delta x = \Delta x_1 + \Delta x_2 = 480\text{ m} + 480\text{ m} = \boxed{960\text{ m}}$$

CHECK The expressions obtained for the displacements in both steps 1 and 2 are velocity multiplied by time, so they are both dimensionally correct.

TAKING IT FURTHER Note that the area under the v_x-versus-t curve (Figure 2-27) is finite. Thus, even though the boat never stops moving, it travels only a finite distance. A better representation of the velocity of a coasting boat might be the exponentially decreasing function $v_x = v_{0x}e^{-b(t-t_1)}$, where b is a positive constant. In that case, the boat would also coast a finite distance in the interval $t_1 \le t \le \infty$.

Physics Spotlight

Linear Accelerators

Linear accelerators are instruments that accelerate electrically charged particles to high speeds along a long, straight track to collide with a target. Large accelerators can impart very high kinetic energies (on the order of billions of electron volts) to charged particles that serve as probes for studying the fundamental particles of matter and the forces that hold them together. (The energy required to remove an electron from an atom is on the order of one electron volt.) In the two-mile-long linear accelerator at Stanford University, electromagnetic waves boost the speed of electrons or positrons as they move through an evacuated copper pipe. When the high-speed particles collide with a target, several different kinds of subatomic particles are produced along with X rays and gamma rays. These particles then pass into devices called particle detectors.

The beige cylinder in the background is the linear accelerator at the heart of the Naval Academy Tandem Accelerator Laboratory. A beam of high-speed protons travels from the accelerator to the target area in the foreground. *(Gene Mosca.)*

Through experiments with such accelerators, physicists have determined that protons and neutrons, once thought to be the ultimate particles of the nucleus, are themselves composed of more fundamental particles called quarks. Another group of particles known as leptons, which include electrons, neutrinos, and a few other particles, have also been identified. Most large accelerator research centers such as the Fermi National Accelerator Laboratory in Batavia, Illinois, use a series of linear and circular accelerators to achieve higher particle speeds. As the speed of a particle approaches the speed of light, the energy required to accelerate it to that speed approaches infinity.

Although the big accelerators may have a high profile, thousands of linear accelerators are used worldwide for a host of practical applications. One of the most common applications is the cathode ray tube (CRT) of a television set or computer monitor. In a CRT, electrons from the cathode (a heated filament) are accelerated in a vacuum toward a positively charged anode. Electromagnets control the direction of the electron beam onto the inside of a screen coated with a phosphor, a material that emits light when struck by electrons. The kinetic energy of electrons in a CRT ranges to a maximum of about 30,000 electron volts. The speed of an electron that has this kinetic energy is about one third of the speed of light.

In the field of medicine, linear accelerators about a thousand times more powerful than a CRT are used for radiation treatment of cancer. "The linear accelerator uses microwave technology (similar to that used for radar) to accelerate electrons in a part of the accelerator called the 'wave guide,' then allows these electrons to collide with a heavy metal target. As a result of the collisions, high-energy x-rays are scattered from the target. A portion of these x-rays is collected and then shaped to form a beam that matches the patient's tumor."*

Other applications of accelerators include the production of radioisotopes for tracers in medicine and biology, sterilization of surgical tools, and analysis of materials to determine their composition. For example, in a technique called particle-induced X-ray emission (PIXE), an ion beam, often consisting of protons, causes target atoms to emit X rays that identify the type of atoms present. This technique has been applied to the study of archeological materials and variety of other types of samples.

SUMMARY

Displacement, velocity, and acceleration are important *defined* kinematic quantities.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Displacement	$\Delta x = x_2 - x_1$	2-1
Graphical interpretation	Displacement is the area under the v_x-versus-t curve.	
2. Velocity		
Average velocity	$v_{\text{av}\,x} = \dfrac{\Delta x}{\Delta t}$ or $v_{\text{av}\,x} = \dfrac{1}{\Delta t}\displaystyle\int_{t_1}^{t_2} v_x\,dt$	2-3, 2-23
Instantaneous velocity	$v_x(t) = \lim\limits_{\Delta t \to 0} \dfrac{\Delta x}{\Delta t} = \dfrac{dx}{dt}$	2-5
Graphical interpretation	The instantaneous velocity is the slope of the x-versus-t curve.	
3. Speed		
Average speed	average speed $= \dfrac{\text{total distance}}{\text{total time}} = \dfrac{s}{t}$	2-2
Instantaneous speed	Instantaneous speed is the magnitude of the instantaneous velocity speed $= \lvert v_x \rvert$	
4. Acceleration		
Average acceleration	$a_{\text{av}\,x} = \dfrac{\Delta v_x}{\Delta t}$	2-7
Instantaneous acceleration	$a_x = \dfrac{dv_x}{dt} = \dfrac{d^2x}{dt^2}$	2-9
Graphical interpretation	The instantaneous acceleration is the slope of the v_x-versus-t curve.	
Acceleration due to gravity	The acceleration of an object near the surface of Earth in free-fall under the influence of gravity alone is directed downward and has magnitude $g = 9.81\ \text{m/s}^2 = 32.2\ \text{ft/s}^2$	
5. Kinematic equations for constant acceleration		
Velocity	$v_x = v_{0x} + a_x t$	2-12
Average velocity	$v_{\text{av}\,x} = \frac{1}{2}(v_{0x} + v_x)$	2-16
Displacement in terms of $v_{\text{av}\,x}$	$\Delta x = x - x_0 = v_{\text{av}\,x} t = \frac{1}{2}(v_{0x} + v_x)t$	
Displacement as a function of time	$\Delta x = x - x_0 = v_{0x} t + \frac{1}{2} a_x t^2$	2-14
v_x^2 as a function of Δx	$v_x^2 = v_{0x}^2 + 2a_x\,\Delta x$	2-15
6. Displacement and velocity as integrals	Displacement is represented graphically as the area under the v_x-versus-t curve. This area is the integral of v_x over time from some initial time t_1 to some final time t_2 and is written $\Delta x = \lim\limits_{\Delta t \to 0} \sum_i v_{i\,x}\,\Delta t_i = \displaystyle\int_{t_1}^{t_2} v_x\,dt$ (2-17) Similarly, change in velocity is represented graphically as the area under the a_x-versus-t curve: $\Delta v_x = \lim\limits_{\Delta t \to 0} \sum_i a_{i\,x}\,\Delta t_i = \displaystyle\int_{t_1}^{t_2} a_x\,dt$ (2-20)	2-17, 2-20

Answers to Concept Checks

2-1 No. The distance between cars will not remain constant. Instead, the distance will continuously decrease. When you first begin breaking, the speed of your car is greater than the speed of the car in front. That is because the car in front began breaking 0.3 s earlier. Because the cars lose speed at the same rate, the speed of your car will remain greater than the speed of the car in front throughout the braking period.

Answers to Practice Problems

2-1 1.2 m/s

2-2 (*a*) 65 km/h (*b*) 2.5 s

2-3 Only (*d*) has the same dimensions on both sides of the equation. Although we cannot obtain the exact equation from dimensional analysis, we can often obtain the functional dependence.

2-4 54 ms

2-5 (a) and (*b*) $y_{max} - y_0 = 11.0$ m (*c*) -14.7 m/s; notice that the final speed is the same as the initial speed

2-6 (*a*) $+0.981$ m/s (*b*) -0.981 m/s
(*c*) $[(-0.981\text{ m/s}) - (+0.981\text{ m/s}]/(0.200\text{ s}) = -9.81\text{ m/s}^2$

2-7 250 m

PROBLEMS

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimates.

Interpret as significant all digits in numerical values that have trailing zeroes and no decimal points.

For all problems, use $g = 9.81$ m/s² for the free-fall acceleration due to gravity and neglect friction and air resistance unless instructed to do otherwise.

• Single-concept, single-step, relatively easy

•• Intermediate-level, may require synthesis of concepts

••• Challenging

SSM Solution is in the Student Solutions Manual

Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • What is the average velocity over the "round trip" of an object that is launched straight up from the ground and falls straight back down to the ground?

2 • An object thrown straight up falls back and is caught at the same place it is launched from. Its time of flight is T; its maximum height is H. Neglect air resistance. The correct expression for its average speed for the entire flight is (*a*) H/T, (*b*) 0, (*c*) $H/(2T)$, (*d*) $2H/T$.

3 • Using the information in the previous question, what is its average speed just for the first half of the trip? What is its average velocity for the second half of the trip? (Answer in terms of H and T.)

4 • Give an everyday example of one-dimensional motion where (*a*) the velocity is westward and the acceleration is eastward, and (*b*) the velocity is northward and the acceleration is northward.

5 • Stand in the center of a large room. Call the direction to your right "positive," and the direction to your left "negative." Walk across the room along a straight line, using a constant acceleration to quickly reach a steady speed along a straight line in the negative direction. After reaching this steady speed, keep your velocity negative but make your acceleration positive. (*a*) Describe how your speed varied as you walked. (*b*) Sketch a graph of x versus t for your motion. Assume you started at $x = 0$. (*c*) Directly under the graph of Part (*b*), sketch a graph of v_x versus t. SSM

6 • True/false: The displacement *always* equals the product of the average velocity and the time interval. Explain your choice.

7 • Is the statement "for an object's velocity to remain constant, its acceleration *must* remain zero" true or false? Explain your choice.

8 •• **MULTISTEP** Draw careful graphs of the position and velocity and acceleration over the time period $0 \le t \le 30$ s for a cart that, in succession, has the following motion. The cart is moving at the constant speed of 5.0 m/s in the $+x$ direction. It passes by the origin at $t = 0.0$ s. It continues on at 5.0 m/s for 5.0 s, after which it gains speed at the constant rate of 0.50 m/s each second for 10.0 s. After gaining speed for 10.0 s, the cart loses speed at the constant rate of 0.50 m/s for the next 15.0 s.

9 • True/false: Average velocity *always* equals one-half the sum of the initial and final velocities. Explain your choice.

10 • Identical twin brothers standing on a horizontal bridge each throw a rock straight down into the water below. They throw rocks at exactly the same time, but one hits the water before the other. How can this be? Explain what they did differently. Ignore any effects due to air resistance.

11 •• Dr. Josiah S. Carberry stands at the top of the Sears Tower in Chicago. Wanting to emulate Galileo, and ignoring the safety of the pedestrians below, he drops a bowling ball from the top of the tower. One second later, he drops a second bowling ball. While the balls are in the air, does their separation (*a*) increase over time, (*b*) decrease, (*c*) stay the same? Ignore any effects due to air resistance. SSM

12 •• Which of the position-versus-time curves in Figure 2-28 best shows the motion of an object (*a*) with positive acceleration, (*b*) with constant positive velocity, (*c*) that is always at rest, and

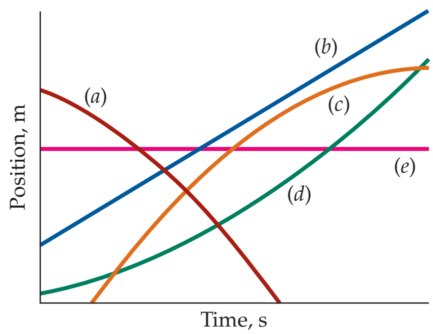

FIGURE 2-28 Problem 12

(*d*) with negative acceleration? (There may be more than one correct answer for each part of the problem.)

13 •• Which of the velocity-versus-time curves in Figure 2-29 best describes the motion of an object (*a*) with constant positive acceleration, (*b*) with positive acceleration that is decreasing with time, (*c*) with positive acceleration that is increasing with time, and (*d*) with no acceleration? (There may be more than one correct answer for each part of the problem.) SSM

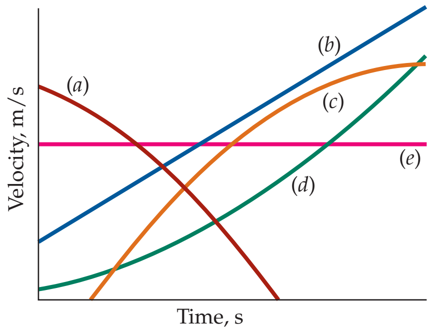

FIGURE 2-29 Problem 13

14 •• The diagram in Figure 2-30 tracks the location of an object moving in a straight line along the x axis. Assume that the object is at the origin at $t = 0$. Of the five times shown, which time (or times) represents when the object is (*a*) farthest from the origin, (*b*) at rest for an instant, (*c*) in the midst of being at rest for a while, and (*d*) moving away from the origin?

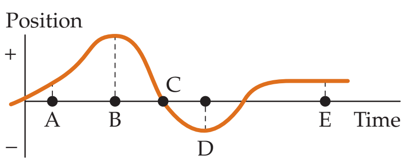

FIGURE 2-30 Problems 14 and 15

15 •• An object moves along a straight line. Its position-versus-time graph is shown in Figure 2-30. At which time or times is its (*a*) speed at a minimum, (*b*) acceleration positive, and (*c*) velocity negative? SSM

16 •• For each of the four graphs of x versus t in Figure 2-31 answer the following questions. (*a*) Is the velocity at time t_2 greater than, less than, or equal to the velocity at time t_1? (*b*) Is the speed at time t_2 greater than, less than, or equal to the speed at time t_1?

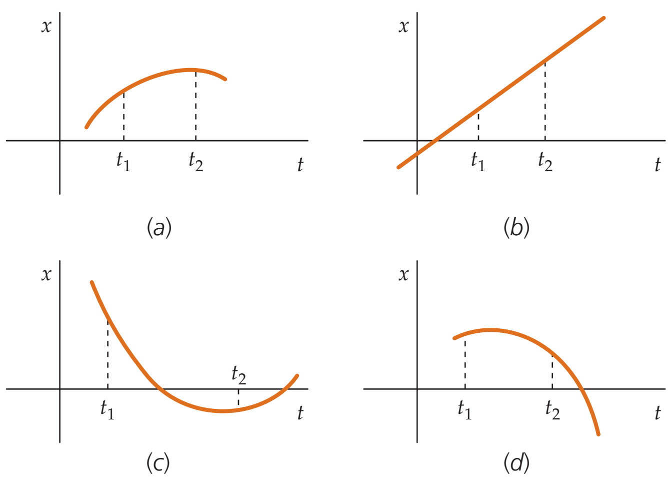

FIGURE 2-31 Problem 16

17 •• True/false:

(*a*) If the acceleration of an object is always zero, then it cannot be moving.

(*b*) If the acceleration of an object is always zero, then its x-versus-t curve must be a straight line.

(*c*) If the acceleration of an object is nonzero at an instant, it may be momentarily at rest at that instant.

Explain your reasoning for each answer. If an answer is *true*, give an example.

18 •• A hard-thrown tennis ball is moving horizontally when it bangs into a vertical concrete wall at perpendicular incidence. The ball rebounds straight back off the wall. Neglect any effects due to gravity for the small time interval described here. Assume that toward the wall is the $+x$ direction. What are the directions of its velocity and acceleration (*a*) just before hitting the wall, (*b*) at maximum impact, and (*c*) just after leaving the wall?

19 •• A ball is thrown straight up. Neglect any effects due to air resistance. (*a*) What is the velocity of the ball at the top of its flight? (*b*) What is its acceleration at that point? (*c*) What is different about the velocity and acceleration at the top of the flight if instead the ball impacts a horizontal ceiling very hard and then returns. SSM

20 •• An object that is launched straight up from the ground, reaches a maximum height H, and falls straight back down to the ground, hitting it T seconds after launch. Neglect any effects due to air resistance. (*a*) Express the average speed for the entire trip as a function of H and T. (*b*) Express the average speed for the same interval of time as a function of the initial launch speed v_0.

21 •• A small lead ball is thrown directly upward. True or false: (Neglect any effects due to air resistance.) (*a*) The magnitude of its acceleration decreases on the way up. (*b*) The direction of its acceleration on its way down is opposite to the direction of its acceleration on its way up. (*c*) The direction of its velocity on its way down is opposite to the direction of its velocity on its way up.

22 •• At $t = 0$, object A is dropped from the roof of a building. At the same instant, object B is dropped from a window 10 m below the roof. Air resistance is negligible. During the descent of B to the ground, the distance between the two objects (*a*) is proportional to t, (*b*) is proportional to t^2, (*c*) decreases, (*d*) remains 10 m throughout.

23 •• CONTEXT-RICH You are driving a Porsche that accelerates uniformly from 80.5 km/h (50 mi/h) at $t = 0.00$ s to 113 km/h (70 mi/h) at $t = 9.00$ s. (*a*) Which graph in Figure 2-32 best describes the velocity of your car? (*b*) Sketch a position-versus-time graph showing the location of your car during these nine seconds, assuming we let its position x be zero at $t = 0$.

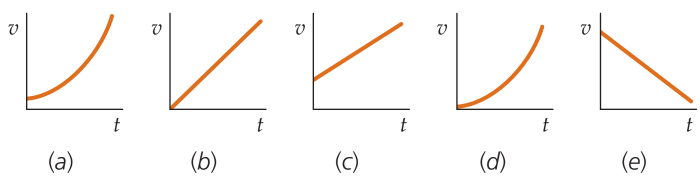

FIGURE 2-32 Problem 23

24 •• A small heavy object is dropped from rest and falls a distance D in a time T. After it has fallen for a time $2T$, what will be its (*a*) fall distance from its initial location, (*b*) its speed, and (*c*) its acceleration? (Neglect air resistance.)

25 •• In a race, at an instant when two horses are running right next to each other and in the same direction (the $+x$ direction), Horse A's instantaneous velocity and acceleration are $+10$ m/s and $+2.0$ m/s^2, respectively, and horse B's instantaneous velocity and acceleration are $+12$ m/s and -1.0 m/s^2, respectively. Which horse is passing the other at this instant? Explain.

26 •• True or false: (*a*) The equation $x - x_o = v_{ox}t + \frac{1}{2}a_x t^2$ is always valid for particle motion in one dimension. (*b*) If the velocity at a given instant is zero, the acceleration at that instant must also be zero. (*c*) The equation $\Delta x = v_{av}\,\Delta t$ holds for all particle motion in one dimension.

27 •• If an object is moving in a straight line at constant acceleration, its instantaneous velocity halfway through any time interval is (*a*) greater than its average velocity, (*b*) less than its average velocity, (*c*) equal to its average velocity, (*d*) half its average velocity, (*e*) twice its average velocity.

28 •• A turtle, seeing his owner put some fresh lettuce on the opposite side of his terrarium, begins to accelerate (at a constant rate) from rest at time $t = 0$, heading directly toward the food. Let t_1 be the time at which the turtle has covered half the distance to his lunch. Derive an expression for the ratio of t_2 to t_1, where t_2 is the time at which the turtle reaches the lettuce.

29 •• The positions of two cars in parallel lanes of a straight stretch of highway are plotted as functions of time in the Figure 2-33. Take positive values of x as being to the right of the origin. Qualitatively answer the following: (*a*) Are the two cars ever side by side? If so, indicate that time (those times) on the axis. (*b*) Are they always traveling in the same direction, or are they moving in opposite directions for some of the time? If so, when? (*c*) Are they ever traveling at the same velocity? If so, when? (*d*) When are the two cars the farthest apart? (*e*) Sketch (no numbers) the velocity versus time curve for each car. SSM

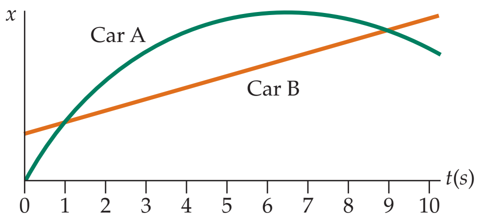

FIGURE 2-33 Problem 29

30 •• A car driving at constant velocity passes the origin at time $t = 0$. At that instant, a truck, at rest at the origin, begins to accelerate uniformly from rest. Figure 2-34 shows a qualitative plot of the velocities of truck and car as functions of time. Compare their displacements (from the origin), velocities, and accelerations at the instant that their curves intersect.

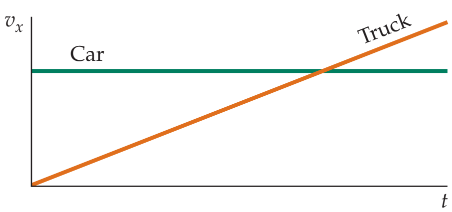

FIGURE 2-34 Problem 30

31 •• Reginald is out for a morning jog, and during the course of his run on a straight track, he has a velocity that depends upon time as shown in Figure 2-35. That is, he begins at rest, and ends at rest, peaking at a maximum velocity v_{max} at an arbitrary time t_{max}. A second runner, Josie, runs throughout the time interval $t = 0$ to $t = t_f$ at a constant speed v_J, so that each has the same displacement during the time interval. Note: t_f is NOT twice t_{max}, but represents an arbitrary time. What is the relation between v_J *and* v_{max}?

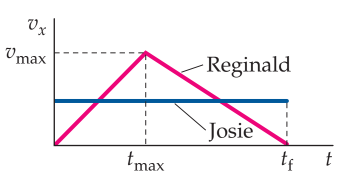

FIGURE 2-35 Problem 31

32 •• Which graph (or graphs), if any, of v_x versus t in Figure 2-36 best describes the motion of a particle with (*a*) positive velocity and increasing speed, (*b*) positive velocity and zero acceleration, (*c*) constant nonzero acceleration, and (*d*) a speed decrease?

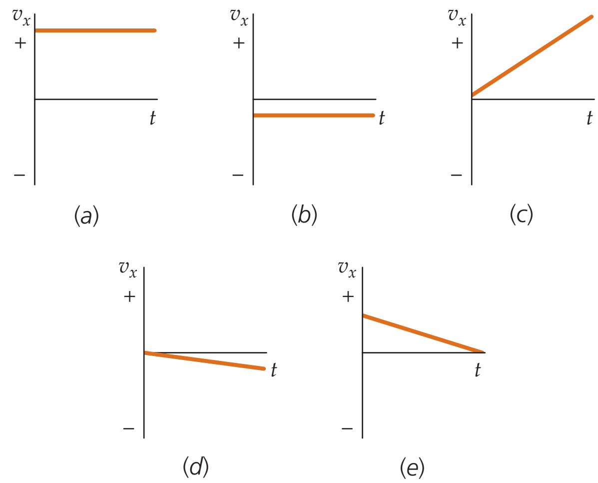

FIGURE 2-36 Problems 32 and 33

33 •• Which graph (or graphs), if any, of v_x versus t in Figure 2-36 best describes the motion of a particle with (*a*) negative velocity and increasing speed, (*b*) negative velocity and zero acceleration, (*c*) variable acceleration, and (*d*) increasing speed?

34 •• Sketch a v-versus-t curve for each of the following conditions: (*a*) Acceleration is zero and constant while velocity is not zero. (*b*) Acceleration is constant but not zero. (*c*) Velocity and acceleration are both positive. (*d*) Velocity and acceleration are both negative. (*e*) Velocity is positive and acceleration is negative. (*f*) Velocity is negative and acceleration is positive. (*g*) Velocity is momentarily zero but the acceleration is not zero.

35 •• Figure 2-37 shows nine graphs of position, velocity, and acceleration for objects in motion along a straight line. Indicate the graphs that meet the following conditions: (*a*) Velocity is constant,

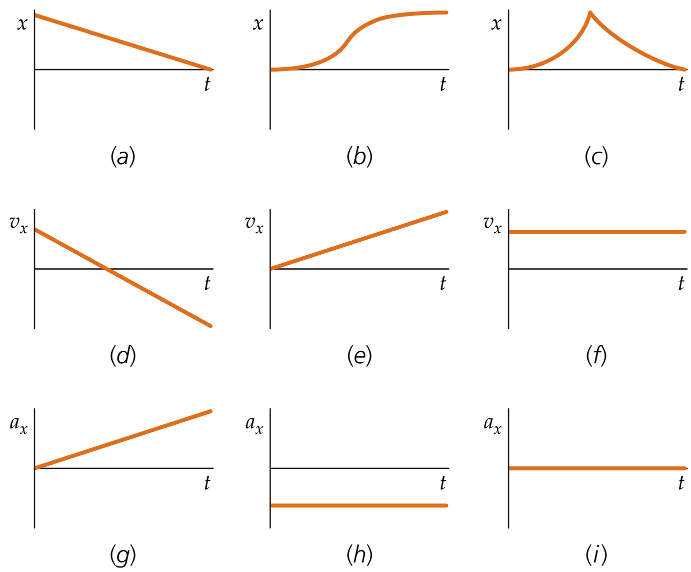

FIGURE 2-37 Problem 35

(*b*) velocity reverses its direction, (*c*) acceleration is constant, and (*d*) acceleration is not constant. (*e*) Which graphs of position, velocity, and acceleration are mutually consistent?

ESTIMATION AND APPROXIMATION

36 • **Context-Rich** While engrossed in thought about the scintillating lecture just delivered by your physics professor you mistakenly walk directly into the wall (rather than through the open lecture hall door). Estimate the magnitude of your average acceleration as you rapidly come to a halt.

37 • **Biological Application** Occasionally, people can survive falling large distances if the surface they land on is soft enough. During a traverse of the Eiger's infamous Nordvand, mountaineer Carlos Ragone's rock anchor gave way and he plummeted 500 feet to land in snow. Amazingly, he suffered only a few bruises and a wrenched shoulder. Assuming that his impact left a hole in the snow 4.0 ft deep, estimate his average acceleration as he slowed to a stop (that is, while he was impacting the snow). SSM

38 •• When we solve free-fall problems near Earth, it's important to remember that air resistance may play a significant role. If its effects are significant, we may get answers that are wrong by orders of magnitude if we ignore it. How can we tell when it is valid to ignore the effects of air resistance? One way is to realize that air resistance increases with increasing speed. Thus, as an object falls and its speed *increases*, its downward acceleration *decreases*. Under these circumstances, the object's speed will approach, as a limit, a value called its *terminal speed*. This terminal speed depends upon such things as the mass and cross-sectional area of the body. Upon reaching its terminal speed, its acceleration is zero. For a "typical" skydiver falling through the air, a typical terminal speed is about 50 m/s (roughly 120 mph). At half its terminal speed, the skydiver's acceleration will be about $\frac{3}{4}g$. Let us take half the terminal speed as a reasonable "upper bound" beyond which we should not use our constant acceleration free-fall relationships. Assuming the skydiver started from rest, (*a*) estimate how far, and for how long, the skydiver falls before we can no longer neglect air resistance. (*b*) Repeat the analysis for a Ping-Pong ball, which has a terminal speed of about 5.0 m/s. (*c*) What can you conclude by comparing your answers for Parts (*a*) and (*b*)?

39 •• **Biological Application** On June 14, 2005, Asafa Powell of Jamaica set a world's record for the 100-m dash with a time $t = 9.77$ s. Assuming he reached his maximum speed in 3.00 s, and then maintained that speed until the finish, estimate his acceleration during the first 3.00 s.

40 •• The photograph in Figure 2-38 is a short-time exposure (1/30 s) of a juggler with two tennis balls in the air. (*a*) The tennis ball near the top of its trajectory is less blurred than the lower one. Why is that? (*b*) Estimate the speed of the ball that he is just releasing from his right hand. (*c*) Determine how high the ball should have gone above the launch point and compare it to an estimate from the picture. *Hint: You have a built-in distance scale if you assume some reasonable value for the height of the juggler.*

FIGURE 2-38
Problem 40
(Courtesy of Chuck Adler.)

41 •• A rough rule of thumb for determining the distance between you and a lightning strike is to start counting the seconds that elapse ("one-Mississippi, two-Mississippi, . . .") until you hear the thunder (sound emitted by the lightning as it rapidly heats the air around it). Assuming the speed of sound is about 750 mi/h, (*a*) estimate how far away is a lightning strike if you counted about 5 s until you heard the thunder. (*b*) Estimate the uncertainty in the distance to the strike in Part (*a*). Be sure to explain your assumptions and reasoning. *Hint: The speed of sound depends on the air temperature, and your counting is far from exact!*

SPEED, DISPLACEMENT, AND VELOCITY

42 • **Engineering Application** (*a*) An electron in a television tube travels the 16-cm distance from the grid to the screen at an average speed of 4.0×10^7 m/s. How long does the trip take? (*b*) An electron in a current-carrying wire travels at an average speed of 4.0×10^{-5} m/s. How long does it take to travel 16 cm?

43 • A runner runs 2.5 km, in a straight line, in 9.0 min and then takes 30 min to walk back to the starting point. (*a*) What is the runner's average velocity for the first 9.0 min? (*b*) What is the average velocity for the time spent walking? (*c*) What is the average velocity for the whole trip? (*d*) What is the average speed for the whole trip? SSM

44 • A car travels in a straight line with an average velocity of 80 km/h for 2.5 h and then with an average velocity of 40 km/h for 1.5 h. (*a*) What is the total displacement for the 4.0-h trip? (*b*) What is the average velocity for the total trip?

45 • One busy air route across the Atlantic Ocean is about 5500 km. The now-retired Concord, a supersonic jet capable of flying at twice the speed of sound, was used for traveling such routes. (*a*) Roughly how long did it take for a one-way flight? (Use 343 m/s for the speed of sound.) (*b*) Compare this time to the time taken by a subsonic jet flying at 0.90 times the speed of sound.

46 • The speed of light, designated by the universally recognized symbol c, has a value, to two significant figures, of 3.0×10^8 m/s. (*a*) How long does it take for light to travel from the Sun to Earth, a distance of 1.5×10^{11} m? (*b*) How long does it take light to travel from the moon to Earth, a distance of 3.8×10^8 m?

47 • Proxima Centauri, the closest star to us besides our own Sun, is 4.1×10^{13} km from Earth. From Zorg, a planet orbiting this star, a Gregor places an order at Tony's Pizza in Hoboken, New Jersey, communicating by light signals. Tony's fastest delivery craft travels at $1.00 \times 10^{-4}c$ (see Problem 46). (*a*) How long does it take Gregor's order to reach Tony's Pizza? (*b*) How long does Gregor wait between sending the signal and receiving the pizza? If Tony's has a "1000-years-or-it's-free" delivery policy, does Gregor have to pay for the pizza? SSM

48 • A car making a 100-km journey travels 40 km/h for the first 50 km. How fast must it go during the second 50 km to average 50 km/h?

49 •• **Context-Rich** Late in ice hockey games, the team that is losing sometimes "pulls" their goalkeeper off the ice to add an additional offensive player and increase their chances of scoring. In such cases, the goalie on the opposing team might have an opportunity to score into the unguarded net 55.0 m away. Suppose you are the goaltender for your university team and are in just such a situation. You launch a shot (in hopes of getting your first career goal) on the frictionless ice. You eventually hear a disappointing "clang" as the puck strikes a goalpost (instead of going in!) exactly 2.50 s later. In this case, how fast did the puck travel? You should assume 343 m/s for the speed of sound.

50 •• Cosmonaut Andrei, your co-worker at the International Space Station, tosses a banana at you at a speed of 15 m/s. At exactly the same instant, you fling a scoop of ice cream at Andrei along exactly the same path. The collision between banana and ice cream produces a banana split 7.2 m from your location 1.2 s after the banana and ice cream were launched. (*a*) How fast did you toss the ice cream? (*b*) How far were you from Andrei when you tossed the ice cream? (Neglect any effects due to gravity.)

51 •• Figure 2-39 shows the position of a particle as a function of time. Find the average velocities for the time intervals *a*, *b*, *c*, and *d* indicated in the figure.

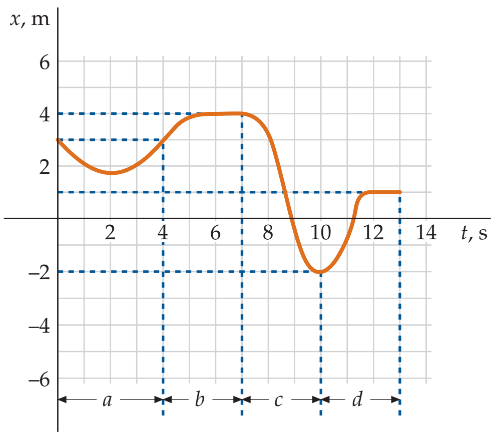

FIGURE 2-39 Problem 51

52 •• ENGINEERING APPLICATION It has been found that, on average, galaxies are moving away from Earth at a speed that is proportional to their distance from Earth. This discovery is known as Hubble's law, named for its discoverer, astrophysicist Sir Edwin Hubble. He found that the recessional speed v of a galaxy a distance r from Earth is given by $v = Hr$, where $H = 1.58 \times 10^{-18}\ \mathrm{s}^{-1}$ is called the Hubble constant. What are the expected recessional speeds of galaxies (*a*) 5.00×10^{22} m from Earth, and (*b*) 2.00×10^{25} m from Earth? (*c*) If the galaxies at each of these distances had traveled at their expected recessional speeds, how long ago would they have been at our location?

53 •• The cheetah can run as fast as 113 km/h, the falcon can fly as fast as 161 km/h, and the sailfish can swim as fast as 105 km/h. The three of them run a relay with each covering a distance L at maximum speed. What is the average speed of this relay team for the entire relay? Compare this average speed with the numerical average of the three individual speeds. Explain carefully why the average speed of the relay team is *not* equal to the numerical average of the three individual speeds. SSM

54 •• Two cars are traveling along a straight road. Car A maintains a constant speed of 80 km/h and car B maintains a constant speed of 110 km/h. At $t = 0$, car B is 45 km behind car A. (*a*) How much farther will car A travel before car B overtakes it? (*b*) How much ahead of A will B be 30 s after it overtakes A?

55 •• MULTISTEP A car traveling at a constant speed of 20 m/s passes an intersection at time $t = 0$. A second car traveling at a constant speed of 30 m/s in the same direction passes the same intersection 5.0 s later. (*a*) Sketch the position functions $x_1(t)$ and $x_2(t)$ for the two cars for the interval $0 \le t \le 20\,\mathrm{s}$. (*b*) Determine when the second car will overtake the first. (*c*) How far from the intersection will the two cars be when they pull even? (*d*) Where is the first car when the second car passes the intersection? SSM

56 •• BIOLOGICAL APPLICATION Bats use echolocation to determine their distance from objects they cannot easily see in the dark. The time between the emission of a high-frequency sound pulse (a click) and the detection of its echo is used to determine such distances. A bat, flying at a constant speed of 19.5 m/s in a straight line toward a vertical cave wall, makes a single clicking noise and hears the echo 0.15 s later. Assuming that she continued flying at her original speed, how close was she to the wall when she received the echo? Assume a speed of 343 m/s for the speed of sound.

57 ••• ENGINEERING APPLICATION A submarine can use *sonar* (sound traveling through water) to determine its distance from other objects. The time between the emission of a sound pulse (a "ping") and the detection of its echo can be used to determine such distances. Alternatively, by measuring the time between *successive* echo receptions of a *regularly timed set* of pings, the submarine's *speed* may be determined by comparing the time between echoes to the time between pings. Assume you are the sonar operator in a submarine traveling at a constant velocity underwater. Your boat is in the eastern Mediterranean Sea, where the speed of sound is known to be 1522 m/s. If you send out pings every 2.00 s, and your apparatus receives echoes reflected from an undersea cliff every 1.98 s, how fast is your submarine traveling?

ACCELERATION

58 • A sports car accelerates in third gear from 48.3 km/h (about 30 mi/h) to 80.5 km/h (about 50 mi/h) in 3.70 s. (*a*) What is the average acceleration of this car in m/s^2? (*b*) If the car maintained this acceleration, how fast would it be moving one second later?

59 • An object is moving along the x axis. At $t = 5.0$ s, the object is at $x = +3.0$ m and has a velocity of $+5.0$ m/s. At $t = 8.0$ s, it is at $x = +9.0$ m and its velocity is -1.0 m/s. Find its average acceleration during the time interval $5.0\ \mathrm{s} < t < 8.0\ \mathrm{s}$. SSM

60 •• A particle moves along the x axis with velocity $v_x = (8.0\ \mathrm{m/s^2})t - 7.0\ \mathrm{m/s}$. (*a*) Find the average acceleration for two different one-second intervals, one beginning at $t = 3.0$ s and the other beginning at $t = 4.0$ s. (*b*) Sketch v_x versus t over the interval $0 < t < 10$ s. (*c*) How do the instantaneous accelerations at the middle of each of the two time intervals specified in Part (*a*) compare to the average accelerations found in Part (*a*)? Explain.

61 •• MULTISTEP The position of a certain particle depends on time according to the equation $x(t) = t^2 - 5.0t + 1.0$, where x is in meters if t is in seconds. (*a*) Find the displacement and average velocity for the interval $3.0\,\mathrm{s} \le t \le 4.0\,\mathrm{s}$. (*b*) Find the general formula for the displacement for the time interval from t to $t + \Delta t$. (*c*) Use the limiting process to obtain the instantaneous velocity for any time t. SSM

62 •• The position of an object as a function of time is given by $x = At^2 - Bt + C$, where $A = 8.0\ \mathrm{m/s^2}$, $B = 6.0$ m/s, and $C = 4.0$ m. Find the instantaneous velocity and acceleration as functions of time.

63 ••• The one-dimensional motion of a particle is plotted in Figure 2-40. (*a*) What is the average acceleration in each of the intervals *AB*, *BC*, and *CE*? (*b*) How far is the particle from its starting point after 10 s? (*c*) Sketch the displacement of the particle as a function of time; label the instants *A*, *B*, *C*, *D*, and *E* on your graph. (*d*) At what time is the particle traveling most slowly?

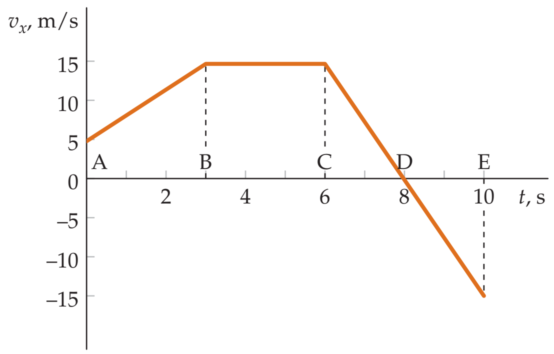

FIGURE 2-40 Problem 63

CONSTANT ACCELERATION AND FREE-FALL

64 • An object projected vertically upward with initial speed v_0 attains a maximum height h above its launch point. Another object projected up with initial speed $2v_0$ from the same height will attain a maximum height of (*a*) 4*h*, (*b*) 3*h*, (*c*) 2*h*, (*d*) *h*. (Air resistance is negligible.)

65 • A car traveling along the x axis starts from rest at $x = 50$ m and accelerates at a constant rate of 8.0 m/s². (*a*) How fast is it going after 10 s? (*b*) How far has it gone after 10 s? (*c*) What is its average velocity for the interval $0 \leq t \leq 10$ s?

66 • An object traveling along the x axis with an initial velocity of +5.0 m/s has a constant acceleration of +2.0 m/s². When its speed is 15 m/s, how far has it traveled?

67 • An object traveling along the x axis at constant acceleration has a velocity of +10 m/s when it is at $x = 6.0$ m and of +15 m/s when it is at $x = 10.0$ m. What is its acceleration? SSM

68 • The speed of an object traveling along the x axis increases at the constant rate of +4.0 m/s each second. At $t = 0.0$ s, its velocity is +1.0 m/s and its position is +7.0 m. How fast is it moving when its position is +8.0 m, and how much time has elapsed from the start at $t = 0.0$ s?

69 •• A ball is launched directly upward from ground level with an initial speed of 20 m/s. (Air resistance is negligible.) (*a*) How long is the ball in the air? (*b*) What is the greatest height reached by the ball? (*c*) How many seconds after launch is the ball 15 m above the release point?

70 •• In the Blackhawk landslide in California, a mass of rock and mud fell 460 m down a mountain and then traveled 8.00 km across a level plain. It has been theorized that the rock and mud moved on a cushion of water vapor. Assume that the mass dropped with the free-fall acceleration and then slid horizontally, losing speed at a constant rate. (*a*) How long did the mud take to drop the 460 m? (*b*) How fast was it traveling when it reached the bottom? (*c*) How long did the mud take to slide the 8.00 km horizontally?

71 •• A load of bricks is lifted by a crane at a steady velocity of 5.0 m/s when one brick falls off 6.0 m above the ground. (*a*) Sketch the position of the brick $y(t)$ versus time, from the moment it leaves the pallet until it hits the ground. (*b*) What is the greatest height the brick reaches above the ground? (*c*) How long does it take to reach the ground? (*d*) What is its speed just before it hits the ground? SSM

72 •• A bolt comes loose from underneath an elevator that is moving upward at a constant speed of 6.0 m/s. The bolt reaches the bottom of the elevator shaft in 3.0 s. (*a*) How high above the bottom of the shaft was the elevator when the bolt came loose? (*b*) What is the speed of the bolt when it hits the bottom of the shaft?

73 •• An object is dropped from rest at a height of 120 m. Find the distance it falls during its final second in the air.

74 •• An object is released from rest at a height h. During the final second of its fall, it traverses a distance of 38 m. Determine h.

75 •• A stone is thrown vertically downward from the top of a 200-m cliff. During the last half second of its flight, the stone travels a distance of 45 m. Find the initial speed of the stone. SSM

76 •• An object is released from rest at a height h. It travels 0.4h during the first second of its descent. Determine the average velocity of the object during its entire descent.

77 •• A bus accelerates from rest at 1.5 m/s² for 12 s. It then travels at constant velocity for 25 s, after which it slows to a stop with an acceleration of magnitude 1.5 m/s². (*a*) What is the total distance that the bus travels? (*b*) What is its average velocity?

78 •• Al and Bert are jogging side-by-side on a trail in the woods at a speed of 0.75 m/s. Suddenly Al sees the end of the trail 35 m ahead and decides to speed up to reach it. He accelerates at a constant rate of 0.50 m/s² while Bert continues on at a constant speed. (*a*) How long does it take Al to reach the end of the trail? (*b*) Once he reaches the end of the trail, he immediately turns around and heads back along the trail with a constant speed of 0.85 m/s. How long does it take him to meet up with Bert? (*c*) How far are they from the end of the trail when they meet?

79 •• You have designed a rocket to be used to sample the local atmosphere for pollution. It is fired vertically with a constant upward acceleration of 20 m/s². After 25 s, the engine shuts off and the rocket continues rising (in freefall) for a while. (Air resistance is negligible.) The rocket eventually stops rising and then falls back to the ground. You want to get a sample of air that is 20 km above the ground. (*a*) Did you reach your height goal? If not, what would you change so that the rocket raches 20 km? (*b*) Determine the total time the rocket is in the air. (*c*) Find the speed of the rocket just before it hits the ground.

80 •• A flowerpot falls from a windowsill of an apartment that is on the tenth floor of an apartment building. A person in an apartment below, coincidentally in possession of a high-speed high-precision timing system, notices that it takes 0.20 s for the pot to fall past his window, which is 4.0-m from top to bottom. How far above the top of the window is the windowsill from which the pot fell? (Neglect any effects due to air resistance.)

81 •• In a classroom demonstration, a glider moves along an inclined track with constant acceleration. It is projected from the low end of the track with an initial velocity. After 8.00 s have elapsed, it is 100 cm from the low end and is moving along the track at a velocity of −15 cm/s. Find the initial velocity and the acceleration. SSM

82 •• A rock dropped from a cliff covers one-third of its total distance to the ground in the last second of its fall. Air resistance is negligible. How high is the cliff?

83 •• A typical automobile under hard braking loses speed at a rate of about 7.0 m/s^2; the typical reaction time to engage the brakes is 0.50 s. A local school board sets the speed limit in a school zone such that all cars should be able to stop in 4.0 m. (*a*) What maximum speed does this imply for an automobile in this zone? (*b*) What fraction of the 4.0 m is due to the reaction time? SSM

84 •• Two trains face each other on adjacent tracks. They are initially at rest, and their front ends are 40 m apart. The train on the left accelerates rightward at 1.0 m/s^2. The train on the right accelerates leftward at 1.3 m/s^2. (*a*) How far does the train on the left travel before the front ends of the trains pass? (*b*) If the trains are each 150 m in length, how long after the start are they completely past one another, assuming their accelerations are constant?

85 •• Two stones are dropped from the edge of a 60-m cliff, the second stone 1.6 *s* after the first. How far below the top of the cliff is the second stone when the separation between the two stones is 36 m?

86 •• A motorcycle officer hidden at an intersection observes a car driven by an oblivious driver who ignores a stop sign and continues through the intersection at constant speed. The police officer takes off in pursuit 2.0 s after the car has passed the stop sign. She accelerates at 4.2 m/s^2 until her speed is 110 km/h, and then continues at this speed until she catches the car. At that instant, the car is 1.4 km from the intersection. (a) How long did it take for the officer to catch up to the car? (*b*) How fast was the car traveling?

87 •• At $t = 0$, a stone is dropped from the top of a cliff above a lake. Another stone is thrown downward 1.6 s later from the same point with an initial speed of 32 m/s. Both stones hit the water at the same instant. Find the height of the cliff.

88 •• A passenger train is traveling at 29 m/s when the engineer sees a freight train 360 m ahead of his train traveling in the same direction on the same track. The freight train is moving at a speed of 6.0 m/s. (*a*) If the reaction time of the engineer is 0.40 s, what is the minimum (constant) rate at which the passenger train must lose speed if a collision is to be avoided? (*b*) If the engineer's reaction time is 0.80 s and the train loses speed at the minimum rate described in Part (*a*), at what rate is the passenger train approaching the freight train when the two collide? (*c*) For both reaction times, how far will the passenger train have traveled in the time between the sighting of the freight train and the collision?

89 •• **Biological Application** The click beetle can project itself vertically with an acceleration of about 400*g* (an order of magnitude more than a human could survive!). The beetle jumps by "unfolding" its 0.60-cm long legs. (*a*) How high can the click beetle jump? (*b*) How long is the beetle in the air? (Assume constant acceleration while in contact with the ground and neglect air resistance.)

90 •• An automobile accelerates from rest at 2.0 m/s^2 for 20 s. The speed is then held constant for 20 s, after which there is an acceleration of −3.0 m/s^2 until the automobile stops. What is the total distance traveled?

91 •• Consider measuring the free-fall motion of a particle (neglect air resistance). Before the advent of computer-driven data-logging software, these experiments typically employed a wax-coated tape placed vertically next to the path of a dropped electrically conductive object. A spark generator would cause an arc to jump between two vertical wires through the falling object and through the tape, thereby marking the tape at fixed time intervals Δt. Show that the change in height during successive time intervals for an object falling from rest follows *Galileo's Rule of Odd Numbers*: $\Delta y_{21} = 3\Delta y_{10}$, $\Delta y_{32} = 5\Delta y_{10}, \ldots$, where Δy_{10} is the change in y during the first interval of duration Δt, Δy_{21} is the change in y during the second interval of duration Δt, etc. SSM

92 •• Starting from rest, a particle travels along the x axis with a constant acceleration of +3.0 m/s^2. At a time 4.0 s following its start, it is at $x = -100$ m. At a time 6.0 s later it has a velocity of +15 m/s. Find its position at this later time.

93 •• If it were possible for a spacecraft to maintain a constant acceleration indefinitely, trips to the planets of the Solar System could be undertaken in days or weeks, while voyages to the nearer stars would only take a few years. (*a*) Using data from the tables at the back of the book, find the time it would take for a one-way trip from Earth to Mars (at Mars' closest approach to Earth). Assume that the spacecraft starts from rest, travels along a straight line, accelerates halfway at 1 *g*, flips around, and decelerates at 1 *g* for the rest of the trip. (*b*) Repeat the calculation for a 4.1×10^{13}-km trip to Proxima Centauri, our nearest stellar neighbor outside of the Sun. (See Problem 47.) SSM

94 •• The Stratosphere Tower in Las Vegas is 1137 ft high. It takes 1 min, 20 s to ascend from the ground floor to the top of the tower using the high-speed elevator. The elevator starts and ends at rest. Assume that it maintains a constant upward acceleration until it reaches its maximum speed, and then maintains a constant acceleration of equal magnitude until it comes to a stop. Find the magnitude of the acceleration of the elevator. Express this acceleration magnitude as a multiple of *g* (the acceleration due to gravity).

95 •• A train pulls away from a station with a constant acceleration of 0.40 m/s^2. A passenger arrives at a point next to the track 6.0 s after the end of the train has passed the very same point. What is the slowest constant speed at which she can run and still catch the train? On a single graph, plot the position versus time curves for both the train and the passenger.

96 ••• Ball A is dropped from the top of a building of height h at the same instant that ball B is thrown vertically upward from the ground. When the balls collide, they are moving in opposite directions, and the speed of A is twice the speed of B. At what height does the collision occur?

97 ••• Solve Problem 96 if the collision occurs when the balls are moving in the same direction and the speed of A is 4 times that of B.

98 ••• Starting at one station, a subway train accelerates from rest at a constant rate of 1.00 m/s^2 for half the distance to the next station, then slows down at the same rate for the second half of the journey. The total distance between stations is 900 m. (*a*) Sketch a graph of the velocity v_x as a function of time over the full journey. (*b*) Sketch a graph of the position as a function of time over the full journey. Place appropriate numerical values on both axes.

99 ••• A speeder traveling at a constant speed of 125 km/h races past a billboard. A patrol car pursues from rest with constant acceleration of (8.0 km/h)/s until it reaches its maximum speed of 190 km/h, which it maintains until it catches up with the speeder. (*a*) How long does it take the patrol car to catch the speeder if it starts moving just as the speeder passes? (*b*) How far does each car travel? (*c*) Sketch $x(t)$ for each car. SSM

100 ••• When the patrol car in Problem 99 (traveling at 190 km/h) is 100 m behind the speeder (traveling at 125 km/h), the speeder sees the police car and slams on his brakes, locking the wheels. (*a*) Assuming that each car can brake at 6.0 m/s^2 and that the driver of the police car brakes instantly as she sees the brake lights of the speeder (reaction time = 0.0 s), show that the cars collide. (*b*) At what time after the speeder applies his brakes do the two cars collide? (*c*) Discuss how reaction time would affect this problem.

101 ••• Leadfoot Lou enters the "Rest-to-Rest" auto competition, in which each contestant's car begins and ends at rest, covering a fixed distance L in as short a time as possible. The intention is to demonstrate driving skills, and to find which car is the best at the *total combination* of speeding up and slowing down. The course is designed so that maximum speeds of the cars are never reached. (*a*) If Lou's car maintains an acceleration (magnitude) of a during speedup, and maintains a deceleration (magnitude) of $2a$ during braking, at what fraction of L should Lou move his foot from the gas pedal to the brake? (*b*) What fraction of the total time for the trip has elapsed at that point? (*c*) What is the fastest speed Lou's car ever reaches? Neglect Lou's reaction time, and answer in terms of a and L.

102 ••• A physics professor, equipped with a rocket backpack, steps out of a helicopter at an altitude of 575 m with zero initial velocity. (Neglect air resistance.) For 8.0 s, she falls freely. At that time, she fires her rockets and slows her rate of descent at 15 m/s^2 until her rate of descent reaches 5.0 m/s. At this point, she adjusts her rocket engine controls to maintain that rate of descent until she reaches the ground. (*a*) On a single graph, sketch her acceleration and velocity as functions of time. (Take upward to be positive.) (*b*) What is her speed at the end of the first 8.0 s? (*c*) What is the duration of her slowing-down period? (*d*) How far does she travel while slowing down? (*e*) How much time is required for the entire trip from the helicopter to the ground? (*f*) What is her average velocity for the entire trip?

INTEGRATION OF THE EQUATIONS OF MOTION

103 • The velocity of a particle is given by $v_x(t) = (6.0\ \text{m/s}^2)t + (3.0\ \text{m/s})$. (*a*) Sketch v versus t and find the area under the curve for the interval $t = 0$ to $t = 5.0$ s. (*b*) Find the position function $x(t)$. Use it to calculate the displacement during the interval $t = 0$ to $t = 5.0$ s. SSM

104 • Figure 2-41 shows the velocity of a particle versus time. (*a*) What is the magnitude, in meters, represented by the area of the shaded box? (*b*) Estimate the displacement of the particle for the two 1-s intervals, one beginning at $t = 1.0$ s and the other at $t = 2.0$ s. (*c*) Estimate the average velocity for the interval $1.0\,\text{s} \le t \le 3.0\,\text{s}$. (*d*) The equation of the curve is $v_x = (0.50\ \text{m/s}^3)t^2$. Find the displacement of the particle for the interval $1.0\ \text{s} \le t \le 3.0\,\text{s}$ by integration and compare this answer with your answer for Part (*b*). Is the average velocity equal to the mean of the initial and final velocities for this case?

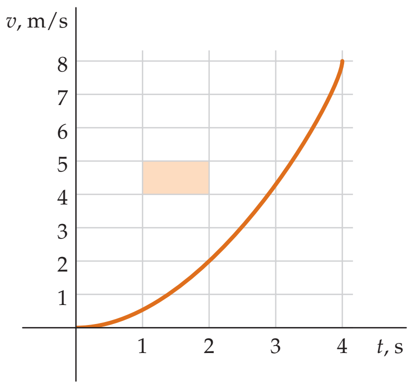

FIGURE 2-41 Problem 104

105 •• The velocity of a particle is given by $v_x = (7.0\ \text{m/s}^3)t^2 - 5.0\ \text{m/s}$. If the particle is at the origin at $t_0 = 0$, find the position function $x(t)$.

106 •• Consider the velocity graph in Figure 2-42. Assuming $x = 0$ at $t = 0$, write correct algebraic expressions for $x(t)$, $v_x(t)$, and $a_x(t)$ with appropriate numerical values inserted for all constants.

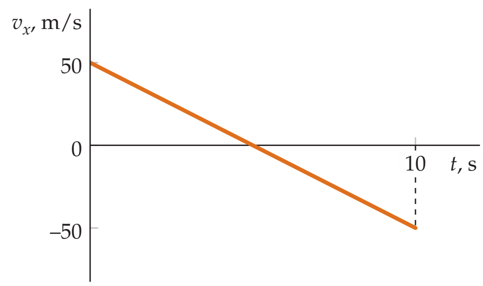

FIGURE 2-42 Problem 106

107 ••• Figure 2-43 shows the acceleration of a particle versus time. (*a*) What is the magnitude, in m/s, of the area of the shaded box? (*b*) The particle starts from rest at $t = 0$. Estimate the velocity at $t = 1.0$ s, 2.0 s, and 3.0 s by counting the boxes under the curve. (*c*) Sketch the curve v_x versus t from your results for Part (*b*); then estimate how far the particle travels in the interval $t = 0$ to $t = 3.0$ s.

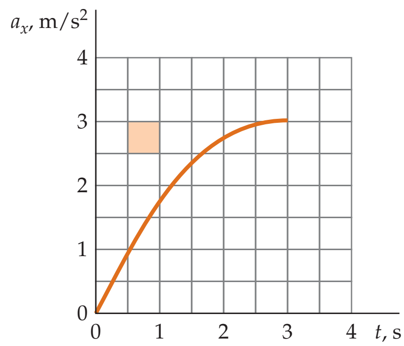

FIGURE 2-43 Problem 107

108 ••• Figure 2-44 is a graph of v_x versus t for a particle moving along a straight line. The position of the particle at time $t = 0$ is $x_0 = 5.0$ m. (*a*) Find x for various times t by counting boxes, and sketch x as a function of t. (*b*) Sketch a graph of the acceleration a_x as a function of the time t. (*c*) Determine the displacement of the particle between $t = 3.0$ s and 7.0 s.

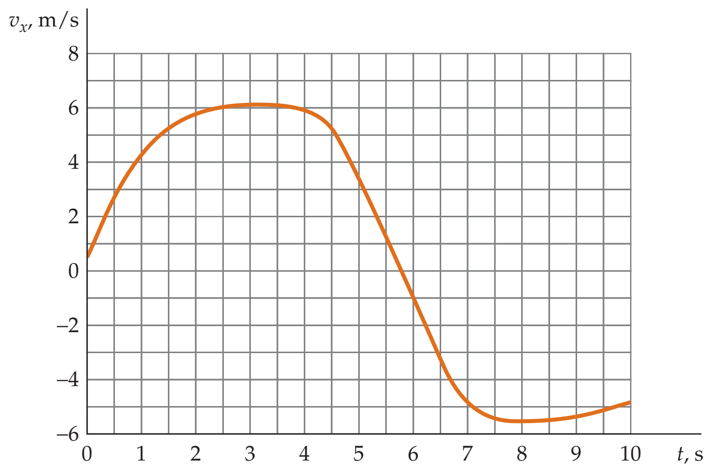

FIGURE 2-44 Problem 108

109 ••• **CONCEPTUAL** Figure 2-45 shows a plot of x versus t for an object moving along a straight line. For this motion, sketch graphs (using the same t axis) of (*a*) v_x as a function of t, and (*b*) a_x as a function of t. (*c*) Use your sketches to qualitatively compare the time(s) when the object is at its largest distance from the origin to the time(s) when its speed is greatest. Explain why the times are *not* the same. (*d*) Use your sketches to qualitatively compare the time(s) when the object is moving fastest to the time(s) when its acceleration is the largest. Explain why the times are *not* the same. SSM

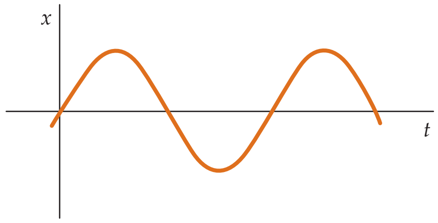

FIGURE 2-45 Problem 109

110 ••• **MULTISTEP** The acceleration of a certain rocket is given by $a_x = bt$, where b is a positive constant. (*a*) Find the position function $x(t)$ if $x = x_0$ and $v_x = v_{0x}$ at $t = 0$. (*b*) Find the position and velocity at $t = 5.0$ s if $x_0 = 0$, $v_{0x} = 0$ and $b = 3.0\ \mathrm{m/s^3}$. (*c*) Compute the average velocity of the rocket between $t = 4.5$ s and 5.5 s at $t = 5.0$ s if $x_0 = 0$, $v_{0x} = 0$ and $b = 3.0\ \mathrm{m/s^3}$. Compare this average velocity with the instantaneous velocity at $t = 5.0$ s.

111 ••• In the time interval from 0.0 s to 10.0 s, the acceleration of a particle traveling in a straight line is given by $a_x = (0.20\ \mathrm{m/s^3})t$. Let to the right be the $+x$ direction. The particle initially has a velocity to the right of 9.5 m/s and is located 5.0 m to the left of the origin. (*a*) Determine the velocity as a function of time during the interval; (*b*) determine the position as a function of time during the interval; (*c*) determine the average velocity between $t = 0.0$ s and 10.0 s, and compare it to the average of the instantaneous velocities at the start and ending times. Are these two averages equal? Explain. SSM

112 ••• Consider the motion of a particle that experiences a variable acceleration given by $a_x = a_{0x} + bt$, where a_{0x} and b are constants and $x = x_0$ and $v_x = v_{0x}$ at $t = 0$. (*a*) Find the instantaneous velocity as a function of time. (*b*) Find the position as a function of time. (*c*) Find the average velocity for the time interval with an initial time of zero and arbitrary final time t. (*d*) Compare the average of the initial and final velocities to your answer to Part (*c*). Are these two averages equal? Explain.

GENERAL PROBLEMS

113 ••• **CONTEXT-RICH** You are a student in a science class that is using the following apparatus to determine the value of g. Two photogates are used. (Note: You may be familiar with photogates in everyday living. You see them in the doorways of some stores. They are designed to ring a bell when someone interrupts the beam while walking through the door.) One photogate is located at the edge of a table that is 1.00 m above the floor, and the second photogate is located directly below the first, at a height 0.500 m above the floor. You are told to drop a marble through these gates, releasing it from rest a negligible distance above the upper gate. The upper gate starts a timer as the ball passes through its beam. The second photogate stops the timer when the ball passes through its beam. (*a*) Prove that the experimental magnitude of free-fall acceleration is given by $g_{\mathrm{exp}} = (2\Delta y)/(\Delta t)^2$, where Δy is the vertical distance between the photogates and Δt is the fall time. (*b*) For your setup, what value of Δt would you expect to measure, assuming g_{exp} is the standard value (9.81 $\mathrm{m/s^2}$)? (*c*) During the experiment, a slight error is made. Instead of locating the first photogate even with the top of the table, your not-so-careful lab partner locates it 0.50 cm lower than the top of the table. However, she does manage to properly locate the second photogate at a height of 0.50 m above the floor. However, she releases the marble from the same height that it was released from when the photogate was 1.00 m above the floor. What value of g_{exp} will you and your partner determine? What percentage difference does this represent from the standard value of g?

114 ••• **MULTISTEP** The position of a body oscillating on a spring is given by $x = A \sin \omega t$, where A and ω (lower case Greek omega) are constants, $A = 5.0$ cm, and $\omega = 0.175\ \mathrm{s^{-1}}$. (*a*) Plot x as a function of t for $0 \le t \le 36$ s. (*b*) Measure the slope of your graph at $t = 0$ to find the velocity at this time. (*c*) Calculate the average velocity for a series of intervals, beginning at $t = 0$ and ending at $t = 6.0$, 3.0, 2.0, 1.0, 0.50, and 0.25 s. (*d*) Compute dx/dt to find the velocity at time $t = 0$. (*e*) Compare your results in Parts (*c*) and (*d*) and explain why your Part (*c*) results approach your Part (*d*) result.

115 ••• **CONCEPTUAL** Consider an object that is attached to a horizontally oscillating piston. The object moves with a velocity given by $v = B \sin(\omega t)$, where B and ω (lower case Greek omega) are constants and ω is in $\mathrm{s^{-1}}$. (*a*) Explain why B is equal to the maximum speed v_{max}. (*b*) Determine the acceleration of the object as a function of time. Is the acceleration constant? (*c*) What is the maximum acceleration (magnitude) in terms of ω and v_{max}. (*d*) At $t = 0$, the object's position is known to be x_0. Determine the position as a function of time in terms of t, ω, x_0 and v_{max}. SSM

116 ••• Suppose the acceleration of a particle is a function of x, where $a_x(x) = (2.0\ \mathrm{s^{-2}})x$. (*a*) If the velocity is zero when $x = 1.0$ m, what is the speed when $x = 3.0$ m? (*b*) How long does it take the particle to travel from $x = 1.0$ m to $x = 3.0$ m.

117 ••• A rock falls through water with a continuously decreasing acceleration. Assume that the rock's acceleration as a function of *velocity* has the form $a_y = g - bv_y$ where b is a positive constant. (The $+y$ direction is directly downward.) (*a*) What are the SI units of b? (*b*) Prove mathematically that if the rock is released from rest at time $t = 0$, the acceleration will depend exponentially on *time* according to $a_y(t) = ge^{-bt}$. (c) What is the terminal speed for the rock in terms of g and b? (See Problem 38 for an explanation of the phenomenon of *terminal speed*.) SSM

118 ••• A small rock sinking through water (see Problem 117) experiences an exponentially decreasing acceleration given by $a_y(t) = ge^{-bt}$, where b is a positive constant that depends on the shape and size of the rock and the physical properties of the water. Based upon this, find expressions for the velocity and position of the rock as functions of time. Assume that its initial position and velocity are both zero and that the $+y$ direction is directly downward.

119 ••• **SPREADSHEET** The acceleration of a skydiver jumping from an airplane is given by $a_y = g - bv_y^2$, where b is a positive constant that depends on the skydiver's cross-sectional area and the density of the surrounding atmosphere she is diving through. The $+y$ directions is directly downward. (*a*) If her initial speed is zero when stepping from a hovering helicopter, show that her speed as a function of time is given by $v_y(t) = v_{\mathrm{t}} \tanh(t/T)$, where v_{t} is the terminal speed (see Problem 38) given by $v_{\mathrm{t}} = \sqrt{g/b}$, and $T = v_{\mathrm{t}}/g$ is a time-scale parameter. (*b*) What fraction of the terminal speed is the speed at $t = T$. (*c*) Use a **spreadsheet** program to graph $v_y(t)$ as a function of time, using a terminal speed of 56 m/s (use this value to calculate b and T). Does the resulting curve make sense?

120 ••• **APPROXIMATION** Imagine that you are standing at a wishing well, wishing that you knew how deep the surface of the water was. Cleverly, you make your wish. Then you take a penny from your pocket and drop it into the well. Exactly three seconds after you dropped the penny, you hear the sound it made when it struck the water. If the speed of sound is 343 m/s, how deep is the well? Neglect any effects due to air resistance.

121 ••• **CONTEXT-RICH** You are driving a car at the 25-mi/h speed limit when you observe the light at the intersection 65 m in front of you turn yellow. You know that at that particular intersection the light remains yellow for exactly 5.0 s before turning red. After you think for 1.0 s, you then accelerate the car at a constant rate. You somehow manage to pass your 4.5-m-long car completely through the 15.0-m-wide intersection just as the light turns red, thus narrowly avoiding a ticket for being in an intersection when the light is red. Immediately after passing through the intersection, you take your foot off the accelerator, relieved. However, down the road you are pulled over for speeding. You assume that you were ticketed for the speed of your car as it exited the intersection. Determine this speed and decide whether you should fight this ticket in court. Explain.

122 ••• For a spherical celestial object of radius R, the acceleration due to gravity g at a distance x from the *center* of the object is $g = g_0R^2/x^2$, where g_0 is the acceleration due to gravity at the object's surface and $x > R$. For the moon, take $g_0 = 1.63\ \text{m/s}^2$ and $R = 3200$ km. If a rock is released from rest at a height of $4R$ above the lunar surface, with what speed does the rock impact the moon? *Hint: Its acceleration is a function of position and increases as the object falls. So do not use constant acceleration free-fall equations, but go back to basics.*

CHAPTER 3

SAILBOATS DO NOT TRAVEL IN STRAIGHT LINES TO THEIR DESTINATIONS, BUT INSTEAD MUST "TACK" BACK AND FORTH ACROSS THE WIND. THIS BOAT MUST SAIL EAST, THEN SOUTH, AND THEN EAST AGAIN, IN ITS JOURNEY TO A SOUTHEASTERN PORT. *(PhotoDisc/Getty Images.)*

Motion in Two and Three Dimensions

? How can we calculate the boat's displacement and its average velocity? (See Example 3-1.)

The motion of a sailboat tacking into the wind or the path of a home-run ball as it flies out of a ballpark cannot be fully described using the equations we presented in Chapter 2. Instead, to describe these motions, we must extend the idea of motion in one dimension discussed in Chapter 2 to two and three dimensions. To do this, we must revisit the concept of vectors and look at how they can be used to analyze and describe motion in more than one dimension.

In this chapter, we will discuss the displacement, velocity, and acceleration vectors in further detail. In addition, we will discuss two specific types of motion: projectile motion and circular motion. The material in this chapter presumes you are familiar with the material that introduces vectors in Sections 6 and 7 of Chapter 1. You are encouraged to review these sections before proceeding in this chapter.

3-1 DISPLACEMENT, VELOCITY, AND ACCELERATION

In Chapter 2, the concepts of displacement, velocity, and acceleration were used to describe the motion of an object moving in a straight line. Now we use the concept of vectors to extend these characteristics of motion in two and three dimensions.

POSITION AND DISPLACEMENT VECTORS

The **position vector** of a particle is a vector drawn from the origin of a coordinate system to the location of the particle. For a particle in the x, y plane at the point with coordinates (x, y), the position vector $\vec{r}$ is

$$\vec{r} = x\hat{i} + y\hat{j} \qquad 3\text{-}1$$

DEFINITION—POSITION VECTOR

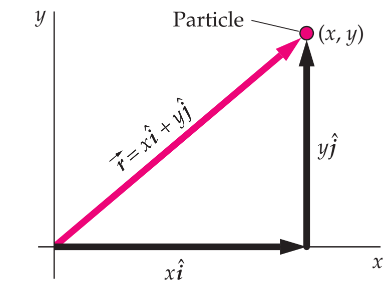

FIGURE 3-1 The x and y components of the position vector $\vec{r}$ for a particle are the x and y (Cartesian) coordinates of the particle.

Note that x and y components of the position vector $\vec{r}$ are the Cartesian coordinates (Figure 3-1) of the particle.

Figure 3-2 shows the actual path or trajectory of the particle. At time t_1, the particle is at P_1, with position vector $\vec{r}_1$; by time t_2, the particle has moved to P_2, with position vector $\vec{r}_2$. The particle's change in position is the displacement vector $\Delta\vec{r}$:

$$\Delta\vec{r} = \vec{r}_2 - \vec{r}_1 \qquad 3\text{-}2$$

DEFINITION—DISPLACEMENT VECTOR

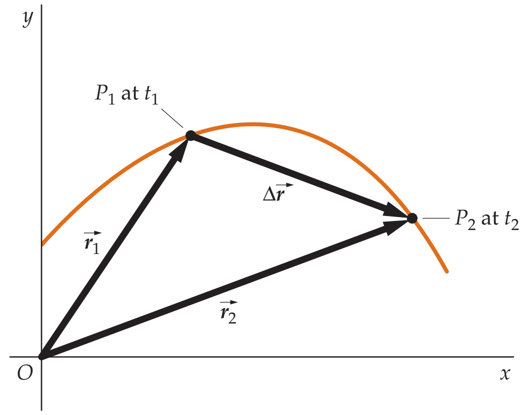

FIGURE 3-2 The displacement vector $\Delta\vec{r}$ is the difference in the position vectors, $\Delta\vec{r} = \vec{r}_2 - \vec{r}_1$. Equivalently, $\Delta\vec{r}$ is the vector that, when added to the initial position vector $\vec{r}_1$, yields the final position vector $\vec{r}_2$. That is, $\vec{r}_1 + \Delta\vec{r} = \vec{r}_2$.

Using unit vectors, we can rewrite this displacement as

$$\Delta\vec{r} = \vec{r}_2 - \vec{r}_1 = (x_2 - x_1)\hat{i} + (y_2 - y_1)\hat{j} = \Delta x\hat{i} + \Delta y\hat{j} \qquad 3\text{-}3$$

! Do not confuse the trajectory in graphs of x-versus-y with the curve in the x-versus-t plots of Chapter 2.

VELOCITY VECTORS

Recall that average velocity is defined as displacement divided by the elapsed time. The result of the displacement vector divided by the elapsed time interval $\Delta t = t_2 - t_1$ is the **average-velocity vector:**

$$\vec{v}_{\text{av}} = \frac{\Delta\vec{r}}{\Delta t} \qquad 3\text{-}4$$

DEFINITION—AVERAGE-VELOCITY VECTOR

The average velocity vector and the displacement vector are in the same direction.

The magnitude of the displacement vector is less than the distance traveled along the curve unless the particle moves along a straight line and never reverses its direction. However, if we consider smaller and smaller time intervals (Figure 3-3), the magnitude of the displacement approaches the distance along the curve, and the angle between $\Delta\vec{r}$ and the tangent to the curve at the beginning of the interval approaches zero. We define the **instantaneous-velocity vector** as the limit of the average-velocity vector as Δt approaches zero:

$$\vec{v} = \lim_{\Delta t \to 0} \frac{\Delta\vec{r}}{\Delta t} = \frac{d\vec{r}}{dt} \qquad 3\text{-}5$$

DEFINITION—INSTANTANEOUS-VELOCITY VECTOR

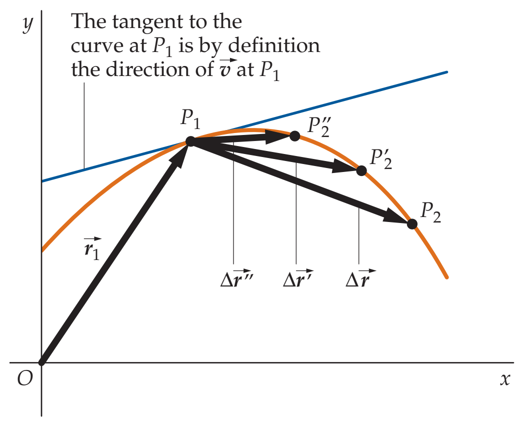

FIGURE 3-3 As the time interval decreases, the angle between direction of $\Delta\vec{r}$ and the tangent to the curve approaches zero.

The instantaneous-velocity vector is the derivative of the position vector with respect to time. Its magnitude is the speed and its direction is along the line tangent to the curve in the direction of motion of the particle.

To calculate the derivative in Equation 3-5, we write the position vectors in terms of their components (Equation 3-1):

$$\Delta\vec{r} = \vec{r}_2 - \vec{r}_1 = (x_2 - x_1)\hat{i} + (y_2 - y_1)\hat{j} = \Delta x\hat{i} + \Delta y\hat{j}$$

Then

$$\vec{v} = \lim_{\Delta t\to 0}\frac{\Delta\vec{r}}{\Delta t} = \lim_{\Delta t\to 0}\frac{\Delta x\hat{i} + \Delta y\hat{j}}{\Delta t} = \lim_{\Delta t\to 0}\left(\frac{\Delta x}{\Delta t}\right)\hat{i} + \lim_{\Delta t\to 0}\left(\frac{\Delta y}{\Delta t}\right)\hat{j}$$

or

$$\vec{v} = \frac{dx}{dt}\hat{i} + \frac{dy}{dt}\hat{j} = v_x\hat{i} + v_y\hat{j} \qquad 3\text{-}6$$

where $v_x = dx/dt$ and $v_y = dy/dt$ are the x and y components of the velocity.

The magnitude of the velocity vector is given by:

$$v = \sqrt{v_x^2 + v_y^2} \qquad 3\text{-}7$$

and the direction of the velocity is given by

$$\theta = \tan^{-1}\frac{v_y}{v_x} \qquad 3\text{-}8$$

Do not trust your calculator to always give the correct value for θ when using Equation 3-8. Most calculators will return the correct value for θ if v_x is positive. If v_x is negative, however, you will need to add 180° (π rad) to the value returned by the calculator.

See **Math Tutorial** *for more information on*
Trigonometry

Example 3-1 The Velocity of a Sailboat

A sailboat has coordinates $(x_1, y_1) = (130\text{ m}, 205\text{ m})$ at $t_1 = 60.0$ s. Two minutes later, at time t_2, it has coordinates $(x_2, y_2) = (110\text{ m}, 218\text{ m})$. (*a*) Find the average velocity $\vec{v}_{av}$ for this two-minute interval. Express $\vec{v}_{av}$ in terms of its rectangular components. (*b*) Find the magnitude and direction of this average velocity. (*c*) For $t \geq 20.0$ s, the position of a second sailboat as a function of time is $x(t) = b_1 + b_2 t$ and $y(t) = c_1 + c_2/t$, where $b_1 = 100$ m, $b_2 = 0.500$ m/s, $c_1 = 200$ m, and $c_2 = 360$ m·s. Find the instantaneous velocity as a function of time t, for $t \geq 20.0$ s.

PICTURE The initial and final positions of the first sailboat are given. Because the motion of the boat is in two dimensions, we need to express the displacement, average velocity, and instantaneous velocity as vectors. Then we can use Equations 3-5 through 3-8 to obtain the requested values.

SOLVE

(*a*) 1. Draw a coordinate system (Figure 3-4) and draw the displacement of the sailboat. Draw the average-velocity vector (it and the displacement vector are in the same direction):

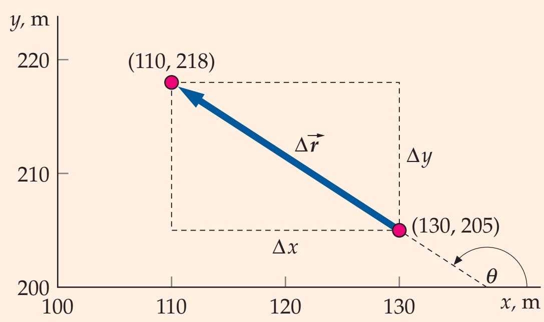

FIGURE 3-4

2. The x and y components of the average velocity $\vec{v}_{av}$ are calculated directly from their definitions:

$$\vec{v}_{av} = v_{x\,av}\hat{i} + v_{y\,av}\hat{j}$$

where

$$v_{x\,av} = \frac{\Delta x}{\Delta t} = \frac{110\text{ m} - 130\text{ m}}{120\text{ s}} = -0.167\text{ m/s}$$

$$v_{y\,av} = \frac{\Delta y}{\Delta t} = \frac{218\text{ m} - 205\text{ m}}{120\text{ s}} = 0.108\text{ m/s}$$

so

$$\vec{v}_{av} = \boxed{-(0.167\text{ m/s})\hat{i} + (0.108\text{ m/s})\hat{j}}$$

(*b*) 1. The magnitude of $\vec{v}_{av}$ is found from the Pythagorean theorem:

$$v_{av} = \sqrt{(v_{x\,av})^2 + (v_{y\,av})^2} = \boxed{0.199\text{ m/s}}$$

2. The ratio of $v_{y\,av}$ to $v_{x\,av}$ gives the tangent of the angle θ between $\vec{v}_{av}$ and the $+x$ direction (we add 180° to the value of −33.0° returned by the calculator because v_x is negative):

$$\tan\theta = \frac{v_{y\,av}}{v_{x\,av}}$$

so

$$\theta = \tan^{-1}\frac{v_{y\,av}}{v_{x\,av}} = \tan^{-1}\frac{0.108\text{ m/s}}{-0.167\text{ m/s}} = -33.0° + 180° = \boxed{147°}$$

(*c*) We find the instantaneous velocity $\vec{v}$ by calculating dx/dt and dy/dt: $\vec{v} = \frac{dx}{dt}\hat{i} + \frac{dy}{dt}\hat{j} = b_2\hat{i} - c_2t^{-2}\hat{j} = \boxed{(0.500\ \text{m/s})\hat{i} - \frac{360\ \text{m}\cdot\text{s}}{t^2}\hat{j}}$

CHECK The magnitude of $\vec{v}_{av}$ is greater than the absolute value of either its x or its y component. With t in seconds, the units for the y component of $\vec{v}$ in Part (*c*) are $\text{m}\cdot\text{s/s}^2 = \text{m/s}$, which are appropriate units for velocity.

RELATIVE VELOCITY

If you are sitting in an airplane that is moving with a velocity of 500 mi/h toward the east, your velocity is the same as that of the airplane. This velocity might be your velocity relative to the surface of Earth, or it might be your velocity relative to the air outside the airplane. (These two relative velocities would be very different if the plane were flying in a jet stream.) In addition, your velocity relative to the airplane itself is zero.

The surface of Earth, the air outside the plane, and the plane itself are frames of reference. A **frame of reference** (or reference frame) is an extended object or collection of objects whose parts are at rest relative to each other. To specify the velocity of an object requires that you specify the frame of reference that the velocity is relative to.

Midair refueling. Each plane is nearly at rest relative to the other, though both are moving with very large velocities relative to Earth. *(Novastock/Dembinsky Photo Associates.)*

We use coordinate axes that are attached to reference frames to make position measurements. (A coordinate axis is said be attached to a reference frame if the coordinate axis is at rest relative to the reference frame.) For a horizontal coordinate axis attached to the plane, your position remains constant. (At least it does if you remain in your seat.) However, for a horizontal coordinate axis attached to the surface of Earth, and for a horizontal coordinate axis attached to the air outside the plane, your position keeps changing. (If you have trouble imagining a coordinate axis attached to the air outside the plane, instead imagine a coordinate axis attached to a balloon that is suspended in, and drifting with, the air. The air and the balloon are at rest relative to each other, and together they form a single reference frame.)

If a particle p moves with velocity $\vec{v}_{pA}$ relative to reference frame A, which is in turn moving with velocity $\vec{v}_{AB}$ relative to reference frame B, the velocity $\vec{v}_{pB}$ of the particle relative to reference frame B is related to $\vec{v}_{pA}$ and $\vec{v}_{AB}$ by

$$\vec{v}_{pB} = \vec{v}_{pA} + \vec{v}_{AB} \tag{3-9}$$

For example, if a person p is on a railroad car C that is moving with velocity $\vec{v}_{CG}$ relative to the ground G (Figure 3-5*a*), and the person is walking with velocity $\vec{v}_{pC}$ (Figure 3-5*b*) relative to the car, then the velocity of the person relative to the ground is the vector sum of these two velocities: $\vec{v}_{pG} = \vec{v}_{pC} + \vec{v}_{CG}$ (Figure 3-5*c*).

The velocity of object A relative to object B is equal in magnitude and opposite in direction to the velocity of object B relative to object A. For example, $\vec{v}_{pC}$ is equal to $-\vec{v}_{Cp}$, where $\vec{v}_{pC}$ is the velocity of the person relative to the car, and $\vec{v}_{Cp}$ is the velocity of the car relative to the person.

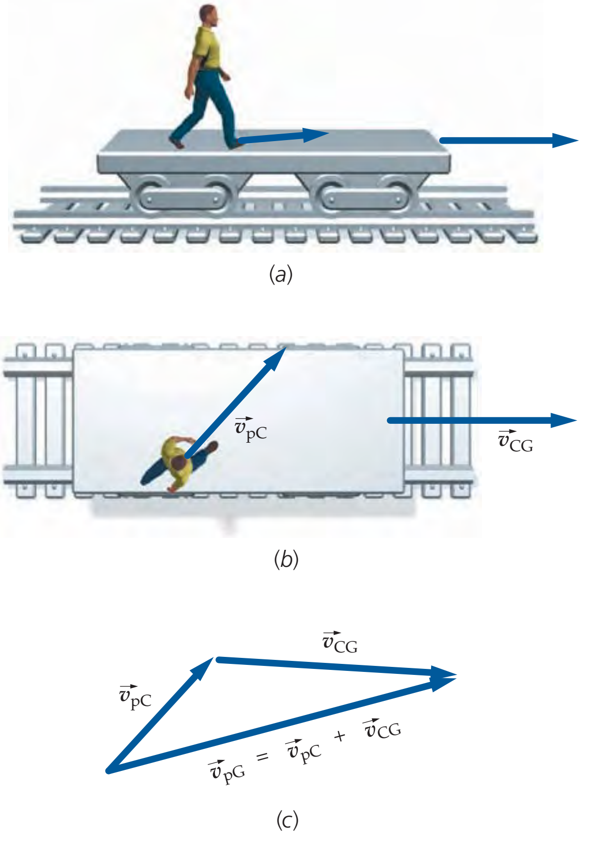

FIGURE 3-5 The velocity of the person relative to the ground is equal to the velocity of the person relative to the car plus the velocity of the car relative the ground.

PROBLEM-SOLVING STRATEGY

Relative Velocity

PICTURE The first step in solving a relative-velocity problem is to identify and label the relevant reference frames. Here, we will call them reference frame A and reference frame B.

SOLVE

1. Using $\vec{v}_{pB} = \vec{v}_{pA} + \vec{v}_{AB}$ (Equation 3-9), relate the velocity of the moving object (particle p) relative to frame A to the velocity of the particle relative to frame B.
2. Sketch a vector addition diagram for the equation $\vec{v}_{pB} = \vec{v}_{pA} + \vec{v}_{AB}$. Use the head-to-tail method of vector addition. Include coordinate axes on the sketch.
3. Solve for the desired quantity. Use trigonometry where appropriate.

CHECK Make sure that you solve for the velocity or position of the moving object relative to the proper reference frame.

! The order of the subscripts used when denoting relative velocity vectors is very important. When using relative velocity vectors, be very careful to write the subscripts in a consistent order.

Example 3-2 A Flying Plane

A pilot wishes to fly a plane due north relative to the ground. The airspeed of the plane is 200 km/h and the wind is blowing from west to east at 90 km/h. (*a*) In which direction should the plane head? (*b*) What is the ground speed of the plane?

PICTURE Because the wind is blowing toward the east, a plane headed due north will drift off course toward the east. To compensate for this crosswind, the plane must head west of due north. The velocity of the plane relative to the ground $\vec{v}_{pG}$ is equal to the velocity of the plane relative to the air $\vec{v}_{pA}$ plus the velocity of the air relative to the ground $\vec{v}_{AG}$.

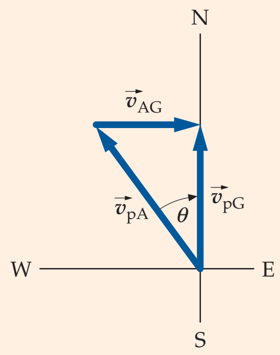

FIGURE 3-6

SOLVE

(a) 1. The velocity of the plane relative to the ground is given by Equation 3-9:

$$\vec{v}_{pG} = \vec{v}_{pA} + \vec{v}_{AG}$$

2. Make a velocity addition diagram (Figure 3-6) showing the addition of the vectors in step 1. Include direction axes:

3. The sine of the angle θ between the velocity of the plane relative to the air and due north equals the ratio of v_{AG} and v_{pA}:

$$\sin\theta = \frac{v_{AG}}{v_{pA}} = \frac{90\text{ km/h}}{200\text{ km/h}} = \frac{9}{20}$$

so

$$\theta = \sin^{-1}\frac{9}{20} = \boxed{27^\circ \text{ west of north}}$$

(*b*) Because $\vec{v}_{AG}$ and $\vec{v}_{pG}$ are mutually perpendicular, we can use the Pythagorean theorem to find the magnitude of $\vec{v}_{pG}$:

$$v_{pA}^2 = v_{pG}^2 + v_{AG}^2$$

so

$$v_{pG} = \sqrt{v_{pA}^2 - v_{AG}^2}$$

$$= \sqrt{(200\text{ km/h})^2 - (90\text{ km/h})^2} = \boxed{180\text{ km/h}}$$

CHECK Heading directly into the 90 km/h wind would result in a ground speed of 200 km/h − 90 km/h = 110 km/h. The Part (*b*) result of 180 km/h is greater than 110 km/h and less than 200 km/h, as expected.

ACCELERATION VECTORS

The **average-acceleration vector** is the ratio of the change in the instantaneous-velocity vector, $\Delta\vec{v}$, to the elapsed time interval Δt:

$$\vec{a}_{\text{av}} = \frac{\Delta\vec{v}}{\Delta t} \qquad 3\text{-}10$$

DEFINITION—AVERAGE-ACCELERATION VECTOR

The **instantaneous-acceleration vector** is the limit of this ratio as Δt approaches zero; in other words, it is the derivative of the velocity vector with respect to time:

$$\vec{a} = \lim_{\Delta t \to 0} \frac{\Delta\vec{v}}{\Delta t} = \frac{d\vec{v}}{dt} \qquad 3\text{-}11$$

DEFINITION—INSTANTANEOUS-ACCELERATION VECTOR

To calculate the instantaneous acceleration, we express $\vec{v}$ in rectangular coordinates:

$$\vec{v} = v_x\hat{i} + v_y\hat{j} + v_z\hat{k} = \frac{dx}{dt}\hat{i} + \frac{dy}{dt}\hat{j} + \frac{dz}{dt}\hat{k}$$

Then

$$\vec{a} = \frac{dv_x}{dt}\hat{i} + \frac{dv_y}{dt}\hat{j} + \frac{dv_z}{dt}\hat{k} = \frac{d^2x}{dt^2}\hat{i} + \frac{d^2y}{dt^2}\hat{j} + \frac{d^2z}{dt^2}\hat{k}$$

$$= a_x\hat{i} + a_y\hat{j} + a_z\hat{k} \qquad 3\text{-}12$$

where the components of $\vec{a}$ are

$$a_x = \frac{dv_x}{dt}, \quad a_y = \frac{dv_y}{dt}, \quad a_z = \frac{dv_z}{dt}.$$

Example 3-3 A Thrown Baseball

The position of a thrown baseball is given by $\vec{r} = [1.5\text{ m} + (12\text{ m/s})t]\hat{i} + [(16\text{ m/s})t - (4.9\text{ m/s}^2)t^2]\hat{j}$. Find its velocity and acceleration as functions of time.

PICTURE Recall that $\vec{r} = x\hat{i} + y\hat{j}$ (Equation 3-1). We can find the x and y components of the velocity and acceleration by taking the time derivatives of x and y.

SOLVE

1. Find the x and y components of $\vec{r}$:

$$x = 1.5\text{ m} + (12\text{ m/s})t$$
$$y = (16\text{ m/s})t - (4.9\text{ m/s}^2)t^2$$

2. The x and y components of the velocity are found by differentiating x and y:

$$v_x = \frac{dx}{dt} = 12\text{ m/s}$$
$$v_y = \frac{dy}{dt} = (16\text{ m/s}) - 2(4.9\text{ m/s}^2)t$$

3. We differentiate v_x and v_y to obtain the components of the acceleration:

$$a_x = \frac{dv_x}{dt} = 0$$
$$a_y = \frac{dv_y}{dt} = -9.8\text{ m/s}^2$$

4. In vector notation, the velocity and acceleration are

$$\vec{v} = \boxed{(12\text{ m/s})\hat{i} + [16\text{ m/s} - (9.8\text{ m/s}^2)t]\hat{j}}$$
$$\vec{a} = \boxed{(-9.8\text{ m/s}^2)\hat{j}}$$

CHECK The units that accompany the quantities for velocity and acceleration are m/s and m/s^2, respectively. Our step 4 results for velocity and acceleration have the correct units of m/s and m/s^2.

For a vector to be constant, both its magnitude and direction must remain constant. If either magnitude or direction changes, the vector changes. Thus, if a car rounds a curve in the road at constant speed, it is accelerating because the velocity is changing due to the change in direction of the velocity vector.

Example 3-4 Rounding a Curve

A car is traveling east at 60 km/h. It rounds a curve, and 5.0 s later it is traveling north at 60 km/h. Find the average acceleration of the car.

PICTURE We can calculate the average acceleration from its definition, $\vec{a}_{av} = \Delta\vec{v}/\Delta t$. To do this, we first calculate $\Delta\vec{v}$, which is the vector that when added to $\vec{v}_i$, results in $\vec{v}_f$.

SOLVE

1. The average acceleration is the change in velocity divided by the elapsed time. To find $\vec{a}_{av}$, we first find the change in velocity:
$$\vec{a}_{av} = \frac{\Delta\vec{v}}{\Delta t}$$
2. To find $\Delta\vec{v}$, we first specify $\vec{v}_i$ and $\vec{v}_f$. Draw $\vec{v}_i$ and $\vec{v}_f$ (Figure 3-7*a*), and draw the vector addition diagram (Figure 3-7*b*) corresponding to $\vec{v}_f = \vec{v}_i + \Delta\vec{v}$:
3. The change in velocity is related to the initial and final velocities:
$$\vec{v}_f = \vec{v}_i + \Delta\vec{v}$$
4. Substitute these results to find the average acceleration:
$$\vec{a}_{av} = \frac{\vec{v}_f - \vec{v}_i}{\Delta t} = \frac{60\text{ km/h}\,\hat{j} - 60\text{ km/h}\,\hat{i}}{5.0\text{ s}}$$
5. Convert 60 km/h to meters per second:
$$60\ \cancel{\text{km}}/\cancel{\text{h}} \times \frac{1\ \cancel{\text{h}}}{3600\text{ s}} \times \frac{1000\text{ m}}{1\ \cancel{\text{km}}} = 16.7\text{ m/s}$$
6. Express the acceleration in meters per second squared:
$$\vec{a}_{av} = \frac{\vec{v}_f - \vec{v}_i}{\Delta t} = \frac{16.7\text{ m/s}\,\hat{j} - 16.7\text{ m/s}\,\hat{i}}{5.0\text{ s}}$$
$$= \boxed{-3.4\text{ m/s}^2\hat{i} + 3.4\text{ m/s}^2\hat{j}}$$

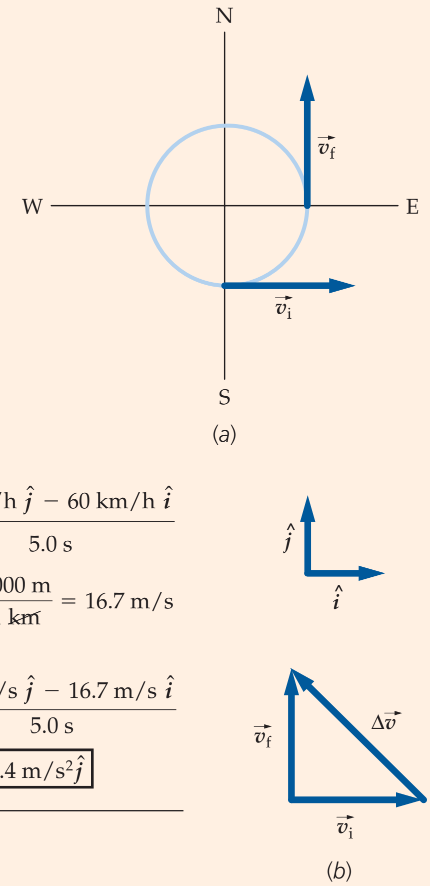

FIGURE 3-7

CHECK The eastward component of the velocity decreases from 60 km/h to zero, so we expect a negative acceleration component in the x direction. The northward component of the velocity increases from zero to 60 km/h, so we expect a positive acceleration component in the y direction. Our step 6 result meets both of these expectations.

TAKING IT FURTHER Note that the car is accelerating even though its speed remains constant.

PRACTICE PROBLEM 3-1 Find the magnitude and direction of the average acceleration vector.

The motion of an object traveling in a circle at constant speed is an example of motion in which the direction of the velocity changes even though its magnitude, the speed, remains constant.

! Do not assume that the acceleration of an object is zero just because the object is traveling at constant speed. For the acceleration to be zero, neither the magnitude nor the direction of the velocity vector can be changing.

THE DIRECTION OF THE ACCELERATION VECTOR

In the next few chapters, you will need to determine the direction of the acceleration vector from a description of the motion. To see how this is done, consider a bungee jumper as she slows down prior to reversing direction at the lowest point of her jump. To find the direction of her acceleration as she loses speed during the last stages of her descent, we draw a series of dots representing her position at

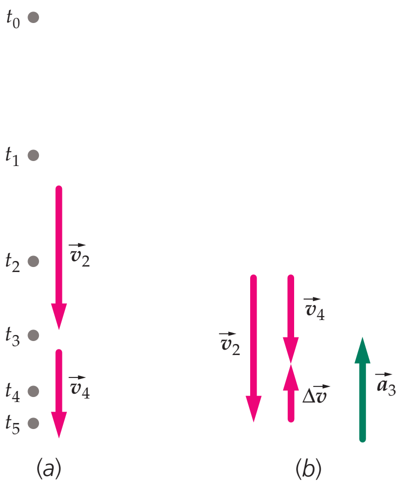

FIGURE 3-8 (*a*) A motion diagram of a bungee jumper losing speed as she descends. The dots are drawn at successive ticks of a clock. (*b*) We draw vectors $\vec{v}_2$ and $\vec{v}_4$ starting from the same point. Then, we draw $\Delta\vec{v}$ from the head of $\vec{v}_2$ to the head of $\vec{v}_4$ to obtain the graphical expression of the relation $\vec{v}_2 + \Delta\vec{v} = \vec{v}_4$. The acceleration $\vec{a}_3$ is in the same direction as $\Delta\vec{v}$.

CONCEPT CHECK 3-1

Figure 3-9 is a motion diagram of the bungee jumper before, during, and after time t_6, when she momentarily come to rest at the lowest point in her descent. During the part of her ascent shown, she is moving upward with increasing speed. Use this diagram to determine the direction of the jumper's acceleration (*a*) at time t_6 and (*b*) at time t_9.

successive ticks of a clock, as shown in Figure 3-8*a*. The faster she moves, the greater the distance she travels between ticks, and the greater the space between the dots in the diagram. Next we number the dots, starting with zero and increasing in the direction of her motion. At time t_0 she is at dot 0, at time t_1 she is at dot 1, and so forth. To determine the direction of the acceleration at time t_3, we draw vectors representing the jumper's velocities at times t_2 and t_4. The average acceleration during the interval t_2 to t_4 equals $\Delta\vec{v}/\Delta t$, where $\Delta\vec{v} = \vec{v}_4 - \vec{v}_2$ and $\Delta t = t_4 - t_2$. We use this result as an estimate of her acceleration at time t_3. That is, $\vec{a}_3 \approx \Delta\vec{v}/\Delta t$. Because $\vec{a}_3$ and $\Delta\vec{v}$ are in the same direction, by finding the direction of $\Delta\vec{v}$ we also find the direction of $\vec{a}_3$. The direction of $\Delta\vec{v}$ is obtained by using the relation $\vec{v}_2 + \Delta\vec{v} = \vec{v}_4$ and drawing the corresponding vector addition diagram (Figure 3-8*b*). Because the jumper is moving faster (the dots are farther apart) at t_2 than at t_4, we draw $\vec{v}_2$ longer than $\vec{v}_4$. From this figure, we can see that $\Delta\vec{v}$, and thus $\vec{a}_3$, is directed upward.

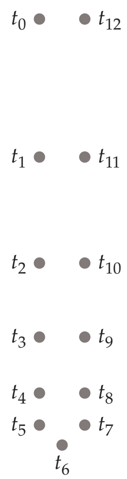

FIGURE 3-9 The dots for the bungee jumper's ascent are drawn to the right of those for her descent so that they do not overlap each other. Her motion, however, is straight down and then straight up.

Example 3-5 The Human Cannonball *Context-Rich*

You are asked to substitute for an ill performer in a circus that is sponsored by your school. The job, should you choose to accept it, is to get shot out of a cannon. Never afraid to accept a challenge, you accept. The barrel of the cannon is inclined an angle of 60° above the horizontal. Your physics teacher offers you extra credit on the next exam if you successfully use a motion diagram to estimate the direction of your acceleration during the ascending portion of the flight.

PICTURE During the ascending portion of the flight, you travel in a curved path with decreasing speed. To estimate the direction of your acceleration you use $\vec{a}_{av} = \Delta\vec{v}/\Delta t$ and estimate the direction of $\Delta\vec{v}$. To estimate the direction of $\Delta\vec{v}$, we draw a motion diagram and then make a sketch of the relation $\vec{v}_i + \Delta\vec{v} = \vec{v}_f$.

SOLVE

1. Make a motion diagram (Figure 3-10*a*) of your motion during the ascending portion of the flight. Because your speed decreases as you ascend, the spacing between adjacent dots on your diagram decreases as you rise:
2. Pick a dot on the motion diagram and draw a velocity vector on the diagram for both the preceding and the following dot. These vectors should be drawn tangent to your trajectory.

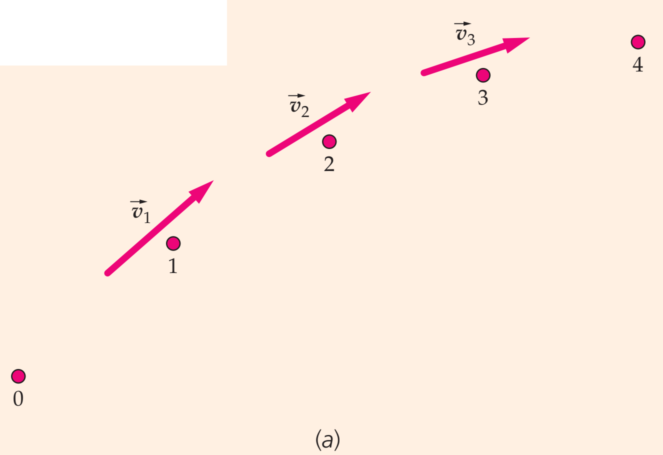

FIGURE 3-10

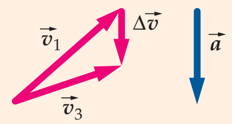
3. Draw the vector addition diagram (Figure 3-10*b*) of the relation $\vec{v}_i + \Delta\vec{v} = \vec{v}_f$. Begin by drawing the two velocity vectors from the same point. These vectors have the same magnitude and direction as the vectors drawn for step 2. Then, draw the $\Delta\vec{v}$ vector from the head of $\vec{v}_i$ to the head of $\vec{v}_f$.
4. Draw the estimated acceleration vector in the same direction as $\Delta\vec{v}$, but not the same length (because $\vec{a} \approx \Delta\vec{v}/\Delta t$).



(*b*)

FIGURE 3.10 *(continued)*

CHECK During the ascent, the upward component of the velocity is decreasing, so we expect $\Delta\vec{v}$ to have a downward vertical component. Our step 3 result satisfies this expectation.

TAKING IT FURTHER The process of finding the direction of the acceleration using a motion diagram is not precise. Therefore, the result is an estimate of the direction of the acceleration, as opposed to a precise determination.

CONCEPT CHECK 3-2

Use a motion diagram to estimate the direction of the acceleration in Example 3-5 during the descending portion of your flight.

3-2 SPECIAL CASE 1: PROJECTILE MOTION

In a home run hit or a field goal kick, the ball follows a particular curved path through the air. This type of motion, known as **projectile motion,** occurs when an object (the projectile) is launched into the air and is allowed to move freely. The projectile might be a ball, a dart, water shooting out of a fountain, or even a human body during a long jump. If air resistance is negligible, then the projectile is said to be in free-fall. For objects in free-fall near the surface of Earth, the acceleration is the downward acceleration due to gravity.

Figure 3-11 shows a particle launched with initial speed v_0 at angle θ_0 above the horizontal. Let the launch point be at (x_0, y_0); y is positive upward and x is positive to the right. The initial velocity $\Delta\vec{v}_0$ then has components

$$v_{0x} = v_0 \cos\theta_0 \qquad \text{3-13}a$$

$$v_{0y} = v_0 \sin\theta_0 \qquad \text{3-13}b$$

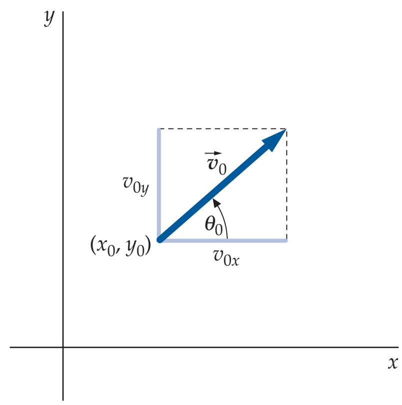


FIGURE 3-11 The components of $\vec{v}_0$ are $v_{0x} = v_0 \cos\theta_0$ and $v_{0y} = v_0 \sin\theta_0$, where θ_0 is the angle above the horizontal of $\vec{v}_0$.

In the absence of air resistance, the acceleration $\vec{a}$ is constant. The projectile has no horizontal acceleration, so the only acceleration is the free-fall acceleration $\vec{g}$, directed downward:

$$a_x = 0 \qquad \text{3-14}a$$

and

$$a_y = -g \qquad \text{3-14}b$$

Because the acceleration is constant, we can use the kinematic equations for constant acceleration presented in Chapter 2. The x component of the velocity $\vec{v}$ is constant because no horizontal acceleration exists:

$$v_x = v_{0x} \qquad \text{3-15}a$$

The y component of the velocity varies with time according to $v_y = v_{0y} + a_y t$ (Equation 2-12), with $a_y = -g$:

$$v_y = v_{0y} - gt \qquad \text{3-15}b$$

Notice that v_x does not depend on v_y and v_y does not depend on v_x: *The horizontal and vertical components of projectile motion are independent.* Dropping a ball from a desktop and projecting a second ball horizontally at the same time can demonstrate the independence of v_x and v_y, as shown in Figure 3-12. Notice that the two balls strike the floor simultaneously.

According to Equation 2-14, the displacements x and y are given by

$$x(t) = x_0 + v_{0x}t \tag{3-16a}$$

$$y(t) = y_0 + v_{0y}t - \tfrac{1}{2}gt^2 \tag{3-16b}$$

The notation $x(t)$ and $y(t)$ simply emphasizes that x and y are functions of time. If the y component of the initial velocity is known, the time t for which the particle is at height y can be found from Equation 3-16*b*. The horizontal position at that time can then be found using Equation 3-16*a*. (Equations 3-14 to 3-16 are expressed in vector form immediately preceding Example 3-10.)

The general equation for the path $y(x)$ of a projectile can be obtained from Equations 3-16 by eliminating the variable t. Choosing $x_0 = 0$ and $y_0 = 0$, we obtain $t = x/v_{0x}$ from Equation 3-16*a*. Substituting this into Equation 3-16*b* gives

$$y(x) = v_{0y}\left(\frac{x}{v_{0x}}\right) - \frac{1}{2}g\left(\frac{x}{v_{0x}}\right)^2 = \left(\frac{v_{0y}}{v_{0x}}\right)x - \left(\frac{g}{2v_{0x}^2}\right)x^2$$

Substituting for the velocity components using $v_{0x} = v_0 \cos\theta_0$ and $v_{0y} = v_0 \sin\theta_0$ yields

$$y(x) = (\tan\theta_0)x - \left(\frac{g}{2v_0^2\cos^2\theta_0}\right)x^2 \tag{3-17}$$

PATH OF PROJECTILE

for the projectile's path. This equation is of the form $y = ax + bx^2$, which is the equation for a parabola passing through the origin. Figure 3-13 shows the path of a projectile with its velocity vector and components at several points. The path is for a projectile that impacts the ground at P. The horizontal distance $|\Delta x|$ between launch and impact at the same elevation is the **horizontal range** R.

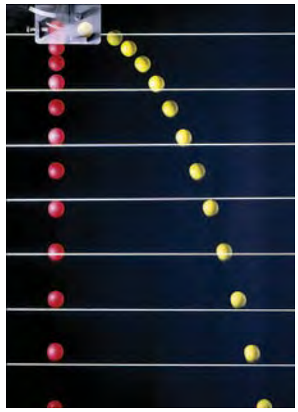

FIGURE 3-12 The red ball is released from rest at the instant the yellow ball rolls off the tabletop. The positions of the two balls are shown at successive equal time intervals. The vertical motion of the yellow ball is identical with the vertical motion of the red ball, thus demonstrating that the vertical motion of the yellow ball is independent of its horizontal motion. *(Richard Megna/Fundamental Photographs.)*

! Do not think that the velocity of a projectile is zero when the projectile is at the highest point in its trajectory. At the highest point in the trajectory v_y is zero, but the projectile may still be moving horizontally.

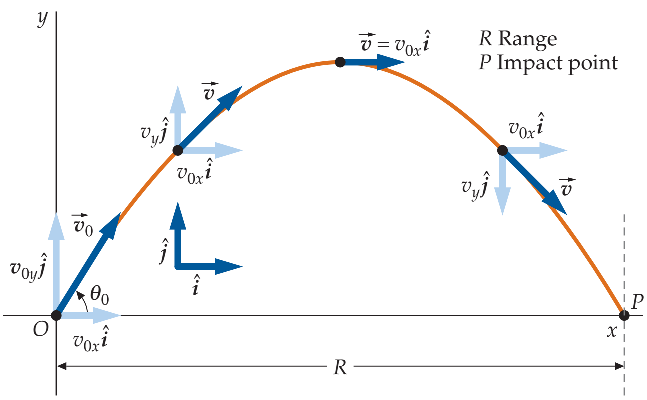

FIGURE 3-13 The path of a projectile, showing velocity components at different times.

Example 3-6 A Cap in the Air

A delighted physics graduate throws her cap into the air with an initial velocity of 24.5 m/s at 36.9° above the horizontal. The cap is later caught by another student. Find (*a*) the total time the cap is in the air, and (*b*) the total horizontal distance traveled. (Ignore effects of air resistance.)

PICTURE We choose the origin to be the initial position of the cap so that $x_0 = y_0 = 0$. We assume it is caught at the same height. The total time the cap is in the air is found by setting $y(t) = 0$ in $y(t) = y_0 + v_{0y}t - \frac{1}{2}gt^2$ (Equation 3-16*b*). We can then use this result in $x(t) = x_0 + v_{0x}t$ (Equation 3-16*a*) to find the total horizontal distance traveled.

SOLVE

(*a*) 1. Setting $y = 0$ in Equation 3-16*b*:

$$y = v_{0y}t - \tfrac{1}{2}gt^2$$
$$0 = t(v_{0y} - \tfrac{1}{2}gt)$$

2. There are two solutions for t:

$$t_1 = 0 \text{ (initial time)}$$
$$t_2 = \frac{2v_{0y}}{g}$$

3. Use trigonometry to relate v_{0y} to v_0 and θ_0 (see Figure 3-11):

$$v_{0y} = v_0 \sin\theta_0$$

4. Substitute for v_{0y} in the step 2 result to find the total time t_2:

$$t_2 = \frac{2v_{0y}}{g} = \frac{2v_0 \sin\theta_0}{g} = \frac{2(24.5\text{ m/s})\sin 36.9°}{9.81\text{ m/s}^2} = \boxed{3.00\text{ s}}$$

(*b*) Use the value for the time in step 4 to calculate the total horizontal distance traveled:

$$x = v_{0x}t_2 = (v_0\cos\theta_0)t_2 = (24.5\text{ m/s})\cos 36.9°(3.00\text{ s}) = \boxed{58.8\text{ m}}$$

CHECK If the cap traveled at a constant speed of 24.5 m/s for 3.00 s it would have traveled a distance of 73.5 m. Because it was launched at an angle, its horizontal speed was less than 24.5 m/s, so we expect its distance traveled to be less than 73.5 m. Our Part (*b*) result of 58.8 m meets this expectation.

TAKING IT FURTHER The vertical component of the initial velocity of the cap is 14.7 m/s, the same as that of the cap in Example 2-13 (Chapter 2), where the cap was thrown straight up with $v_0 = 14.7$ m/s. The time the cap is in the air is also the same as in Example 2-13. Figure 3-14 shows the height y versus t for the cap. This curve is identical to Figure 2-20*a* (Example 2-13) because the caps each have the same vertical acceleration and vertical velocity. Figure 3-14 can be reinterpreted as a graph of y versus x if its time scale is converted to a distance scale, as shown in the figure. This is accomplished by multiplying the time values by 19.6 m/s. This works because the cap moves at (24.5 m/s) cos 36.9° = 19.6 m/s horizontally. The curve y versus x is a parabola (as is the curve y versus t).

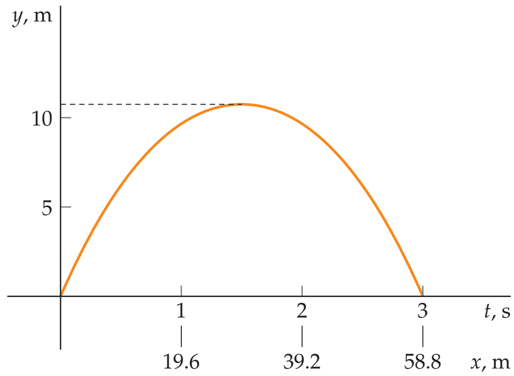

FIGURE 3-14 A plot of y versus t and of y versus x.

Example 3-7 A Supply Drop

A helicopter drops a supply package to flood victims on a raft on a swollen lake. When the package is released, the helicopter is 100 m directly above the raft and flying at a velocity of 25.0 m/s at an angle $\theta_0 = 36.9°$ above the horizontal. (*a*) How long is the package in the air? (*b*) How far from the raft does the package land? (*c*) If the helicopter continues at constant velocity, where is the helicopter when the package lands? (Ignore effects of air resistance.)

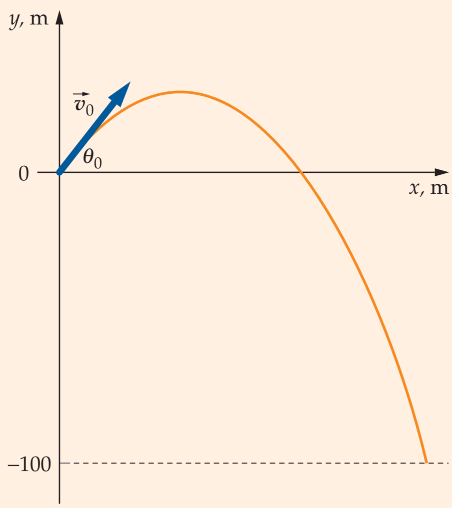

FIGURE 3-15 The parabola intersects the $y = -100$ m line twice, but only one of those times is greater than zero.

PICTURE The time in the air depends only on the vertical motion. Using $y(t) = y_0 + v_{0y}t - \frac{1}{2}gt^2$ (Equation 3-16*b*), you can solve for the time. Choose the origin to be at the location of the package when it is released. The initial velocity of the package is the velocity of the helicopter. The horizontal distance traveled by the package is given by $x(t) = v_{0x}t$ (Equation 3-16*a*), where t is the time the package is in the air.

SOLVE

(*a*) 1. Sketch the trajectory of the package during the time it is in the air. Include coordinate axes as shown in Figure 3-15:

2. To find the time of flight, write $y(t)$ for motion with constant acceleration, then set $y_0 = 0$ and $a_y = -g$ in the equation:

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_yt^2$$
$$y = 0 + v_{0y}t - \tfrac{1}{2}gt^2 = v_{0y}t - \tfrac{1}{2}gt^2$$

3. The solution to the quadratic equation $ax^2 + bx + c = 0$ is given by the quadratic formula:

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

Using this, solve the quadratic equation from step 2 for t:

$y = v_{0y}t - \frac{1}{2}gt^2$

so

$0 = \frac{1}{2}gt^2 - v_{0y}t + y$

and

$$t = \frac{v_{0y} \pm \sqrt{v_{0y}^2 - 2gy}}{g}$$

4. Solve for the time when $y = -100$ m. First, solve for v_{0y}, then use the value for v_{0y} to find t.

$v_{0y} = v_0 \sin\theta_0 = (25.0\text{ m/s})\sin 36.9° = 15.0\text{ m/s}$

so

$$t = \frac{15.0\text{ m/s} \pm \sqrt{(15.0\text{ m/s})^2 - 2(9.81\text{ m/s}^2)(-100\text{ m})}}{9.81\text{ m/s}^2}$$

so

$t = -3.24$ s or $t = 6.30$ s

Because the package is released at $t = 0$, the time of impact cannot be negative. Hence:

$t = \boxed{6.30\text{ s}}$

(*b*) 1. At impact the package has traveled a horizontal distance x, where x is the horizontal velocity times the time of flight. First solve for the horizontal velocity:

$v_{0x} = v_0 \cos\theta_0 = (25.0\text{ m/s})\cos 36.9° = 20.0\text{ m/s}$

2. Next substitute for v_{0x} in $x = x_0 + v_{0x}t$ (Equation 3-16*a*) to find x.

$x = v_{0x}t = (20.0\text{ m/s})(6.30\text{ s}) = \boxed{126\text{ m}}$

(*c*) The coordinates of the helicopter at the time of impact are

$x_{\text{h}} = v_{0x}t = (20.0\text{ m/s})(6.30\text{ s}) = 126\text{ m}$

$y_{\text{h}} = y_{\text{h0}} + v_{\text{h0}}t = 0 + (15.0\text{ m/s})(6.30\text{ s}) = 94.4\text{ m}$

At impact, the helicopter is

$\boxed{\text{194 m directly above the package}}$.

CHECK The helicopter is directly above the package when the package hits the water (and at all other times before then). This is because the horizontal velocities of the package and the helicopter were equal at release, and the horizontal velocities of both remain constant during flight.

TAKING IT FURTHER The positive time is appropriate because it corresponds to a time after the package is dropped (which occurs at $t = 0$). The negative time is when the package would have been at $y = -100$ m if its motion had started earlier as shown in Figure 3-16.

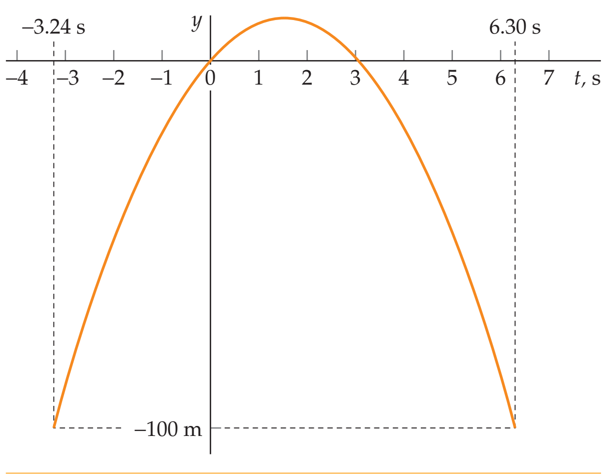

FIGURE 3-16

Example 3-8 Dropping Supplies *Try It Yourself*

Using Example 3-7, find (*a*) the time t_1 for the package to reach its greatest height h above the water, (*b*) its greatest height h, and (*c*) the time t_2 for the package to fall to the water from its greatest height.

PICTURE The time t_1 is the time at which the vertical component of the velocity is zero. Using $v_y(t) = v_{0y} - gt$ (Equation 3-15*b*) solve for t_1.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
(*a*) 1. Write $v_y(t)$ for the package.	$v_y(t) = v_{0y} - gt$
2. Set $v_y(t_1) = 0$ and solve for t_1.	$t_1 = \boxed{1.53\text{ s}}$
(*b*) 1. Find $v_{y\,\text{av}}$ during the time the package is moving up.	$v_{y\,\text{av}} = 7.505\text{ m/s}$
2. Use $v_{y\,\text{av}}$ to find the distance traveled up. Then find h.	$\Delta y = 11.48\text{ m}$, so $h = \boxed{111\text{ m}}$
(*c*) Find the time for the package to fall a distance h.	$t_2 = \boxed{4.77\text{ s}}$

CHECK Note that $t_1 + t_2 = 6.30$ s, in agreement with Example 3-7. Also, note that t_1 is less than t_2. This is as expected because the package rises a distance of 12 m but falls a distance of 112 m.

PRACTICE PROBLEM 3-2 Solve Part (*b*) of Example 3-8 using $y(t)$ (Equation 3-16*b*) instead of finding $v_{y\,\text{av}}$.

HORIZONTAL RANGE OF A PROJECTILE

The horizontal range R of a projectile can be written in terms of its initial speed and initial angle above the horizontal. As in the preceding examples, we find the horizontal range by multiplying the x component of the velocity by the total time that the projectile is in the air. The total flight time T is obtained by setting $y = 0$ and $t = T$ in $y = v_0 t - \frac{1}{2}gt^2$ (Equation 3-16*b*).

$$0 = v_{0y}T - \tfrac{1}{2}gT^2 \qquad T > 0$$

Dividing through by T gives

$$v_{0y} - \tfrac{1}{2}gT = 0$$

The flight time of the projectile is thus

$$T = \frac{2v_{0y}}{g} = \frac{2v_0}{g}\sin\theta_0$$

To find the horizontal range R, we substitute T for t in $x(t) = v_{0x}t$ (Equation 3-16*a*) to obtain

$$R = v_{0x}T = (v_0\cos\theta_0)\left(\frac{2v_0}{g}\sin\theta_0\right) = \frac{2v_0^2}{g}\sin\theta_0\cos\theta_0$$

This can be further simplified by using the trigonometric identity:

$$\sin 2\theta = 2\sin\theta\cos\theta$$

Thus,

$$R = \frac{v_0^2}{g}\sin 2\theta_0 \qquad \text{3-18}$$

HORIZONTAL RANGE OF A PROJECTILE

PRACTICE PROBLEM 3-3

Use Equation 3-18 to verify the answer Part (*b*) of Example 3-6.

Equation 3-18 is useful if you want to find the range for several projectiles that have equal initial speeds. For this case, this equation shows how the range depends on θ. Because the maximum value of $\sin 2\theta$ is 1, and because $\sin 2\theta = 1$ when $\theta = 45°$, the range is greatest when $\theta = 45°$. Figure 3-17 shows graphs of the vertical heights versus the horizontal distances for projectiles with an initial speed of 24.5 m/s and several different initial angles. The angles drawn are 45°, which has the maximum range, and pairs of angles at equal amounts above and below 45°. Notice that the paired angles have the same range. The green curve has an initial angle of 36.9°, as in Example 3-6.

In many practical applications, the initial and final elevations may not be equal, or other considerations are important. For example, in the shot put, the ball ends its flight when it hits the ground, but it is projected from an initial height of about 2 m above the ground. This condition causes the horizontal displacement to be at a maximum at an angle somewhat lower than 45°, as shown in Figure 3-18. Studies of the best shot-putters show that maximum horizontal displacement occurs at an initial angle of about 42°.

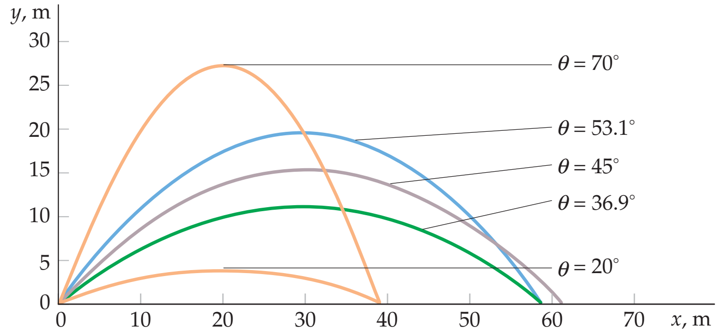

FIGURE 3-17 The initial speed is the same for each trajectory.

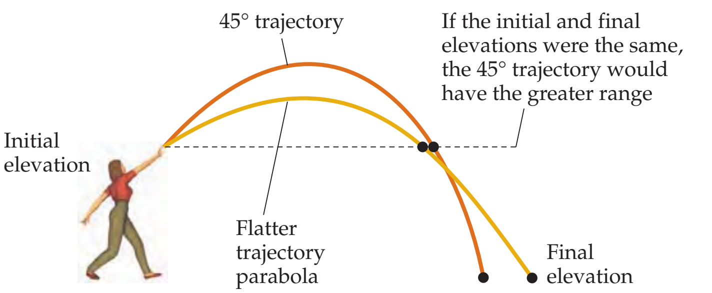

FIGURE 3-18 If a projectile lands at an elevation lower than the initial elevation, the maximum horizontal displacement is achieved when the projection angle is somewhat lower than 45°.

Example 3-9 To Catch a Thief

A police officer chases a master jewel thief across city rooftops. They are both running when they come to a gap between buildings that is 4.00 m wide and has a drop of 3.00 m (Figure 3-19). The thief, having studied a little physics, leaps at 5.00 m/s, at an angle of 45.0° above the horizontal, and clears the gap easily. The police officer did not study physics and thinks he should maximize his horizontal velocity, so he leaps horizontally at 5.00 m/s. (*a*) Does he clear the gap? (*b*) By how much does the thief clear the gap?

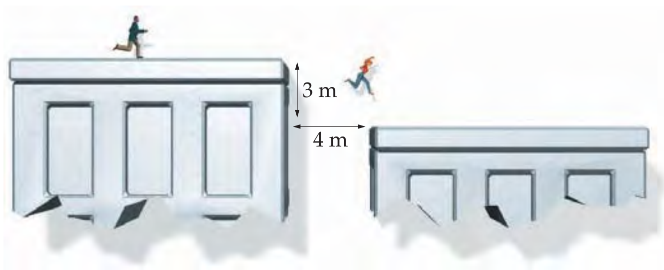

FIGURE 3-19

PICTURE Assuming they both clear the gap, the total time in the air depends only on the vertical aspects of the motion. Choose the origin at the launch point, with upward positive so that Equations 3-16 apply. Use Equation 3-16*b* for $y(t)$ and solve for the time when $y = -3.00$ m for $\theta_0 = 0$ and again for $\theta_0 = 45.0°$. The horizontal distances traveled are the values of x at these times.

SOLVE

(*a*) 1. Write $y(t)$ for the police officer and solve for t when $y = -3.00$ m.

$$y = y_0 + v_{y0}t - \tfrac{1}{2}gt^2 - 3.00\text{ m} = 0 + 0 - \tfrac{1}{2}(9.81\text{ m/s}^2)t^2$$
$$t = 0.782\text{ s}$$

2. Substitute this into the equation for $x(t)$ and find the horizontal distance traveled during this time.

$$x = x_0 + v_{x0}t$$
$$x = 0 + (5.00\text{ m/s})(0.782\text{ s})$$
$$x = \boxed{3.91\text{ m}}$$

Because 3.91 m is less than 4.00 m, it appears the police officer fails to make it across the gap between buildings.

(*b*) 1. Write $y(t)$ for the thief and solve for t when $y = -3.00$ m. $y(t)$ is a quadratic equation with two solutions, but only one of its solutions is acceptable.	$y = y_0 + v_{y0}t - \frac{1}{2}gt^2 - 3.00\text{ m} = 0 + (5.00\text{ m/s})\sin 45.0° - \frac{1}{2}(9.81\text{ m/s}^2)t^2$ $t = -0.500$ s or $t = 1.22$ s She must land at a time after she leaps, so $t = 1.22$ s
2. Find the horizontal distance covered for the positive value of t.	$x = x_0 + v_{0x}t = 0 + (5.00\text{ m/s})\cos 45°(1.22\text{ s}) = 4.31\text{ m}$
3. Subtract 4.0 m from this distance.	$4.31\text{ m} - 4.00\text{ m} = \boxed{0.31\text{ m}}$

CHECK The policeman's horizontal speed remains 5.00 m/s during his flight. So, the policeman travels the 4.00 m to the next building in 4.00 m/(5.00 m/s) = 0.800 s. Because our Part (*a*) step 1 result is less than 0.800 s, we know he falls below the second roof before reaching the second building—in agreement with our Part (*a*) step 2 result.

TAKING IT FURTHER By modeling the policeman as a particle, we found that he was slightly below the second roof at impact. However, we cannot conclude that he did not complete the jump because he is not a particle. It is likely that he would raise his feet enough for them to clear the edge of the second roof.

PROJECTILE MOTION IN VECTOR FORM

For projectile motion, we have $a_x = 0$ and $a_y = -g$ (Equations 3-14*a* and 3-14*b*), where the $+y$ direction is directly upward. To express these equations in vector form, we multiply both sides of each equation by the appropriate unit vector and then add the two resulting equations. That is, $a_x\hat{i} = 0\hat{i}$ plus $a_y\hat{j} = -g\hat{j}$ gives

$$a_x\hat{i} + a_y\hat{j} = -g\hat{j} \quad \text{or} \quad \vec{a} = \vec{g} \qquad \text{3-14}c$$

where $\vec{g}$ is the free-fall acceleration vector. The magnitude of $\vec{g}$ is $g = 9.81\text{ m/s}^2$ (at sea level and at 45° latitude).

Combining equations $v_x = v_{0x}$ and $v_y = v_{0y} - gt$ in like manner gives

$$\vec{v} = \vec{v}_0 + \vec{g}t \quad (\text{or } \Delta\vec{v} = \vec{g}t) \qquad \text{3-15}c$$

where $\vec{v} = v_x\hat{i} + v_y\hat{j}$, $\vec{v}_0 = v_{0x}\hat{i} + v_{0y}\hat{j}$, and $\vec{g} = -g\hat{j}$. Repeating the process, this time for Equations $x(t) = x_0 + v_{0x}t$ and $y(t) = y_0 + v_{0y}t - \frac{1}{2}gt^2$, gives

$$\vec{r} = \vec{r}_0 + \vec{v}_0 t + \tfrac{1}{2}\vec{g}t^2 \quad (\text{or } \Delta\vec{r} = \vec{v}_0 t + \tfrac{1}{2}\vec{g}t^2) \qquad \text{3-16}c$$

where $\vec{r} = x\hat{i} + y\hat{j}$ and $\vec{r}_0 = x_0\hat{i} + y_0\hat{j}$. The vector forms of the kinematic equations (Equations 3-15*c* and 3-16*c*) are useful for solving a number of problems, including the following example.

Example 3-10 The Ranger and the Monkey

A park ranger with a tranquilizer dart gun intends to shoot a monkey hanging from a branch. The ranger points the barrel directly at the monkey, not realizing that the dart will follow a parabolic path that will pass below the present position of the creature. The monkey, seeing the gun discharge, immediately lets go of the branch and drops out of the tree, expecting to avoid the dart. (*a*) Show that the monkey will be hit regardless of the initial speed of the dart as long as this speed is great enough for the dart to travel the horizontal distance to the tree. Assume the reaction time of the monkey is negligible. (*b*) Let $\vec{v}_{d0}$ be the initial velocity of the dart relative to the monkey. Find the velocity of the dart *relative to the monkey* at an arbitrary time t during the dart's flight.

PICTURE In this example, both the monkey and the dart exhibit projectile motion. To show that the dart hits the monkey, we have to show that at some time t, the dart and the monkey have the same coordinates, regardless of the initial speed of the dart. To do this, we apply

Equation 3-16*c* to both the monkey and the dart. For Part (*b*), we can use Equation 3-15*c*, keeping in mind the relative reference frames.

SOLVE

(*a*) 1. Apply Equation 3-16*c* to the monkey at arbitrary time *t*:

$$\Delta\vec{r}_{m} = \tfrac{1}{2}\vec{g}t^2$$

(The initial velocity of the monkey is zero.)

2. Apply Equation 3-16*c* to the dart at arbitrary time *t*:

$$\Delta\vec{r}_{d} = \vec{v}_{d0}t + \tfrac{1}{2}\vec{g}t^2$$

where $\vec{v}_{d0}$ is the velocity of the dart as it leaves the gun.

3. Make a sketch of the monkey, the dart, and the gun, as shown in Figure 3-20. Show the dart and the monkey at their initial locations and at their locations a time *t* later. On the figure draw a vector representing each term in the step 1 and 2 results:

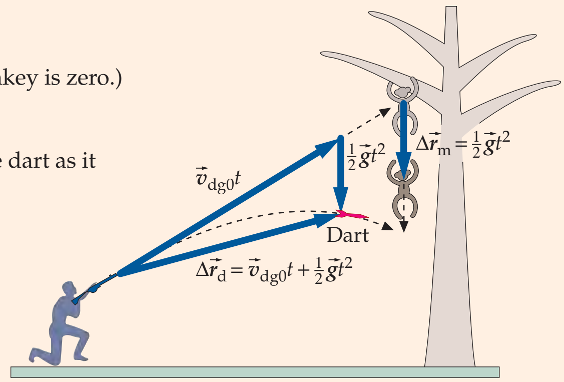

FIGURE 3-20

4. Note that at time *t* the dart and the monkey both are a distance $\frac{1}{2}gt^2$ below the line of sight of the gun:

$\boxed{\text{The dart will strike the monkey}}$ when the dart reaches the monkey's line of fall.

(*b*) 1. The velocity of the dart relative to the monkey equals the velocity of the dart relative to the gun plus the velocity of the gun relative to the monkey:

$$\vec{v}_{dm} = \vec{v}_{dg} + \vec{v}_{gm}$$

2. The velocity of the gun relative to the monkey is the negative of the velocity of the monkey relative to the gun:

$$\vec{v}_{dm} = \vec{v}_{dg} - \vec{v}_{mg}$$

3. Using $\vec{v} = \vec{v}_0 + \vec{g}t$ (Equation 3-15*c*), express both the velocity of the dart relative to the gun and the velocity of the monkey relative to the gun:

$$\vec{v}_{dg} = \vec{v}_{dg0} + \vec{g}t$$
$$\vec{v}_{mg} = \vec{g}t$$

4. Substitute these expressions into the Part (*b*) step 2 result:

$$\vec{v}_{dm} = (\vec{v}_{dg0} + \vec{g}t) - (\vec{g}t) = \boxed{\vec{v}_{dg0}}$$

CHECK The Part (*a*) step 4 and the Part (*b*) step 4 results are in agreement with each other. They agree that the dart will strike the monkey if the dart reaches the monkey's line of fall before the monkey lands on the ground.

TAKING IT FURTHER Relative to the falling monkey, the dart moves with constant speed v_{dg0} in a straight line. The dart strikes the monkey at time $t = L/v_{d0}$, where *L* is the distance from the muzzle of the gun to the initial position of the monkey.

In a familiar lecture demonstration, a target is suspended by an electromagnet. When the dart leaves the gun, the circuit to the magnet is broken and the target falls. The demonstration is then repeated using a different initial velocity of the dart. For a large value of v_{dg0}, the target is hit very near its original height, and for some lesser value of v_{dg0} it is hit just before it reaches the floor.

PRACTICE PROBLEM 3-4 A hockey puck at ice level is struck such that it misses the net and just clears the top of the Plexiglas wall of height $h = 2.80$ m. The flight time at the moment the puck clears the wall is $t_1 = 0.650$ s, and the horizontal position is $x_1 = 12.0$ m. (*a*) Find the initial speed and direction of the puck. (*b*) When does the puck reach its maximum height? (*c*) What is the maximum height of the puck?

3-3 SPECIAL CASE 2: CIRCULAR MOTION

Figure 3-21 shows a pendulum bob swinging back and forth in a vertical plane. The path of the bob is a segment of a circular path. Motion along a circular path, or a segment of a circular path, is called **circular motion.**

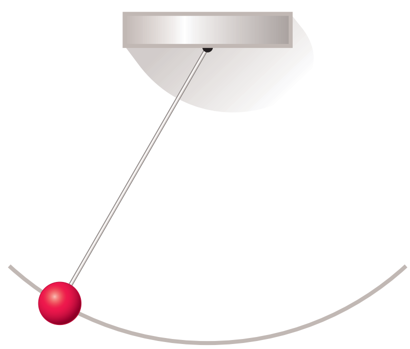

FIGURE 3-21 A pendulum bob swings along a circular arc centered at the point of support of the string.

Example 3-11 A Swinging Pendulum *Conceptual*

Consider the motion of the pendulum bob shown in Figure 3-21. Using a motion diagram (see Example 3-5), find the direction of the acceleration vector when the bob is swinging from left to right and (*a*) on the descending portion of the path, (*b*) passing through the lowest point on the path, and (*c*) on the ascending portion of the path.

PICTURE As the bob descends, it both gains speed and changes direction. The acceleration is related to the change in velocity by $\vec{a} \approx \Delta\vec{v}/\Delta t$. The direction of the acceleration at a point can be estimated by constructing a vector addition diagram for the relation $\vec{v}_i + \Delta\vec{v} = \vec{v}_f$ to find the direction of $\Delta\vec{v}$, and thus the direction of the acceleration vector.

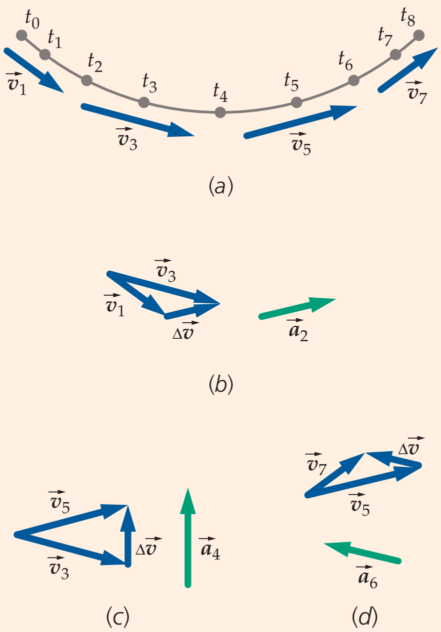

FIGURE 3-22

SOLVE

(*a*) 1. Make a motion diagram for a full left-to-right swing of the bob (Figure 3-22*a*). The spacing between dots is greatest at the lowest point where the speed is greatest.

2. Pick the dot at t_2 on the descending portion of the motion and draw a velocity vector on the diagram for both the preceding and the following dot (the dots at t_1 and t_3). The velocity vectors should be drawn tangent to the path and with lengths proportional to the speed (Figure 3-22*a*).

3. Draw the vector addition diagram (Figure 3-22*b*) for the relation $\vec{v}_i + \Delta\vec{v} = \vec{v}_f$. On this diagram draw the acceleration vector. Because $\vec{a} \approx \Delta\vec{v}/\Delta t$, $\vec{a}$ is in the same direction as $\Delta\vec{v}$.

(*b*) Repeat steps 2 and 3 (Figure 3-22*c*) for the point at t_4, the lowest point on the path.

(*c*) Repeat steps 2 and 3 (Figure 3-22*d*) for the point at t_6, a point on the ascending portion of the path.

CHECK At the lowest point (at t_4) the horizontal component of $\vec{v}$ is a maximum, so we expect the horizontal component of $\vec{a}$ to be zero. Near the lowest point, the upward component of $\vec{v}$ is negative just prior to $t = t_4$ and is positive just after $t = t_4$, so the upward component of $\vec{v}$ is increasing at $t = t_4$. This means we expect the upward component of $\vec{a}$ to be positive at $t = t_4$. The acceleration vector in Figure 3-22*c* is in agreement with both of these expectations.

In Example 3-11, we saw that the acceleration vector is directed straight upward at the lowest point of the pendulum's swing (Figure 3-23)—toward point *P* at the center of the circle. Where the speed is increasing (on the descending portion), the acceleration vector has a component in the direction of the velocity vector as well as a component in the direction toward *P*. Where the speed is decreasing, the acceleration vector has a component in the direction opposite to the direction of the velocity vector, as well as a component in the direction toward *P*.

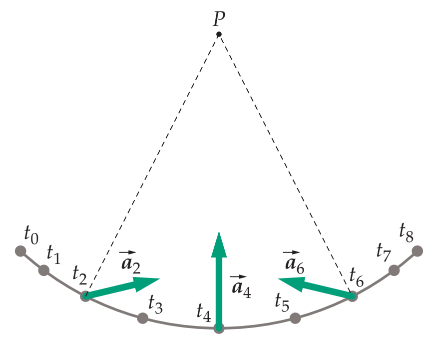

FIGURE 3-23

As a particle moves along a circular arc, the direction from the particle toward *P* (toward the center of the circle) is called the **centripetal direction** and the direction of the velocity vector is called the **tangential direction.** In Figure 3-23, the acceleration vector at the lowest point of the pendulum bob's path is in the centripetal direction. At virtually all other points along the path, the acceleration vector has both a tangential component and a centripetal component.

UNIFORM CIRCULAR MOTION

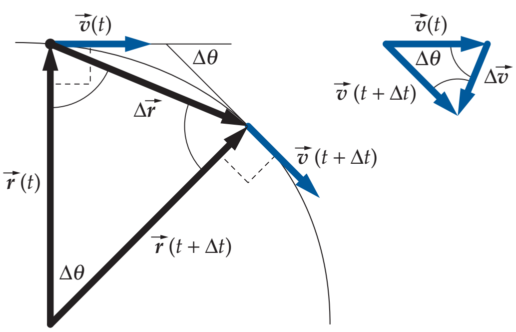

FIGURE 3-24

Motion in a circle at constant speed is called **uniform circular motion.** Even though the speed of a particle moving in uniform circular motion is constant, the moving particle is accelerating. To find an expression for the acceleration of a particle during uniform circular motion, we will extend the method used in Example 3-11 to relate the acceleration to the speed and the radius of the circle. The position and velocity vectors for a particle moving in a circle at constant speed are shown in Figure 3-24. The angle $\Delta\theta$ between $\vec{v}(t)$ and $\vec{v}(t + \Delta t)$ is equal to the angle between $\vec{r}(t)$ and $\vec{r}(t + \Delta t)$ because $\vec{r}$

and $\vec{v}$ both rotate through the same angle $\Delta\theta$ during time Δt. An isosceles triangle is formed by the two velocity vectors and the $\Delta\vec{v}$ vector, and a second isosceles triangle is formed by the two position vectors and the $\Delta\vec{r}$ vector.

To find the direction of the acceleration vector we examine the triangle formed by the two velocity vectors and the $\Delta\vec{v}$ vector. The sum of the angles of any triangle is 180° and the base angles of any isosceles triangle are equal. In the limit that Δt approaches zero, $\Delta\theta$ also approaches zero, so in this limit the two base angles each approach 90°. This means that in the limit that $\Delta t \to 0$, $\Delta\vec{v}$ is perpendicular to $\vec{v}$. If $\Delta\vec{v}$ is drawn from the position of the particle, then it points in the centripetal direction.

The two triangles are similar, and corresponding lengths of similar geometric figures are proportional. Thus,

$$\frac{|\Delta\vec{v}|}{|\Delta\vec{r}|} = \frac{v}{r}$$

Multiplying both sides by $|\Delta\vec{r}|\,/\Delta t$ gives

$$\frac{|\Delta\vec{v}|}{\Delta t} = \frac{v}{r}\frac{|\Delta\vec{r}|}{\Delta t} \qquad \text{3-19}$$

In the limit that $\Delta t \to 0$, $|\Delta\vec{v}|/\Delta t$ approaches a, the magnitude of the instantaneous acceleration, and $|\Delta\vec{r}|/\Delta t$ approaches v (the speed). Thus, in the limit that $\Delta t \to 0$, Equation 3-19 becomes $a = v^2/r$. The acceleration vector is in the centripetal direction, so $a_c = a$, where a_c is the component of the acceleration vector in the centripetal direction. Substituting a_c for a, we have

$$a_c = \frac{v^2}{r} \qquad \text{3-20}$$

CENTRIPETAL ACCELERATION

Centripetal acceleration is the component of the acceleration vector in the centripetal direction. The motion of a particle moving in a circle with constant speed is often described in terms of the time T required for one complete revolution, called the **period.** During one period, the particle travels a distance of $2\pi r$ (where r is the radius of the circle), so its speed v is related to r and T by

$$v = \frac{2\pi r}{T} \qquad \text{3-21}$$

Example 3-12 A Satellite's Motion

A satellite moves at constant speed in a circular orbit about the center of Earth and near the surface of Earth. If the magnitude of its acceleration is $g = 9.81\ \mathrm{m/s^2}$, find (*a*) its speed, and (*b*) the time for one complete revolution.

PICTURE Because the satellite orbits near the surface of Earth, we take the radius of the orbit to be 6370 km, the radius of Earth. Then, we can use Equations 3-20 and 3-21 to find the satellite's speed and the time for the satellite to make one complete revolution around Earth.

SOLVE

(*a*) Make a sketch of the satellite orbiting Earth in a low-Earth orbit (Figure 3-25). Include the velocity and acceleration vectors:

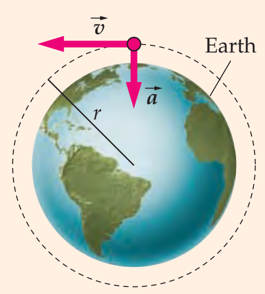

FIGURE 3-25 A satellite in a circular, low-Earth orbit.

Set the centripetal acceleration v^2/r equal to g and solve for the speed v:

$$a_c = \frac{v^2}{r} = g, \quad \text{so}$$

$$v = \sqrt{rg} = \sqrt{(6370\text{ km})(9.81\text{ m/s}^2)}$$

$$= \boxed{7.91\text{ km/s} = 17{,}700\text{ mi/h} = 4.91\text{ mi/s}}$$

(*b*) Use Equation 3-21 to get the period T:

$$T = \frac{2\pi r}{v} = \frac{2\pi(6370\text{ km})}{7.91\text{ km/s}} = \boxed{5060\text{ s} = 84.3\text{ min}}$$

CHECK It is well known that the orbital period for satellites orbiting just above the atmosphere of Earth is about 90 min, so the Part (*b*) result of 84.3 min is close to what we would expect.

TAKING IT FURTHER For actual satellites in orbit a few hundred kilometers above Earth's surface, the orbital radius r is a few hundred kilometers greater than 6370 km. As a result, the acceleration is slightly less than 9.81 m/s^2 because of the decrease in the gravitational force with distance from the center of Earth. Orbits just above Earth's atmosphere are referred to as "low Earth orbits." Many satellites, including the Hubble telescope and the International Space Station, are in low Earth orbits. Information about these and other satellites can be found at www.nasa.gov.

PRACTICE PROBLEM 3-5 A car rounds a curve of radius 40 m at 48 km/h. What is its centripetal acceleration?

TANGENTIAL ACCELERATION

A particle moving in a circle with *varying speed* has a component of acceleration tangent to the circle, a_t, as well as the radially inward centripetal acceleration, v^2/r. For general motion along a curve, we can treat a portion of the curve as an arc of a circle (Figure 3-26). The particle then has centripetal acceleration $a_c = v^2/r$ toward the center of curvature, and if the speed v is changing, it has a tangential acceleration given by

$$a_t = \frac{dv}{dt} \qquad \text{3-22}$$

TANGENTIAL ACCELERATION

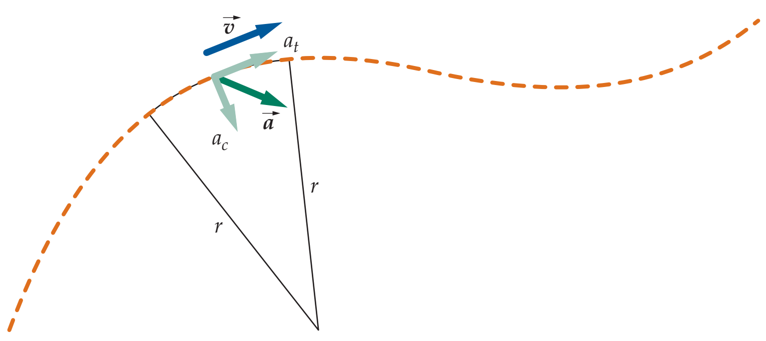

FIGURE 3-26 The tangential and centripetal acceleration components of a particle moving along a curved path.

PRACTICE PROBLEM 3-6

You are in a cart on a rollercoaster track that is entering a loop-the-loop. At the instant you are one fourth the way through the loop-the-loop your cart is going straight up at 20 m/s, and is losing speed at 5.0 m/s^2. The radius of curvature of the track is 25 m. What are your centripetal and tangential acceleration components at that instant?

Physics Spotlight

GPS: Vectors Calculated While You Move

If you fly to another city and rent a car to reach your destination, you might rent a Global Positioning System (GPS) navigation computer with the car. Many people use GPS navigators, but not everyone knows that these computers constantly calculate vectors for you.

Twenty-four GPS satellites orbit Earth at an altitude of 11,000 mi.* At most times and places, at least three satellites are visible (above the horizon). In many cases, four or more satellites are visible. Each satellite broadcasts a continual stream that includes its identification, information about its orbit, and a time marker that is precise to one billionth of a second.† The satellite's internal clocks and orbits are checked by a ground station that can send correction information.

A GPS receiver listens for the signals from the satellites. When it can get a lock on three or more satellite signals, it calculates how far away each satellite is by the difference between the satellite's time marker and the time on the receiver's clock when the marker is detected. From the known orbits of each satellite and the distance to each satellite, the receiver can triangulate its position. A calculation from three satellites will give the longitude and latitude of the receiver. A calculation from four satellites will also give altitude.

The navigation systems used in automobiles obtain information from GPS satellites and use the information to calculate the position and velocity of the car. At times, they calculate the car's displacement vector using a procedure called *dead reckoning*. *(Andrew Fox/Corbis.)*

But where do vectors come in? The receiver does not just triangulate its position once—that would give a point position. The receiver constantly listens for the satellites and calculates changes in the receiver position from changes in the triangulation results. It calculates any changes in distance and direction from the last known position. Within a very short time it has taken several readings, enough to calculate the velocity of your travel. The result? A speed in a particular direction—a velocity vector—is always part of the receiver's calculations.

But this vector is not there just to draw a pretty line on the screen for you. There are times when it is not possible to get a good reading on a receiver. Perhaps you have driven under a bridge or through a tunnel. If the GPS receiver is unable to lock onto a meaningful signal, it will start from your last known position. It will then use your last known velocity and direction to calculate a *dead reckoning*. It will assume that you are continuing in the same direction and at the same speed until it is able to get a reliable signal from enough satellites. Once it is able to receive good signals again, it will make corrections to your position and your course.

When GPS was pioneered, the time signal broadcast by the satellites was encoded with distortion, or *selective availability*, which could be removed only with decoding receivers enabled for defense purposes. The military could track location to within six meters, while civilians could track location to within only around 45 meters.** That coding was turned off in the year 2000. Theoretically, a GPS receiver would be able to tell your position down to the width of your finger,‡ given the right signals, and give equally precise and accurate measurements of your speed and direction—all from at least 11,000 miles away.

* The actual number of operational satellites varies. It is more than twenty-four, in case of satellite failure. "Block II Satellite Information." *ftp://tycho.usno.navy.mil/pub/gps/gpsb2.txt* United States Naval Observatory. March 2006.

Summary

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Kinematic Vectors		
Position vector	The position vector $\vec{r}$ points from the origin of the coordinate system to the particle.	
Instantaneous-velocity vector	The velocity vector $\vec{v}$ is the rate of change of the position vector. Its magnitude is the speed, and it points in the direction of motion. $$\vec{v} = \lim_{\Delta t \to 0} \frac{\Delta \vec{r}}{\Delta t} = \frac{d\vec{r}}{dt}$$	3-5
Instantaneous-acceleration vector	$$\vec{a} = \lim_{\Delta t \to 0} \frac{\Delta \vec{v}}{\Delta t} = \frac{d\vec{v}}{dt}$$	3-11
2. Relative Velocity	If a particle p moves with velocity $\vec{v}_{pA}$ relative to reference frame A, which is in turn moving with velocity $\vec{v}_{AB}$ relative to reference frame B, the velocity of p relative to B is $$\vec{v}_{pB} = \vec{v}_{pA} + \vec{v}_{AB}$$	3-9
3. Projectile Motion with No Air Resistance	The $+x$ direction is horizontal and the $+y$ direction is upward for the equations in this section.	
Independence of motion	In projectile motion, the horizontal and vertical motions are independent.	
Acceleration	$$a_x = 0 \quad \text{and} \quad a_y = -g$$	
Dependence on time	$$v_x(t) = v_{0x} + a_x t \quad \text{and} \quad v_y(t) = v_{0y} + a_y t$$ $$\Delta x = v_{0x}t + \tfrac{1}{2}a_x t^2 \quad \text{and} \quad \Delta y = v_{0y}t + \tfrac{1}{2}a_y t^2$$ where $v_{x0} = v_0 \cos\theta_0$ and $v_{y0} = v_0 \sin\theta_0$. Alternatively, $$\Delta\vec{v} = \vec{g}t \quad \text{and} \quad \Delta\vec{r} = \vec{v}_0 t + \tfrac{1}{2}\vec{g}t^2$$	2-12 2-14 3-15*c*, 3-16*c*
Horizontal displacement	The horizontal displacement is found by multiplying v_{0x} by the total time the projectile is in the air.	
3. Circular Motion		
Centripetal acceleration	$$a_c = \frac{v^2}{r}$$	3-20
Tangential acceleration	$$a_t = \frac{dv}{dt}$$ where v is the *speed*.	3-22
Period	$$v = \frac{2\pi r}{T}$$	3-21

Answers to Concept Checks

3-1 (*a*) upward, (*b*) upward

3-2 vertically downward

Answers to Practice Problems

3-1 $a_{av} = 4.7\ \text{m/s}^2$ at 45° west of north

3-2 $$y(t) = y_0 + v_{0y}t - \tfrac{1}{2}gt^2$$
$$= 0 + (25.0\ \text{m/s})\sin 36.9°\,(1.43\ \text{s}) + \tfrac{1}{2}(9.81\ \text{m/s}^2)(1.43\ \text{s})^2$$
$$= 11.48\ \text{m}$$
$$\therefore h = 111\ \text{m}$$

3-3 $$R = \frac{v_0^2}{g}\sin 2\theta_0 = \frac{(24.5\ \text{m/s})^2}{9.81\ \text{m/s}^2}\sin(2\times 36.9°) = 58.8°$$

3-4 (*a*) $\vec{v}_0 = 20.0$ m/s at $\theta_0 = 22.0°$, (*b*) $t = 0.764$ s, (*c*) $v_{y\,av}t = 2.86$ m

3-5 $4.44\ \text{m/s}^2$

3-6 $a_c = 16\ \text{m/s}^2$ and $a_t = -5.0\ \text{m/s}^2$

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • Can the magnitude of the displacement of a particle be less than the distance traveled by the particle along its path? Can its magnitude be more than the distance traveled? Explain. SSM

2 • Give an example in which the distance traveled is a significant amount, yet the corresponding displacement is zero. Can the reverse be true? If so, give an example.

3 • What is the average velocity of a batter who hits a home run (from when he hits the ball to when he touches home plate after rounding the bases)?

4 • A baseball is hit so its initial velocity upon leaving the bat makes an angle of 30° above the horizontal. It leaves that bat at a height of 1.0 m above the ground and lands untouched for a single. During its flight, from just after it leaves the bat to just before it hits the ground, describe how the angle between its velocity and acceleration vectors changes. Neglect any effects due to air resistance.

5 • If an object is moving toward the west at some instant, in what direction is its acceleration? (*a*) north, (*b*) east, (*c*) west, (*d*) south, (*e*) may be any direction.

6 • Two astronauts are working on the lunar surface to install a new telescope. The acceleration due to gravity on the moon is only 1.64 m/s^2. One astronaut tosses a wrench to the other astronaut, but the speed of throw is excessive and the wrench goes over her colleague's head. When the wrench is at the highest point of its trajectory, (*a*) its velocity and acceleration are both zero, (*b*) its velocity is zero but its acceleration is nonzero, (*c*) its velocity is nonzero but its acceleration is zero, (*d*) its velocity and acceleration are both nonzero, (*e*) insufficient information is given to choose between any of the previous choices.

7 • The velocity of a particle is directed toward the east while the acceleration is directed toward the northwest, as shown in Figure 3-27. The particle is (*a*) speeding up and turning toward the north, (*b*) speeding up and turning toward the south, (*c*) slowing down and turning toward the north, (*d*) slowing down and turning toward the south, (*e*) maintaining constant speed and turning toward the south.

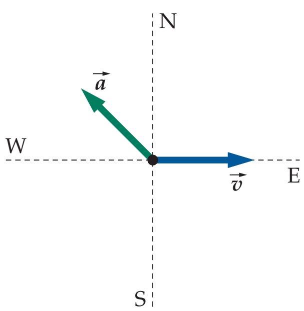

FIGURE 3-27
Problem 7

8 • Assume you know the position vectors of a particle at two points on its path, one earlier and one later. You also know the time it took the particle to move from one point to the other. Then, you can compute the particle's (*a*) average velocity, (*b*) average acceleration, (*c*) instantaneous velocity, and (*d*) instantaneous acceleration.

9 • Consider the path of a moving particle. (*a*) How is the velocity vector related geometrically to the path of the particle? (*b*) Sketch a curved path and draw the velocity vector for the particle for several positions along the path.

10 • The acceleration of a car is zero when it is (*a*) turning right at a constant speed, (*b*) driving up a long straight incline at constant speed, (*c*) traveling over the crest of a hill at constant speed, (*d*) bottoming out at the lowest point of a valley at constant speed, (*e*) speeding up as it descends a long straight decline.

11 • Give examples of motion in which the directions of the velocity and acceleration vectors are (*a*) opposite, (*b*) the same, and (*c*) mutually perpendicular. SSM

12 • How is it possible for a particle moving at constant speed to be accelerating? Can a particle with constant velocity be accelerating at the same time?

13 •• Imagine throwing a dart straight upward so that it sticks into the ceiling. After it leaves your hand, it steadily slows down as it rises before it sticks. (*a*) Draw the dart's velocity vector at times t_1 and t_2, where t_1 and t_2 occur after it leaves your hand but before it hits the ceiling and $t_2 - t_1$ is small. From your drawing, find the direction of the change in velocity $\Delta\vec{v} = \vec{v}_2 - \vec{v}_1$, and thus the direction of the acceleration vector. (*b*) After it has stuck in the ceiling for a few seconds, the dart falls down to the floor. As it falls it speeds up, of course, until it hits the floor. Repeat Part (*a*) to find the direction of its acceleration vector as it falls. (*c*) Now imagine tossing the dart horizontally. What is the direction of its acceleration vector after it leaves your hand, but before it strikes the floor? SSM

14 • As a bungee jumper approaches the lowest point in her descent, the rubber cord holding her stretches and she loses speed as she continues to move downward. Assuming that she is dropping straight down, make a motion diagram to find the direction of her acceleration vector as she slows down by drawing her velocity vectors at times t_1 and t_2, where t_1 and t_2 are two instants during the portion of her descent in which she is losing speed and $t_2 - t_1$ is small. From your drawing find the direction of the change in velocity $\Delta\vec{v} = \vec{v}_2 - \vec{v}_1$, and thus the direction of the acceleration vector.

15 • After reaching the lowest point in her jump at time t_{low}, a bungee jumper moves upward, gaining speed for a short time until gravity again dominates her motion. Draw her velocity vectors at times t_1 and t_2, where $t_2 - t_1$ is small and $t_1 < t_{low} < t_2$. From your drawing find the direction of the change in velocity $\Delta\vec{v} = \vec{v}_2 - \vec{v}_1$, and thus the direction of the acceleration vector at time t_{low}.

16 • A river is 0.76 km wide. The banks are straight and parallel (Figure 3-28). The current is 4.0 km/h and is parallel to the banks. A boat has a maximum speed of 4.0 km/h in still water. The pilot of the boat

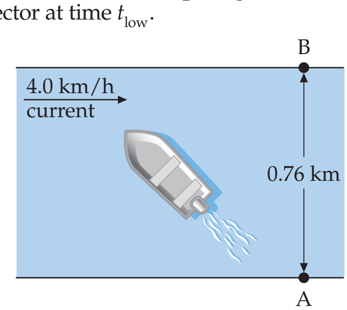

FIGURE 3-28
Problem 16

wishes to go on a straight line from A to B, where the line AB is perpendicular to the banks. The pilot should (*a*) head directly across the river, (*b*) head 53° upstream from the line AB, (*c*) head 37° upstream from the line AB, (*d*) give up—the trip from A to B is not possible with a boat of this limited speed, (*e*) do none of the above.

17 • During a heavy rain, the drops are falling at a constant velocity and at an angle of 10° west of the vertical. You are walking in the rain and notice that only the top surfaces of your clothes are getting wet. In what direction are you walking? Explain. SSM

18 • In Problem 17, what is your walking speed if the speed of the drops relative to the ground is 5.2 m/s?

19 • True or false (ignore any effects due to air resistance):
(*a*) When a projectile is fired horizontally, it takes the same amount of time to reach the ground as an identical projectile dropped from rest from the same height.
(*b*) When a projectile is fired from a certain height at an upward angle, it takes longer to reach the ground than does an identical projectile dropped from rest from the same height.
(*c*) When a projectile is fired horizontally from a certain height, it has a higher speed upon reaching the ground than does an identical projectile dropped from rest from the same height.

20 • A projectile is fired at 35° above the horizontal. Any effects due to air resistance are negligible. At the highest point in its trajectory, its speed is 20 m/s. The initial velocity had a horizontal component of (*a*) 0, (*b*) (20 m/s) cos 35°, (*c*) (20 m/s) sin 35°, (*d*) (20 m/s)/cos 35°, (*e*) 20 m/s.

21 • A projectile is fired at 35° above the horizontal. Any effects due to air resistance are negligible. The initial velocity of the projectile in Problem 20 has a vertical component that is (*a*) less than 20 m/s, (*b*) greater than 20 m/s, (*c*) equal to 20 m/s, (*d*) cannot be determined from the data given. SSM

22 • A projectile is fired at 35° above the horizontal. Any effects due to air resistance are negligible. The projectile lands at the same elevation of launch, so the vertical component of the impact velocity of the projectile is (*a*) the same as the vertical component of its initial velocity in both magnitude and sign, (*b*) the same as the vertical component of its initial velocity in magnitude but opposite in sign, (*c*) less than the vertical component of its initial velocity in magnitude but with the same sign, (*d*) less than the vertical component of its initial velocity in magnitude but with the opposite sign.

23 • Figure 3-29 represents the parabolic trajectory of a projectile going from A to E. Air resistance is negligible. What is the direction of the acceleration at point B? (*a*) up and to the right, (*b*) down and to the left, (*c*) straight up, (*d*) straight down, (*e*) the acceleration of the ball is zero.

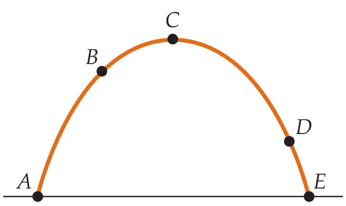

FIGURE 3-29 Problems 23 and 24

24 • Figure 3-29 represents the trajectory of a projectile going from *A* to *E*. Air resistance is negligible. (*a*) At which point(s) is the speed the greatest? (*b*) At which point(s) is the speed the least? (*c*) At which two points is the speed the same? Is the velocity also the same at these points?

25 • True or false:
(*a*) If an object's speed is constant, then its acceleration must be zero.
(*b*) If an object's acceleration is zero, then its speed must be constant.
(*c*) If an object's acceleration is zero, its velocity must be constant.
(*d*) If an object's speed is constant, then its velocity must be constant.
(*e*) If an object's velocity is constant, then its speed must be constant. SSM

26 • The initial and final velocities of a particle are as shown in Figure 3-30. Find the direction of the average acceleration.

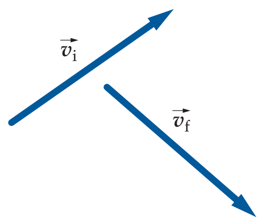

FIGURE 3-30 Problem 26

27 •• The automobile path shown in Figure 3-31 is made up of straight lines and arcs of circles. The automobile starts from rest at point A. After it reaches point B, it travels at constant speed until it reaches point E. It comes to rest at point F. (*a*) At the middle of each segment (AB, BC, CD, DE, and EF), what is the direction of the velocity vector? (*b*) At which of these points does the automobile have a nonzero acceleration? In those cases, what is the direction of the acceleration? (*c*) How do the magnitudes of the acceleration compare for segments BC and DE?

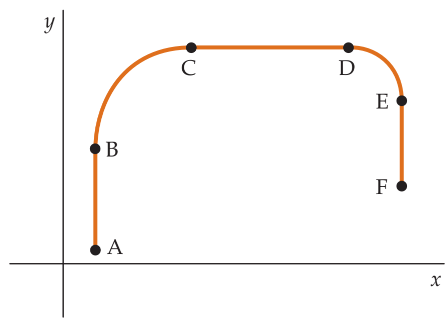

FIGURE 3-31 Problem 27

28 •• Two cannons are pointed directly toward each other, as shown in Figure 3-32. When fired, the cannonballs will follow the trajectories shown—P is the point where the trajectories cross each other. If we want the cannonballs to hit each other, should the gun crews fire cannon A first, cannon B first, or should they fire simultaneously? Ignore any effects due to air resistance.

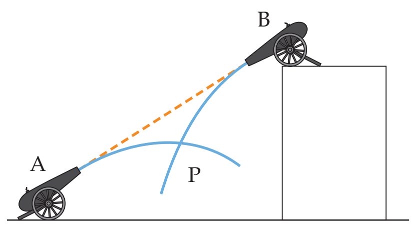

FIGURE 3-32 Problem 28

29 •• Galileo wrote the following in his *Dialogue concerning the two world systems:* "Shut yourself up . . . in the main cabin below decks on some large ship, and . . . hang up a bottle that empties drop by drop into a wide vessel beneath it. When you have observed [this] carefully . . . have the ship proceed with any speed you like, so long as the motion is uniform and not fluctuating this way and that . . . . The droplets will fall as before into the vessel beneath without dropping towards the stern, although while the drops are in the air the ship runs many spans." Explain this quotation.

30 •• A man swings a stone attached to a rope in a horizontal circle at constant speed. Figure 3-33 represents the path of the rock looking down from above. (*a*) Which of the vectors could represent the velocity of the stone? (*b*) Which could represent the acceleration?

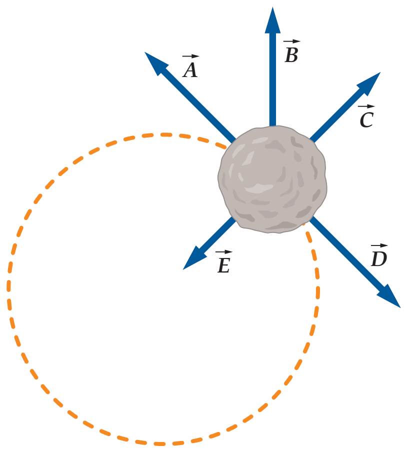

FIGURE 3-33 Problem 30

31 •• True or false:

(*a*) An object cannot move in a circle unless it has centripetal acceleration.
(*b*) An object cannot move in a circle unless it has tangential acceleration.
(*c*) An object moving in a circle cannot have a variable speed.
(*d*) An object moving in a circle cannot have a constant velocity.

32 •• Using a motion diagram, find the direction of the acceleration of the bob of a pendulum when the bob is at a point where it is just reversing its direction.

33 •• **CONTEXT-RICH** During your rookie bungee jump, your friend records your fall using a camcorder. By analyzing it frame by frame, he finds that the y component of your velocity is (recorded every 1/20 of a second) as follows:

t (s)	12.05	12.10	12.15	12.20	12.25	12.30	12.35	12.40	12.45
v_y (m/s)	−0.78	−0.69	−0.55	−0.35	−0.10	0.15	0.35	0.49	0.53

(*a*) Draw a motion diagram. Use it to find the direction and relative magnitude of your average acceleration for each of the eight successive 0.050-s time intervals in the table. (*b*) Comment on how the y component of your acceleration does or does not vary in sign and magnitude as you reverse your direction of motion. SSM

ESTIMATION AND APPROXIMATION

34 •• **CONTEXT-RICH** Estimate the speed in mph with which water comes out of a garden hose using your past observations of water coming out of garden hoses and your knowledge of projectile motion.

35 •• **CONTEXT-RICH** You won a contest to spend a day with a baseball team during spring training. You are allowed to try to hit some balls thrown by a pitcher. Estimate the acceleration during the hit of a fastball thrown by a major league pitcher when you hit the ball squarely—straight back at the pitcher. You will need to make reasonable choices for ball speeds, both just before and just after the ball is hit, and of the contact time of the ball with the bat.

36 •• Estimate how far you can throw a ball if you throw it (*a*) horizontally while standing on level ground, (*b*) at $\theta = 45°$ above horizontal while standing on level ground, (*c*) horizontally from the top of a building 12 m high, (*d*) at $\theta = 45°$ above horizontal from the top of a building 12 m high. Ignore any effects due to air resistance.

37 •• In 1978, Geoff Capes of Great Britain threw a heavy brick a horizontal distance of 44.5 m. Find the approximate speed of the brick at the highest point of its flight, neglecting any effects due to air resistance. Assume the brick landed at the same height it was launched.

POSITION, DISPLACEMENT, VELOCITY, AND ACCELERATION VECTORS

38 • A wall clock has a minute hand with a length of 0.50 m and an hour hand with a length of 0.25 m. Take the center of the clock as the origin, and use a Cartesian coordinate system with the positive x axis pointing to 3 o'clock and the positive y axis pointing to 12 o'clock. Using unit vectors $\hat{i}$ and $\hat{j}$, express the position vectors of the tip of the hour hand ($\vec{A}$) and the tip of the minute hand ($\vec{B}$) when the clock reads (*a*) 12:00, (*b*) 3:00, (*c*) 6:00, (*d*) 9:00.

39 • In Problem 38, find the displacements of the tip of each hand (that is, $\Delta\vec{A}$ and $\Delta\vec{B}$) when the time advances from 3:00 P.M. to 6:00 P.M. SSM

40 • In Problem 38, write the vector that describes the displacement of a fly if it quickly goes from the tip of the minute hand to the tip of the hour hand at 3:00 P.M.

41 • **CONCEPTUAL, APPROXIMATION** A bear, awakening from winter hibernation, staggers directly northeast for 12 m and then due east for 12 m. Show each displacement graphically and graphically determine the single displacement that will take the bear back to her cave to continue her hibernation.

42 • A scout walks 2.4 km due east from camp, then turns left and walks 2.4 km along the arc of a circle centered at the campsite, and finally walks 1.5 km directly toward the camp. (*a*) How far is the scout from camp at the end of his walk? (*b*) In what direction is the scout's position relative to the campsite? (*c*) What is the ratio of the final magnitude of the displacement to the total distance walked.

43 • The faces of a cubical storage cabinet in your garage have 3.0-m-long edges that are parallel to the xyz coordinate planes. The cube has one corner at the origin. A cockroach, on the hunt for crumbs of food, begins at that corner and walks along three edges until it is at the far corner. (*a*) Write the roach's displacement using the set of $\hat{i}$, $\hat{j}$, and $\hat{k}$ unit vectors, and (*b*) find the magnitude of its displacement. SSM

44 • **CONTEXT-RICH** You are the navigator of a ship at sea. You receive radio signals from two transmitters A and B, which are 100 km apart, one due south of the other. The direction finder shows you that transmitter A is at a heading of 30° south of east from the ship, while transmitter B is due east. Calculate the distance between your ship and transmitter B.

45 • A stationary radar operator determines that a ship is 10 km due south of him. An hour later the same ship is 20 km due southeast. If the ship moved at constant speed and always in the same direction, what was its velocity during this time?

46 • A particle's position coordinates (x, y) are (2.0 m, 3.0 m) at $t = 0$; (6.0 m, 7.0 m) at $t = 2.0$ s; and (13 m, 14 m) at $t = 5.0$ s. (*a*) Find the magnitude of the average velocity from $t = 0$ to $t = 2.0$ s. (*b*) Find the magnitude of the average velocity from $t = 0$ to $t = 5.0$ s.

47 • A particle moving at a velocity of 4.0 m/s in the $+x$ direction is given an acceleration of 3.0 m/s^2 in the $+y$ direction for 2.0 s. Find the final speed of the particle. SSM

48 • Initially, a swift-moving hawk is moving due west with a speed of 30 m/s; 5.0 s later it is moving due north with a speed of 20 m/s. (*a*) What are the magnitude and direction of $\Delta\vec{v}_{av}$ during this 5.0-s interval? (*b*) What are the magnitude and direction of $\vec{a}_{av}$ during this 5.0-s interval?

49 • At $t = 0$, a particle located at the origin has a velocity of 40 m/s at $\theta = 45°$. At $t = 3.0$ s, the particle is at $x = 100$ m and $y = 80$ m and has a velocity of 30 m/s at $\theta = 50°$. Calculate (*a*) the average velocity, and (*b*) the average acceleration of the particle during this 3.0-s interval.

50 •• At time zero, a particle is at $x = 4.0$ m and $y = 3.0$ m and has velocity $\vec{v} = (2.0\text{ m/s})\hat{i} + (-9.0\text{ m/s})\hat{j}$. The acceleration of the particle is constant and is given by $\vec{a} = (4.0\text{ m/s}^2)\hat{i} + (3.0\text{ m/s}^2)\hat{j}$. (*a*) Find the velocity at $t = 2.0$ s. (*b*) Express the position vector at $t = 4.0$ s in terms of $\hat{i}$ and $\hat{j}$. In addition, give the magnitude and direction of the position vector at this time.

51 •• A particle has a position vector given by $\vec{r} = (30t)\hat{i} + (40t - 5t^2)\hat{j}$, where r is in meters and t is in seconds. Find the instantaneous-velocity and instantaneous-acceleration vectors as functions of time t. SSM

52 •• A particle has a constant acceleration of $\vec{a} = (6.0\text{ m/s}^2)\hat{i} + (4.0\text{ m/s}^2)\hat{j}$. At time $t = 0$, the velocity is zero and the position vector is $\vec{r}_0 = (10\text{ m})\hat{i}$. (*a*) Find the velocity and position vectors as functions of time t. (*b*) Find the equation of the particle's path in the xy plane and sketch the path.

53 •• Starting from rest at a dock, a motor boat on a lake heads north while gaining speed at a constant 3.0 m/s^2 for 20 s. The boat then heads west and continues for 10 s at the speed that it had at 20 s. (*a*) What is the average velocity of the boat during the 30-s trip? (*b*) What is the average acceleration of the boat during the 30-s trip? (*c*) What is the displacement of the boat during the 30-s trip? SSM

54 •• Starting from rest at point A, you ride your motorcycle north to point B 75.0 m away, increasing speed at a steady rate of 2.00 m/s^2. You then gradually turn toward the east along a circular path of radius 50.0 m at constant speed from B to point C, until your direction of motion is due east at C. You then continue eastward, slowing at a steady rate of 1.00 m/s^2 until you come to rest at point D. (*a*) What is your average velocity and acceleration for the trip from A to D? (*b*) What is your displacement during your trip from A to C? (*c*) What distance did you travel for the entire trip from A to D?

RELATIVE VELOCITY

55 •• A plane flies at an airspeed of 250 km/h. A wind is blowing at 80 km/h toward the direction 60° east of north. (*a*) In what direction should the plane head in order to fly due north relative to the ground? (*b*) What is the speed of the plane relative to the ground?

56 •• A swimmer *heads* directly across a river, swimming at 1.6 m/s relative to the water. She arrives at a point 40 m downstream from the point directly across the river, which is 80 m wide. (*a*) What is the speed of the river current? (*b*) What is the swimmer's speed relative to the shore? (*c*) In what direction should the swimmer head in order to arrive at the point directly opposite her starting point?

57 •• A small plane departs from point A heading for an airport 520 km due north at point B. The airspeed of the plane is 240 km/h and there is a steady wind of 50 km/h blowing directly toward the southeast. Determine the proper heading for the plane and the time of flight. SSM

58 •• Two boat landings are 2.0 km apart on the same bank of a stream that flows at 1.4 km/h. A motorboat makes the round trip between the two landings in 50 min. What is the speed of the boat relative to the water?

59 •• **ENGINEERING APPLICATION, CONTEXT-RICH** During a radio-controlled model-airplane competition, each plane must fly from the center of a 1.0-km-radius circle to any point on the circle and back to the center. The winner is the plane that has the shortest round-trip time. The contestants are free to fly their planes along any route as long as the plane begins at the center, travels to the circle, and then returns to the center. On the day of the race, a steady wind blows out of the north at 5.0 m/s. Your plane can maintain an air speed of 15 m/s. Should you fly your plane upwind on the first leg and downwind on the trip back, or across the wind, flying east and then west? Optimize your chances by calculating the round-trip time for both routes using your knowledge of vectors and relative velocities. With this prerace calculation, you can determine the best route and have a major advantage over the competition!

60 •• **CONTEXT-RICH** You are piloting a small plane that can maintain an air speed of 150 kt (knots, or nautical miles per hour) and you want to fly due north (azimuth = 000°) relative to the ground. (*a*) If a wind of 30 kt is blowing from the east (azimuth = 090°), calculate the heading (azimuth) you must ask your copilot to maintain. (*b*) At that heading, what will be your ground speed?

61 •• Car A is traveling east at 20 m/s toward an intersection. As car A crosses the intersection, car B starts from rest 40 m north of the intersection and moves south steadily gaining speed at 2.0 m/s^2. Six seconds after A crosses the intersection find (*a*) the position of B relative to A, (*b*) the velocity of B relative to A, (*c*) the acceleration of B relative to A. *Hint: Let the unit vectors $\hat{i}$ and $\hat{j}$ be toward the east and north, respectively, and express your answers using $\hat{i}$ and $\hat{j}$.* SSM

62 •• While walking between gates at an airport, you notice a child running along a moving walkway. Estimating that the child runs at a constant speed of 2.5 m/s relative to the surface of the walkway, you decide to try to determine the speed of the walkway itself. You watch the child run on the entire 21-m walkway in one direction, immediately turn around, and run back to his starting point. The entire trip takes a total elapsed time of 22 s. Given this information, what is the speed of the moving walkway relative to the airport terminal?

63 •• Ben and Jack are shopping in a department store. Ben leaves Jack at the bottom of the escalator and walks east at a speed of 2.4 m/s. Jack gets on the escalator, which is inclined at an angle of 37° above the horizontal, and travels eastward and upward at a speed of 2.0 m/s. (*a*) What is the velocity of Ben relative to Jack? (*b*) At what speed should Jack walk up the escalator so that he is always directly above Ben (until he reaches the top)? SSM

64 ••• A juggler traveling in a train on level track throws a ball straight up, relative to the train, with a speed of 4.90 m/s. The train has a velocity of 20.0 m/s due east. As observed by the juggler, (*a*) what is the ball's total time of flight, and (*b*) what is the displacement of the ball during its rise? According to a friend standing on the ground next to the tracks, (*c*) what is the ball's initial speed, (*d*) what is the angle of the launch, and (*e*) what is the displacement of the ball during its rise?

CIRCULAR MOTION AND CENTRIPETAL ACCELERATION

65 • What is the magnitude of the acceleration of the tip of the minute hand of the clock in Problem 38? Express it as a fraction of the magnitude of free-fall acceleration g.

66 • **CONTEXT-RICH** You are designing a centrifuge to spin at a rate of 15,000 rev/min. (*a*) Calculate the maximum centripetal acceleration that a test-tube sample held in the centrifuge arm 15 cm from the rotation axis must withstand. (*b*) It takes 1 min, 15 s for the centrifuge to spin up to its maximum rate of revolution from rest. Calculate the *magnitude* of the tangential acceleration of the centrifuge while it is spinning up, assuming that the tangential acceleration is constant.

67 ••• Earth rotates on its axis once every 24 hours, so that objects on its surface execute uniform circular motion about the axis with a period of 24 hours. Consider only the effect of this rotation on the person on the surface. (Ignore Earth's orbital motion about the Sun.) (*a*) What is the speed and what is the magnitude of the acceleration of a person standing on the equator? (Express the magnitude of this acceleration as a percentage of g.) (*b*) What is the direction of the acceleration vector? (*c*) What is the speed and what is the magnitude of the acceleration of a person standing on the surface at 35°N latitude? (*d*) What is the angle between the direction of the acceleration of the person at 35°N and the direction of the acceleration of the person at the equator if both persons are at the same longitude? SSM

68 •• Determine the acceleration of the moon toward Earth, using values for its mean distance and orbital period from the Terrestrial and Astronomical Data table in this book. Assume a circular orbit. Express the acceleration as a fraction of g.

69 •• (*a*) What are the period and speed of a person on a carousel if the person has an acceleration with a magnitude of 0.80 m/s^2 when she is standing 4.0 m from the axis? (*b*) What are her acceleration magnitude and speed if she then moves to a distance of 2.0 m from the carousel center and the carousel keeps rotating with the same period?

70 ••• Pulsars are neutron stars that emit X rays and other radiation in such a way that we on Earth receive pulses of radiation from the pulsars at regular intervals equal to the period that they rotate. Some of these pulsars rotate with periods as short as 1 ms! The Crab Pulsar, located inside the Crab Nebula in the constellation Orion, has a period currently of length 33.085 ms. It is estimated to have an equatorial radius of 15 km, an average radius for a neutron star. (*a*) What is the value of the centripetal acceleration of an object on the surface at the equator of the pulsar? (*b*) Many pulsars are observed to have periods that lengthen slightly with time, a phenomenon called "spin down." The rate of slowing of the Crab Pulsar is 3.5×10^{-13} s per second, which implies that if this rate remains constant, the Crab Pulsar will stop spinning in 9.5×10^{10} s (about 3000 years from today). What is the tangential acceleration of an object on the equator of this neutron star?

71 ••• **BIOLOGICAL APPLICATION** Human blood contains plasma, platelets, and blood cells. To separate the plasma from other components, centrifugation is used. Effective centrifugation requires subjecting blood to an acceleration of $2000g$ or more. In this situation, assume that blood is contained in test tubes that are 15 cm long and are full of blood. These tubes ride in the centrifuge tilted at an angle of 45.0° above the horizontal (Figure 3-34). (*a*) What is the distance of a sample of blood from the rotation axis of a centrifuge rotating at 3500 rpm, if it has an acceleration of $2000g$? (*b*) If the blood at the center of the tubes revolves around the rotation axis at the radius calculated in Part (*a*), calculate the accelerations experienced by the blood at each end of the test tube. Express all accelerations as multiples of g.

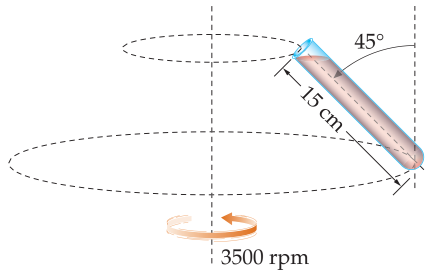

FIGURE 3-34 Problem 71

PROJECTILE MOTION AND PROJECTILE RANGE

72 • While trying out for the position of pitcher on your high school baseball team, you throw a fastball at 87 mi/h toward home plate, which is 18.4 m away. How far does the ball drop due to effects of gravity by the time it reaches home plate? (Ignore any effects due to air resistance.)

73 • A projectile is launched with speed v_0 at an angle of θ_0 above the horizontal. Find an expression for the maximum height it reaches above its starting point in terms of v_0, θ_0, and g. (Ignore any effects due to air resistance.)

74 •• A cannonball is fired with initial speed v_0 at an angle 30° above the horizontal from a height of 40 m above the ground. The projectile strikes the ground with a speed of $1.2v_0$. Find v_0. (Ignore any effects due to air resistance.)

75 •• In Figure 3-35, what is the minimum initial speed of the dart if it is to hit the monkey before the monkey hits the ground, which is 11.2 m below the initial position of the monkey, if $x = 50$ m and $h = 10$ m? (Ignore any effects due to air resistance.)

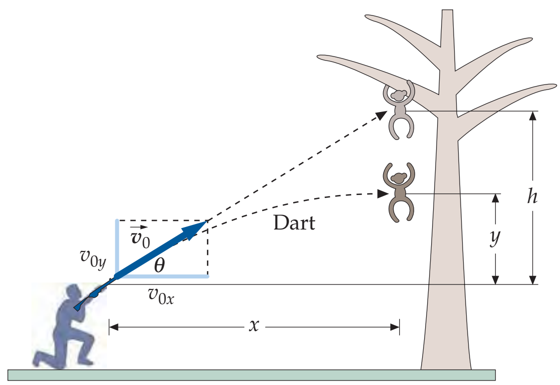

FIGURE 3-35 Problem 75

76 •• A projectile is launched from ground level with an initial speed of 53 m/s. Find the launch angle (the angle the initial velocity vector is above the horizontal) such that the maximum height of the projectile is equal to its horizontal range. (Ignore any effects due to air resistance.)

77 •• A ball launched from ground level lands 2.44 s later on a level field 40.0 m away from the launch point. Find the magnitude of the initial velocity vector and the angle it is above the horizontal. (Ignore any effects due to air resistance.) SSM

78 •• Consider a ball that is launched from ground level with initial speed v_0 at an angle θ_0 above the horizontal. If we consider its speed to be v at some height h above the ground, show that for a given value of h, v is independent of θ_0. (Ignore any effects due to air resistance.)

79 ••• At $\frac{1}{2}$ of its maximum height, the speed of a projectile is $\frac{3}{4}$ of its initial speed. What was its launch angle? (Ignore any effects due to air resistance.)

80 •• A cargo plane is flying horizontally at an altitude of 12 km with a speed of 900 km/h when a large crate falls out of the rear loading ramp. (Ignore any effects due to air resistance.) (*a*) How long does it take the crate to hit the ground? (*b*) How far horizontally is the crate from the point where it fell off when it hits the ground? (*c*) How far is the crate from the aircraft when the crate hits the ground, assuming that the plane continues to fly with the same velocity?

81 •• Wile E. Coyote (*Carnivorus hungribilus*) is chasing the Roadrunner (*Speedibus cantcatchmi*) yet again. While running down the road, they come to a deep gorge, 15.0 m straight across and 100 m deep. The Roadrunner launches himself across the gorge at a launch angle of 15° above the horizontal, and lands with 1.5 m to spare. (*a*) What was the Roadrunner's launch speed? (*b*) Wile E. Coyote launches himself across the gorge with the same initial speed, but at a different launch angle. To his horror, he is short of the other lip by 0.50 m. What was his launch angle? (Assume that it was less than 15°.) SSM

82 •• A cannon barrel is elevated 45° above the horizontal. It fires a ball with a speed of 300 m/s. (*a*) What height does the ball reach? (*b*) How long is the ball in the air? (*c*) What is the horizontal range of the cannon ball? (Ignore any effects due to air resistance.)

83 •• A stone thrown horizontally from the top of a 24-m tower hits the ground at a point 18 m from the base of the tower. (Ignore any effects due to air resistance.) (*a*) Find the speed with which the stone was thrown. (*b*) Find the speed of the stone just before it hits the ground. SSM

84 •• A projectile is fired into the air from the top of a 200-m cliff above a valley (Figure 3-36). Its initial velocity is 60 m/s at 60° above the horizontal. Where does the projectile land? (Ignore any effects due to air resistance.)

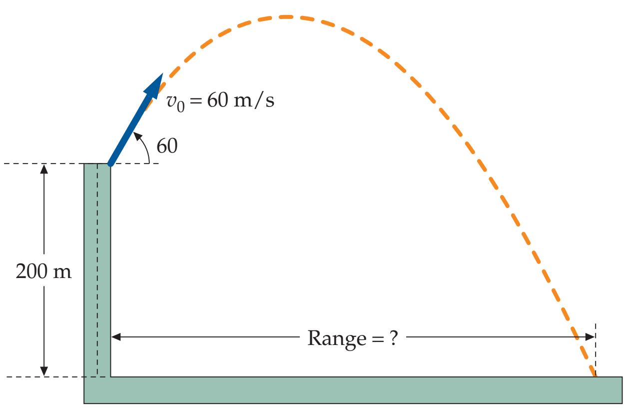

FIGURE 3-36 Problem 84

85 •• The range of a cannonball fired horizontally from a cliff is equal to the height of the cliff. What is the direction of the velocity vector of the projectile as it strikes the ground? (Ignore any effects due to air resistance.)

86 •• An archer fish launches a droplet of water from the surface of a small lake at an angle of 60° above the horizontal. He is aiming at a juicy spider sitting on a leaf 50 cm to the east and on a branch 25 cm above the water surface. The fish is trying to knock the spider into the water so that the fish can eat the spider. (*a*) What must the speed of the water droplet be for the fish to be successful? (*b*) When it hits the spider, is the droplet rising or falling?

87 •• **CONTEXT-RICH** You are trying out for the position of place-kicker on a professional football team. With the ball teed 50.0 m from the goalposts with a crossbar 3.05 m off the ground, you kick the ball at 25.0 m/s and 30° above the horizontal. (*a*) Is the field goal attempt good? (*b*) If so, by how much does it clear the bar? If not, by how much does it go under the bar? (*c*) How far behind the plane of the goalposts does the ball land? SSM

88 •• The speed of an arrow fired from a compound bow is about 45.0 m/s. (*a*) A Tartar archer sits astride his horse and launches an arrow into the air, elevating the bow at an angle of 10° above the horizontal. If the arrow is 2.25 m above the ground at launch, what is the arrow's horizontal range? Assume that the ground is level, and ignore any effects due to air resistance. (*b*) Now assume that his horse is at full gallop, moving in the same direction that the archer will fire the arrow. Also assume that the archer elevates the bow at the same elevation angle as in Part (*a*) and fires. If the horse's speed is 12.0 m/s, what is the arrow's horizontal range now?

89 The roof of a two-story house makes an angle of 30° with the horizontal. A ball rolling down the roof rolls off the edge at a speed of 5.0 m/s. The distance to the ground from that point is 7.0 m. (*a*) How long is the ball in the air? (*b*) How far from the base of the house does it land? (*c*) What is its speed and direction just before landing?

90 •• Compute $dR/d\theta_0$ from $R = (v_0^2/g)\sin(2\theta_0)$ and show that setting $dR/d\theta_0 = 0$ gives $\theta_0 = 45°$ for the maximum range.

91 •• In a science fiction short story written in the 1970s, Ben Bova described a conflict between two hypothetical colonies on the moon—one founded by the United States and the other by the USSR. In the story, colonists from each side started firing bullets at each other, only to find to their horror that their rifles had large enough muzzle velocities so that the bullets went into orbit. (*a*) If the magnitude of free-fall acceleration on the moon is 1.67 m/s^2, what is the maximum range of a rifle bullet with a muzzle velocity of 900 m/s? (Assume the curvature of the surface of the moon is negligible.) (*b*) What would the muzzle velocity have to be to send the bullet into a circular orbit just above the surface of the moon?

92 ••• On a level surface, a ball is launched from ground level at an angle of 55° above the horizontal, with an initial speed of 22 m/s. It lands on a hard surface, and bounces, reaching a peak height of 75% of the height it reached on its first arc. (Ignore any effects due to air resistance.) (*a*) What is the maximum height reached in its first parabolic arc? (*b*) How far horizontally from the launch point did it strike the ground the first time? (*c*) How far horizontally from the launch point did the ball strike the ground the second time? Assume the horizontal component of the velocity remains constant during the collision of the ball with the ground. *Hint: You cannot assume that the angle with which the ball leaves the ground after the first collision is the same as the initial launch angle.*

93 ••• In the text, we calculated the range for a projectile that lands at the same elevation from which it is fired as $R = (v_0^2/g)\sin 2\theta_0$. A golf ball hit from an elevated tee at 45.0 m/s and an angle of 35.0° lands on a green 20.0 m below the tee (Figure 3-37). (Ignore any effects due to air resistance.) (*a*) Calculate the range using the equation $R = (v_0^2/g)\sin 2\theta_0$ even though the ball is hit from an elevated tee. (*b*) Show that the range for the more general problem (Figure 3-37) is given by $R = \left(1+\sqrt{1-\frac{2gy}{v_0^2\sin^2\theta_0}}\right)\frac{v_0^2}{2g}\sin 2\theta_0$, where y is the height of the green above the tee. That is, $y = -h$. (*c*) Compute the range using this formula. What is the percentage error in neglecting the elevation of the green?

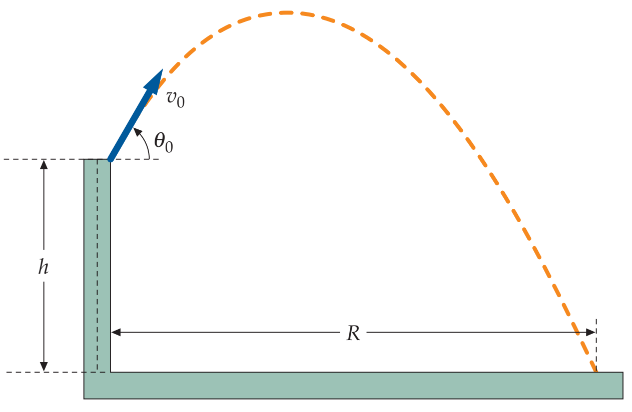

FIGURE 3-37 Problem 93

94 ••• **MULTISTEP** In the text, we calculated the range for a projectile that lands at the same elevation from which it is fired as $R = (v_0^2/g)\sin 2\theta_0$ if the effects of the air resistance are negligible. (*a*) Show that for the same conditions the change in the range for a small change in free-fall acceleration g, and the same initial speed and angle, is given by $\Delta R/R = -\Delta g/g$. (*b*) What would be the length of a homerun at a high altitude where g is 0.50% less than at sea level if the homerun at sea level traveled 400 ft?

95 ••• **MULTISTEP, APPROXIMATION** In the text, we calculated the range for a projectile that lands at the same elevation from which it is fired as $R = (v_0^2/g)\sin 2\theta_0$ if the effects of the air resistance are negligible. (*a*) Show that for the same conditions the change in the range for a small change in launch speed, and the same initial angle and free-fall acceleration, is given by $\Delta R/R = 2\Delta v_0/v_0$. (*b*) Suppose a projectile's range was 200 m. Use the formula in Part (*a*) to estimate its increase in range if the launch speed were increased by 20.0%. (*c*) Compare your answer in (*b*) to the increase in range by calculating the increase in range directly from $R = (v_0^2/g)\sin 2\theta_0$. If the results for Parts (*b*) and (*c*) are different, is the estimate too small or large, and why? SSM

96 ••• A projectile, fired with unknown initial velocity, lands 20.0 s later on the side of a hill, 3000 m away horizontally and 450 m vertically above its starting point. (Ignore any effects due to air resistance.) (*a*) What is the vertical component of its initial velocity? (*b*) What is the horizontal component of its initial velocity? (*c*) What was its maximum height above its launch point? (*d*) As it hit the hill, what speed did it have and what angle did its velocity make with the vertical?

97 ••• A projectile is launched over level ground at an initial elevation angle of θ. An observer standing at the launch site sees the projectile at the point of its highest elevation and measures the angle ϕ shown in Figure 3-38. Show that $\tan\phi = \frac{1}{2}\tan\theta$. (Ignore any effects due to air resistance.) SSM

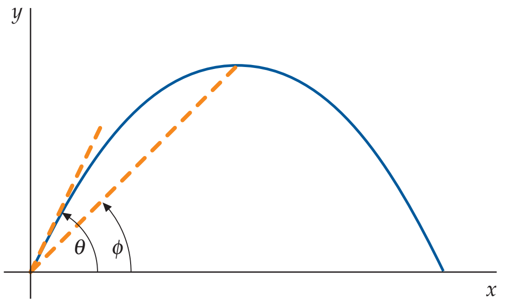

FIGURE 3-38 Problem 97

98 ••• A toy cannon is placed on a ramp that has a slope of angle ϕ. (*a*) If the cannonball is projected up the hill at an angle of θ_0 above the horizontal (Figure 3-39) and has a muzzle speed of v_0, show that the range R of the cannonball (as measured along the ramp) is given by

$$R = \frac{2v_0^2\cos^2\theta_0(\tan\theta_0 - \tan\phi)}{g\cos\phi}$$

Ignore any effects due to air resistance.

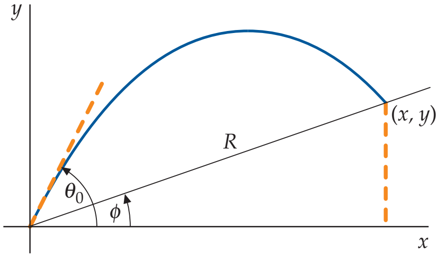

FIGURE 3-39 Problem 98

99 ••• A rock is thrown from the top of a 20-m-high building at an angle of 53° above the horizontal. (*a*) If the horizontal range of the throw is equal to the height of the building, with what speed was the rock thrown? (*b*) How long is it in the air? (*c*) What is the velocity of the rock just before it strikes the ground? (Ignore any effects due to air resistance.)

100 ••• A woman throws a ball at a vertical wall 4.0 m away (Figure 3-40). The ball is 2.0 m above ground when it leaves the woman's hand with an initial velocity of 14 m/s at 45°, as shown. When the ball hits the wall, the horizontal component of its velocity is reversed; the vertical component remains unchanged. (*a*) Where does the ball hit the ground? (*b*) How long was the ball in the air before it hit the wall? (*c*) Where did the ball hit the wall? (*d*) How long was the ball in the air after it left the wall? Ignore any effects due to air resistance.

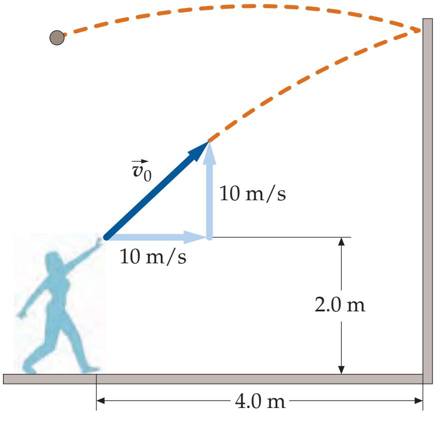

FIGURE 3-40 Problem 100

101 ••• **ENGINEERING APPLICATION** Catapults date from thousands of years ago, and were used historically to launch everything from stones to horses. During a battle in what is now Bavaria, inventive artillerymen from the united German clans launched giant *spaetzle* from their catapults toward a Roman fortification whose walls were 8.50 m high. The catapults launched the *spaetzle* projectiles from a height of 4.00 m above the ground and a distance of 38.0 m from the walls of the fortification at an angle of 60.0 degrees above the horizontal (Figure 3-41). If the projectiles were to hit the top of the wall, splattering the Roman soldiers atop the wall with pulverized pasta, (*a*) what launch speed was necessary? (*b*) How long were the *spaetzle* in the air? (*c*) At what speed did the projectiles hit the wall? Ignore any effects due to air resistance.

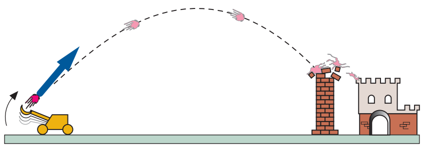

FIGURE 3-41 Problem 101

102 ••• The distance from the pitcher's mound to home plate is 18.4 m. The mound is 0.20 m above the level of the field. A pitcher throws a fastball with an initial speed of 37.5 m/s. At the moment the ball leaves the pitcher's hand, it is 2.30 m above the mound. (*a*) What should the angle between $\vec{v}_0$ and the horizontal be so that the ball crosses the plate 0.70 m above ground? (Ignore any effects due to air resistance.) (*b*) With what speed does the ball cross the plate? SSM

103 ••• You are watching your friend play hockey. During the course of the game, he strikes the puck in such a way that, when it is at its highest point, it just clears the surrounding 2.80-m-high Plexiglas wall that is 12.0 m away. Find (*a*) the vertical component of its initial velocity, (*b*) the time it takes to reach the wall, and (*c*) the horizontal component of its initial velocity, and its initial speed and angle. (Ignore any effects due to air resistance.)

104 ••• Carlos is on his trail bike, approaching a creek bed that is 7.0 m wide. A ramp with an incline of 10° has been built for daring people who try to jump the creek. Carlos is traveling at his bike's maximum speed, 40 km/h. (*a*) Should Carlos attempt the jump or brake hard? (*b*) What is the minimum speed a bike must have to make this jump? Assume equal elevations on either side of the creek. (Ignore any effects due to air resistance.)

105 ••• If a bullet that leaves the muzzle of a gun at 250 m/s is to hit a target 100 m away at the level of the muzzle (1.7 m above the level ground), the gun must be aimed at a point above the target. (*a*) How far above the target is that point? (*b*) How far behind the target will the bullet strike the ground? (Ignore any effects due to air resistance.) SSM

GENERAL PROBLEMS

106 •• During a do-it-yourself roof repair project, you are on the roof of your house and accidentally drop your hammer. The hammer then slides down the roof at constant speed of 4.0 m/s. The roof makes an angle of 30° with the horizontal, and its lowest point is 10 m from the ground. (*a*) How long after leaving the roof does the hammer hit the ground? (*b*) What is the horizontal distance traveled by the hammer between the instant it leaves the roof and the instant it hits the ground? (Ignore any effects due to air resistance.)

107 •• A squash ball typically rebounds from a surface with 25% of the speed with which it initially struck the surface. Suppose a squash ball is served in a shallow trajectory, from a height above the ground of 45 cm, at a launch angle of 6.0° degrees above the horizontal, and at a distance of 12 m from the front wall. (*a*) If it strikes the front wall exactly at the top of its parabolic trajectory, determine how high above the floor the ball strikes the wall. (*b*) How far horizontally from the wall does it strike the floor, after rebounding? (Ignore any effects due to air resistance.)

108 •• A football quarterback throws a pass at an angle of 36.5°. He releases the pass 3.50 m behind the line of scrimmage. His receiver left the line of scrimmage 2.50 s earlier, goes straight downfield at a constant speed of 7.50 m/s. In order that the pass land gently in the receiver's hands without the receiver breaking stride, with what speed must the quarterback throw the pass? Assume that the ball is released at the same height it is caught and that the receiver is straight downfield from the quarterback at the time of release. (Ignore any effects due to air resistance.)

109 •• Suppose a test pilot is able to safely withstand an acceleration of up to 5.0 times the acceleration due to gravity (that is, remain conscious and alert enough to fly). During the course of maneuvers, he is required to fly the plane in a horizontal circle at its top speed of 1900 mi/h. (*a*) What is the radius of the smallest circle he will be able to safely fly the plane in? (*b*) How long does it take him to go halfway around this minimum-radius circle?

110 •• A particle moves in the *xy* plane with constant acceleration. At $t = 0$ the particle is at $\vec{r}_1 = (4.0\text{ m})\hat{i} + (3.0\text{ m})\hat{j}$, with velocity $\vec{v}_1$. At $t = 2.0$ s, the particle has moved to $\vec{r}_2 = (10\text{ m})\hat{i} - (2.0\text{ m})\hat{j}$ and its velocity has changed to $\vec{v}_2 = (5.0\text{ m/s})\hat{i} - (6.0\text{ m/s})\hat{j}$. (*a*) Find $\vec{v}_1$. (*b*) What is the acceleration of the particle? (*c*) What is the velocity of the particle as a function of time? (*d*) What is the position vector of the particle as a function of time?

111 •• Plane A is flying due east at an air speed of 400 mph. Directly below, at a distance of 4000 ft, plane B is headed due north, flying at an air speed of 700 mph. Find the velocity vector of plane B relative to A. SSM

112 •• A diver steps off the cliffs at Acapulco, Mexico, 30.0 m above the surface of the water. At that moment, he activates his rocket-powered backpack horizontally, which gives him a constant horizontal acceleration of 5.00 m/s^2 but does not affect his vertical motion. (*a*) How long does he take to reach the surface of the water? (*b*) How far out from the base of the cliff does he enter the water, assuming the cliff is vertical? (*c*) Show that his flight path is a straight line. (Ignore any effects of air resistance.)

113 •• A small steel ball is projected horizontally off the top of a long flight of stairs. The initial speed of the ball is 3.0 m/s. Each step is 0.18 m high and 0.30 m wide. Which step does the ball strike first? SSM

114 •• Suppose you can throw a ball a maximum horizontal distance L when standing on level ground. How far can you throw it from the top of a building of height h if you throw it at (*a*) 0°, (*b*) 30°, (*c*) 45°? (Ignore any effects due to air resistance.)

115 ••• Darlene is a stunt motorcyclist in a traveling circus. For the climax of her show, she takes off from the ramp at angle θ_0, clears a ditch of width L, and lands on an elevated ramp (height h) on the other side (Figure 3-42). (*a*) For a given height h, find the minimum necessary takeoff speed v_{min} needed to make the jump successfully. (*b*) What is v_{min} for $L = 8.0$ m, $\theta = 30°$, and $h = 4.0$ m?

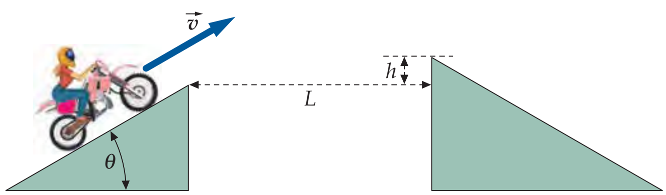

FIGURE 3-42 Problem 115

(*c*) Show that regardless of her takeoff speed, the maximum height of the platform is $h < L\tan\theta_0$. Interpret this result physically. (Neglect any effects due to air resistance and treat the rider and the bike as if they were a single particle.)

116 ••• A small boat is headed for a harbor 32 km directly northwest of its current position when it is suddenly engulfed in heavy fog. The captain maintains a compass bearing of northwest and a speed of 10 km/h relative to the water. The fog lifts 3.0 h later and the captain notes that he is now exactly 4.0 km south of the harbor. (*a*) What was the average velocity of the current during those 3.0 h? (*b*) In what direction should the boat have been heading to reach its destination along a straight course? (*c*) What would its travel time have been if it had followed a straight course?

117 •• Galileo showed that, if any effects due to air resistance are ignored, the ranges for projectiles (on a level field) whose angles of projection exceed or fall short of 45° by the same amount are equal. Prove Galileo's result. SSM

118 •• Two balls are thrown with equal speeds from the top of a cliff of height h. One ball is thrown at an angle of α above the horizontal. The other ball is thrown at an angle of β below the horizontal. Show that each ball strikes the ground with the same speed, and find that speed in terms of h and the initial speed v_0. (Ignore any effects due to air resistance.)

119 •• In his car, a driver tosses an egg vertically from chest height so that the peak of its path is just below the ceiling of the passenger compartment, which is 65 cm above his release point. He catches the egg at the same height that he releases it. If you are a roadside observer and measure the horizontal distance between catch and release points to be 19 m, (*a*) how fast is the car moving? (*b*) In your reference frame, at what angle above the horizontal was the egg thrown?

120 ••• A straight line is drawn on the surface of a 16-cm-radius turntable from the center to the perimeter. A bug crawls along this line from the center outward as the turntable spins counterclockwise at a constant 45 rpm. Its walking speed relative to the turntable is a steady 3.5 cm/s. Let its initial heading be in the positive x direction. As the bug reaches the edge of the turntable (still traveling at 3.5 cm/s radially, relative to the turntable), what are the x and y components of the velocity of the bug?

121 ••• On a windless day, a stunt pilot is flying his vintage World War I Sopwith Camel from Dubuque, Iowa, to Chicago, Illinois, for an air show. Unfortunately, he is unaware that his plane's ancient magnetic compass has a serious problem in that what it records as "north" is in fact 16.5° east of true north. At one moment during his flight, the airport in Chicago notifies him that he is, in reality, 150 km due west of the airport. He then turns due east, according to his plane's compass, and flies for 45 minutes at 150 km/h. At that point, he expects to see the airport and begin final descent. What is the plane's actual distance from Chicago and what should be the pilot's heading if he is to fly directly toward Chicago?

122 ••• **ENGINEERING APPLICATION, CONTEXT-RICH** A cargo plane in flight lost a package because somebody forgot to close the rear cargo doors. You are on the team of safety experts trying to analyze what happened. From the point of takeoff, while climbing to altitude, the airplane traveled in a straight line and at a constant speed of 275 mi/h at an angle of 37° above the horizontal. During the ascent, the package slid off the back ramp. You found the package in a field a distance of 7.5 km from the takeoff point. To complete the investigation you need to know exactly how long after takeoff the package slid off the back ramp of the plane. (Consider the sliding speed to be negligible.) Calculate the time at which the package fell off the back ramp. (Ignore any effects due to air resistance.)

CHAPTER 4

THIS AIRPLANE IS ACCELERATING AS IT HEADS DOWN THE RUNWAY BEFORE TAKEOFF. NEWTON'S LAWS RELATE AN OBJECT'S ACCELERATION TO ITS MASS AND THE FORCES ACTING ON IT. *(John Neubauer/FPG/Getty.)*

? If you were a passenger on this plane, how might you use Newton's laws to determine the plane's acceleration? (See Example 4-9.)

Newton's Laws

Now that we have studied how objects move in one, two, and three dimensions, we can ask the questions "Why do objects start to move?" and "What causes a moving object to change speed or change direction?"

These questions occupied the mind of Sir Isaac Newton, who was born in 1642, the year Galileo died. As a student at Cambridge, where he was later a mathematics professor, Newton studied the work of Galileo and Kepler. He wanted to figure out why planets move in ellipses at speeds dependent on their distance to the Sun, and even why the solar system stays together at all. During his lifetime, he developed both his law of gravitation, which we will examine in Chapter 12, and his three basic laws of motion that form the basis of classical mechanics.

Newton's laws relate the forces objects exert on each other, and relate any change in the motion of an object to the forces that act on it. Newton's laws of motion are the tools that enable us to analyze a wide range of mechanical phenomena. Although we may already have an intuitive idea of a force as a push or a pull, like that exerted by our muscles or by stretched rubber bands and springs, Newton's laws allow us to refine our understanding of forces.

In this chapter, we describe Newton's three laws of motion and begin using them to solve problems involving objects in motion and at rest.

4-1 NEWTON'S FIRST LAW: THE LAW OF INERTIA

Give a shove to a piece of ice on a counter top: It slides, and then slows to a stop. If the counter is wet, the ice will travel farther before stopping. A piece of dry ice (frozen carbon dioxide) riding on a cushion of carbon dioxide vapor slides quite far with little change in velocity. Before Galileo, it was thought that a steady force, such as a push or pull, was always needed to keep an object moving with constant velocity. But Galileo, and later Newton, recognized that the slowing of objects in everyday experience is due to the force of friction. If friction is reduced, the rate of slowing is reduced. A water slick or a cushion of gas is especially effective at reducing friction, allowing the object to slide a great distance with little change in velocity. Galileo reasoned that, if we could remove all external forces including friction from an object, then the velocity of the object would never change—a property of matter he described as **inertia.** This conclusion, restated by Newton as his first law, is also called the **law of inertia.**

A modern wording of Newton's first law is

> **First law.** An object at rest stays at rest *unless* acted on by an external force. An object in motion continues to travel with constant speed in a straight line *unless* acted on by an external force.
>
> NEWTON'S FIRST LAW

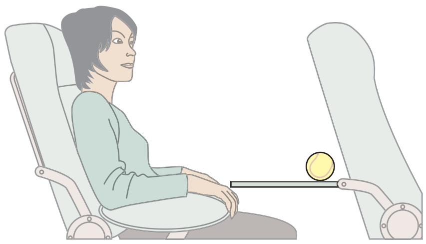
Friction is greatly reduced by a cushion of air that supports the hovercraft. *(Jose Dupont/Explorer/Photo Researchers.)*

INERTIAL REFERENCE FRAMES

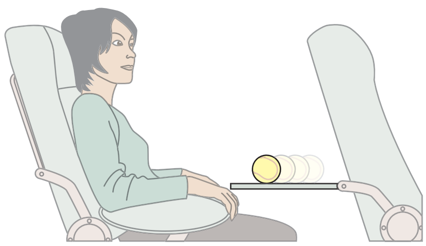
Newton's first law makes no distinction between an object at rest and an object moving with constant (nonzero) velocity. Whether an object remains at rest or remains moving with constant velocity depends on the reference frame in which the object is observed. Suppose you are a passenger on an airplane that is flying along a straight path at constant altitude and you carefully place a tennis ball on your seat tray (which is horizontal). Relative to the plane, the ball will remain at rest as long as the plane continues to fly at constant velocity relative to the ground. Relative to the ground, the ball remains moving with the same velocity as the plane (Figure 4-1*a*).

Now, suppose that the pilot opens the throttle and the plane suddenly accelerates forward (relative to the ground). You will then observe that the ball on your tray suddenly starts to roll toward the rear of the plane, accelerating (relative to the plane) even though there is no horizontal force acting on it (Figure 4-1*b*). In this accelerating reference frame of the plane, Newton's first-law statement does not apply. Newton's first-law statement applies *only* in reference frames known as inertial reference frames. In fact, Newton's first law gives us the criterion for determining if a reference frame is an inertial frame:

> If no forces act on an object, any reference frame for which the acceleration of the object remains zero is an **inertial reference frame.**
>
> INERTIAL REFERENCE FRAME



(*a*)



(*b*)

FIGURE 4-1 The plane is flying horizontally in a straight path at constant speed when you place a tennis ball on the tray. (*a*) The plane continues to fly at constant velocity (relative to the ground) and the ball remains at rest on the tray. (*b*) The pilot suddenly opens the throttle and plane rapidly gains speed (relative to the ground). The ball does not gain speed as quickly as the plane, so it accelerates (relative to the plane) toward the back of the plane.

Both the plane, when cruising at constant velocity, and the ground are, to a good approximation, inertial reference frames. Any reference frame moving with constant velocity relative to an inertial reference frame is also an inertial reference frame.

A reference frame attached to the ground is not quite an inertial reference frame because of the small acceleration of the ground due to the rotation of Earth and

> ! Newton's first-law statement applies *only* to inertial reference frames.

the small acceleration of Earth itself due to its revolution around the Sun. However, these accelerations are of the order of $0.01\,\mathrm{m/s^2}$ or less, so to a good approximation, a reference frame attached to the surface of Earth is an inertial reference frame.

4-2 FORCE AND MASS

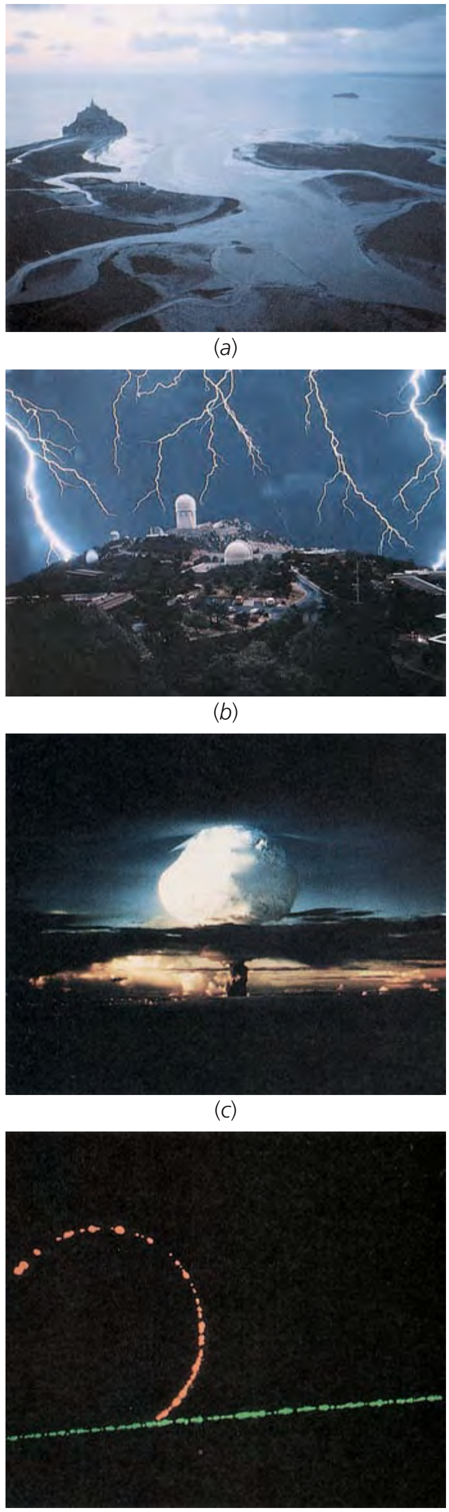
Using Newton's first law and the concept of inertial reference frames, we can define a **force** as an external influence or action on an object that causes the object to change velocity, that is, to accelerate relative to an inertial reference frame. (We assume that no other forces are acting on the object.) Force is a vector quantity. It has both magnitude (the size or strength of the force) and direction.

Forces are exerted on objects by other objects, and forces that are due to one object being physically touched by a second object are known as **contact forces.** Common examples of contact forces include hitting a ball with a bat, your hand pulling on a fishing line, your hands pushing on a shopping cart, and the force of friction between your sneakers and the floor. Note that in each case there is direct physical contact between the object applying the force and the object to which the force is applied. Other forces act on an object without direct physical contact with a second object. These forces, referred to as **action-at-a-distance forces,** include the gravitational force, the magnetic force, and the electric force.

THE FUNDAMENTAL INTERACTIONS OF NATURE

Forces are interactions between particles. Traditionally, physicists explain all interactions observed in nature in terms of four basic interactions that occur between elementary particles (see Figure 4-2):

1. The gravitational interaction—the long-range interaction between particles due to their mass. It is believed by some that the gravitational interaction involves the exchange of hypothetical particles called gravitons.
2. The electromagnetic interaction—the long-range interaction between electrically charged particles involving the exchange of photons.
3. The weak interaction—the extremely short-range interaction between subnuclear particles involving the exchange or production of W and Z bosons. The electromagnetic and weak interactions are now viewed as a single unified interaction called the electroweak interaction.
4. The strong interaction—the long-range interaction between hadrons, which themselves consist of quarks, that binds protons and neutrons together to form the atomic nuclei. It involves the exchange of mesons between hadrons, or gluons between quarks.



(*a*) (*b*) (*c*) (*d*)

FIGURE 4-2 (*a*) The magnitude of the gravitational force between Earth and an object near Earth's surface is the weight of the object. The gravitational interaction between the Sun and the other planets is responsible for keeping the planets in their orbits around the Sun. Similarly, the gravitational interaction between Earth and the moon keeps the moon in its nearly circular orbit around Earth. The gravitational forces exerted by the moon and the Sun on the oceans of Earth are responsible for the diurnal and semidiurnal tides. Mont-Saint-Michel, France, shown in the photo, is an island when the tide is in. (*b*) The electromagnetic interaction includes both the electric and the magnetic forces. A familiar example of the electric interaction is the attraction between small bits of paper and a comb that is electrified after being run through hair. The lightning bolts above the Kitt Peak National Observatory, shown in the photo, are the result of the electromagnetic interaction. (*c*) The strong nuclear interaction between elementary particles called hadrons, which include protons and neutrons, the constituents of atomic nuclei. This interaction results from the interaction of quarks, which are the building blocks of hadrons, and is responsible for holding nuclei together. The hydrogen bomb explosion shown here illustrates the strong nuclear interaction. (*d*) The weak nuclear interaction between leptons (which include electrons and muons) and between hadrons (which include protons and neutrons). This false-color cloud chamber photograph illustrates the weak interaction between a cosmic ray muon (green) and an electron (red) knocked out of an atom. *((a) Cotton Coulson/Woodfin Camp and Assoc.; (b) Gary Ladd; (c) Los Alamos National Lab; (d) Science Photo Library/Photo Researchers.)*

The everyday forces that we observe between macroscopic objects are due to either the gravitational or the electromagnetic interactions. Contact forces, for example, are actually electromagnetic in origin. They are exerted between the surface molecules of the objects in contact. Action-at-a-distance forces are due to the fundamental interactions of gravity and electromagnetism. These two forces act between particles that are separated in space. Although Newton could not explain how forces act through empty space, later scientists introduced the concept of a field, which acts as an intermediary agent. For example, we consider the attraction of Earth by the Sun in two steps. The Sun creates a condition in space that we call the gravitational field. This field then exerts a force on Earth. Similarly, Earth produces a gravitational field that exerts a force on the Sun. Your weight is the force exerted by the gravitational field of Earth on you. When we study electricity and magnetism (Chapters 22–31) we will study electric fields, which are produced by electrical charges, and magnetic fields, which are produced by electrical charges in motion. The strong and weak interactions are discussed in Chapter 42.

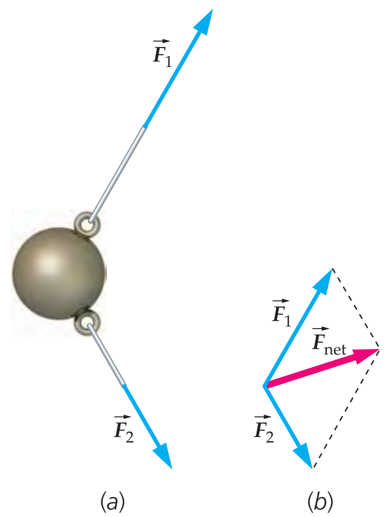


FIGURE 4-3 (*a*) The forces $\vec{F}_1$ and $\vec{F}_2$ pull on the sphere. (*b*) The effect of the two forces is as if a single force $\vec{F}_{net} = \vec{F}_1 + \vec{F}_2$ acts on the sphere instead of the two distinct forces $\vec{F}_1$ and $\vec{F}_2$.

COMBINING FORCES

If two or more individual forces simultaneously act on an object, the result is as if a single force, equal to the vector sum of the individual forces, acts in place of the individual forces. (That forces combine this way is called the **principle of superposition.**) The vector sum of the individual forces on an object is called the **net force** $\vec{F}_{net}$ on the object. That is,

$$\vec{F}_{net} = \vec{F}_1 + \vec{F}_2 + \cdots$$

where $\vec{F}_1$, $\vec{F}_2$, . . . are the individual forces. Figure 4-3 shows an object being pulled in two directions by ropes. The effect is as if a single force equal to the net force acts on the object.

The SI unit of force is the newton (N). The newton is defined in the next section. One newton is equal to the weight of a modest-sized apple.

CONCEPT CHECK 4-1

Is the net force an actual force?

MASS

Objects intrinsically resist being accelerated. Imagine kicking both a soccer ball and a bowling ball. The bowling ball resists being accelerated much more than does the soccer ball, as would be evidenced by your sore toes. This intrinsic property is called the object's **mass.** It is a measure of the object's inertia. The greater an object's mass, the more the object resists being accelerated.

As noted in Chapter 1, the object chosen as the international standard for mass is a platinum-iridium alloy cylinder carefully preserved at the International Bureau of Weights and Measures at Sèvres, France. The mass of this standard object is 1 **kilogram** (kg), the SI unit of mass.

A convenient standard unit for mass in atomic and nuclear physics is the **unified atomic mass unit** (u), which is defined as one-twelfth of the mass of the carbon-12 (^{12}C) atom. The unified atomic mass unit is related to the kilogram by

$$1\ \text{u} = 1.660\,540 \times 10^{-27}\ \text{kg}$$

The concept of mass is defined as a constant of proportionality in Newton's second law. To measure the mass of an object, we compare its mass with a standard mass, such as the 1-kg standard kept at Sèvres. The comparison is accomplished using Newton's second law, and a procedure for doing this is described in Section 4-3 immediately following Example 4-1.

4-3 NEWTON'S SECOND LAW

Newton's first law tells us what happens when there is *no* force acting on an object. But what happens when there are forces exerted on the object? Consider again a block of ice sliding with constant velocity on a smooth, *frictionless* surface. If you push on the ice, you exert a force $\vec{F}$ that causes the ice's velocity to change. The harder you push, the greater the resulting acceleration $\vec{a}$. The acceleration, $\vec{a}$, of any object is directly proportional to the net force $\vec{F}_{\text{net}}$ exerted on it, and the reciprocal of the mass of the object is the proportionality constant. In addition, the acceleration vector and the net force vector are in the same direction. Newton summarized these observations in his second law of motion:

> **Second law.** The acceleration of an object is directly proportional to the net force acting on it, and the reciprocal of the mass of the object is the constant of proportionality. Thus,
>
> $$\vec{a} = \frac{\vec{F}_{\text{net}}}{m}, \quad \text{where} \quad \vec{F}_{\text{net}} = \sum \vec{F} \qquad 4\text{-}1$$
>
> NEWTON'S SECOND LAW

A net force on an object causes it to accelerate. It is a matter of cause and effect. The net force is the cause and the effect is the acceleration.*

A net force of 1 newton gives a 1-kg mass an acceleration of $1\,\text{m/s}^2$, so

$$1\text{ N} = (1\text{ kg})(1\text{ m/s}^2) = 1\text{ kg}\cdot\text{m/s}^2 \qquad 4\text{-}2$$

Thus, a force of 2 N gives a 2-kg mass an acceleration of $1\,\text{m/s}^2$, and so on.

In the U.S. customary system, the unit of force is the *pound* (lb), where $1\text{ lb} \approx 4.45\text{ N}$,† and the unit of mass is the *slug*. The pound is defined to be the force required to produce an acceleration of 1 ft/s^2 on a mass of 1 slug:

$$1\text{ lb} = 1\text{ slug}\cdot\text{ft/s}^2$$

It follows that $1\text{ slug} \approx 14.6\text{ kg}$.

The Equation 4-1 is frequently expressed:

$$\vec{F}_{\text{net}} = m\vec{a}$$

and we will express it this way most of the time.

! Newton's second-law statement, like Newton's first–law statement, can be applied *only* in inertial reference frames.

CONCEPT CHECK 4-2

Is $m\vec{a}$ a force?

Example 4-1 A Sliding Ice-Cream Carton

A force exerted by a stretched rubber band (see Figure 4-4) produces an acceleration of $5.0\,\text{m/s}^2$ on an ice-cream carton of mass $m_1 = 1.0\,\text{kg}$. When a force exerted by an identical rubber band stretched by the same amount is applied to a carton of ice cream of mass m_2, it produces an acceleration of $11\,\text{m/s}^2$. (*a*) What is the mass of the second carton of ice cream? (*b*) What is the magnitude of the force exerted by the rubber band on the carton?

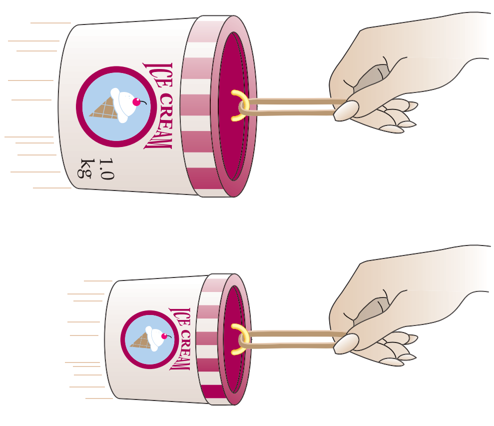

FIGURE 4-4

PICTURE We can apply Newton's second law, $\Sigma\vec{F} = m\vec{a}$, to each object and solve for the mass of the ice-cream carton and the magnitude of the force. The magnitudes of the forces exerted by the rubber bands are equal.

SOLVE

(*a*) 1. Apply $\Sigma\vec{F} = m\vec{a}$ to each object. There is only one force on each object, and we only need to consider magnitudes of the vector quantities:

$$F_1 = m_1a_1 \quad \text{and} \quad F_2 = m_2a_2$$

---

* Newton's second law relates the net force and the acceleration. Not everyone agrees that the net force is the cause and the acceleration is the effect.

† The pound we are talking about is the pound force (i.e., 1 pound force is exactly equal to 4.448 221 615 260 5 N). There is also a pound mass, which is exactly equal to 0.453 592 37 kg.

2. Because the applied forces are equal in magnitude, the ratio of the masses is equal to the reciprocal of the ratio of the accelerations:

$$F_1 = F_2 \Rightarrow m_1a_1 = m_2a_2 \quad \text{and} \quad \frac{m_2}{m_1} = \frac{a_1}{a_2}$$

3. Solve for m_2 in terms of m_1, which is 1.0 kg:

$$m_2 = \frac{a_1}{a_2}m_1 = \frac{5.0\ \text{m/s}^2}{11\ \text{m/s}^2}(1.0\ \text{kg}) = \boxed{0.45\ \text{kg}}$$

(*b*) The magnitude F_1 is found by using the mass and acceleration of either object:

$$F_1 = m_1a_1 = (1.0\ \text{kg})(5.0\ \text{m/s}^2) = \boxed{5.0\ \text{N}}$$

CHECK A mass of 0.45 kg is a plausible mass for a carton of ice cream. One kilogram weighs about 2.2 pounds. So, the carton weighs about one pound and is the size of a one-pint carton.

PRACTICE PROBLEM 4-1 A net force of 3.0 N produces an acceleration of 2.0 m/s² on an object of unknown mass. What is the mass of the object?

To describe mass quantitatively, we can apply identical forces to two masses and compare their accelerations. If a force of magnitude F produces acceleration of magnitude a_1 when applied to an object of mass m_1, and an identical force produces acceleration of magnitude a_2 when applied to an object of mass m_2, then $m_1a_1 = m_2a_2$ (or $m_2/m_1 = a_1/a_2$). That is

If $F_1 = F_2$ then

$$\frac{m_2}{m_1} = \frac{a_1}{a_2} \qquad 4\text{-}3$$

COMPARING MASSES

This definition agrees with our intuitive idea of mass. If a force is applied to an object and a force of equal magnitude is applied to a second object, then the object with more mass will accelerate less. The ratio a_1/a_2 produced by forces of equal magnitude acting on two objects is independent of the magnitude, direction, or type of force used. In addition, mass is an intrinsic property of an object that does not depend on the object's location—it remains the same whether the object is on Earth, on the moon, or in deep space.

Example 4-2 A Walk in Space *Context-Rich*

You're stranded in space away from your spaceship. Fortunately, you have a propulsion unit that provides a constant net force $\vec{F}$ for 3.0 s. After 3.0 s, you have moved 2.25 m. If your mass is 68 kg, find $\vec{F}$.

The propulsion unit (not shown) is pushing the astronaut to the right. *(NASA/Science Source/Photo Researchers.)*

PICTURE The force acting on you is constant, so your acceleration is also constant. We can use the kinematic equations of Chapters 2 and 3 to find $\vec{a}$, and then obtain the force from $\Sigma\vec{F} = m\vec{a}$. We choose the $+x$ direction to be in the direction of $\vec{F}$ (Figure 4-5), so $\vec{F} = F_x\hat{i}$ and $F_x = ma_x$.

SOLVE

1. To find the acceleration, we use Equation 2-14 with $v_0 = 0$:

$$\Delta x = v_0t + \tfrac{1}{2}a_xt^2 = 0 + \tfrac{1}{2}a_xt^2$$

$$a_x = \frac{2\Delta x}{t^2} = \frac{2(2.25\ \text{m})}{(3.0\ \text{s})^2} = 0.50\ \text{m/s}^2$$

$$\vec{a} = a_x\hat{i} = 0.50\ \text{m/s}^2\hat{i}$$

2. Because $\vec{F}$ is the *net* force, $\Sigma\vec{F}_i = \vec{F}$. Therefore, we substitute $\vec{a} = 0.50\,\text{m/s}^2\hat{i}$ and $m = 68\,\text{kg}$ into this equation to find the force:

$$\vec{F} = ma_x\hat{i} = (68\,\text{kg})(0.50\,\text{m/s}^2)\hat{i} = \boxed{34\,\text{N}\hat{i}}$$

CHECK The acceleration is $0.50\,\text{m/s}^2$, which is about 5% of $g = 9.81\,\text{m/s}^2$. This value seems plausible. If the magnitude of the acceleration were equal to g you would move a lot farther than 2.25 m in 3 s.

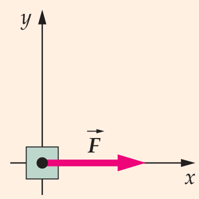

FIGURE 4-5

Example 4-3 A Particle Subjected to Two Forces

A particle of mass 0.400 kg is subjected simultaneously to two forces $\vec{F}_1 = -2.00\,\text{N}\hat{i} - 4.00\,\text{N}\hat{j}$ and $\vec{F}_2 = -2.60\,\text{N}\hat{i} + 5.00\,\text{N}\hat{j}$ (Figure 4-6). If the particle is at the origin and starts from rest at $t = 0$, find (*a*) its position $\vec{r}$ and (*b*) its velocity $\vec{v}$ at $t = 1.60\,\text{s}$.

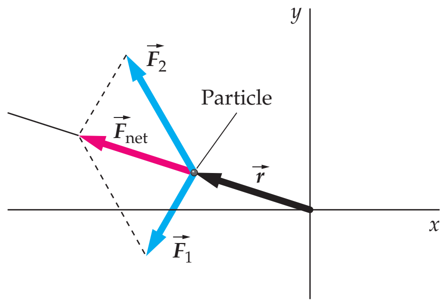

FIGURE 4-6 The acceleration is in the direction of the net force. The particle is released from rest at the origin. Following release, it moves in the direction of the net force, which is also the direction of the acceleration vector.

PICTURE Apply $\Sigma\vec{F} = m\vec{a}$ to find the acceleration. Once the acceleration is known, we can use the kinematic equations of Chapters 2 and 3 to determine the particle's position and velocity as functions of time.

SOLVE

(*a*) 1. Write the general equation for the position vector $\vec{r}$ as a function of time t for constant acceleration $\vec{a}$ in terms of $\vec{r}_0$, $\vec{v}_0$, and $\vec{a}$, and substitute $\vec{r}_0 = \vec{v}_0 = 0$.

$$\vec{r} = \vec{r}_0 + \vec{v}_0 t + \tfrac{1}{2}\vec{a}t^2 = 0 + 0 + \tfrac{1}{2}\vec{a}t^2 = \tfrac{1}{2}\vec{a}t^2$$

2. Use $\Sigma\vec{F} = m\vec{a}$ to write the acceleration $\vec{a}$ in terms of the resultant force $\Sigma\vec{F}$ and the mass m.

$$\vec{a} = \frac{\Sigma\vec{F}}{m}$$

3. Compute $\Sigma\vec{F}$ from the given forces.

$$\Sigma\vec{F} = \vec{F}_1 + \vec{F}_2 = (-2.00\,\text{N}\,\hat{i} - 4.00\,\text{N}\,\hat{j}) + (-2.60\,\text{N}\,\hat{i} + 5.00\,\text{N}\,\hat{j}) = -4.60\,\text{N}\,\hat{i} + 1.00\,\text{N}\,\hat{j}$$

4. Find the acceleration $\vec{a}$.

$$\vec{a} = \frac{\Sigma\vec{F}}{m} = -11.5\,\text{m/s}^2\,\hat{i} + 2.50\,\text{m/s}^2\,\hat{j}$$

5. Find the position $\vec{r}$ for a general time t.

$$\vec{r} = \tfrac{1}{2}\vec{a}t^2 = \tfrac{1}{2}a_x t^2\hat{i} + \tfrac{1}{2}a_y t^2\hat{j} = (-5.75\,\text{m/s}^2\,\hat{i} + 1.25\,\text{m/s}^2\,\hat{j})t^2$$

6. Find $\vec{r}$ at $t = 1.60\,\text{s}$.

$$\vec{r} = \boxed{-14.7\,\text{m}\,\hat{i} + 3.20\,\text{m}\,\hat{j}}$$

(*b*) Write the velocity $\vec{v}$ by taking the time derivative of the step-5 result. Evaluate the velocity at $t = 1.6\,\text{s}$.

$$\vec{v}(t) = \frac{d\vec{r}}{dt} = 2(-5.75\,\text{m/s}^2\,\hat{i} + 1.25\,\text{m/s}^2\,\hat{j})t$$

$$\vec{v}(1.6\,\text{s}) = \boxed{-18.4\,\text{m/s}\,\hat{i} + 4.00\,\text{m/s}\,\hat{j}}$$

CHECK The position, velocity, acceleration, and net force vectors all have negative x components and positive y components. This is as expected for motion starting from rest at the origin and moving with constant acceleration.

4-4 THE FORCE DUE TO GRAVITY: WEIGHT

If you drop an object near Earth's surface, it accelerates toward Earth. If air resistance is negligible, all objects fall with the same acceleration, called the free-fall acceleration $\vec{g}$. The force causing this acceleration is the **gravitational force** ($\vec{F}_g$) exerted by Earth on the object. The *weight* of the object is the magnitude of the gravitational force on it. If the gravitational force is the *only* force acting on an object, the object is said to be in **freefall.** We can apply Newton's second law ($\Sigma\vec{F} = m\vec{a}$) to an object of mass m that is in freefall with acceleration $\vec{g}$ to obtain an expression for the gravitation force $\vec{F}_g$:

$$\vec{F}_g = m\vec{g} \tag{4-4}$$

WEIGHT

Because $\vec{g}$ is the same for all objects, it follows that the gravitational force on an object is proportional to its mass. Near Earth, the vector $\vec{g}$ is the gravitational force per unit mass exerted by the planet Earth on any object and is called the **gravitational field** of Earth. Near the surface of Earth, the magnitude of $\vec{g}$ has the value

$$g = 9.81\,\mathrm{N/kg} = 9.81\,\mathrm{m/s^2} \tag{4-5}$$

When working problems in the U.S. customary system, we substitute F_g/g for mass m, where F_g is the magnitude of the gravitational force, in pounds, and g is the magnitude of the acceleration due to gravity in feet per second squared. Because $9.81\,\mathrm{m} = 32.2\,\mathrm{ft}$,

$$g = 32.2\,\mathrm{ft/s^2} \tag{4-6}$$

Careful measurements show that near Earth $\vec{g}$ varies with location. $\vec{g}$ points toward the center of Earth and, at points above the surface of Earth, the magnitude of $\vec{g}$ varies inversely with the square of the distance to the center of Earth. Thus, an object weighs slightly less at very high altitudes than it does at sea level. The gravitational field also varies slightly with latitude because Earth is not exactly spherical but is slightly flattened at the poles. Thus weight, unlike mass, is not an intrinsic property of an object. Although the weight of an object varies from place to place because of variations in g, these variations are too small to be noticed in most practical applications on or near the surface of Earth.

! Weight is not an intrinsic property of an object.

An example should help clarify the difference between mass and weight. Consider a bowling ball near the moon. Its weight is the magnitude of the gravitational force exerted on it by the moon, but that force is a mere sixth of the magnitude of the gravitational force exerted on the bowling ball when it is similarly positioned on Earth. The ball weighs about one-sixth as much on the moon, and lifting the ball on the moon requires one-sixth the force. However, because the mass of the ball is the same on the moon as on Earth, throwing the ball horizontally at a specified speed requires the same force on the moon as on Earth.

Although the weight of an object may vary from one place to another, at any particular location the weight of the object is proportional to its mass. Thus, we can conveniently compare the masses of two objects at a given location by comparing their weights.

Our sensation of the gravitational force on us comes from other forces that balance it. When you sit on a chair, you feel a force exerted by the chair that balances the gravitational force on you and prevents you from accelerating toward the floor. When you stand on a spring scale, your feet feel the force exerted by the scale. The scale is calibrated to read the magnitude of the force it exerts (by the compression of its springs) to balance the gravitational force on you. The magnitude of this force is called your **apparent weight.** If there is no force to balance your weight, as in free-fall, your apparent weight is zero. This condition, called **weightlessness,** is experienced by astronauts in orbiting satellites. A satellite in a circular orbit near the surface of Earth is accelerating toward Earth. The only force acting on the satellite is that of gravity, so it is in free-fall. Astronauts in the satellite are also in free-fall. The only force on them is the gravitational force on them, which produces the acceleration $\vec{g}$. Because there is no force balancing the force of gravity, the astronauts have zero apparent weight.

Example 4-4 An Accelerating Student

The net force acting on a 130-lb student has a magnitude of 25.0 lb. What is the magnitude of her acceleration?

PICTURE Apply Newton's second law and solve for the acceleration. The mass can be found from the student's weight.

SOLVE

According to Newton's second law, the student's acceleration is the force divided by her mass, and her mass is equal to her weight divided by g:

$$a = \frac{F_{\text{net}}}{m} = \frac{F_{\text{net}}}{F_g/g} = \frac{25.0\text{ lb}}{(130\text{ lb})/(32.2\text{ ft/s}^2)} = \boxed{6.19\text{ ft/s}^2}$$

CHECK The force is slightly less than one-fifth of her weight, so we expect the acceleration to be slightly less than one-fifth of g. $(32.2\text{ ft/s}^2)/5 = 6.44\text{ ft/s}^2$, and 6.19 ft/s^2 is slightly less than 6.44 ft/s^2, so the result is plausible.

TAKING IT FURTHER Rearranging the equation in the solution gives

$$m = \frac{F_{\text{net}}}{a} = \frac{F_g}{g}$$

This arrangement reveals that you can solve for her acceleration without first solving for the mass. For any object, the ratio of F_{net} to a equals the ratio of F_g to g.

PRACTICE PROBLEM 4-2 What force is needed to give an acceleration of 3.0 ft/s^2 to a 5.0-lb block?

4-5 CONTACT FORCES: SOLIDS, SPRINGS, AND STRINGS

Many forces are exerted by one body in contact with another. In this section, we will examine some of the more common contact forces.

SOLIDS

If a surface is pushed against, it pushes back. Consider the ladder leaning against a wall shown in Figure 4-7. At the region of contact, the ladder pushes against the wall with a horizontal force, compressing the distance between the molecules in the surface of the wall. Like mattress springs, the compressed molecules in the wall push back on the ladder with a horizontal force. Such a force, *perpendicular* to the contacting surfaces, is called a **normal force** (the word *normal* means perpendicular). The wall bends slightly in response to a load, though this is rarely noticeable to the unaided eye.

Normal forces can vary over a wide range of magnitudes. A horizontal tabletop, for instance, will exert an upward normal force on any object resting on it. As long as the table doesn't break, this normal force will balance the downward gravitational force on the object. Furthermore, if you press down on the object, the magnitude of the upward normal force exerted by the table will increase, countering the extra force, thus preventing the object from accelerating downward.

In addition, surfaces in contact can exert forces on each other that are *parallel* to the contacting surfaces. Consider the large block on the floor shown in Figure 4-8. If the block is pushed sideways with a gentle enough force, it will not slide. The surface of the floor exerts a force back on the block, opposing its tendency to slide in the direction of the push. However, if the block is pushed sideways with a sufficiently large force, it will start to slide. To keep the block sliding, it is necessary to continue to push it. If the sideways push is not sustained, the contact force will slow the motion of the box until it stops. A component of a contact force that opposes sliding, or

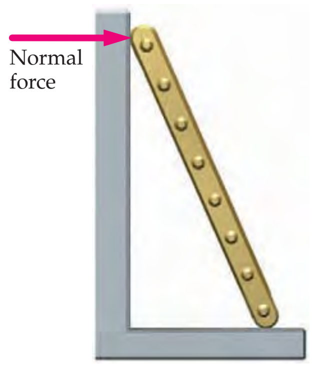

FIGURE 4-7 The wall supports the ladder by pushing on the ladder with a force normal to the wall.

FIGURE 4-8 The man is pushing on a block. The frictional force exerted by the floor on the block opposes its sliding motion or its tendency to slide.

the tendency to slide, is called a **frictional force;** it acts parallel to the contacting surfaces. (Frictional forces are treated more extensively in Chapter 5.)

A construction dumpster (Figure 4-9*a*) is situated on a road with a steep incline. Gravity pulls the dumpster downward, so to prevent the dumpster from moving, the road must exert an upward force $\vec{F}$ of equal magnitude on the dumpster (Figure 4-9*b*). The force $\vec{F}$ is a contact force by the road on the dumpster. A contact force such as this one is often thought of as two distinct forces, one, called the normal force $\vec{F}_n$, directed perpendicular to the road surface, and a second, called the frictional force $\vec{f}$, that is directed parallel to the road surface. The frictional force opposes any tendency of the dumpster to slide down the hill.

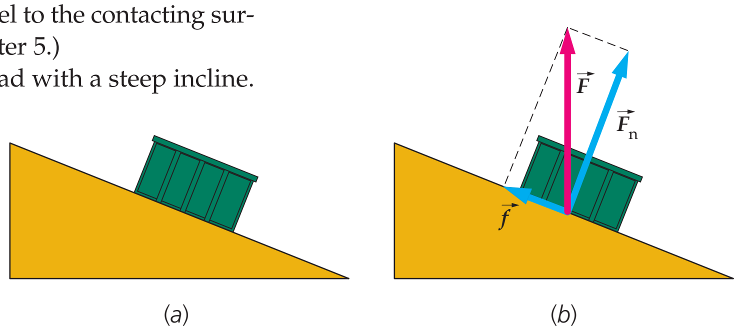

FIGURE 4-9 (*a*) A dumpster is parked on a steep incline. (*b*) The contact force by the road on the dumpster is represented either as the single force $\vec{F}$, or as a superposition of a normal force $\vec{F}_n$ and a frictional force $\vec{f}$.

SPRINGS

When a spring is stretched from its unstressed length by a distance x, the force it exerts is found experimentally to be

$$F_x = -kx \qquad 4\text{-}7$$

HOOKE'S LAW

where the positive constant k, called the **force constant** (or spring constant), is a measure of the stiffness of the spring (Figure 4-10). A negative value of x means the spring has been compressed a distance $|x|$ from its unstressed length. The negative sign in Equation 4-7 signifies that when the spring is stretched (or compressed) in one direction, the force it exerts is in the opposite direction. This relation, known as **Hooke's law,** turns out to be quite important. An object at rest under the influence of forces that balance is said to be in *static equilibrium.* If a small displacement results in a net restoring force toward the equilibrium position, the equilibrium is called *stable equilibrium.* For small displacements, nearly all restoring forces obey Hooke's law.

The molecular force of attraction between atoms in a molecule or solid varies much like that of a spring. We can therefore use two masses on a spring to model a diatomic molecule, or a set of masses connected by springs to model a solid as shown in Figure 4-11.

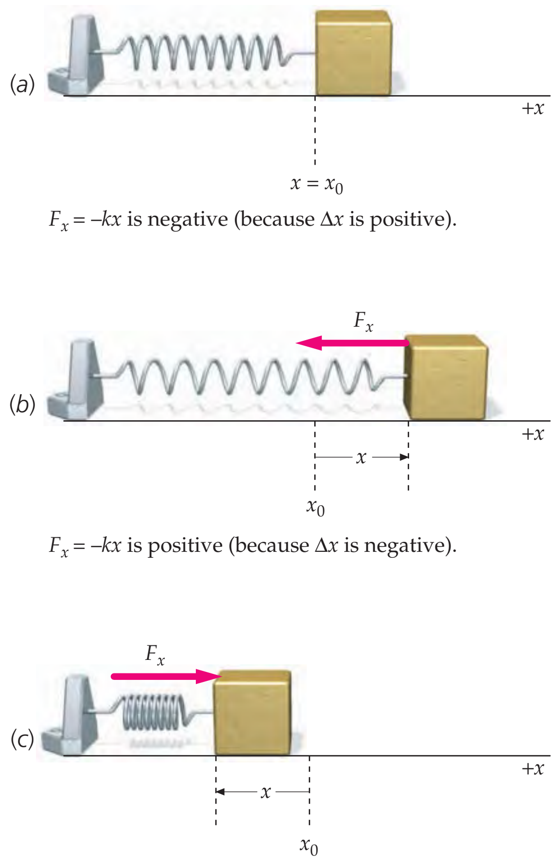

FIGURE 4-10 A horizontal spring. (*a*) When the spring is unstressed, it exerts no force on the block. (*b*) When the spring is stretched so that x is positive, it exerts a force of magnitude kx in the $-x$ direction. (*c*) When the spring is compressed so that x is negative, the spring exerts a force of magnitude $k|x|$ in the $+x$ direction.

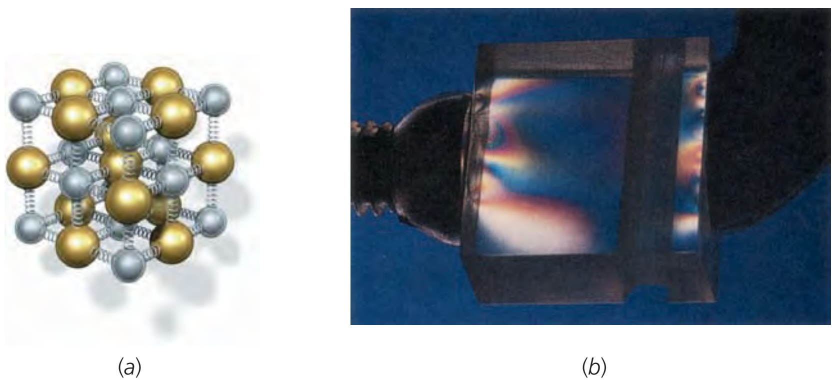

FIGURE 4-11 (*a*) Model of a solid consisting of atoms connected to each other by springs. The springs are very stiff (large force constant) so that when a weight is placed on the solid, its deformation is not visible. However, compression such as that produced by the clamp on the plastic block in (*b*) leads to stress patterns that are visible when viewed with polarized light. *((b) Fundamental Photographs.)*

Example 4-5 The Slam Dunk

A 110-kg basketball player hangs on the rim following a slam dunk (Figure 4-12). Prior to dropping to the floor, he hangs motionless with the front of the rim deflected down a distance of 15 cm. Assume the rim can be approximated by a spring and calculate the force constant k.

PICTURE Because the acceleration of the player is zero, the net force exerted on him must also be zero. The upward force exerted by the rim balances his weight. Let $y = 0$ be the original position of the rim and choose down to be the $+y$ direction. Then the displacement of the rim y_e is positive, the weight $F_{gy} = mg$ is positive, and the force $F_y = -ky_e$ exerted by the rim is negative.

SOLVE

1. Apply $\Sigma F_y = m\vec{a}_y$ to the player. The acceleration of the player is zero:

$$\Sigma F_y = ma_y$$
$$F_{gy} + F_y = 0$$

2. Use Hooke's law (Equation 4-7) to find F_y:

$$F_y = -ky_e$$

3. Substitute expressions or values for the force components in step 1 and solve for k:

$$F_{gy} + F_y = 0$$
$$mg + (-ky_e) = 0$$
$$k = \frac{mg}{y_e} = \frac{(110\text{ kg})(9.8\text{ N/kg})}{0.15\text{ m}}$$
$$= \boxed{7.2 \times 10^3\text{ N/m}}$$

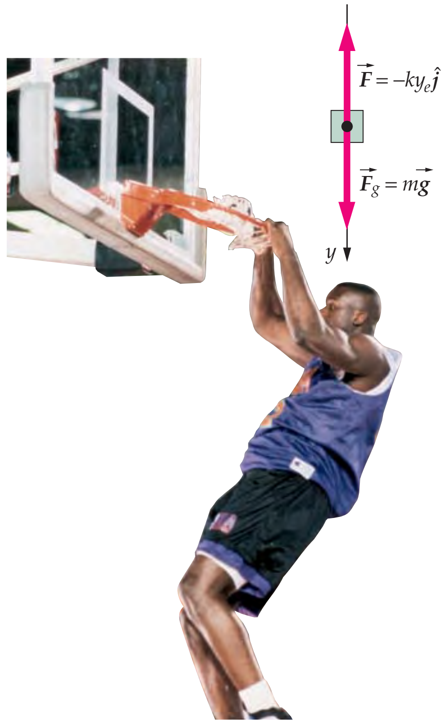

FIGURE 4-12 *(AFP-Getty Images.)*

CHECK The weight of any object, in newtons, is almost ten times larger than the object's mass in kilograms. Thus, the weight is more than 1000 N. A deflection of only 0.10 m would mean k would be 10,000 N/m, so getting $k = 7200$ N/m for a deflection of 0.15 m seems about right.

TAKING IT FURTHER Although a basketball rim doesn't look much like a spring, the rim is sometimes suspended by a hinge with a spring that is distorted when the front of the rim is pulled down. As a result, the upward force the rim exerts on the player's hands is proportional to the rim front's displacement and oppositely directed. Note that we used N/kg for the units of g so that kg cancels, giving N/m for the units of k. We can use either 9.81 N/kg or 9.81 m/s^2 for g, whichever is more convenient, because 1 N/kg = 1 m/s^2.

PRACTICE PROBLEM 4-3 A 4.0-kg bunch of bananas is suspended motionless from a spring balance whose force constant is 300 N/m. By how much is the spring stretched?

PRACTICE PROBLEM 4-4 A spring of force constant 400 N/m is attached to a 3.0-kg block that rests on a horizontal air track that renders friction negligible. What extension of the spring is needed to give the block an acceleration of 4.0 m/s^2 upon release?

PRACTICE PROBLEM 4-5 An object of mass m oscillates at the end of an ideal spring of force constant k. The time for one complete oscillation is the period T. Assuming that T depends on m and k, use dimensional analysis to find the form of the relationship $T = f(m, k)$, ignoring numerical constants. This is most easily found by looking at the units. Note that the units of k are N/m = (kg · m/s^2)/m = kg/s^2, and the units of m are kg.

STRINGS

Strings (ropes) are used to pull things. We can think of a string as a spring with such a large force constant that the extension of the string is negligible. Strings are flexible, however, so unlike springs, they cannot push things. Instead, they flex or bend sharply. The magnitude of the force that one segment of a string exerts on an adjacent segment is called **tension,** T. It follows that if a string pulls on an object, the magnitude of the force on the object equals the tension. The concept of tension in a string or rope is further developed in Section 4-8.

4-6 PROBLEM SOLVING: FREE-BODY DIAGRAMS

Imagine a sled being pulled across icy ground by a sled dog. The dog pulls on a rope attached to the sled (Figure 4-13*a*) with a horizontal force causing the sled to gain speed. We can think of the sled and rope together as a single particle. What forces act on the sled-rope particle? Both the dog and the ice touch the sled-rope, so we know that the dog and the ice exert contact forces on it. We also know that Earth exerts a gravitational force on the sled-rope (the sled-rope's weight). Thus, a total of three forces act on the sled-rope (assuming that friction is negligible):

1. The gravitational force on the sled-rope $\vec{F}_g$.
2. The contact force $\vec{F}_n$ exerted by the ice on the runners. (Without friction, the contact force is directed normal to the ice.)
3. The contact force $\vec{F}$ exerted by the dog on the rope.

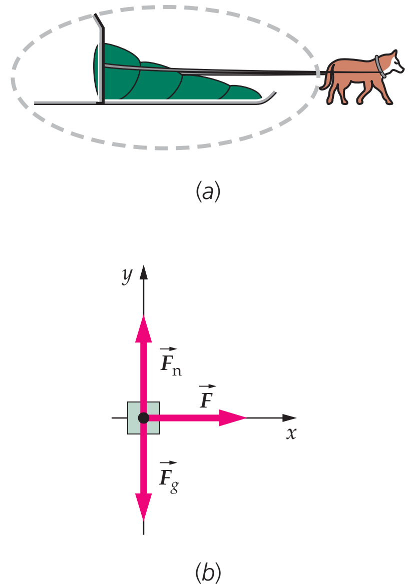

FIGURE 4-13 (*a*) A dog pulling a sled. The first step in problem solving is to isolate the system to be analyzed. In this case, the closed dashed curve represents the boundary between the sled-rope object and its surroundings. (*b*) The forces acting on the sled in Figure 4.13*a*.

A diagram that shows schematically all the forces acting on a system, such as Figure 4-13*b*, is called a **free-body diagram.** It is called a free-body diagram because the body (object) is drawn free from its surroundings.

Drawing the force vectors on a free-body diagram to scale requires that we first determine the direction of the acceleration vector using kinematic methods. We know the object is moving to the right with increasing speed. It follows from kinematics that its acceleration vector is in the direction that the velocity vector is changing—the forward direction. Note that $\vec{F}_n$ and $\vec{F}_g$ in the diagram have equal magnitudes. We know the magnitudes are equal because the vertical component of the acceleration is zero. As a qualitative check on the plausibility of our free-body diagram, we draw a vector-addition diagram (Figure 4-14) verifying that the vector sum of the forces is in the same direction as the acceleration vector.

We can now apply Newton's second law to determine the x and y components of the net force on the sled-rope particle. The x component of Newton's second law gives

$$\Sigma F_x = F_{nx} + F_{gx} + F_x = ma_x$$
$$0 + 0 + F = ma_x$$

or

$$a_x = \frac{F}{m}$$

The y component of Newton's second law gives

$$\Sigma F_y = F_{ny} + F_{gy} + F_y = ma_y$$
$$F_n - F_g + 0 = 0$$

or

$$F_n = F_g$$

Thus, the sled-rope particle has an acceleration in the $+x$ direction of F/m and the magnitude of the vertical force $\vec{F}_n$ exerted by the ice is $F_n = F_g = mg$.

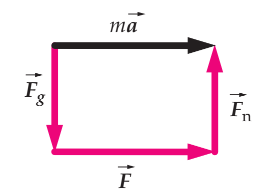

FIGURE 4-14 The vector sum of the forces in the free-body diagram is equal the mass times the acceleration vector.

PROBLEM-SOLVING STRATEGY

Applying Newton's Second Law

PICTURE Make sure you identify all of the forces acting on a particle. Then, determine the direction of the acceleration vector of the particle, if possible. Knowing the direction of the acceleration vector will help you choose the best coordinate axes for solving the problem.

SOLVE

1. Draw a neat diagram that includes the important features of the problem.
2. Isolate the object (particle) of interest, and identify each force that acts on it.
3. Draw a free-body diagram showing each of these forces.
4. Choose a suitable coordinate system. If the direction of the acceleration vector is known, choose a coordinate axis parallel to that direction. For objects sliding along a surface, choose one coordinate axis parallel to the surface and the other perpendicular to it.
5. Apply Newton's second law, $\Sigma\vec{F} = m\vec{a}$, usually in component form.
6. Solve the resulting equations for the unknowns.

CHECK Make sure your results have the correct units and seem plausible. Substituting extreme values into your symbolic solution is a good way to check your work for errors.

Example 4-6 A Dogsled Race

During your winter break, you enter a dogsled race in which students replace the dogs. Wearing cleats for traction, you begin the race by pulling on a rope attached to the sled with a force of 150 N at 25° above the horizontal. The mass of the sled–passenger–rope particle is 80 kg and there is negligible friction between the sled runners and the ice. Find (*a*) the acceleration of the sled and (*b*) the magnitude of the normal force exerted by the surface on the sled.

PICTURE Three forces act on the particle: its weight $\vec{F}_g$, which acts downward; the normal force $\vec{F}_n$, which acts upward; and the force with which you pull the rope $\vec{F}$, directed 25° above the horizontal. Because the forces are not all parallel to a single line, we study the system by applying Newton's second law to the x and y directions separately.

SOLVE

(*a*) 1. Sketch a free-body diagram (Figure 4-15*b*) of the sled-passenger-rope particle. Include a coordinate system with one of the coordinate axes in the direction of the acceleration. The particle moves to the right with increasing speed, so we know the acceleration is also to the right:

2. *Note:* Use the head-to-tail method of vector addition to verify that the sum of the forces on the free-body diagram can be in the direction of the acceleration (Figure 4-16):

3. Apply Newton's second law to the particle. Write out the equation in both vector and component form:

$$\vec{F}_n + \vec{F}_g + \vec{F} = m\vec{a} \quad \text{or}$$
$$F_{nx} + F_{gx} + F_x = ma_x$$
$$F_{ny} + F_{gy} + F_y = ma_y$$

4. Express the x components of $\vec{F}_n$, $\vec{F}_g$, and $\vec{F}$:

$$F_{nx} = 0, \quad F_{gx} = 0, \quad \text{and} \quad F_x = F\cos\theta$$

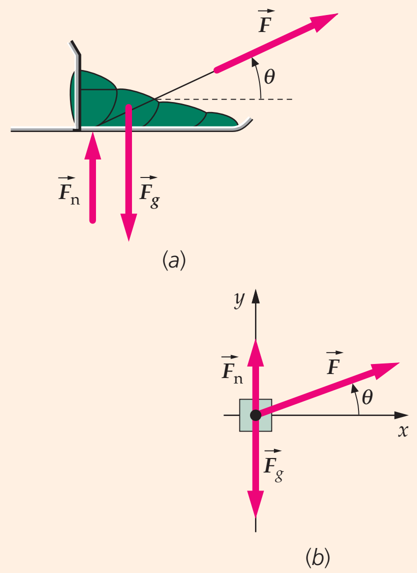

FIGURE 4-15

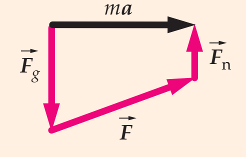

FIGURE 4-16 The vector sum of the forces in the free-body diagram is equal the mass times the acceleration vector.

5. Substitute the step-4 results into the x component equation in step 3. Then solve for the acceleration a_x:

$$\Sigma \vec{F}_x = 0 + 0 + F\cos\theta = ma_x \quad \text{so}$$

$$a_x = \frac{F\cos\theta}{m} = \frac{(150\text{ N})\cos 25°}{80\text{ kg}} = \boxed{1.7\text{ m/s}^2}$$

(*b*) 1. Express the y component of $\vec{a}$:

$$a_y = 0$$

2. Express the y components of $\vec{F}_n$, $\vec{F}_g$, and $\vec{F}$:

$$F_{ny} = F_n, \quad F_{gy} = -mg, \quad \text{and} \quad F_y = F\sin\theta$$

3. Substitute the Part (*b*) steps 1 and 2 results into the y component equation in Part (*a*) step 3. Then solve for F_n:

$$\Sigma F_y = F_n - mg + F\sin\theta = 0$$

$$F_n = mg - F\sin\theta$$

$$= (80\text{ kg})(9.81\text{ N/kg}) - (150\text{ N})\sin 25° = \boxed{7.2 \times 10^2\text{ N}}$$

CHECK Note that only the x component of $\vec{F}$, which is $F\cos\theta$, causes the object to accelerate. We expect the acceleration to be less if the rope is not horizontal. Also, we expect the normal force exerted by the ice to counter less than the full weight of the object because part of the weight is countered by the force exerted by the rope.

PRACTICE PROBLEM 4-6 If $\theta = 25°$, what is the maximum of the magnitude of the force $\vec{F}$ that can be applied to the rope without lifting the sled off the surface?

Example 4-7 Unloading a Truck *Context-Rich*

You are working for a big delivery company, and must unload a large, fragile package from your truck, using a delivery ramp (Figure 4-17). If the downward component of the velocity of the package when it reaches the bottom of the ramp is greater than 2.50 m/s (2.50 m/s is the speed an object would have if it were dropped from a height of about 1 ft), the package will break. What is the largest angle at which you can safely unload? The ramp is 1.00 m high, has rollers (i.e., the ramp is approximately frictionless), and is inclined at an angle θ to the horizontal.

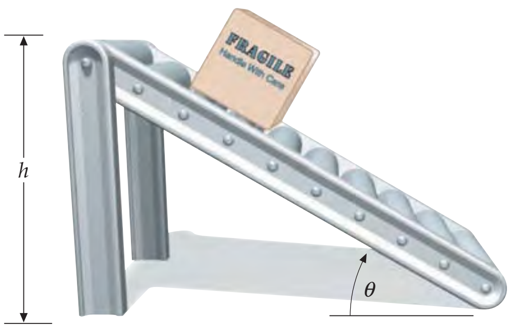

FIGURE 4-17

PICTURE Two forces act on the box, the gravitational force $\vec{F}_g$ and the normal force $\vec{F}_n$ of the ramp on the box. Because these forces are not antiparallel, they cannot sum to zero. So, there is a net force on the box causing it to accelerate. The ramp constrains the box to move parallel to its surface. We choose down the incline as the $+x$ direction. To determine the acceleration, we apply Newton's second law to the box. Once the acceleration is known, we can use kinematics to determine the largest safe angle.

SOLVE

1. First we draw a free-body diagram (Figure 4-18). Two forces act on the package, the gravitational force and the normal force. We choose the direction of the acceleration, down the ramp, as the $+x$ direction. *Note:* The angle between $\vec{F}_g$ and the $-y$ direction is the same as the angle between the horizontal and the incline as we see from the free-body diagram. We can also see that $F_{gx} = F_g \sin\theta$.

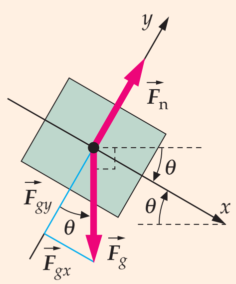

FIGURE 4-18

2. To find a_x we apply Newton's second law ($\Sigma F_x = ma_x$) to the package. (*Note:* $\vec{F}_n$ is perpendicular to the x axis and $F_g = mg$.)

$$F_{nx} + F_{gx} = ma_x \quad \text{where}$$

$$F_{nx} = 0 \quad \text{and} \quad F_{gx} = F_g \sin\theta = mg\sin\theta$$

3. Substituting and solving for the acceleration gives:

$$0 + mg\sin\theta = ma_x \quad \text{so} \quad a_x = g\sin\theta$$

4. Relate the downward component of the velocity of the box to its velocity component v_x in the x direction:

$$v_d = v_x \sin\theta$$

5. The velocity component v_x is related to the displacement Δx along the ramp by the kinematic equation:

$$v_x^2 = v_{0,x}^2 + 2a_x\,\Delta x$$

6. Substituting for a_x in the kinematic equation (step 5) and setting $v_{0,x}$ to zero gives:

$$v_x^2 = 2g\sin\theta\,\Delta x$$

7. From Figure 4-17, we can see that when Δx equals the length of the ramp, $\Delta x \sin\theta = h$, where h is the height of the ramp: $v_x^2 = 2gh$
8. Solve for v_d using the step-4 result and the expression for v_x from step 7: $v_d = \sqrt{2gh}\sin\theta$
9. Solve for the maximum angle: $2.50\text{ m/s} = \sqrt{2(9.81\text{ m/s}^2)(1.00\text{ m})}\sin\theta_{max}$

   $\therefore\ \theta_{max} = \boxed{34.4°}$

CHECK At an angle of 34.4°, the downward component of the velocity will be slightly greater then half the speed that the box would have if it were dropped from a height of 1.00 m.

TAKING IT FURTHER The acceleration down the incline is constant and equal to $g\sin\theta$. In addition, the speed v at the bottom depends upon h but not upon the angle θ.

PRACTICE PROBLEM 4-7 Apply $\Sigma F_y = ma_y$ to the package and show that $F_n = mg\cos\theta$.

Example 4-8 Picture Hanging *Try It Yourself*

A picture weighing 8.0 N is supported by two wires with tensions T_1 and T_2, as shown in Figure 4-19. Find each tension.

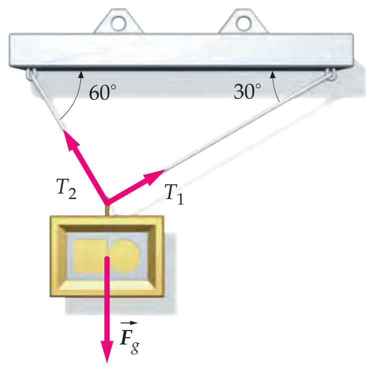

FIGURE 4-19

PICTURE Because the picture does not accelerate, the net force acting on it must be zero. The three forces acting on the picture (the gravitational force $\vec{F}_g$, and the tension forces $\vec{T}_1$ and $\vec{T}_2$) must therefore sum to zero.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps: / **Answers**

1. Draw a free-body diagram for the picture (Figure 4-20). On your diagram show the x and y components of each tension force.
2. Apply $\Sigma\vec{F} = m\vec{a}$ in vector form to the picture. $\quad \vec{T}_1 + \vec{T}_2 + \vec{F}_g = m\vec{a}$
3. Resolve each force into its x and y components. This gives you two equations for the two unknowns T_1 and T_2. The acceleration is zero.

   $T_{1x} + T_{2x} + F_{gx} = 0$

   $T_1\cos 30° - T_2\cos 60° + 0 = 0$ and

   $T_{1y} + T_{2y} + F_{gy} = 0$

   $T_1\sin 30° + T_2\sin 60° - F_g = 0$
4. Solve the x component equation for T_2. $\quad T_2 = T_1\dfrac{\cos 30°}{\cos 60°}$
5. Substitute your result for T_2 (from step 4) into the y component equation and solve for T_1.

   $T_1\sin 30° + \left(T_1\dfrac{\cos 30°}{\cos 60°}\right)\sin 60° - F_g = 0$

   $T_1 = 0.50F_g = \boxed{4.0\text{ N}}$
6. Use your result for T_1 to find T_2. $\quad T_2 = T_1\dfrac{\cos 30°}{\cos 60°} = \boxed{6.9\text{ N}}$

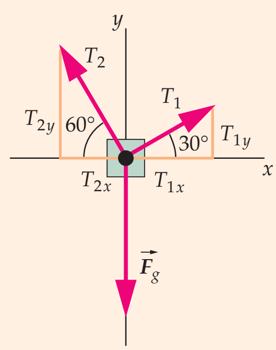

FIGURE 4-20

CHECK The more vertical of the two wires supports the greater share of the load, as you might expect. Also, we see that $T_1 + T_2 > 8$ N. The "extra" force is due to the wires pulling to the right and left.

Example 4-9 An Accelerating Jet Plane

As your jet plane speeds down the runway on takeoff, you decide to determine its acceleration, so you take out your yo-yo and note that when you suspend it, the string makes an angle of 22.0° with the vertical (Figure 4-21*a*). (*a*) What is the acceleration of the plane? (*b*) If the mass of the yo-yo is 40.0 g, what is the tension in the string?

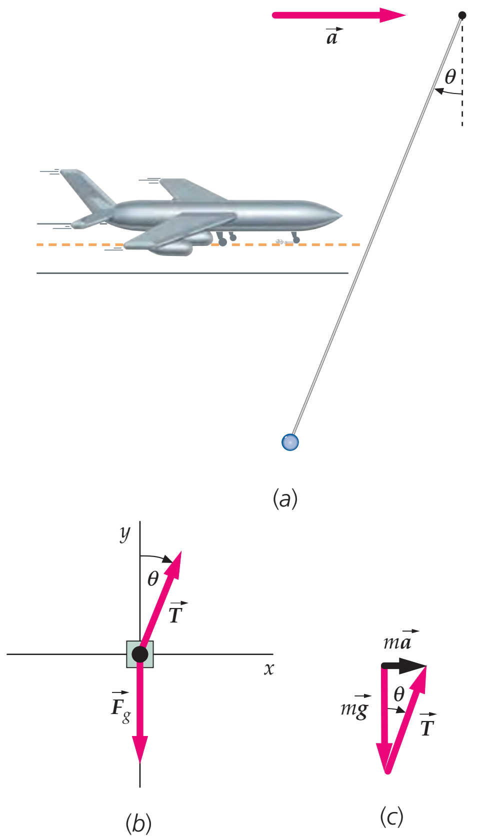

FIGURE 4-21

PICTURE Both the yo-yo and plane have the same acceleration. The net force on the yo-yo is in the direction of its acceleration—to the right. This force is supplied by the horizontal component of the tension force $\vec{T}$. The vertical component of $\vec{T}$ balances the gravitational force $\vec{F}_g$ on the yo-yo. We choose a coordinate system in which the $+x$ direction is in the direction of the acceleration vector $\vec{a}$ and the $+y$ direction is vertically upward. Writing Newton's second law for both the x and y directions gives two equations to determine the two unknowns, a and T.

SOLVE

(*a*) 1. Draw a free-body diagram for the yo-yo (Figure 4-21*b*). Choose the $+x$ direction to be the direction of the yo-yo's acceleration vector.

2. Apply $\Sigma F_x = ma_x$ to the yo-yo. Then simplify using trigonometry:

$$T_x + F_{gx} = ma_x$$
$$T\sin\theta + 0 = ma_x$$
or
$$T\sin\theta = ma_x$$

3. Apply $\Sigma F_y = ma_y$ to the yo-yo. Then, simplify using trigonometry (Figure 4-21) and $F_g = mg$. Since the acceleration is in the $+x$ direction, $a_y = 0$:

$$T_y + F_{gy} = ma_y$$
$$T\cos\theta - mg = 0$$
or
$$T\cos\theta = mg$$

4. Divide the step-2 result by the step 3 result and solve for the acceleration. Because the acceleration vector is in the $+x$ direction, $a = a_x$:

$$\frac{T\sin\theta}{T\cos\theta} = \frac{ma_x}{mg} \quad \text{so} \quad \tan\theta = \frac{a_x}{g} \quad \text{and}$$
$$a_x = g\tan\theta = (9.81\ \mathrm{m/s^2})\tan 22.0° = \boxed{3.96\ \mathrm{m/s^2}}$$

(*b*) Using the step-3 result, solve for the tension:

$$T = \frac{mg}{\cos\theta} = \frac{(0.0400\ \mathrm{kg})(9.81\ \mathrm{m/s^2})}{\cos 22.0°} = \boxed{0.423\ \mathrm{N}}$$

CHECK At $\theta = 0$, $\cos\theta = 1$ and $\tan\theta = 0$. Substituting these values into the expressions in the last two steps of the solution gives and $a_x = 0$ and $T = mg$, as expected.

TAKING IT FURTHER Notice that for the Part (*b*) result T is greater than the gravitational force on the yo-yo ($mg = 0.392\,\mathrm{N}$) because the cord not only keeps the yo-yo from falling but also accelerates it in the horizontal direction. Here we use the units m/s² for g (instead of N/kg) because we are calculating acceleration.

PRACTICE PROBLEM 4-8 For what acceleration magnitude a would the tension in the string be equal to 3.00 mg? What is θ in this case?

Our next example is the application of Newton's second law to objects that are at rest relative to a reference frame that is itself accelerating.

Example 4-10 "Weighing" Yourself in an Elevator

Suppose that your mass is 80 kg, and you are standing on a scale fastened to the floor of an elevator. The scale measures force and is calibrated in newtons. What does the scale read when (*a*) the elevator is rising with upward acceleration of magnitude a; (*b*) the elevator is descending with downward acceleration of magnitude a'; (*c*) the elevator is rising at 20 m/s and its speed is decreasing at a rate of $8.0\,\mathrm{m/s^2}$?

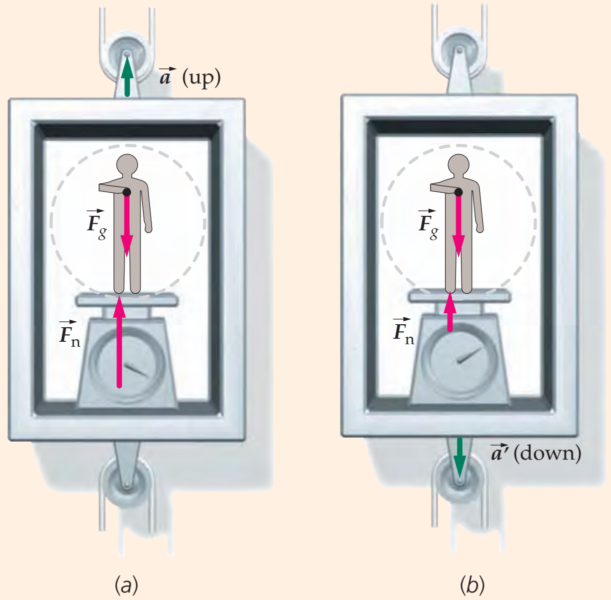

FIGURE 4-22

PICTURE The scale reading is the magnitude of the normal force exerted by the scale on you (Figure 4-22). Because you are at rest relative to the elevator, you and the elevator have the same acceleration. Two forces act on you: the downward force of gravity, $\vec{F}_g = m\vec{g}$, and the upward normal force from the scale, F_n. The sum of these forces gives you the observed acceleration. We choose upward to be the $+y$ direction.

SOLVE

(*a*) 1. Draw a free-body diagram of yourself (Figure 4-23):

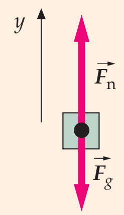

FIGURE 4-23

2. Apply $\Sigma F_y = ma_y$:

$$F_{ny} + F_{gy} = ma_y$$
$$F_n - mg = ma_y$$

3. Solve for F_n. This is the reading on the scale (your apparent weight):

$$F_n = mg + ma_y = m(g + a_y)$$

4. $a_y = +a$:

$$F_n = \boxed{m(g + a)}$$

(*b*) $a_y = -a'$. Substitute for a_y in the Part-(*a*), step-3 result:

$$F_n = m(g + a_y) = \boxed{m(g - a')}$$

(*c*) The velocity is positive but decreasing, so the acceleration is negative. Thus, $a_y = -8.0\,\mathrm{m/s^2}$. Substitute into the Part-(*a*), step-3 result:

$$F_n = m(g + a_y) = (80\ \mathrm{kg})(9.81\ \mathrm{m/s^2} - 8.0\ \mathrm{m/s^2})$$
$$= 144.8\ \mathrm{N} = \boxed{1.40 \times 10^2\ \mathrm{N}}$$

CHECK Independent of whether the elevator is ascending or descending, if its acceleration is upward you would expect to "feel heavier" and expect your apparent weight to be greater than mg. This is in keeping with the Part-(*a*) result. If its acceleration is downward you would expect to "feel lighter" and expect your apparent weight to be less than mg. The results for Parts (*b*) and (*c*) are in agreement with these expectations.

PRACTICE PROBLEM 4-9 A descending elevator comes to a stop with an acceleration of magnitude $4.00\,\mathrm{m/s^2}$. If your mass is 70.0 kg and you are standing on a force scale in the elevator, what does the scale read as the elevator is stopping?

4-7 NEWTON'S THIRD LAW

Newton's third law describes an important property of forces: forces always occur in pairs. For example, if a force is exerted on some object A, there must be another object B exerting the force. Newton's third law states that these forces are equal in magnitude and opposite in direction. That is, if object A exerts a force on object B, then B exerts an equally strong but oppositely directed force on A.

> **Third law.** When two bodies interact, the force $\vec{F}_{BA}$ exerted by object B on object A is equal in magnitude and opposite in direction to the force $\vec{F}_{AB}$ exerted by object A on object B. Thus,
>
> $$\vec{F}_{BA} = -\vec{F}_{AB} \qquad 4\text{-}8$$
>
> NEWTON'S THIRD LAW

Each pair of forces is called a Newton's third-law **(N3L) pair.** It is common to refer to one force in the pair as an action and the other as a reaction. This terminology is unfortunate because it sounds like one force "reacts" to the other, which is not the case. The two forces occur simultaneously. Either can be called the action and the other the reaction. If we refer to a force acting on a particular object as an action force, then the corresponding reaction force must act on a different object.

In Figure 4-24, a block rests on a table. The force $\vec{F}_{gEB}$ acting downward on the block is the gravitational force by Earth on the block. An equal and opposite force $\vec{F}_{gBE}$ is the gravitational force exerted on Earth by the block. These forces form an action–reaction pair. If they were the only forces present, the block would accelerate downward because it would have only a single force acting on it (and Earth would accelerate upward for the same reason). However, the upward force $\vec{F}_{nTB}$ by the table on the block balances the gravitational force on the block. In addition, there is a downward force $\vec{F}_{nBT}$ by the block on the table. The forces $\vec{F}_{nBT}$ and $\vec{F}_{nTB}$ form a Newton's third law pair and, thus, are equal and opposite.

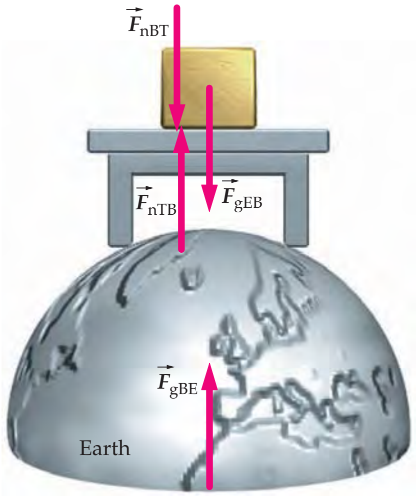

FIGURE 4-24

! Newton's third-law force pairs are *always* equal and opposite.

! No two external forces acting on *the same object* can ever constitute a Newton's third-law pair.

CONCEPT CHECK 4-3

Do the forces $\vec{F}_{gBE}$ and $\vec{F}_{nBT}$ in Figure 4-24 form a Newton's third-law pair?

Example 4-11 The Horse Before the Cart *Conceptual Example*

A horse refuses to pull a cart (Figure 4-25*a*). The horse reasons, "according to Newton's third law, whatever force I exert on the cart, the cart will exert an equal and opposite force on me, so the net force will be zero and I will have no chance of accelerating the cart." What is wrong with this reasoning?

PICTURE Because we are interested in the motion of the cart, we draw a simple diagram for it (Figure 4-25*b*). The force exerted by the horse on the cart is labeled $\vec{F}_{HC}$. (This force is actually exerted on the harness. Because the harness is attached to the cart, we consider it a part of the cart.) Other forces acting on the cart are the gravitational force of Earth on the cart $\vec{F}_{gEC}$, the normal force of the pavement on the cart $\vec{F}_{n\,PC}$ and the frictional force exerted by the pavement on the cart, labeled $\vec{f}_{PC}$.

SOLVE

1. Draw a free-body diagram for the cart (see Figure 4-25*c*). Because the cart does not accelerate vertically, the vertical forces must sum to zero. The horizontal forces are $\vec{F}_{HC}$ to the right and $\vec{f}_{PC}$ to the left. The cart will accelerate to the right if $|\vec{F}_{HC}|$ is greater than $|\vec{f}_{PC}|$.

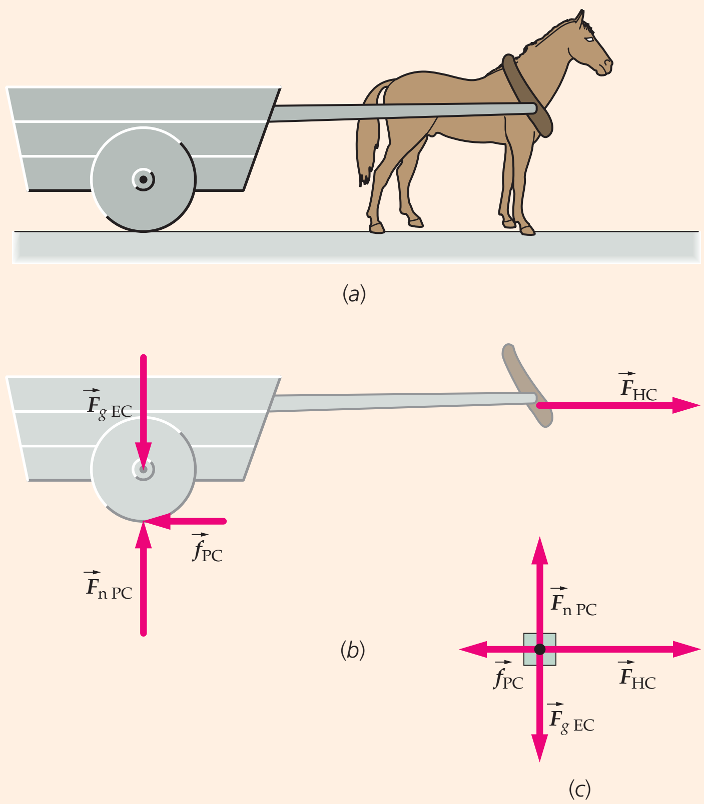

FIGURE 4-25

2. Note that the reaction force to $\vec{F}_{HC}$, which we call $\vec{F}_{CH}$, is exerted on the horse, not on the cart (Figure 4-25*d*). It has no effect on the motion of the cart, but it does affect the motion of the horse. If the horse is to accelerate to the right, there must be a force $\vec{F}_{PH}$ (to the right) exerted on the horse's hooves by the pavement that is greater in magnitude than $\vec{F}_{CH}$.

Because the reaction force to $\vec{F}_{HC}$ is exerted on the horse, it has no effect on the motion of the cart. This is the flaw in the horse's reasoning.

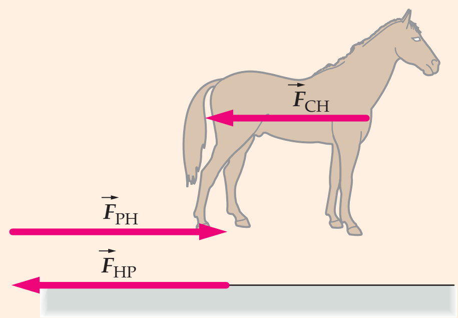

FIGURE 4-25 *(continued)*

CHECK All forces on the cart have C for a rightmost subscript, and all forces on the horse have H for a rightmost subscript. Thus, we have not drawn both forces of a Newton's third-law force pair on either the horse or the cart.

TAKING IT FURTHER This example illustrates the importance of drawing a simple diagram when solving mechanics problems. Had the horse done so, he would have seen that he need only push back hard against the pavement so that the pavement will push him forward.

CONCEPT CHECK 4-4

As you stand facing a friend, place your palms against your friend's palms and push. Can your friend exert a force on you if you do not exert a force back? Try it.

4-8 PROBLEM SOLVING: PROBLEMS WITH TWO OR MORE OBJECTS

In some problems, the motions of two (or more) objects are influenced by the interactions between the objects. For example, such objects might touch each other, or they might be connected to each other by a string or spring.

The tension in a string or rope is the magnitude of the force that one segment of the rope exerts on a neighboring segment. The tension can vary throughout the length of the rope. For a rope dangling from a girder at the ceiling of a gymnasium, the tension is greatest at points near the ceiling because a short segment of rope next to the ceiling has to support the weight of all the rope below it. For the problems in this book, however, you can almost always assume that the masses of strings and ropes are negligible, so variations in tension due to the weight of a string or rope can be neglected. Conveniently, this also means that you may assume that variations in the tension due to the acceleration of a string or rope can also be neglected.

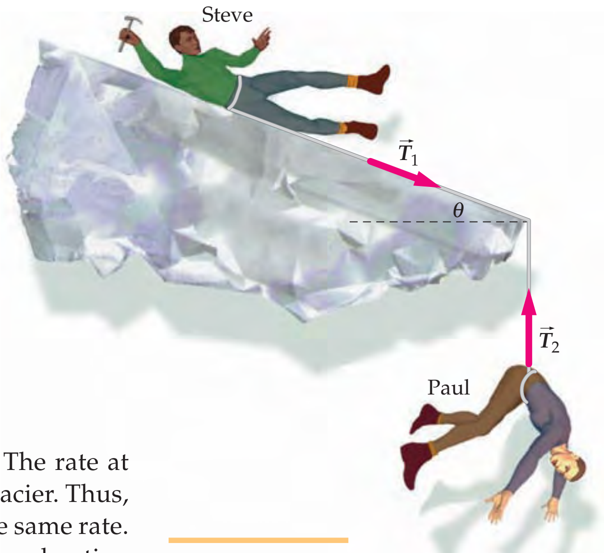

FIGURE 4-26

Consider, for example, the motion of Steve and Paul in Figure 4-26. The rate at which Paul descends equals the rate at which Steve slides along the glacier. Thus, their speeds remain equal. If Paul gains speed, Steve gains speed at the same rate. That is, their tangential accelerations remain equal. (The tangential acceleration of a particle is the component of the acceleration that is tangent to the path of the particle.)

The free-body diagram of a segment of the rope attached to Steve, where Δm_s is the segment's mass, is shown in Figure 4-27. Applying Newton's second law to the segment gives $T - T' = \Delta m_s a_x$. If the mass of the segment is negligible, then $T = T'$. To give a segment of negligible mass any finite acceleration, a net force of only a negligible magnitude is needed. (That is, only a negligible difference in tension is needed to give a rope segment of negligible mass any finite acceleration.)

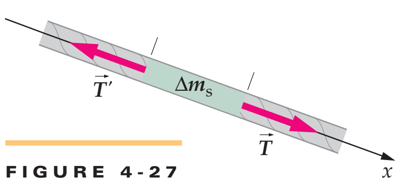

FIGURE 4-27

Next, we consider the entire rope connecting Steve and Paul. Neglecting gravity, there are three forces acting on the rope. Steve and Paul each exert a force on it, as does the ice at the edge of the glacier. Neglecting any friction between the ice and the rope means that the force exerted by the ice is always a normal force (Figure 4-28). A normal force has no component tangent to the rope, so it cannot produce a change in the tension. Thus, the tension is the same throughout the entire length of the rope. To summarize, if a taut rope of negligible mass changes direction by passing over a frictionless surface, the tension is the same throughout the rope. The following box summarizes the steps for solving such problems.

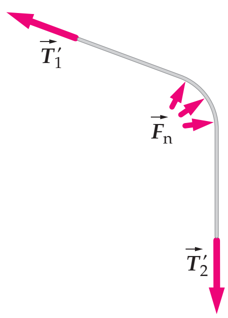

FIGURE 4-28

CONCEPT CHECK 4-5

Suppose that instead of passing over the edge of a glacier, the rope passed around a pulley with frictionless bearings as shown in Figure 4-29. Would the tension then be the same throughout the length of the rope?

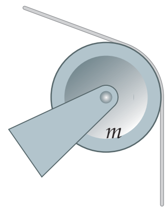

FIGURE 4-29

PROBLEM-SOLVING STRATEGY

Applying Newton's Laws to Problems with Two or More Objects

PICTURE Remember to draw a separate free-body diagram for each object. The unknowns can be obtained by solving simultaneous equations.

SOLVE

1. Draw a separate free-body diagram for each object. Use a separate coordinate system for each object. Remember, if two objects touch, the forces they exert on each other are equal and opposite (Newton's third law).
2. Apply Newton's second law to each object.
3. Solve the resultant equations, together with any equations describing interactions and constraints, for the unknown quantities.

CHECK Make sure your answer is consistent with the free-body diagrams that you have created.

Example 4-12 The Ice Climbers

Paul (mass m_P) accidentally falls off the edge of a glacier as shown in Figure 4-26. Fortunately, he is connected by a long rope to Steve (mass m_S), who has a climbing ax. Before Steve sets his ax to stop them, Steve slides without friction along the ice, attached by the rope to Paul. Assume there is no friction between the rope and the glacier. Find the acceleration of each person and the tension in the rope.

PICTURE The tension forces $\vec{T}_1$ and $\vec{T}_2$ have equal magnitudes because the rope is assumed massless and the glacial ice is assumed frictionless. The rope does not stretch or become slack, so Paul and Steve have equal speeds at all times. Their accelerations $\vec{a}_S$ and $\vec{a}_P$ must therefore be equal in magnitude (but not in direction). Steve accelerates down the face of the glacier whereas Paul accelerates straight downward. We can solve this problem by applying $\Sigma\vec{F} = m\vec{a}$ to each person, and then solving for the accelerations and the tension.

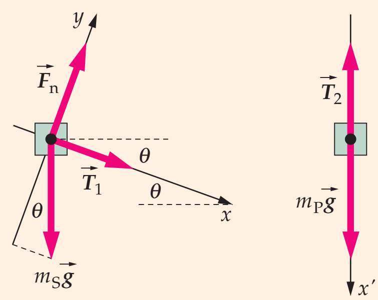

FIGURE 4-30

SOLVE

1. Draw separate free-body diagrams for Steve and Paul (Figure 4-30). Put axes x and y on Steve's diagram, choosing the direction of Steve's acceleration as the $+x$ direction. Choose the direction of Paul's acceleration as the $+x'$ direction.

2. Apply $\Sigma F_x = ma_x$ in the x direction to Steve:

$$F_{nx} + T_{1x} + m_S g_x = m_S a_{Sx}$$

3. Apply $\Sigma F_{x'} = ma_{x'}$ in the x' direction to Paul:

$$T_{2x'} + m_P g_{x'} = m_P a_{Px'}$$

4. Because they are connected by a taut rope that does not stretch, the accelerations of Paul and Steve are related. Express this relation:

$$a_{Px'} = a_{Sx} = a_t$$

a_t stands for the acceleration component in the *tangential* direction. (The direction of the motion.)

5. Because the rope is of negligible mass and slides over the ice with negligible friction, the forces $\vec{T}_1$ and $\vec{T}_2$ are simply related. Express this relation:
$$T_2 = T_1 = T$$
6. Substitute the steps-4 and -5 results into the step-2 and step-3 equations:
$$T + m_S g \sin\theta = m_S a_t$$
$$-T + m_P g = m_P a_t$$
7. Solve the step-6 equations for the acceleration by eliminating T and solving for a_t:
$$a_t = \boxed{\frac{m_S \sin\theta + m_P}{m_S + m_P} g}$$
8. Substitute the step-7 result into either step-6 equation and solve for T:
$$T = \boxed{\frac{m_S m_P}{m_S + m_P}(1 - \sin\theta)g}$$

CHECK If m_P is very much greater than m_S, we expect the acceleration to be approximately g and the tension to be approximately zero. Taking the limit as m_S approaches 0 does indeed give $a_t = g$ and $T = 0$ for this case. If m_P is much less than m_S, we expect the acceleration to be approximately $g \sin\theta$ (see step 3 of Example 4-7) and the tension to be zero. Taking the limit as m_P approaches 0 in steps 7 and 8, we indeed obtain at $a_t = g \sin\theta$ and $T = 0$. At an extreme value of the inclination ($\theta = 90°$) we again check our answers. Substituting $\theta = 90°$ in steps 7 and 8, we obtain $a_t = g$ and $T = 0$. This seems right since Steve and Paul would be in free-fall for $\theta = 90°$.

TAKING IT FURTHER In Step 1 we chose down the incline and straight down to be positive to keep the solution as simple as possible. With this choice, when Steve moves in the $+x$ direction (down the surface of the glacier), Paul moves in the $+x'$ direction (straight downward).

PRACTICE PROBLEM 4-10 (*a*) Find the acceleration if $\theta = 15°$ and if the masses are $m_S = 78\,\text{kg}$ and $m_P = 92\,\text{kg}$. (*b*) Find the acceleration if these two masses are interchanged.

Example 4-13 Building a Space Station

You are an astronaut constructing a space station, and you push on a box of mass m_1 with force $\vec{F}_{A1}$. The box is in direct contact with a second box of mass m_2 (Figure 4-31). (*a*) What is the acceleration of the boxes? (*b*) What is the magnitude of the force each box exerts on the other?

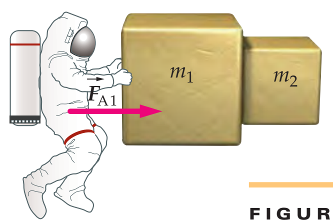

FIGURE 4-31

PICTURE Force $\vec{F}_{A1}$ is a contact force and only acts on box 1. Let $\vec{F}_{21}$ be the force exerted by box 2 on box 1, and $\vec{F}_{12}$ be the force exerted by box 1 on box 2. In accord with Newton's third law, these forces are equal and opposite ($\vec{F}_{21} = -\vec{F}_{12}$), so $F_{21} = F_{12}$. Apply Newton's second law to each box separately. The motions of the two boxes are identical, so the accelerations $\vec{a}_1$ and $\vec{a}_2$ are equal.

SOLVE

(*a*) 1. Draw free-body diagrams for the two boxes (Figure 4-32).

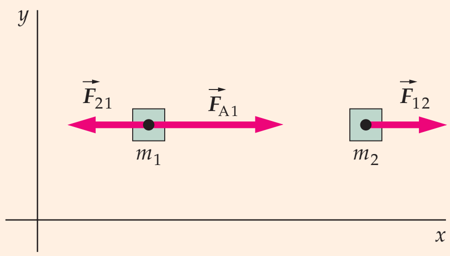

FIGURE 4-32

2. Apply $\Sigma\vec{F} = m\vec{a}$ to box 1.
$$F_{A1} - F_{21} = m_1 a_{1x}$$
3. Apply $\Sigma\vec{F} = m\vec{a}$ to box 2.
$$F_{12} = m_2 a_{2x}$$
4. Express both the relation between the two accelerations and the relation between the magnitudes of the forces the blocks exert on each other. The accelerations are equal because the speeds are equal at all times, so the rate of change of the speeds are equal. The forces are equal in magnitude because the forces constitute a N3L force pair:
$$a_{2x} = a_{1x} = a_x$$
$$F_{21} = F_{12} = F$$
5. Substitute these back into the step-2 and step-3 results and solve for a_x.
$$a_x = \boxed{\frac{F_{A1}}{m_1 + m_2}}$$

(*b*) Substitute your expression for a_x into either the step-2 or the step-3 result and solve for F.
$$F = \boxed{\frac{m_2}{m_1 + m_2} F_{A1}}$$

CHECK Note that the result in step 5 is the same as if the force $\vec{F}_{A1}$ had acted on a single mass equal to the sum of the masses of the two boxes. In fact, because the two boxes have the same acceleration, we can consider them to be a single particle with mass $m_1 + m_2$.

Physics Spotlight

Roller Coasters and the Need for Speed

Roller coasters have fascinated people since the spectacular Promenades Aeriennes (Aerial Walks) opened in Paris in 1817.* Until recently, though, ride designers were stuck with one major limitation—the ride needed to start at the top of a large hill.

In the 1970s, Anton Schwartzkopf, a German amusement park designer, was inspired by planes taking off from an aircraft carrier. In 1976, the Shuttle Loop roller coaster opened. A multiton weight was cranked to the top of a tower near the roller coaster. One end of a cable was attached to the weight, while the other was hooked to the coaster, in order to pull it. The weight dropped and quickly pulled the cable with the attached train of cars. In less than 3 seconds, the coaster train accelerated to 60 miles per hour.

At the same time, Schwartzkopf came up with a second catapult-style method of launching a coaster. A 5-ton flywheel was spun at high speed. A cable was connected to the coaster and the fly wheel. In less than 3 seconds, the coaster train, with up to 28 passengers, accelerated to speeds of 60 miles per hour. Both of these methods pioneered the use of catapult-style launches in roller coasters.†

Two new methods of launching roller coasters have allowed roller coasters to travel at even faster speeds. Intamin AG has created a *hydraulic,* or liquid-driven, system to pull the cable. The car alone for the Top Thrill Dragster weighs 12,000 pounds. Eighteen passengers are usually along for the ride, as well. The car is weighed as it passes over sensors, and a computer calculates just how fast the cable needs to go in order to catapult the car and passengers so they reach the top of the 420-foot first hill. Then, the liquid-filled motors quickly provide of up to 10,000 horsepower to wind the cable at up to 500 rpm, and to accelerate the coaster car to 120 miles per hour in 4 seconds.‡

Stan Checketts invented the first *pneumatic,* or compressed-air, roller coaster. The Thrust Air 2000™ is powered by a single, very large blast of air. The eight-passenger car is weighed as it passes over sensors. Then, four compressors swing into action. They pump air into a storage tank sitting at the base of a tower. The compressed air is measured into a shot tank, depending on the weight of the car. Finally, the air rapidly releases through a valve in the top of the tower, pushing against a piston that drives the catapult pulley system. The fully loaded car accelerates to 80 miles per hour in 1.8 seconds. A minimum of 40,000 pounds of thrust is needed to produce this acceleration. For comparison, a single F-15 jet engine is rated at a maximum 29,000 pounds of thrust.§ Roller coasters now are powered by a thrust more powerful than a jet engine. Something to think about the next time you pass by an amusement park.

The Hypersonic XLC at Paramount's King's Dominion Amusement Park, Virginia, the world's first compressed-airlaunched roller coaster, goes from 0 to 80 miles per hour in 1.8 seconds.

SUMMARY

1. Newton's laws of motion are fundamental laws of nature that serve as the basis for our understanding of mechanics.
2. Mass is an *intrinsic* property of an object.
3. Force is an important *derived* dynamic quantity.

TOPIC	RELEVANT EQUATIONS AND REMARKS
1. Newton's Laws	
First law	An object at rest stays at rest *unless* acted on by an external force. An object in motion continues to travel with constant velocity *unless* acted on by an external force. (Reference frames in which these statement hold are called inertial reference frames.)
Second law	The acceleration of an object is directly proportional to the net force acting on it. The reciprocal of the mass of the object is the proportionality constant. Thus $\vec{F}_{\text{net}} = m\vec{a}, \quad \text{where} \quad \vec{F}_{\text{net}} = \Sigma\vec{F}$ 4-1
Third law	When two bodies interact, the force $\vec{F}_{\text{BA}}$ exerted by object B on object A is equal in magnitude and opposite in direction to the force $\vec{F}_{\text{AB}}$ exerted by object A on object B: $\vec{F}_{\text{BA}} = -\vec{F}_{\text{AB}}$ 4-8
2. Inertial Reference Frames	Our statements of Newton's first and second laws are valid only in inertial reference frames. Any reference frame that is moving with constant velocity relative to an inertial reference frame is itself an inertial reference frame, and any reference frame that is accelerating relative to an inertial frame is not an inertial reference frame. Earth's surface is, to a good approximation, an inertial reference frame.
3. Force, Mass, and Weight	
Force	Force is defined in terms of the acceleration it produces on a given object. A force of 1 newton (N) is that force which produces an acceleration of $1\,\text{m/s}^2$ on a mass of 1 kilogram (kg).
Mass	Mass is an intrinsic property of an object. It is the measure of the inertial resistance of the object to acceleration. Mass does not depend on the location of the object. Applying identical forces to each of two objects and measuring their respective accelerations allows the masses of two objects to be compared. The ratio of the masses of the objects is equal to the inverse ratio of the accelerations produced: $\frac{m_2}{m_1} = \frac{a_1}{a_2}$
Gravitational Force	The gravitational force $\vec{F}_g$ on an object near the surface of Earth is the force of gravitational attraction exerted by Earth on the object. It is proportional to the gravitational field $\vec{g}$ (which is equal to the free-fall acceleration), and the mass m of the object is the proportionality constant: $\vec{F}_g = m\vec{g}$ 4-4 The weight of an object is the magnitude of the gravitational force on the object.
4. Fundamental Forces	All the forces observed in nature can be explained in terms of four basic interactions:
	1. The gravitational interaction
	2. The electromagnetic interaction
	3. The weak interaction*
	4. The strong nuclear interaction (also called the *hadronic force*)
5. Contact Forces	Contact forces of support and friction and those exerted by springs and strings are due to molecular forces that arise from the basic electromagnetic force.
Hooke's law	When an unstressed spring is compressed or extended by a small amount Δx, the restoring force it exerts is proportional to Δx: $F_x = -k\Delta x$ 4-7

* The electromagnetic and weak interactions are now viewed as the electroweak interaction.

Answers to Concept Checks

4-1 No, the net force is not an actual force. It is the vector sum of the actual forces.

4-2 No, it is the net force that causes the acceleration of the mass.

4-3 No, they do not.

4-4 No. Doing so would be contrary to Newton's third law.

4-5 No. Doing away with friction in the bearing is one thing, but the pulley still has mass. A difference in tension is needed in order to change the rate of rotation of the pulley wheel. Pulleys with non-negligible mass are studied in Chapter 8.

Answers to Practice Problems

4-1 1.5 kg

4-2 0.47 lb

4-3 13 cm

4-4 3.0 cm

4-5 $T = C\sqrt{m/k}$ where C is some dimensionless constant. The correct expression for the period, as we will see in Chapter 14, is $T = 2\pi\sqrt{m/k}$.

4-6 1.9 kN

4-7 Applying Newton's second law (for y components), we see from the free-body diagram (Figure 4-18) that $\Sigma F_y = ma_y \Rightarrow F_n - F_g \cos\theta = 0$, where we have used that a_y equals zero. Thus, $F_n = F_g \cos\theta$.

4-8 $a = 27.8\ \mathrm{m/s^2}$, $\theta = 70.5°$

4-9 967 N

4-10 (*a*) $a_t = 0.66g$, (*b*) $a_t = 0.60g$

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

For all problems, use $g = 9.81\ \mathrm{m/s^2}$ for the free-fall acceleration due to gravity and neglect friction and air resistance unless instructed to do otherwise.

• Single-concept, single-step, relatively easy

•• Intermediate-level, may require synthesis of concepts

••• Challenging

SSM Solution is in the *Student Solutions Manual*

Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • While on a very smooth level transcontinental plane flight, your coffee cup sits motionless on your tray. Are there forces acting on the cup? If so, how do they differ from the forces that would be acting on the cup if it sat on your kitchen table at home?

2 • You are passing another car on a highway and determine that, relative to you, the car you pass has an acceleration $\vec{a}$ toward the west. However, the driver of the other car is maintaining a constant speed and direction relative to the road. Is the reference frame of your car an inertial one? If not, in which direction (east or west) is your car accelerating relative to the other car?

3 • **CONTEXT-RICH** You are riding in a limousine that has opaque windows that do not allow you to see outside. The car is on a flat horizontal plain, so the car can accelerate by speeding up, slowing down, or turning. Equipped with just a small heavy object on the end of a string, how can you use it to determine if the limousine is changing either speed or direction? Can you determine the limousine's velocity? SSM

4 •• If only a single nonzero force acts on an object, does the object accelerate relative to all inertial reference frames? Is it possible for such an object to have zero velocity in some inertial reference frame and not in another? If so, give a specific example.

5 •• A baseball is acted upon by a single known force. From this information alone, can you tell in which direction the baseball is moving relative to some reference frame? Explain.

6 •• A truck moves directly away from you at constant velocity (as observed by you while standing in the middle of the road). It follows that (*a*) no forces act on the truck, (*b*) a constant net force acts on the truck in the direction of its velocity, (*c*) the net force acting on the truck is zero, (*d*) the net force acting on the truck is its weight.

7 • **ENGINEERING APPLICATION** Several space probes have been launched that are now far out in space. *Pioneer 10*, for example, was launched in the 1970s and is still moving away from the Sun and its planets. Is the mass of *Pioneer 10* changing? Which of the known fundamental forces continue to act on it? Does it have a net force on it?

8 •• **ENGINEERING APPLICATION** Astronauts in apparent weightlessness during their stay on the International Space Station must carefully monitor their masses because significant loss of body mass is known to cause serious medical problems. Give an example of how you might design equipment to measure the mass of an astronaut on the orbiting space station.

9 •• **CONTEXT-RICH** You are riding in an elevator. Describe two situations in which your apparent weight is greater than your true weight. SSM

10 •• Suppose you are in a train moving at constant velocity relative to the ground. You toss a ball to your friend several seats in front of you. Use Newton's second law to explain why you cannot use your observations of the tossed ball to determine the train's velocity relative to the ground.

11 •• Explain why, of the fundamental interactions, gravitational interaction is the main concern in our everyday lives. One other on this list also plays an increasingly significant role in our rapidly advancing technology. Which one is that? Why are the others not obviously important?

12 •• Give an example of an object that has three forces acting on it, and (*a*) accelerates, (*b*) moves at constant (nonzero) velocity, and (*c*) remains at rest.

13 •• Suppose a block of mass m_1 rests on a block of mass m_2 and the combination rests on a table as shown in Figure 4-33. Tell the name of the force and its category (contact versus action-at-a-distance) for each of the following forces: (*a*) force exerted by m_1 on m_2, (*b*) force exerted by m_2 on m_1, (*c*) force exerted by m_2 on the table, (*d*) force exerted by the table on m_2, (*e*) force exerted by Earth on m_2. Which, if any, of these forces constitute a Newton's third-law pair of forces? SSM

FIGURE 4-33 Problem 13

14 •• **CONTEXT-RICH** You yank a fish you have just caught on your line upward from rest into your boat. Draw a free-body diagram of the fish after it has left the water and as it gains speed as it rises. In addition, tell the type (tension, spring, gravity, normal, friction, etc.) and category (contact versus action-at-a-distance) of each force on your diagram. Which, if any, pairs of the forces on your diagram constitute a Newton's third-law pair? Can you tell the relative magnitudes of the forces on your diagram from the information given? Explain.

15 •• If you gently set a fancy plate on the table, it will not break. However if you drop it from a height, it might very well break. Discuss the forces that act on the plate (as it contacts the table) in both these situations. Use kinematics and Newton's second law to describe what is different about the second situation that causes the plate to break?

16 •• For each of the following forces, give what produces it, what object it acts on, its direction, and the reaction force. (*a*) The force you exert on your briefcase as you hold it while standing at the bus stop. (*b*) The normal force on the soles of your feet as you stand barefooted on a horizontal wood floor. (*c*) The gravitational force on you as you stand on a horizontal floor. (*d*) The horizontal force exerted on a baseball by a bat as the ball is hit straight up the middle toward center field for a single.

17 •• For each case, identify the force (including its direction) that causes the acceleration. (*a*) A sprinter at the very start of the race. (*b*) A hockey puck skidding freely but slowly coming to rest on the ice. (*c*) A long fly ball at the top of its arc. (*d*) A bungee jumper at the very bottom of her descent.

18 • True or false:

(*a*) If two external forces that are both equal in magnitude and opposite in direction act on the same object, the two forces can never be a Newton's third-law pair.

(*b*) The two forces of a Newton's third-law pair are equal only if the objects involved are not accelerating.

19 •• An 80-kg man on ice skates is pushing his 40-kg son, also on skates, with a force of 100 N. Together, they move across the ice steadily gaining speed. (*a*) The force exerted by the boy on his father is (1) 200 N, (2) 100 N, (3) 50 N, or (4) 40 N. (*b*) How do the magnitudes of the two accelerations compare? (*c*) How do the directions of the two accelerations compare?

20 •• A girl holds a stone in her hand and can move it up or down or keep it still. True or false: (*a*) The force exerted by her hand on the rock is always the same magnitude as the force of gravity on the stone. (*b*) The force exerted by her hand on the rock is the reaction force to the force of gravity on the stone. (*c*) The force exerted by her hand on the stone is always the same magnitude as the force on her hand by the stone, but in the opposite direction. (*d*) If the girl moves her hand down at a constant speed, then her upward force on the stone is less than the force of gravity on the stone. (*e*) If the girl moves her hand downward but slows the stone to rest, then the force of the stone on the girl's hand is the same magnitude as the force of gravity on the stone.

21 •• A 2.5-kg object hangs at rest from a string attached to the ceiling. (*a*) Draw a free-body diagram of the object, indicate the reaction force to each force drawn and tell what object the reaction force acts on. (*b*) Draw a free-body diagram of the string, indicate the reaction force to each force drawn, and tell what object each reaction force acts on. Do not neglect the mass of the string. SSM

22 •• (*a*) Which of the free-body diagrams in Figure 4-34 represents a block sliding down a frictionless inclined surface? (*b*) For the correct diagram, label the forces and tell which are contact forces and which are action-at-a-distance forces. (*c*) For each force in the correct diagram, identify the reaction force, the object it acts on and its direction.

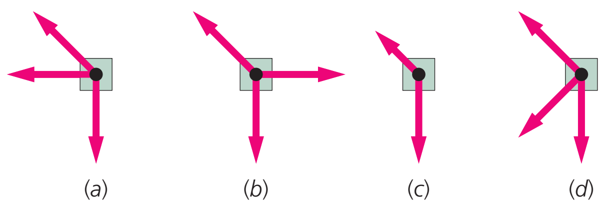

FIGURE 4-34 Problem 22

23 •• A wooden box on the floor is pressed against a compressed, horizontal spring that is attached to a wall. The horizontal floor beneath the box is frictionless. Draw the free-body diagram of the box in the following cases. (*a*) The box is held at rest against the compressed spring. (*b*) The force holding the box against the spring no longer exists, but the box is still in contact with the spring. (*c*) When the box no longer has contact with the spring.

24 •• Imagine yourself seated on a wheeled desk chair at your desk. Consider friction forces between the chair and the floor to be negligible. However, the friction forces between the desk and the floor are not negligible. When sitting at rest, you decide you need

another cup of coffee. You push horizontally against the desk, and the chair rolls backward away from the desk. (*a*) Draw a free-body diagram of yourself during the push and clearly indicate which force was responsible for your acceleration. (*b*) What is the reaction force to the force that caused your acceleration? (*c*) Draw the free-body diagram of the desk and explain why it did not accelerate. Does this violate Newton's third law? Explain.

25 ••• The same (net) horizontal force F is applied for a fixed time interval Δt to each of two objects, having masses m_1 and m_2, that sit on a flat, frictionless surface. (Let $m_1 > m_2$.) (*a*) Assuming the two objects are initially at rest, what is the ratio of their accelerations during the time interval, in terms of F, m_1 and m_2? (*b*) What is the ratio of their speeds v_1 and v_2 at the end of the time interval? (*c*) How far apart are the two objects (and which is ahead) at the end of the time interval?

ESTIMATION AND APPROXIMATION

26 •• **CONCEPTUAL** Most cars have four springs attaching the body to the frame, one at each wheel position. Devise an experimental method of estimating the force constant of one of the springs using your known weight and the weights of several of your friends. Assume the 4 springs are identical. Use the method to estimate the force constant of your car's springs.

27 •• Estimate the force exerted on the goalie's glove by the puck when he catches a hard slap shot for a save. SSM

28 •• A baseball player slides into second base during a steal attempt. Assuming reasonable values for the length of the slide, the speed of the player at the beginning of the slide, and the speed of the player at the end of the slide, estimate the average force of friction acting on the player.

29 •• **ENGINEERING APPLICATION** A race car skidding out of control manages to slow down to 90 km/h before crashing head-on into a brick wall. Fortunately, the driver is wearing a safety harness. Using reasonable values for the mass of the driver and the stopping distance, estimate the average force exerted on the driver by the safety harness, including its direction. Neglect any effects of frictional forces on the driver by the seat.

NEWTON'S FIRST AND SECOND LAWS: MASS, INERTIA, AND FORCE

30 • A particle is traveling in a straight line at a constant speed of 25.0 m/s. Suddenly, a constant force of 15.0 N acts on it, bringing it to a stop in a distance of 62.5 m. (*a*) What is the direction of the force? (*b*) Determine the time it takes for the particle to come to a stop. (*c*) What is its mass?

31 • An object has an acceleration of 3.0 m/s^2 when a single force of magnitude F_0 acts on it. (*a*) What is the magnitude of its acceleration when the magnitude of this force is doubled? (*b*) A second object has an acceleration magnitude of 9.0 m/s^2 under the influence of a single force of magnitude F_0. What is the ratio of the mass of the second object to that of the first object? (*c*) If the two objects are glued together to form a composite object, what acceleration magnitude will a single force of magnitude F_0 acting on the composite object produce?

32 • A tugboat tows a ship with a constant force of magnitude F_1. The increase in the ship's speed during a 10-s interval is 4.0 km/h. When a second tugboat applies an additional constant force of magnitude F_2 in the same direction, the speed increases by 16 km/h during a 10-s interval. How do the magnitudes of F_1 and F_2 compare? (Neglect the effects of water resistance and air resistance.)

33 • A single constant force of magnitude 12 N acts on a particle of mass m. The particle starts from rest and travels in a straight line a distance of 18 m in 6.0 s. Find m.

34 • A net force of $(6.0\ \mathrm{N})\hat{\imath} - (3.0\ \mathrm{N})\hat{\jmath}$ acts on a 1.5 kg object. Find the acceleration $\vec{a}$.

35 •• A bullet of mass 1.80×10^{-3} kg moving at 500 m/s impacts a tree stump and penetrates 6.00 cm into the wood before coming to rest. (*a*) Assuming that the acceleration of the bullet is constant, find the force (including direction) exerted by the wood on the bullet. (*b*) If the same force acted on the bullet and it had the same impact speed but half the mass, how far would it penetrate into the wood? SSM

36 •• A cart on a horizontal, linear track has a fan attached to it. The cart is positioned at one end of the track, and the fan is turned on. Starting from rest, the cart takes 4.55 s to travel a distance of 1.50 m. The mass of the cart plus fan is 355 g. Assume that the cart travels with constant acceleration. (*a*) What is the net force exerted on the cart–fan combination? (*b*) Mass is added to the cart until the total mass of the cart–fan combination is 722 g, and the experiment is repeated. How long does it take for the cart, starting from rest, to travel 1.50 m now? Ignore the effects due to friction.

37 •• A horizontal force of magnitude F_0 causes an acceleration of magnitude 3.0 m/s^2 when it acts on an object of mass m sliding on a frictionless surface. Find the magnitude of the acceleration of the same object in the circumstances shown in Figure 4-35*a* and 4-35*b*.

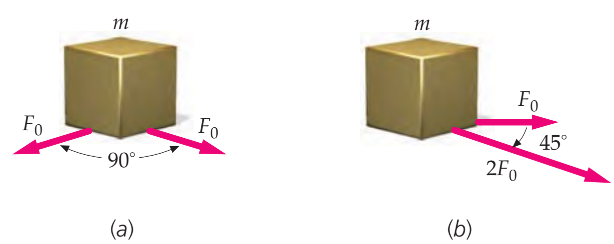

FIGURE 4-35 Problem 37

38 •• Al and Bert stand in the middle of a large frozen lake (frictionless surface). Al pushes on Bert with a force of 20 N for 1.5 s. Bert's mass is 100 kg. Assume that both are at rest before Al pushes Bert. (*a*) What is the speed that Bert reaches as he is pushed away from Al? (*b*) What speed does Al reach if his mass is 80 kg?

39 •• If you push a block whose mass is m_1 across a frictionless floor with a horizontal force of a magnitude F_0, the block has an acceleration of 12 m/s^2. If you push on a different block whose mass is m_2 with a horizontal force of magnitude F_0, its acceleration is 3.0 m/s^2. (*a*) What acceleration will a horizontal force of magnitude F_0 give to a single block with mass $m_2 - m_1$? (*b*) What acceleration will a horizontal force of magnitude F_0 give to a single block with mass $m_2 + m_1$?

40 •• **MULTISTEP** To drag a 75.0-kg log along the ground at constant velocity, your tractor has to pull it with a horizontal force of 250 N. (*a*) Draw the free-body diagram of the log. (*b*) Use Newton's laws to determine the force of friction on the log. (*c*) What is the normal force of the ground on the log? (*d*) What horizontal force must you exert if you want to give the log an acceleration of 2.00 m/s^2 assuming the force of friction does not change. Redraw the log's free-body diagram for this situation.

41 •• A 4.0-kg object is subjected to two constant forces, $\vec{F}_1 = (2.0\ \mathrm{N})\hat{\imath} + (-3.0\ \mathrm{N})\hat{\jmath}$ and $\vec{F}_2 = (4.0\ \mathrm{N})\hat{\imath} - (11\ \mathrm{N})\hat{\jmath}$. The object is at rest at the origin at time $t = 0$. (*a*) What is the object's acceleration? (*b*) What is its velocity at time $t = 3.0$ s? (*c*) Where is the object at time $t = 3.0$ s?

MASS AND WEIGHT

42 • On the moon, the acceleration due to the effect of gravity is only about 1/6 of that on Earth. An astronaut whose weight on Earth is 600 N travels to the lunar surface. His mass, as measured on the moon, will be (*a*) 600 kg, (*b*) 100 kg, (*c*) 61.2 kg, (*d*) 9.81 kg, (*e*) 360 kg.

43 • Find the weight of a 54-kg student in (*a*) newtons, and (*b*) pounds.

44 • Find the mass of a 165-lb engineer in kilograms.

45 •• **ENGINEERING APPLICATION** To train astronauts to work on the moon, where the free-fall acceleration is only about 1/6 of that on Earth, NASA submerges them in a tank of water. If an astronaut who is carrying a backpack, air conditioning unit, oxygen supply, and other equipment, has a total mass of 250 kg, determine the following quantities. (*a*) her weight including backpack, etc. on Earth, (*b*) her weight on the moon, (*c*) the required upward buoyancy force of the water during her training for the moon's environment on Earth SSM

46 •• It is the year 2075 and space travel is common. A physics professor brings his favorite teaching demonstration with him to the moon. The apparatus consists of a very smooth (frictionless) horizontal table and an object to slide on it. On Earth, when the professor attaches a spring (force constant 50 N/m) to the object and pulls horizontally so the spring stretches 2.0 cm, the object accelerates at 1.5 m/s^2. (*a*) Draw the free-body diagram of the object and use it and Newton's laws to determine the object's mass. (*b*) What would the object's acceleration be under identical conditions on the moon?

FREE-BODY DIAGRAMS: STATIC EQUILIBRIUM

47 • **ENGINEERING APPLICATION, MULTISTEP** A 35.0-kg traffic light is supported by two wires as in Figure 4-36. (*a*) Draw the light's free-body diagram and use it to answer the following question qualitatively: Is the tension in wire 2 greater than or less than the tension in wire 1? (*b*) Verify your answer by applying Newton's laws and solving for the two tensions.

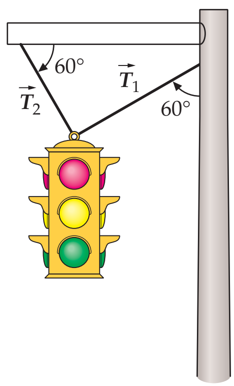

FIGURE 4-36 Problem 47

48 • A 42.6-kg lamp is hanging from wires as shown in Figure 4-37. The ring has negligible mass. The tension T_1 in the vertical wire is (*a*) 209 N, (*b*) 418 N, (*c*) 570 N, (*d*) 360 N, (*e*) 730 N.

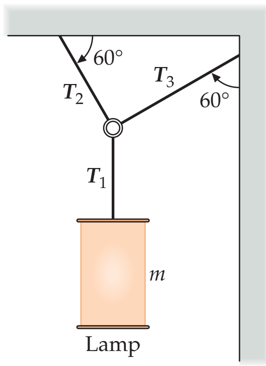

FIGURE 4-37 Problem 48

49 •• In Figure 4-38*a*, a 0.500-kg block is suspended at the midpoint of a 1.25-m-long string. The ends of the string are attached to the ceiling at points separated by 1.00 m. (*a*) What angle does the string make with the ceiling? (*b*) What is the tension in the string? (*c*) The 0.500-kg block is removed and two 0.250-kg blocks are attached to the string such that the lengths of the three string segments are equal (Figure 4-38*b*). What is the tension in each segment of the string? SSM

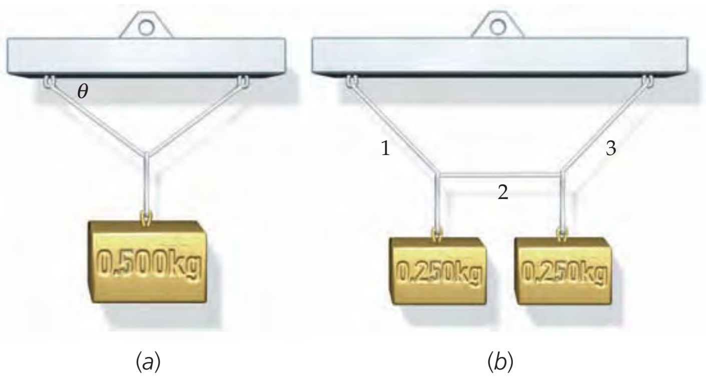

FIGURE 4-38 Problem 49

50 •• A ball weighing 100-N is shown suspended from a system of cords (Figure 4-39). What are the tensions in the horizontal and angled cords?

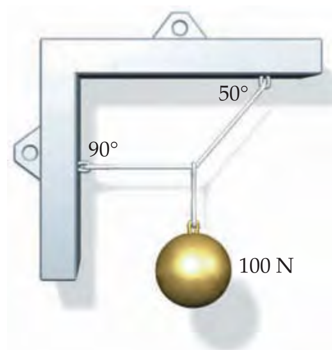

FIGURE 4-39 Problem 50

51 •• A 10-kg object on a frictionless table is subjected to two horizontal forces, $\vec{F}_1$ and $\vec{F}_2$, with magnitudes $F_1 = 20$ N and $F_2 = 30$ N, as shown in Figure 4-40. Find the third horizontal force $\vec{F}_3$ that must be applied so that the object is in static equilibrium. SSM

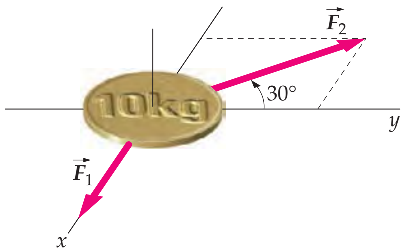

FIGURE 4-40 Problem 51

52 •• For the systems to be in equilibrium in Figure 4-41*a*, Figure 4-41*b*, and Figure 4-41*c*, find the unknown tensions and masses.

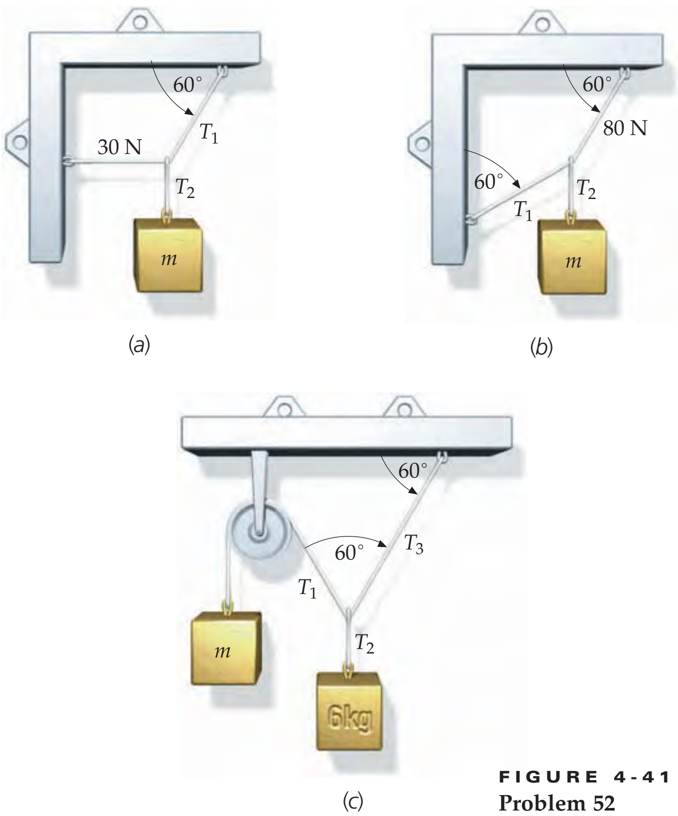

FIGURE 4-41 Problem 52

53 •• **Engineering Application** Your car is stuck in a mud hole. You are alone, but you have a long, strong rope. Having studied physics, you tie the rope tautly to a telephone pole and pull on it sideways, as shown in Figure 4-42. (*a*) Find the force exerted by the rope on the car when the angle θ is 3.00° and you are pulling with a force of 400 N, but the car does not move. (*b*) How strong must the rope be if it takes a force of 600 N to move the car when θ is 4.00°?

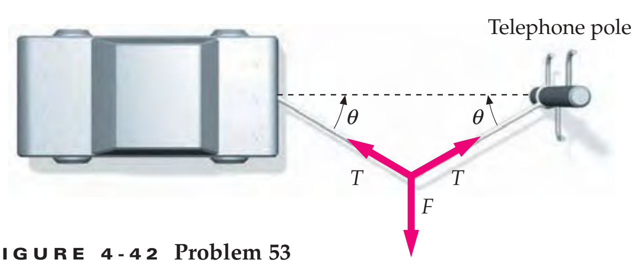

FIGURE 4-42 Problem 53

54 ••• **Engineering Application, Multistep** Balloon arches are often seen at festivals or celebrations; they are made by attaching helium-filled balloons to a rope that is fixed to the ground at each end. The lift from the balloons raises the structure into the arch shape. Figure 4-43*a* shows the geometry of such a structure: N balloons are attached at equally spaced intervals along a massless rope of length L, which is attached to two supports at its ends. Each balloon provides a lift force of magnitude F. The horizontal and vertical coordinates of the point on the rope where the ith balloon is attached are x_i and y_i, and T_i is the tension in the ith segment. (Note segment 0 is the segment between the point of attachment and the first balloon, and segment N is the segment between the last balloon and the other point of attachment). (*a*) Figure 4-43*b* shows a free-body diagram for the ith balloon. From this diagram, show that the horizontal component of the force T_i (call it $T_{\rm H}$) is the same for all the string segments. (*b*) By considering the vertical component of the forces, use Newton's laws to derive the following relationship between the tension in the ith and $(i-1)$th segments: $T_{i-1}\sin\theta_{i-1} - T_i\sin\theta_i = F$. (*c*) Show that $\tan\theta_0 = -\tan\theta_{N+1} = NF/2T_{\rm H}$. (*d*) From the diagram and the two expressions above, show that $\tan\theta_i = (N - 2i)F/2T_{\rm H}$ and that $y_i = \frac{L}{N+1}\sum_{j=0}^{i-1}\cos\theta_j$, $y_i = \frac{L}{N+1}\sum_{j=0}^{i-1}\sin\theta_j$.

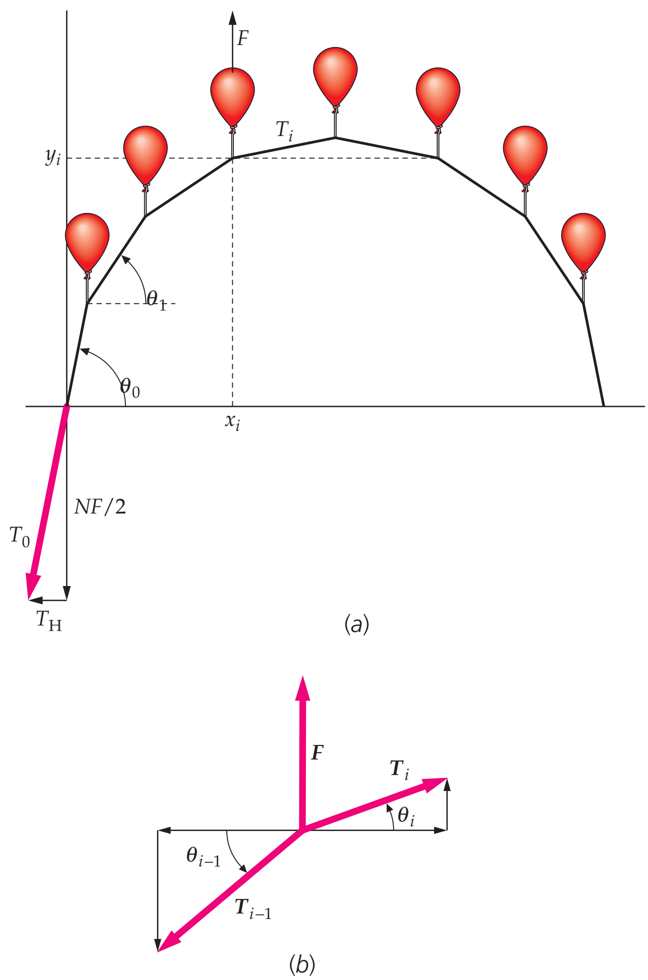

FIGURE 4-43 Problem 54

55 ••• **Engineering Application, Spreadsheet** (*a*) Consider a numerical solution to Problem 54. Write a **spreadsheet** program to make a graph of the shape of a balloon arch. Use the following parameters: $N = 10$ (balloons), each providing a lift force $F = 1.0$ N and each attached to a rope of length $L = 11$ m, with a horizontal component of tension $T_H = 10$ N. How far apart are the two points of attachment? How high is the arch at its highest point? (*b*) Note that we have not specified the spacing between the supports—it is determined by the other parameters. Vary T_H while keeping the other parameters the same until you create an arch that has a spacing of 8.0 m between the supports. What is T_H then? As you increase T_H, the arch should get flatter and more spread out. Does your spreadsheet model show this?

FREE-BODY DIAGRAMS: INCLINED PLANES AND THE NORMAL FORCE

56 • A large box whose mass is 20.0 kg rests on a frictionless floor. A mover pushes on the box with a force of 250 N at an angle 35.0° below the horizontal. Draw the box's free-body diagram and use it to determine the acceleration of the box.

57 • A 20.0 kg box rests on a frictionless ramp with a 15.0° slope. The mover pulls on a rope attached to the box to pull it up the incline (Figure 4-44). If the rope makes an angle of 40.0° with the horizontal, what is the smallest force F the mover will have to exert to move the box up the ramp?

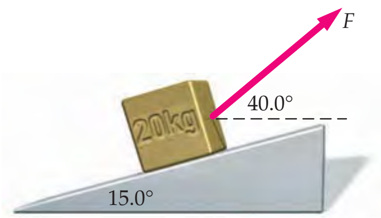

FIGURE 4-44 Problem 57

58 • In Figure 4-45, the objects are attached to spring scales calibrated in newtons. Give the reading(s) of the balance(s) in each case, assuming that both the scales and the strings are massless.

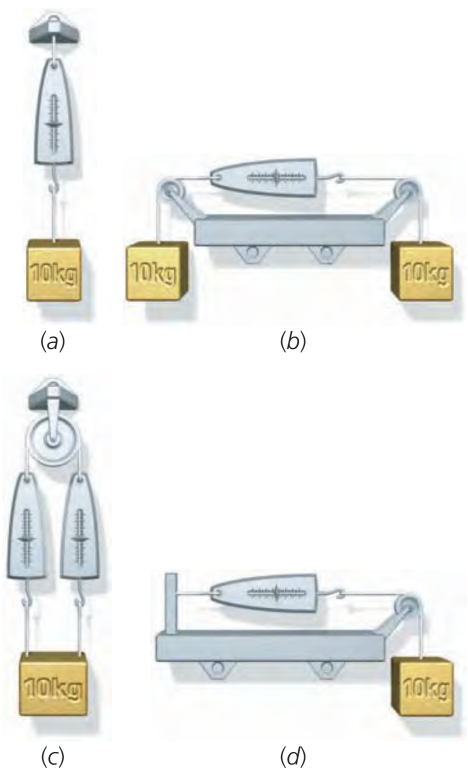

FIGURE 4-45 Problem 58

59 •• A box is held in position on a frictionless incline by a cable (Figure 4-46). (*a*) If $\theta = 60°$ and $m = 50$ kg, find the tension in the cable and the normal force exerted by the incline. (*b*) Find the tension as a function of θ and m, and check your result for plausibility in the special cases of $\theta = 0°$ and $\theta = 90°$.

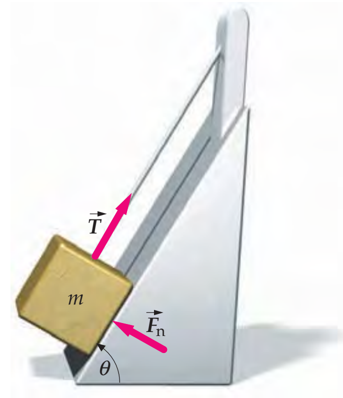

FIGURE 4-46 Problem 59

60 •• A horizontal force of 100 N pushes a 12-kg block up a frictionless incline that makes an angle of 25° with the horizontal. (*a*) What is the normal force that the incline exerts on the block? (*b*) What is the magnitude of acceleration of the block?

61 •• A 65-kg student weighs himself by standing on a force scale mounted on a skateboard that is rolling down an incline, as shown in Figure 4-47. Assume there is no friction so that the force exerted by the incline on the skateboard is normal to the incline. What is the reading on the scale if $\theta = 30°$? SSM

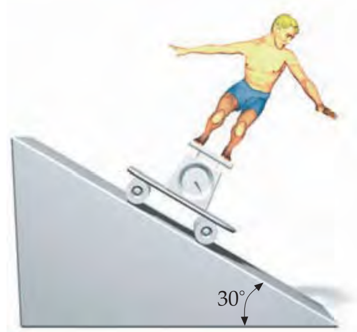

FIGURE 4-47 Problem 61

62 •• A block of mass m slides across a frictionless floor and then up a frictionless ramp (Figure 4-48). The angle of the ramp is θ and the speed of the block before it starts up the ramp is v_0. The block will slide up to some maximum height h above the floor before stopping. Show that h is independent of m and θ by deriving an expression for h in terms of v_0 and g.

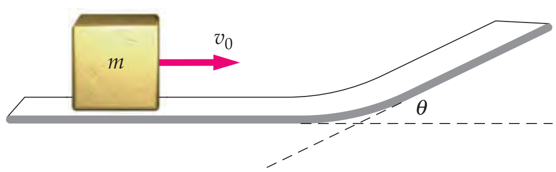

FIGURE 4-48 Problem 62

FREE-BODY DIAGRAMS: ELEVATORS

63 • **CONCEPTUAL** (*a*) Draw the free-body diagram (with accurate relative force magnitudes) for an object that is hung by a rope from the ceiling of an elevator that is ascending but slowing. (*b*) Repeat Part (*a*) but for the situation in which the elevator is descending and speeding up. (*c*) Can you tell the difference between the two diagrams? Explain why the diagrams do not tell anything about the object's velocity. SSM

64 • A 10.0-kg block is suspended from the ceiling of an elevator by a cord rated to withstand a tension of 150 N. Shortly after the elevator starts to ascend, the cord breaks. What was the minimum acceleration of the elevator when the cord broke?

65 •• A 2.0-kg block hangs from a spring scale calibrated in newtons that is attached to the ceiling of an elevator (Figure 4-49). What does the scale read when (*a*) the elevator is ascending with a constant speed of 30 m/s; (*b*) the elevator is descending with a constant speed of 30 m/s; (*c*) the elevator is ascending at 20 m/s and gaining speed at a rate of 3.0 m/s^2? (*d*) Suppose that from $t = 0$ to $t = 5.0$ s, the elevator ascends at a constant speed of 10 m/s. Its speed is then steadily reduced to zero during the next 4.0 s, so that it is at rest at $t = 9.0$ s. Describe the reading of the scale during the interval $0 < t < 9.0$ s.

FIGURE 4-49 Problem 65

FREE-BODY DIAGRAMS: SEVERAL OBJECTS AND NEWTON'S THIRD LAW

66 •• **CONCEPTUAL** Two boxes of mass m_1 and m_2 connected by a massless string are being pulled along a horizontal frictionless surface by the tension force in a second string, as shown in Figure 4-50. (*a*) Draw the free-body diagram of both boxes separately and show that $T_1/T_2 = m_1/(m_1 + m_2)$. (*b*) Is this result plausible? Explain. Does your answer make sense both in the limit that $m_2/m_1 \gg 1$ and in the limit that $m_2/m_1 \ll 1$? Explain.

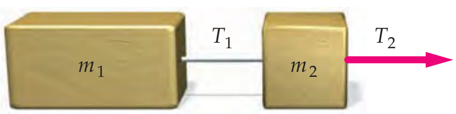

FIGURE 4-50 Problem 66

67 •• A box of mass $m_2 = 3.5$ kg rests on a frictionless horizontal shelf and is attached by strings to boxes of masses $m_1 = 1.5$ kg and $m_3 = 2.5$ kg as shown in Figure 4-51. Both pulleys are frictionless and massless. The system is released from rest. After it is released, find (*a*) the acceleration of each of the boxes, and (*b*) the tension in each string.

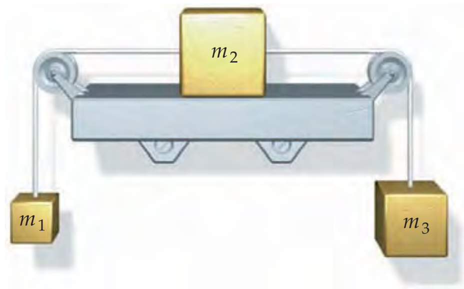

FIGURE 4-51 Problem 67

68 •• Two blocks are in contact on a frictionless horizontal surface. The blocks are accelerated by a single horizontal force $\vec{F}$ applied to one of them (Figure 4-52). Find the acceleration and the contact force of block 1 on block 2 (*a*) in terms of F, m_1 and m_2, and (*b*) for the specific values $F = 3.2$ N, $m_1 = 2.0$ kg and $m_2 = 6.0$ kg.

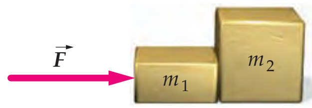

FIGURE 4-52 Problem 68

69 •• Repeat Problem 68, but with the two blocks interchanged. Are your answers for this problem the same as in Problem 68? Explain.

70 •• Two 100-kg boxes are dragged along a horizontal frictionless surface at a constant acceleration of 1.00 m/s^2, as shown in Figure 4-53. Each rope has a mass of 1.00 kg. Find the magnitude of the force $\vec{F}$ and the tension in the ropes at points A, B, and C.

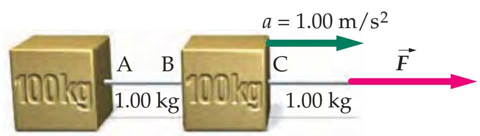

FIGURE 4-53 Problem 70

71 •• A block of mass m is being lifted vertically by a uniform rope of mass M and length L. The rope is being pulled upward by a force applied to its top end, and the rope and block are accelerating upward with an acceleration of magnitude a. Show that the tension in the rope at a distance x (where $x < L$) above the block is given by $(a + g)[m + (x/L)M]$. SSM

72 •• A chain consists of 5 links, each having a mass of 0.10 kg. The chain is being pulled upward by a force applied by your hand to its top link, giving the chain an upward acceleration of 2.5 m/s^2. Find (*a*) the force magnitude F exerted on the top link by your hand; (*b*) the net force on each link; and (*c*) the magnitude of the force that each link exerts on the link below it.

73 •• **MULTISTEP** A 40.0-kg object supported by a vertical rope. The rope, and thus the object, is then accelerated from rest upward so that it attains a speed of 3.50 m/s in 0.700 s. (*a*) Draw the object's free-body diagram with the relative lengths of the vectors showing the relative magnitudes of the forces. (*b*) Use the free-body diagram and Newton's laws to determine the tension in the rope. SSM

74 •• **ENGINEERING APPLICATION, MULTISTEP** A 15000-kg helicopter is lowering a 4000-kg truck to the ground by a cable of fixed length. The truck, helicopter, and cable are descending at 15.0 m/s and must be slowed to 5.00 m/s in the next 50.0 m of descent to prevent damaging the truck. Assume a constant rate of slowing. (*a*) Draw the free-body diagram of the truck. (*b*) Determine the tension in the cable. (*c*) Determine the lift force on the helicopter blades.

75 •• Two objects are connected by a massless string, as shown in Figure 4-54. The incline and the massless pulley are frictionless. Find the acceleration of the objects and the tension in the string (*a*) in terms of θ, m_1, and m_2, and for (*b*) $\theta = 30°$ and $m_1 = m_2 = 5.0\,\text{kg}$.

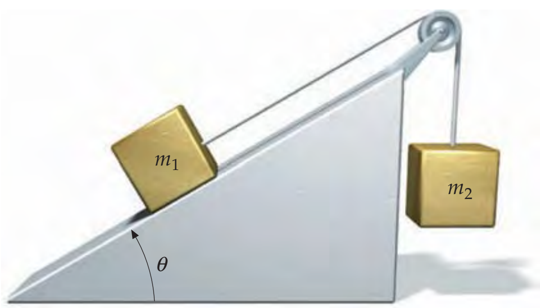

FIGURE 4-54 Problem 75

76 •• **ENGINEERING APPLICATION** During a stage production of *Peter Pan*, the 50-kg actress playing Peter has to fly in vertically (descend). To be in time with the music, she must, starting from rest, be lowered a distance of 3.2 m in 2.2 s at a constant acceleration. Backstage, a smooth surface sloped at 50° supports a counterweight of mass m, as shown in Figure 4-55. Show the calculations that the stage manager must perform to find (*a*) the mass of the counterweight that must be used and (*b*) the tension in the wire.

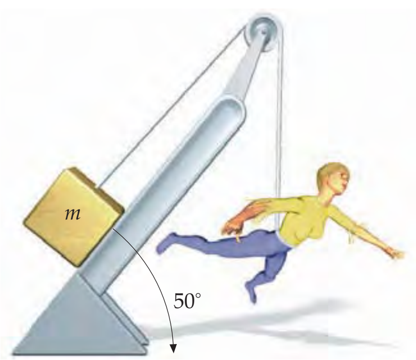

FIGURE 4-55 Problem 76

77 •• An 8.0-kg block and a 10-kg block, connected by a rope that passes over a frictionless peg, slide on frictionless incline, (Figure 4-56). (*a*) Find the acceleration of the blocks and the tension in the rope. (*b*) The two blocks are replaced by two others of masses m_1 and m_2 such that there is no acceleration. Find whatever information you can about the masses of these two new blocks.

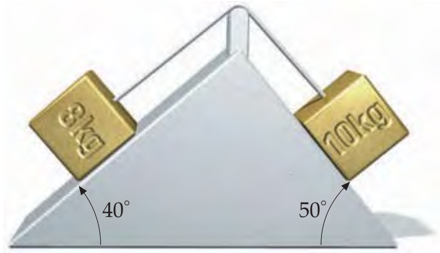

FIGURE 4-56 Problem 77

78 •• A heavy rope of length 5.0 m and mass 4.0 kg lies on a frictionless horizontal table. One end is attached to a 6.0-kg block. The other end of the rope is pulled by a constant horizontal 100-N force. (*a*) What is the acceleration of the system? (*b*) Give the tension in the rope as a function of position along the rope.

79 •• A 60-kg housepainter stands on a 15-kg aluminum platform. The platform is attached to a rope that passes through an overhead pulley, which allows the painter to raise herself and the platform (Figure 4-57). (*a*) With what force F must she pull down on the rope to accelerate herself and the platform upward at a rate of $0.80\,\text{m/s}^2$? (*b*) When her speed reaches 1.0 m/s, she pulls in such a way that she and the platform go up at a constant speed. What force is she exerting on the rope now? (Ignore the mass of the rope.) SSM

FIGURE 4-57 Problem 79

80 ••• Figure 4-58 shows a 20-kg block sliding on a 10-kg block. All surfaces are frictionless and the pulley is massless and frictionless. Find the acceleration of each block and the tension in the string that connects the blocks.

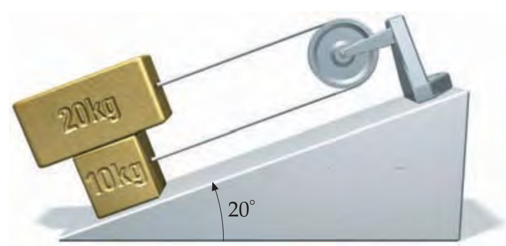

FIGURE 4-58 Problem 80

81 ••• A 20-kg block with a pulley attached slides along a frictionless ledge. It is connected by a massless string to a 5.0-kg block via the arrangement shown in Figure 4-59. Find (*a*) the acceleration of each block, and (*b*) the tension in the connecting string.

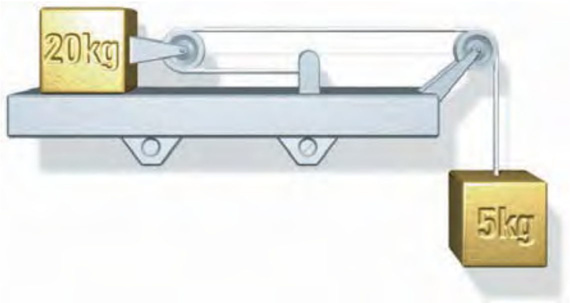

FIGURE 4-59 Problem 81

82 •• **MULTISTEP** The apparatus in Figure 4-60 is called an *Atwood's machine* and is used to measure the free-fall acceleration g by measuring the acceleration of the two blocks connected by a string over a pulley. Assume a massless, frictionless pulley and a massless string. (*a*) Draw the free-body diagram of each block. (*b*) Use the free-body diagrams and Newton's laws to show that the magnitude of the acceleration of either block and the tension in the string are $a = (m_1 - m_2)g/(m_1 + m_2)$ and $T = 2m_1m_2g/(m_1 + m_2)$. (*c*) Do these expressions give plausible results if $m_1 = m_2$, in the limit that $m_1 \gg m_2$ and in the limit that $m_1 \ll m_2$? Explain.

FIGURE 4-60 Problems 82 and 83

83 •• If one of the masses of the Atwood's machine in Figure 4-60 is 1.2 kg, what should be the other mass so that the displacement of either mass during the first second following release is 0.30 m? Assume a massless, frictionless pulley and a massless string.

84 ••• The acceleration of gravity g can be determined by measuring the time t it takes for a mass m_2 in an Atwood's machine described in Problem 82 to fall a distance L, starting from rest. (*a*) Using the results of Problem 82 (note the acceleration is constant), find an expression for g in terms of L, t, m_1, and m_2. (*b*) Show that a small error in the time measurement dt, will lead to an error in g by an amount dg given by $dg/g = -2dt/t$. (*c*) Assume that the only significant uncertainty in the experimental measurements is the time of fall. If $L = 3.00$ m and m_1 is 1.00 kg, find the value of m_2 such that g can be measured with an accuracy of ± 5 percent with a time measurement that is accurate to ± 0.1 s.

GENERAL PROBLEMS

85 •• A pebble of mass m rests on the block of mass m_2 of the ideal Atwood's machine in Figure 4-60. Find the force exerted by the pebble on the block of mass m_2.

86 •• A simple accelerometer can be made by suspending a small massive object from a string attached to a fixed point on an accelerating object. Suppose such an accelerometer is attached to point P on the ceiling of an automobile traveling in a straight line on a flat surface at constant acceleration. Due to the acceleration, the string will make an angle θ with the vertical. (*a*) Show that the magnitude of the acceleration a is related to the angle θ by $a = g\tan\theta$. (*b*) Suppose the automobile brakes steadily to rest from 50 km/h over a distance of 60 m. What angle will the string make with the vertical? Will the suspended object be positioned below and ahead or below and behind point P during the braking?

87 •• **ENGINEERING APPLICATION** The mast of a sailboat is supported at the bow and stern by stainless steel wires, the forestay and backstay, anchored 10 m apart (Figure 4-61). The 12.0-m-long mast weighs 800 N and stands vertically on the deck of the boat. The mast is positioned 3.60 m behind where the forestay is attached. The tension in the forestay is 500 N. Find the tension in the backstay and the force that the mast exerts on the deck. SSM

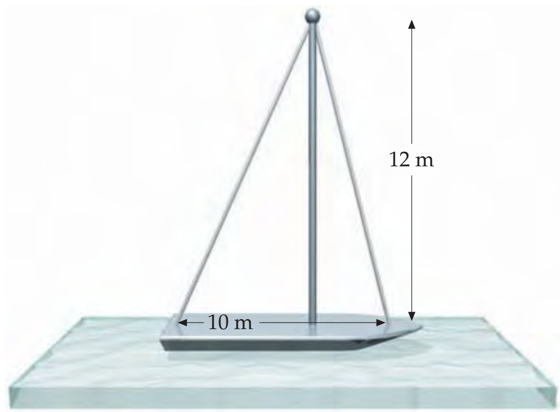

FIGURE 4-61 Problem 87

88 •• A 50-kg block is suspended from a uniform 1.5-m-long chain that is hanging from the ceiling. The mass of the chain itself is 20 kg. Determine the tension in the chain (*a*) at the point where the chain is attached to the block, (*b*) midway up the chain, and (*c*) at the point where the chain is attached to the ceiling.

89 •• The speed of the head of a red headed woodpecker reaches 5.5 m/s before impact with the tree. If the mass of the head is 0.060 kg and the average force on the head is 6.0 N, find (*a*) the acceleration of the head (assuming constant acceleration), (*b*) the depth of penetration into the tree, and (*c*) the time it takes for the head to come to a stop.

90 •• **MULTISTEP** A frictionless surface is inclined at an angle of 30.0° to the horizontal. A 270-g block on the ramp is attached to a 75.0-g block using a pulley, as shown in Figure 4-62. (*a*) Draw two free-body diagrams, one for the 270-g block and the other for the 75.0-g block. (*b*) Find the tension in the string and the acceleration of the 270-g block. (*c*) The 270-g block is released from rest.

FIGURE 4-62 Problem 90

How long does it take for it to slide a distance of 1.00 m along the surface? Will it slide up the incline, or down the incline?

91 •• A box of mass m_1 is pulled along a frictionless horizontal surface by a horizontal force $\vec{F}$ that is applied to the end of a rope of mass m_2 (see Figure 4-63). Neglect any sag of the rope. (*a*) Find the acceleration of the rope and block, assuming them to be one object. (*b*) What is the net force acting on the rope? (*c*) Find the tension in the rope at the point where it is attached to the block.

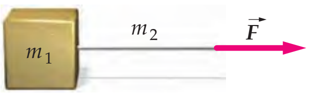

FIGURE 4-63 Problem 91

92 •• A 2.0-kg block rests on a frictionless wedge that has a 60° incline and an acceleration $\vec{a}$ to the right such that the mass remains stationary relative to the wedge (Figure 4-64). (*a*) Draw the free-body diagram of the block and use it to determine the magnitude of the acceleration. (*b*) What would happen if the wedge were given an acceleration larger than this value? Smaller than this value?

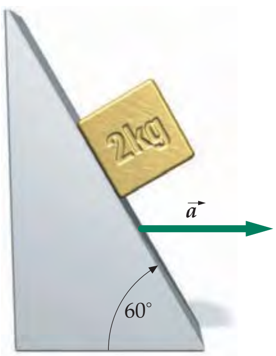

FIGURE 4-64 Problem 92

93 ••• The masses attached to each side of an ideal Atwood's machine consist of a stack of five washers, each of mass m, as shown in Figure 4-65. The tension in the string is T_0. When one of the washers is removed from the left side, the remaining washers accelerate and the tension decreases by 0.300 N. (*a*) Find m. (*b*) Find the new tension and the acceleration of each mass when a second washer is removed from the left side. SSM

FIGURE 4-65 Problems 93 and 94

94 •• Consider the ideal Atwood's machine in Figure 4-65. When N washers are transferred from the left side to the right side, the right side descends 47.1 cm in 0.40 s. Find N.

95 •• Blocks of mass m and $2m$ are on a horizontal frictionless surface (Figure 4-66). The blocks are connected by a horizontal string. In addition, forces $\vec{F}_1$ and $\vec{F}_2$ are applied as shown. (*a*) If the forces shown are constant, find the tension in the connecting string. (*b*) If the magnitudes of the forces vary with time as $F_1 = Ct$ and $F_2 = 2Ct$, where C equals to 5.00 N/s and t is time, find the time t_0 at which the tension in the string equals to 10.0 N.

FIGURE 4-66 Problem 95

96 •• Elvis Presley has supposedly been sighted numerous times since his death on August 16, 1977. The following is a chart of what Elvis's weight would be if he were sighted on the surfaces of other objects in our solar system. Use the chart to determine: (*a*) Elvis's mass on Earth, (*b*) Elvis's mass on Pluto, and (*c*) the free-fall acceleration on Mars. (*d*) Compare the free-fall acceleration on Pluto to the free-fall acceleration on the moon.

Planet	Elvis's Weight (N)
Mercury	431
Venus	1031
Earth	1133
Mars	431
Jupiter	2880
Saturn	1222
Pluto	58
Moon	191

97 ••• **CONTEXT-RICH** As a prank, your friends have kidnapped you in your sleep, and transported you out onto the ice covering a local pond. When you wake up you are 30.0 m from the nearest shore. The ice is so slippery (i.e. frictionless) that you cannot seem to get yourself moving. You realize that you can use Newton's third law to your advantage, and choose to throw the heaviest thing you have, one boot, in order to get yourself moving. Take your weight to be 595 N. (*a*) What direction should you throw your boot so that you will most quickly reach the shore? (*b*) If you throw your 1.20-kg boot with an average force of 420 N, and the throw takes 0.600 s (the time interval over which you apply the force), what is the magnitude of the force that the boot exerts on you? (Assume constant acceleration.) (*c*) How long does it take you to reach shore, including the short time in which you were throwing the boot?

98 ••• The pulley of an ideal Atwood's machine is given an upward acceleration a, as shown in Figure 4-67. Find the acceleration of each mass and the tension in the string that connects them. The speeds of the two blocks are not equal in this situation

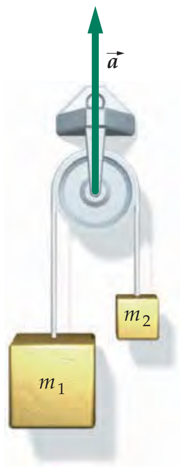

FIGURE 4-67 Problem 98

99 •• **ENGINEERING APPLICATION, CONTEXT-RICH, SPREADSHEET** You are working for an automotive magazine and putting a certain new automobile (mass 650 kg) through its paces. While accelerating from rest, its onboard computer records its velocity as a function of time as follows:

v_x **(m/s):**	0	10	20	30	40	50
t **(s):**	0	1.8	2.8	3.6	4.9	6.5

(*a*) Using a **spreadsheet,** find the average acceleration of the five time intervals and graph the velocity versus time and acceleration versus time for this car. (*b*) Where on the graph of velocity versus time is the net force on the car highest and lowest? Explain your reasoning. (*c*) What is the average net force on the car over the whole trip? (*d*) From the graph of velocity versus time, estimate the total distance covered by the car.

CHAPTER 5

DAYTONA INTERNATIONAL SPEEDWAY, THE "WORLD CENTER OF RACING," FEATURES A 2.5-MILE TRI-OVAL TRACK, WHICH HAS FOUR-STORY, 31-DEGREE-HIGH BANKED CURVES. IN THE DAYTONA 500 RACE THE STOCK CARS TRAVEL THROUGH THE CURVES AT SPEEDS CLOSE TO 200 MPH. SURPRISINGLY, THE FIERY CRASHES THAT THE DAYTONA 500 IS FAMOUS FOR, WITH THEIR ACCOMPANYING INJURIES AND FATALITIES, ARE USUALLY NOT CAUSED BY SKIDDING ON THE CURVES. *(PhotoDisc/Getty Images.)*

Additional Applications of Newton's Laws

? What factors determine how fast a car can go through a curve without skidding? (See Example 5-12.)

In Chapter 4, we introduced Newton's laws and applied them to situations where action was restricted to straight-line motion and frictional forces were introduced. We now will consider some more general applications and how Newton's laws can be used to explain innumerable properties of the world in which we live.

In this chapter, we will extend the application of Newton's laws to motion along curved paths, and we will analyze the effects of resistive forces such as friction and air drag. We will also introduce the concept of the center of mass of a system of particles and show how modeling the system as a single particle located at the center of mass can result in being able to predict the bulk motion of such a system.

5-1 FRICTION

If you shove a book that is resting on a desktop, the book will probably skid across the desktop. If the desktop is long enough, the book will eventually skid to a stop. This happens because a frictional force is exerted by the desktop on the book in a direction opposite to the book's velocity. This force, which acts on the surface of the book in contact with the desktop, is known as a *frictional force*. Frictional forces are a necessary part of our lives. Without friction our ground-based transportation system, from walking to automobiles, could not function. Friction allows you to start walking, and once you are already moving, friction allows you to change either your speed or direction. Friction allows you to start, steer, and stop a car. Friction holds a nut on a screw, a nail in wood, and a knot in a piece of rope. However, as important as friction is, it is often not desirable. Friction causes wear whenever moving pieces of machinery are in contact, and large amounts of time and money are spent trying to reduce such effects.

Friction is a complex, incompletely understood phenomenon that arises from the attraction between the molecules of one surface and the molecules on a second surface in close contact. The nature of this attraction is electromagnetic—the same as the molecular bonding that holds an object together. This short-ranged attractive force becomes negligible at distances of only a few atomic diameters.

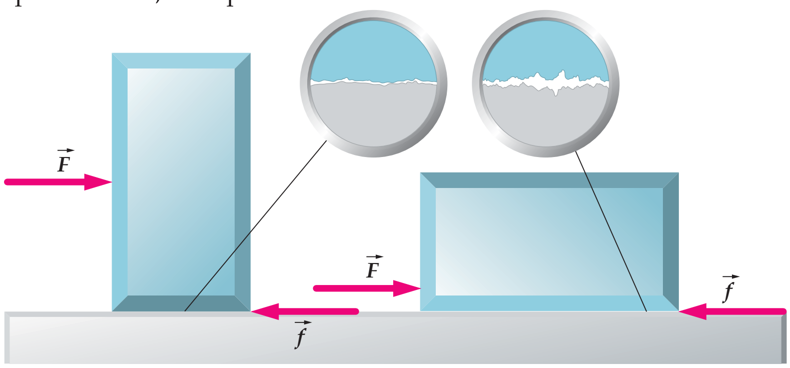

FIGURE 5-1 The microscopic area of contact between box and floor is only a small fraction of the macroscopic area of the box's bottom surface. The microscopic area of contact is proportional to the normal force exerted between the surfaces. If the box rests on its side, the macroscopic area is increased, but the force per unit area is decreased, so the microscopic area of contact is unchanged. Whether the box is upright or on its side, the same horizontal applied force F is required to keep it sliding at constant speed.

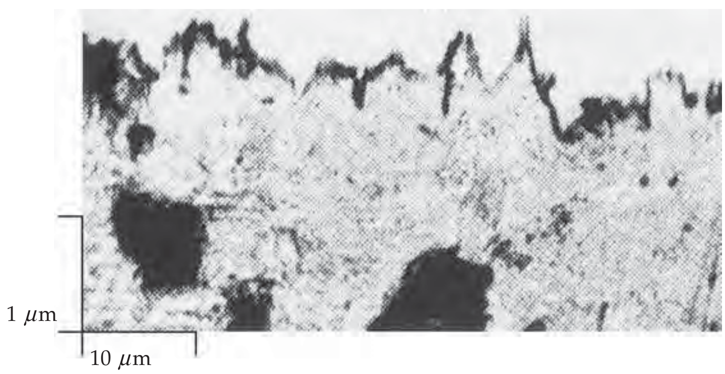
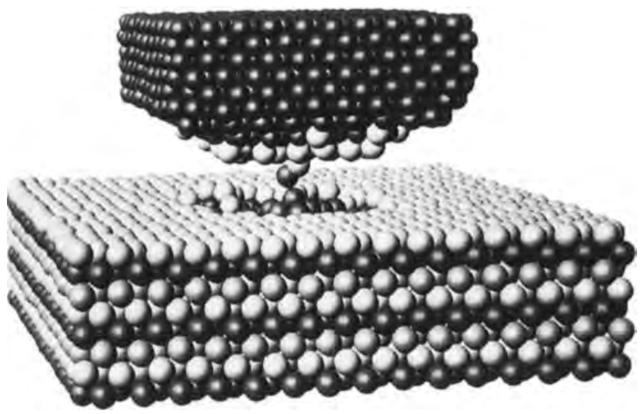
As shown in Figure 5-1, ordinary objects that look smooth and feel smooth are rough and bumpy at the microscopic (atomic) scale. This is the case even if the surfaces are highly polished. When surfaces come into contact, they touch only at prominences, called *asperities,* shown in Figure 5-1. The normal force exerted by a surface is exerted at the tips of these asperities where the normal force per unit area is very large, large enough to flatten the tips of the asperities. If the two surfaces are pressed together more strongly, the normal force increases and so does this flattening, resulting in a larger microscopic contact area. Under a wide range of conditions the microscopic area of contact is proportional to the normal force. The frictional force is proportional to the microscopic contact area; so, like the microscopic contact area, it is proportional to the normal force.



Magnified section of a polished steel surface showing surface irregularities. The irregularities are about $= 5 \times 10^{-7}$m high, a height that corresponds to several thousand atomic diameters. *(From F. P. Bowden and D. Tabor,* Lubrication of Solids, *Oxford University Press, 2000.)*



The computer graphic shows gold atoms (bottom) adhering to the fine point of a nickel probe (top) that has been in contact with the gold surface. *(Uzi Landman and David W. Leudtke/Georgia Institute of Technology.)*

STATIC FRICTION

Suppose you apply a small horizontal force $\vec{F}$ (Figure 5-2) to a large box resting on the floor. The box may not move noticeably because the force of static friction $\vec{f}_s$, exerted by the floor on the box, balances the force you apply. **Static friction** is the frictional force that acts when there is no sliding between the two surfaces in contact—it is the force that keeps the box from sliding. The force of static friction, which opposes the applied force on the box, can vary in magnitude from zero to some maximum value $f_{s\,max}$, depending on how hard you push. That is, as you push on the box, the opposing force of static friction increases to remain equal in magnitude to the applied force until the magnitude of the applied force exceeds $f_{s\,max}$. Data show that $f_{s\,max}$ is proportional to the strength of the forces pressing the two surfaces together. That is, $f_{s\,max}$ is proportional to the magnitude of the normal force exerted by one surface on the other:

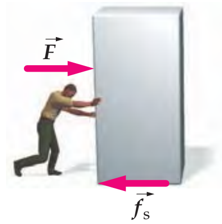


FIGURE 5-2

$$f_{s\,max} = \mu_s F_n \qquad 5\text{-}1$$

STATIC FRICTION RELATION

where the proportionality constant μ_s, is the **coefficient of static friction.** This coefficient depends on what materials the surfaces in contact are made of as well as the temperatures of the surfaces. If you exert a horizontal force with a magnitude that is less than or equal to $f_{s\,max}$ on the box, the static frictional force will just balance this horizontal force and the box will remain at rest. If you exert a horizontal force even slightly greater than $f_{s\,max}$ on the box, then the box will begin to slide. Thus, we can write Equation 5-1 as:

$$f_s \leq \mu_s F_n \qquad 5\text{-}2$$

The direction of the static frictional force is such that it opposes the tendency of the box to slide.

! Equation 5-2 is an inequality because the magnitude of the force of static friction ranges from zero up to $f_{s\,max}$.

! If the horizontal force you exert on the box is toward the left, then the static frictional force is toward the right. The static frictional force always opposes any tendency to slide.

KINETIC FRICTION

If you push the box in Figure 5-2 hard enough, it will slide across the floor. As it slides, the floor exerts a force of **kinetic friction** $\vec{f}_k$ (also called sliding friction) that opposes the motion. To keep the box sliding with constant velocity, you must exert a force on the box that is equal in magnitude and opposite in direction to the force of kinetic friction exerted by the floor.

Like the magnitude of a maximum static frictional force, the magnitude of a kinetic frictional force f_k is proportional to the microscopic contact area and the strength of the forces pressing the two surfaces together. That is, f_k is proportional to the normal force F_n one surface exerts on the other:

$$f_k = \mu_k F_n \qquad 5\text{-}3$$

KINETIC FRICTION RELATION

where the proportionality constant μ_k, is the **coefficient of kinetic friction.** The coefficient of kinetic friction depends on what materials the surfaces in contact are made of as well as the temperature of the contacting surfaces. Unlike static friction, the force of kinetic friction is independent of the magnitude of the applied horizontal force. Experiments show that μ_k is approximately constant for a wide range of speeds.

Figure 5-3 shows a plot of the frictional force exerted on the box by the floor as a function of the applied force. The force of friction balances the applied force until the box starts to slide, which occurs when the applied force exceeds $\mu_s F_n$ by an infinitesimal amount. As the box slides, the frictional force remains equal to $\mu_k F_n$. For any given contacting surfaces, μ_k is less than μ_s. This means you have to push harder to get the box to begin sliding than to keep it sliding at constant speed. Table 5-1 lists some approximate values of μ_s and μ_k for various pairs of surfaces.

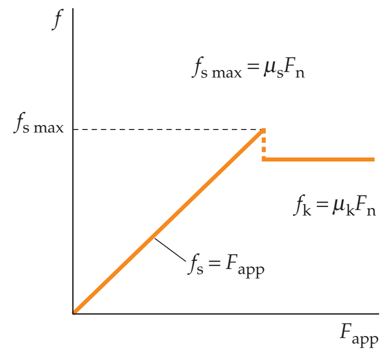

FIGURE 5-3

Table 5-1 Approximate Values of Frictional Coefficients

Materials	μ_s	μ_k
Steel on steel	0.7	0.6
Brass on steel	0.5	0.4
Copper on cast iron	1.1	0.3
Glass on glass	0.9	0.4
Teflon on Teflon	0.04	0.04
Teflon on steel	0.04	0.04
Rubber on concrete (dry)	1.0	0.80
Rubber on concrete (wet)	0.30	0.25
Waxed ski on snow (0°C)	0.10	0.05

ROLLING FRICTION

When a perfectly rigid wheel rolls *at constant speed* along a perfectly rigid horizontal road without slipping, no frictional force slows its motion. However, because real tires and roads continually deform (Figure 5-4) and because the tread and the road are continually peeled apart, in the real world the road exerts a force of **rolling friction** $\vec{f}_r$ that opposes the motion. To keep the wheel rolling with constant velocity, you must exert a force on the wheel that is equal in magnitude and opposite in direction to the force of rolling friction exerted on the wheel by the road.

The **coefficient of rolling friction** μ_r is the ratio of the magnitudes of the rolling frictional force f_r and the normal force F_n:

$$f_r = \mu_r F_n \qquad 5\text{-}4$$

ROLLING FRICTION RELATION

where μ_r depends on the nature of the surfaces in contact and the composition of the wheel and road. Typical values of μ_r are 0.01 to 0.02 for rubber tires on concrete and 0.001 to 0.002 for steel wheels on steel rails. Coefficients of rolling friction are typically less than coefficients of kinetic friction by one to two orders of magnitude. Rolling friction is considered to be negligible in this book, except where it is specifically stated that it is significant.

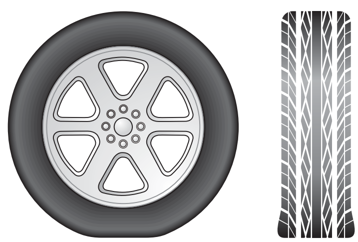

FIGURE 5-4 As the car moves down the highway, the rubber flexes radially inward where the tread initiates contact with the pavement, and flexes radially outward where the tread loses contact with the road. The tire is not perfectly elastic, so the forces exerted on the tread by the pavement that flex the tread inward are greater than those exerted on the tread by the pavement as the tread flexes back as it leaves the pavement. This imbalance of forces results in a force opposing the rolling of the tire. This force is called a rolling frictional force. The more the tire flexes, the greater the rolling frictional force.

SOLVING PROBLEMS INVOLVING STATIC, KINETIC, AND ROLLING FRICTION

The following examples illustrate how to solve problems involving static and kinetic friction. The guidelines for approaching these types of problems are as follows:

PROBLEM-SOLVING STRATEGY

Solving Problems Involving Friction

PICTURE Determine which types of friction are involved in solving a problem. Objects experience static friction when no sliding exists between the surfaces of the objects that are in contact. The force of static friction opposes the tendency of the surfaces to slide on each other. The maximum static frictional force $f_{s\,max}$ is equal to the product of the normal force and the coefficient of static friction. If two surfaces are sliding against each other, they experience kinetic frictional forces (unless the problem states that one of the surfaces is frictionless). Rolling friction occurs because a rolling object and the surface that the object is rolling on continually deform and the object and the surface are continually peeling apart.

SOLVE

1. Construct a free-body diagram with the y axis normal to (and the x axis parallel to) the contacting surfaces. The direction of the frictional force is such that it opposes slipping, or the tendency to slip.
2. Apply $\Sigma F_y = ma_y$ and solve for the normal force F_n.
   If the friction is *kinetic* or *rolling*, relate the frictional and normal forces using $f_k = \mu_k F_n$ or $f_r = \mu_r F_n$, respectively.
   If the friction is *static*, relate the frictional and normal forces using $f_s \le \mu_s F_n$ (or $f_{s\,max} = \mu_s F_n$).
3. Apply $\Sigma F_x = ma_x$ to the object and solve for the desired quantity.

CHECK In making sure that your answer makes sense, remember that coefficients of friction are dimensionless and that you must account for all forces (for example, tensions in ropes).

Example 5-1 A Game of Shuffleboard

A cruise-ship passenger uses a shuffleboard cue to push a shuffleboard disk of mass 0.40 kg horizontally along the deck so that the disk leaves the cue with a speed of 8.5 m/s. The disk then slides a distance of 8.0 m before coming to rest. Find the coefficient of kinetic friction between the disk and the deck.

PICTURE The force of kinetic friction is the only horizontal force acting on the disk after it separates from the cue. The acceleration is constant, because the frictional force is constant. We can find the acceleration using the constant-acceleration equations of Chapter 2 and relate the acceleration to μ_k using $\Sigma F_x = ma_x$.

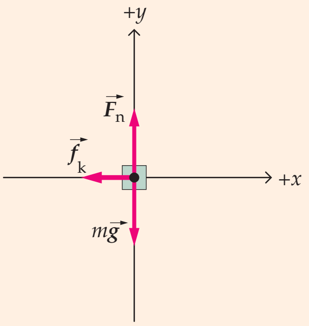

FIGURE 5-5

SOLVE

1. Draw a free-body diagram for the disk after it leaves the cue (Figure 5-5). Choose as the $+x$ direction the direction of the disk's velocity:

2. The coefficient of kinetic friction relates the magnitudes of the frictional and normal forces:

$$f_k = \mu_k F_n$$

3. Apply $\Sigma F_y = ma_y$ to the disk. Solve for the normal force. Then, using the relationship from step 2, solve for the frictional force:

$$\Sigma F_y = ma_y$$
$$F_n - mg = 0 \Rightarrow F_n = mg$$
$$\text{so} \quad f_k = \mu_k mg$$

4. Apply $\Sigma F_x = ma_x$ to the disk. Using the step-3 result, solve for the acceleration:

$$\Sigma F_x = ma_x$$
$$-f_k = ma_x$$
$$\text{so} \quad -\mu_k mg = ma_x \quad \text{so} \quad a_x = -\mu_k g$$

5. The acceleration is constant. Relate it to the total distance traveled and the initial velocity using $v_x^2 = v_{0x}^2 + 2a_x\Delta x$ (Equation 2-15). Using the step-4 result, solve for μ_k:

$$v_x^2 = v_{0x}^2 + 2a_x\,\Delta x \;\Rightarrow\; 0 = v_{0x}^2 - 2\mu_k g\,\Delta x$$

$$\text{so}\quad \mu_k = \frac{v_{0x}^2}{2g\,\Delta x} = \frac{(8.5\ \text{m/s})^2}{2(9.81\ \text{m/s}^2)(8.0\ \text{m})} = \boxed{0.46}$$

CHECK The value obtained for μ_k is dimensionless and within the range of values for other materials listed in Table 5-1, so it is plausible.

TAKING IT FURTHER Note that the acceleration and the coefficient of friction are independent of the mass m. The greater the mass, the harder it is to stop the disk, but a greater mass is accompanied by a greater normal force, and thus a greater frictional force. The net result is that the mass has no effect on the acceleration (or the stopping distance).

Example 5-2 A Sliding Coin

A hardcover book (Figure 5-6) is resting on a tabletop with its front cover facing upward. You place a coin on this cover and very slowly open the book until the coin starts to slide. The angle θ_{max} (known as the *angle of repose*) is the angle the front cover makes with the horizontal just as the coin starts to slide. Find the coefficient of static friction μ_s between the book cover and the coin in terms of θ_{max}.

FIGURE 5-6 *(Ramón Rivera-Moret.)*

PICTURE The forces acting on the coin are the gravitational force $F_g = mg$, the normal force F_n, and the frictional force f. Because the coin is on the verge of sliding (but not yet sliding), the frictional force is a static frictional force directed up the incline. Because the coin remains stationary, its acceleration is zero. We use Newton's second law to relate this acceleration to the forces on the coin, and then solve for the fictional force.

SOLVE

1. Draw a free-body diagram for the coin when the book cover inclined at angle θ, where $\theta \le \theta_{max}$ (Figure 5-7). Draw the y axis normal to the book cover:

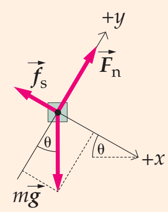

FIGURE 5-7

2. The coefficient of static friction relates the frictional and normal forces:

$$f_s \le \mu_s F_n$$

3. We apply $\Sigma F_y = ma_y$ to the coin and solve for the normal force:

$$\Sigma F_y = ma_y$$
$$F_n - mg\cos\theta = 0 \;\Rightarrow\; F_n = mg\cos\theta$$

4. Substitute for F_n in $f_s \le \mu_s F_n$ (Equation 5-1):

$$f_s \le \mu_s F_n \;\Rightarrow\; f_s \le \mu_s mg\cos\theta$$

5. Apply $\Sigma F_x = ma_x$ to the coin. Then solve for the friction force:

$$\Sigma F_x = ma_x$$
$$-f_s + mg\sin\theta = 0 \;\Rightarrow\; f_s = mg\sin\theta$$

6. Substituting $mg\sin\theta$ for f_s in the step-4 result gives:

$$mg\sin\theta \le \mu_s mg\cos\theta \;\Rightarrow\; \tan\theta \le \mu_s$$

7. θ_{max}, the largest angle satisfying the condition $\tan\theta \le \mu_s$, is the largest angle such that the coin does not slide:

$$\boxed{\mu_s = \tan\theta_{max}}$$

CHECK The coefficient of friction is dimensionless, and so is the tangent function. Also, for $0 < \theta_{max} < 45°, \tan\theta_{max}$ is between zero and one. One would expect the coin to slide before the angle reached 45° and one would expect the coefficient of static friction to be between zero and one. Thus, the step-7 result is plausible.

PRACTICE PROBLEM 5-1 The coefficient of static friction between a car's tires and the road on a particular day is 0.70. What is the steepest angle of inclination of the road for which the car can be parked with all four wheels locked and not slide down the hill?

Erosion due to a stream cutting across a beach. Even though the edge weaves in and out, the angle of the slope remains constant. The angle of the slope is the angle of repose for the granular material. *(David R. Bailey.)*

CONCEPT CHECK 5-1

The car in Practice Problem 5-1 is parked at the steepest angle of inclination with all four wheels locked. Would the car slide down the incline if only two of the wheels are locked?

Example 5-3 Pulling a Sled

Two children sitting on a sled at rest in the snow ask you to pull them. You oblige by pulling on the sled's rope, which makes an angle of 40° with the horizontal (Figure 5-8). The children have a combined mass of 45 kg and the sled has a mass of 5.0 kg. The coefficients of static and kinetic friction are $\mu_s = 0.20$ and $\mu_k = 0.15$ and the sled is initially at rest. Find both the magnitude of the frictional force exerted by the snow on the sled and the acceleration of the children and sled if the tension in the rope is (*a*) 100 N and (*b*) 140 N.

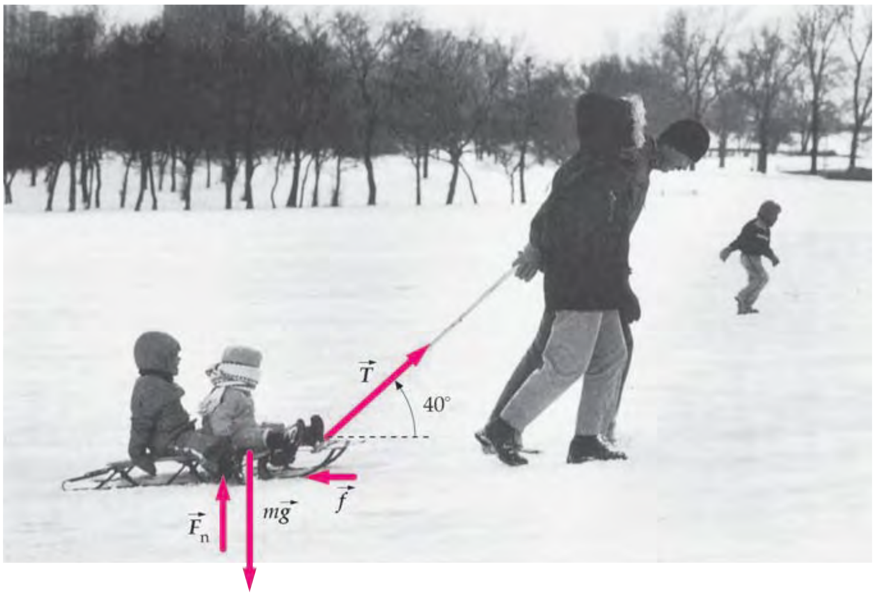

FIGURE 5-8 *(Jean-Claude LeJeune/Stock Boston.)*

PICTURE First, we need to find out whether the frictional force is static or kinetic. To do this, we see if the given tension forces satisfy the relation $f_s \le \mu_s F_n$. Once we have done that, we can select the correct expression for the frictional force, and solve the corresponding expression for f.

SOLVE

(*a*) 1. Draw a free-body diagram for the sled (Figure 5-9):

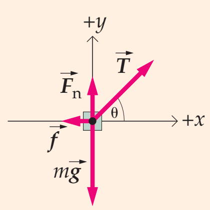

FIGURE 5-9

2. Write down the static friction relation. If this relation is satisfied, the sled does not begin sliding:

$$f_s \le \mu_s F_n$$

3. Apply $\Sigma F_y = ma_y$ to the sled and solve for the normal force:

$$\Sigma F_y = ma_y$$
$$F_n + T\sin\theta - mg = 0 \Rightarrow F_n = mg - T\sin\theta$$

4. Apply $\Sigma F_x = ma_x$ (with $a_x = 0$) to the sled and solve for the static frictional force:

$$\Sigma f_x = ma_x$$
$$-f_s + T\cos\theta = 0 \Rightarrow f_s = T\cos\theta$$

5. Substitute the step-4 and step-5 results into the step-2 result:

$$T\cos\theta \le \mu_s(mg - T\sin\theta)$$

6. Check to see if the given tension of 100 N satisfies the nonslip condition (the step-3 inequality):

$$(100\text{ N})\cos 40° \le 0.20[(50\text{ kg})(9.81\text{ N/kg}) - (100\text{ N})\sin 40°]$$
$$77\text{ N} \le 85\text{ N}$$

The inequality *is* satisfied, thus the sled *is not* sliding.

7. Because the sled is not sliding, the frictional force is that of static friction. To find the frictional force, use the step-3 expression for f_s:

$$a_x = 0$$
$$f_s = T\cos\theta = (100\text{ N})\cos 40° = \boxed{77\text{ N}}$$

(*b*) 1. Check the step-4 result from Part (*a*) with $T = 140$ N. If the relation is satisfied, the sled does not slide:

$$(140\text{ N})\cos 40° \le 0.20[(50\text{ kg})(9.81\text{ N/kg}) - (140\text{ N})\sin 40°]$$
$$107\text{ N} \le 80\text{ N}$$

The inequality *is not* satisfied, thus the sled *is* sliding.

2. Because the sled is sliding, the friction is kinetic friction, where $f_k = \mu_k F_n$. In Part (*a*) step-3 we applied $\Sigma F_y = ma_y$ to the sled and found $F_n = mg - T\sin\theta$. Using these results, solve for the kinetic frictional force:

$$f_k = \mu_k F_n$$
$$f_k = \mu_k(mg - T\sin\theta)$$
$$= 0.15[(50\text{ kg})(9.81\text{ N/kg}) - (140\text{ N})\sin 40°]$$
$$= \boxed{60\text{ N}}$$

3. Apply $\Sigma F_x = ma_x$ to the sled and solve for the frictional force. Then substitute the Part (*b*) step-2 result for f_k and solve for the acceleration:

$$\Sigma F_x = ma_x$$
$$-f_k + T\cos\theta = ma_x \Rightarrow a_x = \frac{-f_k + T\cos\theta}{m}$$
$$\text{so}\quad a_x = \frac{(-60\text{ N}) + (140\text{ N})\cos 40°}{50\text{ kg}} = \boxed{0.94\text{ m/s}^2}$$

CHECK We expect a_x to be greater than or equal to zero, so we expect the magnitude of the frictional force to be less than or equal to the x component of the tension force. In Part (*a*) the magnitude of the frictional force and x component of the tension force both equal 77 N, and in Part (*b*) the magnitude of the frictional force equals 60 N and the x component of the tension force is 140 N cos 40° = 107 N.

TAKING IT FURTHER Note two important points about this example: (1) the normal force is less than the weight of the children and the sled. This is so because the vertical component of the tension helps the ground counter the gravitational force; and (2) in Part (*a*), the force of static friction is less than $\mu_s F_n$.

PRACTICE PROBLEM 5-2 What is the maximum force you can pull the rope at the specified angle without the sled beginning to slide?

Example 5-4 A Sliding Block

The block of mass m_2 in Figure 5-10 has been adjusted so that the block of mass m_1 is on the verge of sliding. (*a*) If $m_1 = 7.0$ kg and $m_2 = 5.0$ kg, what is the coefficient of static friction between the table and the block? (*b*) With a slight nudge, the blocks move with acceleration of magnitude a. Find a if the coefficient of kinetic friction between the table and the block is $\mu_k = 0.54$.

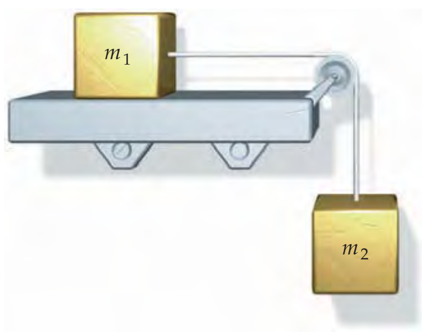

FIGURE 5-10

PICTURE Apply Newton's second law to each block. By neglecting the masses of both the rope and the pulley, and by neglecting friction in the pulley bearing, the tension has the same magnitude throughout the rope, so $T_1 = T_2 = T$. Because the rope remains taut but does not stretch, the accelerations have the same magnitude, so $a_1 = a_2 = a$.

To find the coefficient of static friction μ_s, as requested in Part (*a*), set the force of static friction on m_1 equal to its maximum value $f_{s\,max} = \mu_s F_n$ and set the acceleration equal to zero.

SOLVE

(*a*) 1. Draw a free-body diagram for each block (Figure 5-11). Choose the $+x$ and $+x'$ directions to be the same as the directions of the accelerations of blocks 1 and 2, respectively. That is, the $+x$ direction is to the right and the $+x'$ direction is vertically downward:

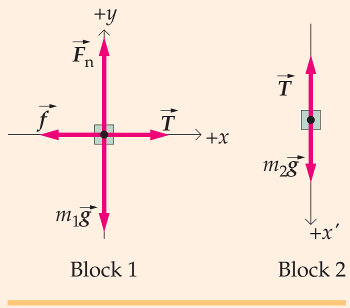

FIGURE 5-11

2. Apply $\Sigma F_y = ma_y$ to block 1 and solve for the normal force. Then solve for the static frictional force.

$\Sigma F_y = m_1 a_{1y}$

$F_n - m_1 g = 0 \Rightarrow F_n = m_1 g$

so

$f_{s\,max} = \mu_s F_n$ so $f_{s\,max} = \mu_s m_1 g$

3. Apply $\Sigma F_x = ma_x$ to block 1 and solve for the frictional force. Then substitute into the step-2 result.

$\Sigma F_x = m_1 a_{1x}$

$T - f_{s\,max} = 0 \Rightarrow T = f_{s\,max}$

so

$T = \mu_s m_1 g$

4. Apply $\Sigma F_x = ma_x$ to block 2 and solve for the tension. Then substitute into the step-3 result.

$\Sigma F_{x'} = m_2 a_{2x'} \Rightarrow m_2 g - T = 0$

so

$T = m_2 g$ and $m_2 g = \mu_s m_1 g$

5. Solve the step-4 result for μ_s.

$$\mu_s = \frac{m_2}{m_1} = \frac{5.0\text{ kg}}{7.0\text{ kg}} = \boxed{0.71}$$

(*b*) 1. During sliding, the frictional force is kinetic and the accelerations have the same magnitude a. Relate the kinetic frictional force f_k to the normal force. The normal force was found in step 2 of Part (*a*).

$f_k = \mu_k F_n$

so

$f_k = \mu_k m_1 g$

$|\vec{a}_1| = a_{1x} = a$ and $|\vec{a}_2| = a_{2x'} = a$

2. Apply $\Sigma F_x = ma_x$ to block 1. Then substitute for the frictional force using the result from step 1 of Part (*b*).

$\Sigma F_x = m_1 a_{1x} \Rightarrow T - f_k = m_1 a$

so

$T - \mu_k m_1 g = m_1 a$

3. Apply $\Sigma F_{x'} = ma_{x'}$ to block 2.

$\Sigma F_{x'} = m_2 a_{2x'} \Rightarrow m_2 g - T = m_2 a$

4. Add the equations in steps 2 and 3 of Part (*b*) and solve for a.

$$a = \frac{m_2 - \mu_k m_1}{m_1 + m_2} g = \boxed{1.0\text{ m/s}^2}$$

CHECK Note that if $m_1 = 0$ the expression for the acceleration reduces to $a = g$ as one would expect.

PRACTICE PROBLEM 5-3 What is the tension in the rope when the blocks are sliding?

Example 5-5 The Runaway Buggy *Context-Rich*

A runaway baby buggy is sliding without friction across a frozen pond toward a hole in the ice (Figure 5-12). You race after the buggy on skates. As you grab it, you and the buggy are moving toward the hole at speed v_0. The kinetic coefficient of friction between your skates and the ice as you turn out the blades to brake is μ_k. D is the distance between the buggy and the hole at the instant you reach the buggy, m_B is the mass of the buggy (including its precious cargo), and m_Y is your mass. (*a*) What is the lowest value of D such that you stop the buggy before it reaches the hole in the ice? (*b*) What force do you exert on the buggy as you slow it?

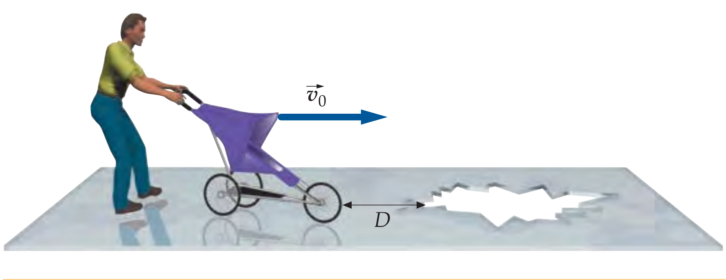

FIGURE 5-12

PICTURE Initially, you and the buggy are moving toward the hole with speed v_0, which we take to be in the $+x$ direction. If you exert a force $\vec{F}_{YB}$ on the buggy, the buggy, in accord with Newton's third law, exerts a force $\vec{F}_{BY}$ on you. Apply Newton's second law to determine the acceleration. After finding the acceleration, find the distance D the buggy travels while slowing to a stop. The lowest value of D is that for which your speed reaches zero just as the buggy reaches the hole.

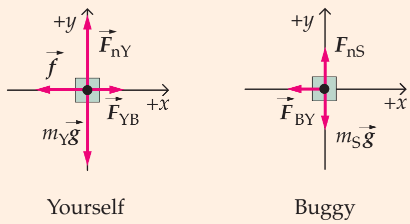

FIGURE 5-13

SOLVE

(*a*) 1. Draw separate free-body diagrams for yourself and the buggy (Figure 5-13).

2. To find the frictional force of the ice on you, you need to first find the normal force of the ice on you:

$$f_{IYk} = \mu_k F_{IYn}$$

3. Apply $\Sigma F_y = ma_y$ to yourself and solve first for the normal force and then for the frictional force:

$$\Sigma F_y = ma_y \Rightarrow F_{IYn} - m_Y g = 0 \quad (a_y = 0)$$

and $f_{IYk} = \mu_k F_{IYn}$ so $f_{IYk} = \mu_k m_Y g$

4. Apply $\Sigma F_x = ma_x$ to yourself. Then substitute in the step-3 result:

$$\Sigma F_x = ma_x \Rightarrow F_{BY} - f_{IYk} = m_Y a_x$$

so $F_{BY} - \mu_k m_Y g = m_Y a_x$

5. Apply $\Sigma F_x = ma_x$ to the buggy:

$$\Sigma F_x = m_B a_x \Rightarrow F_{YB} = m_B a_x$$

6. $\vec{F}_{BY}$ and $\vec{F}_{YB}$ form an N3L force pair, so they are equal in magnitude:

$$F_{BY} = F_{YB}$$

7. Add the step-4 and step-5 results and use $F_{BY} - F_{YB} = 0$ to simplify:

$$-F_{YB} + (F_{BY} - \mu_s m_Y g) = m_B a_x + m_Y a_x$$

$$0 - \mu_s m_Y g = m_B a_x + m_Y a_x$$

8. Solve the step-7 result for a_x:

$$a_x = -\frac{\mu_k m_Y}{m_Y + m_B} g \quad (a_x \text{ is negative, as expected.})$$

9. Substitute the step-8 result into a kinematic equation and solve for the magnitude of the displacement D:

$$v_x^2 = v_{0x}^2 + 2a_x \Delta x \Rightarrow 0 = v_0^2 + 2a_x D$$

so

$$D = \frac{-v_0^2}{2a_x} = \boxed{\left(1 + \frac{m_B}{m_Y}\right)\frac{v_0^2}{2\mu_k g}}$$

(*b*) F_{YB} can be found by combining the results for steps 5 and 8:

$$F_{YB} = m_B |a_x| = \boxed{\frac{\mu_k m_B g}{1 + (m_Y/m_B)}}$$

CHECK For large values of m_B/m_Y, D is large, as expected.

TAKING IT FURTHER The minimum value of D is proportional to v_0^2 and inversely proportional to μ_k. Figure 5-14 shows the stopping distance D versus initial velocity squared for values of m_B/m_Y equal to 0.1, 0.3, and 1.0, with $\mu_k = 0.5$. Note that the larger the mass ratio m_B/m_Y, the greater the distance D needed to stop for a given initial velocity. This is akin to braking to a stop in a car that is pulling a trailer that does not have its own brakes. The mass of the trailer increases the stopping distance for a given speed.

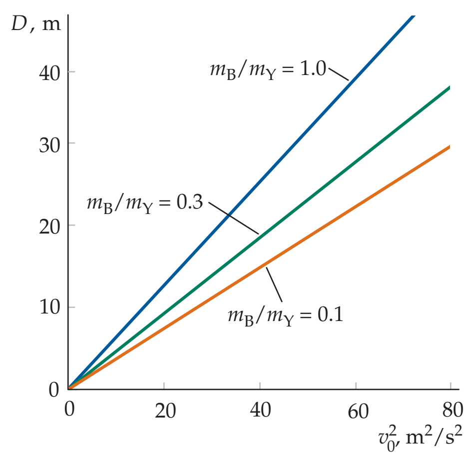

FIGURE 5-14

Example 5-6 Pulling a Child on a Toboggan *Try It Yourself*

A child of mass m_C sits on a toboggan of mass m_T, which in turn sits on a frictionless frozen pond (Figure 5-15). The toboggan is pulled with a horizontal applied force $\vec{F}_{ap}$ as shown. The coefficients of static and sliding friction between the child and toboggan are μ_s and μ_k. (*a*) Find the maximum value of F_{ap} for which the child will not slide relative to the toboggan. (*b*) Find the acceleration of the toboggan and the acceleration of the child when F_{ap} is greater than this value.

FIGURE 5-15

PICTURE The only force accelerating the child forward is the frictional force exerted by the toboggan on the child. In Part (*a*) the challenge is to find F_{ap} when this frictional force is static and maximum. To do this, apply $\sum\vec{F} = m\vec{a}$ to the child and solve for the acceleration when the static frictional force is maximum. Then apply $\sum\vec{F} = m\vec{a}$ to the toboggan and solve for F_{ap}. In Part (*b*), we follow a parallel procedure. However, in Part (*b*) the minimum value of F_{ap} is given and we solve for the acceleration of the toboggan.

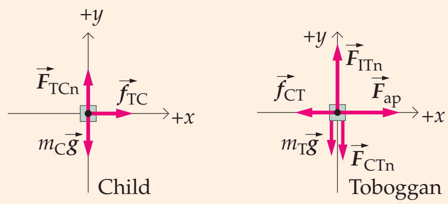

FIGURE 5-16 The force $\vec{F}_{ITn}$ is the normal force exerted by the ice on the toboggan.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
(*a*) 1. Draw one free-body diagram for the child and another for the toboggan (Figure 5-16).	
2. Apply $\sum F_x = ma_x$ to the toboggan:	$\sum F_{Tx} = m_T a_{Tx} \Rightarrow F_{ap} - f_{CTs\,max} = m_T a_{Tx}$
3. Apply $\sum F_y = ma_y$ to the child and solve for the normal force. Then apply $f_{x\,max} = \mu_s F_n$ and solve for the frictional force.	$\sum F_{Cy} = m_C a_y \Rightarrow F_{TCn} - m_C g = 0$ so $F_{TCn} = m_C g$ $f_{s\,max} = \mu F_n \Rightarrow f_{TCs\,max} = \mu_s F_{TCn}$ so $f_{TCs\,max} = \mu_s m_C g$
4. Apply $\sum F_x = ma_x$ to the child and solve for the acceleration.	$\sum F_{Cx} = m_C a_{Cx} \Rightarrow f_{TCs\,max} = m_C a_{Cx}$ so $\mu_s m_C g = m_C a_{Cx} \Rightarrow a_{Cx} = \mu_s g$
5. Equate the magnitudes of the forces in each N3L force pair appearing in the two free-body diagrams. In addition, express the relation between the accelerations due to the nonslipping constraint.	$F_{TCn} = F_{CTn}$ and $f_{TCs\,max} = f_{CTs\,max}$ and $a_{Cx} = a_{Tx} = a_x$
6. Substitute the step-4 and step-5 results into the step-2 result and solve for F_{ap}.	$F_{ap} - \mu_s m_C g = m_T \mu_s g$ so $F_{ap} = \boxed{(m_C + m_T)\mu_s g}$
(*b*) 1. Equate the magnitudes of each N3L force pair and express the relation between the accelerations if the child is slipping on the toboggan.	$F_{TCn} = F_{CTn} = F_n$ and $f_{TCk} = f_{CTk} = f_k$ and $a_{Cx} < a_{Tx}$
2. Solve for the magnitude of the kinetic frictional force using the result from step 3 of Part (*a*) for the normal force.	$f_k = \mu_k F_n$ so $f_k = \mu_k m_C g$
3. Apply $\sum F_x = ma_x$ to the child and solve for *her acceleration*.	$\sum F_{Cx} = m_C a_{Cx} \Rightarrow f_k = m_C a_{Cx}$ so $\mu_k m_C g = m_C a_{Cx} \Rightarrow a_{Cx} = \boxed{\mu_k g}$
4. Apply $\sum F_x = ma_x$ to the toboggan. Using the result from step 2 of Part (*b*), solve for *its acceleration*.	$\sum F_{Tx} = m_T a_{Tx} \Rightarrow F_{ap} - f_k = m_T a_{Tx}$ so $F_{ap} - \mu_k m_C g = m_T a_{Tx} \Rightarrow a_{Tx} = \boxed{\dfrac{F_{ap} - \mu_k m_C g}{m_T}}$

CHECK The Part (*a*) result is what we expect if the child does not slip on the toboggan. If we model the child and the toboggan as a single particle and apply Newton's second law to it, we obtain $F_{ap} = (m_C + m_T)a_x$. If we substitute $\mu_s(m_C + m_T)g$ (our Part-(*a*) step-6 result) for F_{ap}, we get $\mu_s(m_C + m_T)g = (m_C + m_T)a_x$. Dividing both sides by the sum of the masses gives $a_x = \mu_s g$, our Part-(*a*) step-3 result. Thus, our Part (*a*) effort is consistent with modeling the sled and child as a single particle.

TAKING IT FURTHER In this example, the frictional force does not oppose the motion of the child, it causes it. Without friction, the girl would slip back relative to the toboggan. However, even though the child moves, or tends to move, backward (leftward) *relative to the toboggan*, she moves forward *relative to the ice*. Friction forces oppose relative motion, or tendency toward relative motion, between two surfaces in contact. In addition, relative to the child, the toboggan slips, or tends to slip, forward. The friction force on the toboggan is directed rearward, opposing this slipping forward, or tendency toward slipping forward.

! Note that frictional forces *do not always* oppose motion. However, frictional forces between contacting surfaces *do always* oppose relative motion, or the tendency toward relative motion, between the two contacting surfaces.

FRICTION, CARS, AND ANTILOCK BRAKES

Figure 5-17 shows the forces acting on a front-wheel-drive car that is just starting to move from rest on a horizontal road. The gravitational force F_g on the car is balanced by the normal forces F_n and F_n' exerted on the tires. To start the car moving, the engine delivers power to the axle that makes the front wheels start to rotate. If the road were perfectly frictionless, the front wheels would merely spin. When friction is present, the frictional force exerted by the road on the tires is in the forward direction, opposing the tendency of the tire surface to slip backward. This frictional force enables the acceleration needed for the car to start moving forward. If the power delivered by the engine is not so great that the surface of the tire slips on the surface of the road, the wheels will roll without slipping and that part of the tire tread touching the road remains at rest relative to the road. (The part in contact with the road continuously changes as the tire rolls.) The friction between the road and the tire tread is then that of static friction. The largest frictional force that the tire can exert on the road (and that the road can exert on the tire) is $\mu_s F_n$.

For a car moving in a straight line with speed v relative to the road, the center of each of its wheels also moves with speed v, as shown in Figure 5-18. If a wheel is rolling without slipping, its top is moving faster than v, whereas its bottom is moving slower than v. However, *relative to the car*, each point on the perimeter of the wheel moves in a circle with the same speed v. Moreover, the speed of the point on the tire momentarily in contact with the ground is zero *relative to the ground*. (Otherwise, the tire would be skidding along the road.)

If the engine supplies excessive power, the tire will slip and the wheels will spin. Then the force that accelerates the car is the force of kinetic friction, which is less than the maximum force of static friction. If we are stuck on ice or snow, our chances of getting free are better if we avoid spinning the wheels by using a light touch on the accelerator pedal. Similarly, when braking a car to a stop, the force exerted by the road on the tires may be either static friction or kinetic friction, depending on how hard the brakes are applied. If the brakes are applied so hard that the wheels lock, the tires will skid along the road and the stopping force will be that of kinetic friction. If the brakes are applied less forcefully, so that no slipping occurs between the tires and the road, the stopping force will be that of static friction.

When wheels do lock and tires skid, two undesirable things happen. The minimum stopping distance is increased and the ability to control the direction of the motion of the car is greatly diminished. Obviously, this loss of directional control can have dire consequences. Antilock braking systems (ABS) in cars are designed to prevent the wheels from locking even if the brakes are applied hard. These systems have wheel-speed sensors. If the control unit senses that a wheel is about to lock, the module signals the brake pressure modulator to drop, hold, and then restore the pressure to that wheel up to 15 times per second. This varying of pressure is much like "pumping" the brake, but with the ABS system, the wheel that is locking is the only one being pumped. This is called *threshold braking*. With threshold braking, maximum friction for stopping is maintained.

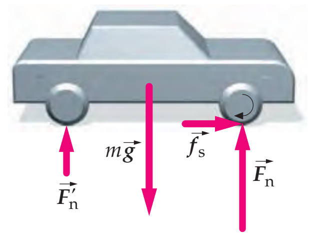

FIGURE 5-17 Forces acting on a car with front-wheel drive that is accelerating from rest. The normal force $\vec{F}_n$ on the front tires is usually larger than the normal force $\vec{F}_n'$ on the rear tires because typically the engine of the car is mounted near the front of the car. There is no drag force from the air shown because the car is just starting to move. There would be a rearward-directed rolling frictional force on all wheels, but that force has been ignored.

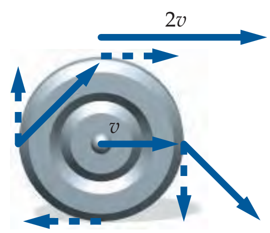

FIGURE 5-18 In this figure, dashed lines represent velocities relative to the body of the car; solid lines represent velocities relative to the ground.

Example 5-7 The Effect of Antilock Brakes

A car is traveling at 30 m/s along a horizontal road. The coefficients of friction between the road and the tires are $\mu_s = 0.50$ and $\mu_k = 0.40$. How far does the car travel before stopping if (*a*) the car is braked with an antilock braking system so that threshold braking is sustained, and (*b*) the car is braked hard with no antilock braking system so that the wheels lock? (*Note:* Skidding heats up the tires and the coefficients of friction vary with changes in temperature. These temperature effects are neglected in this example.)

PICTURE The force that stops a car when it brakes without skidding is the force of static friction exerted by the road on the tires (Figure 5-19). We use Newton's second law to solve for the frictional force and the car's acceleration. Kinematics is then used to find the stopping distance.

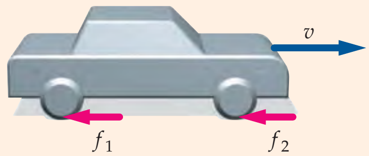

FIGURE 5-19

SOLVE

(*a*) 1. Draw a free-body diagram for the car (Figure 5-20). Treat all four wheels as if they were a single point of contact with the ground. Assume further that the brakes are applied to all four wheels. The $\vec{f}$ in the free-body diagram is the total of the frictional forces on individual wheels:

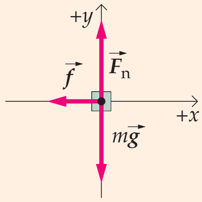

FIGURE 5-20

2. Assuming that the acceleration is constant, we use Equation 2-15 to relate the stopping distance Δx to the initial velocity v_{0x}:

$$v_x^2 = v_{0x}^2 + 2a_x\,\Delta x$$

When $v_x = 0$, $\Delta x = -\dfrac{v_{0x}^2}{2a_x}$

3. Apply $\Sigma F_y = ma_y$ to the car and solve for the normal force. Then apply $f_{x\max} = \mu_s F_n$ and solve for the frictional force:

$$\Sigma F_y = ma_y \;\Rightarrow\; F_n - mg = 0 \quad \text{so} \quad F_n = mg$$

$$f_{s\max} = \mu_s F_n \quad \text{so} \quad f_{s\max} = \mu_s mg$$

4. Apply $\Sigma F_x = ma_x$ to the car and solve for the acceleration:

$$\Sigma F_x = ma_x \;\Rightarrow\; -f_{s\max} = ma_x$$

Substituting $\mu_s mg$ for $f_{s\max}$ gives $-\mu_s mg = ma_x \;\Rightarrow\; a_x = -\mu_s g$

5. Substituting for a_x in the equation for Δx in step 2 gives the stopping distance:

$$\Delta x = -\frac{v_{0x}^2}{2a_x} = \frac{v_{0x}^2}{2\mu_s g} = \frac{(30\text{ m/s})^2}{2(0.50)(9.81\text{ m/s}^2)} = \boxed{0.92 \times 10^2\text{ m}}$$

(*b*) 1. When the wheels lock, the force exerted by the road on the car is that of kinetic friction. Using reasoning similar to that in Part (*a*), we obtain for the acceleration:

$$a_x = -\mu_k g$$

2. The stopping distance is then:

$$\Delta x = -\frac{v_{0x}^2}{2a_x} = \frac{v_{0x}^2}{2\mu_k g} = \frac{(30\text{ m/s})^2}{2(0.40)(9.81\text{ m/s}^2)} = \boxed{1.1 \times 10^2\text{ m}}$$

CHECK The calculated displacements are both positive as expected. In addition, the antilock brake system significantly shortens the stopping distance of the car as expected.

TAKING IT FURTHER Notice that the stopping distance is more than 20% greater when the wheels are locked. Also note that the stopping distance is independent of the car's mass—the stopping distance is the same for a subcompact car as for a large truck—provided the coefficients of friction are the same. The tires heat up dramatically when skidding occurs. This produces a change in μ_k that was not taken into account in this solution.

5-2 DRAG FORCES

When an object moves through a fluid such as air or water, the fluid exerts a **drag force** or retarding force that opposes the motion of the object. The drag force depends on the shape of the object, the properties of the fluid, and the speed of the object relative to the fluid. Unlike ordinary friction, the drag force increases as the speed of the object increases. At very low speeds, the drag force is approximately proportional to the speed of the object; at higher speeds, it is more nearly proportional to the square of the speed.

Consider an object dropped from rest and falling under the influence of the force of gravity, which we assume to be constant. The magnitude of the drag force is

$$F_d = bv^n \qquad \text{5-5}$$

DRAG FORCE RELATION

where b is a constant.

The drag force on the parachute slows this dragster. *(IHRA/Live Nation.)*

As shown in Figure 5-21, the forces acting on the object are a constant downward force mg and an upward force bv^n. If we take downward as the $+y$ direction, we obtain from Newton's second law

$$mg - bv^n = ma_y \tag{5-6}$$

Solving this equation for the acceleration gives:

$$a_y = g - \frac{b}{m}v^n \tag{5-7}$$

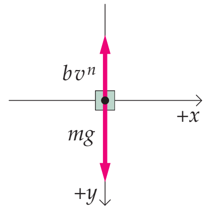

FIGURE 5-21 Free-body diagram showing forces on an object falling through the air.

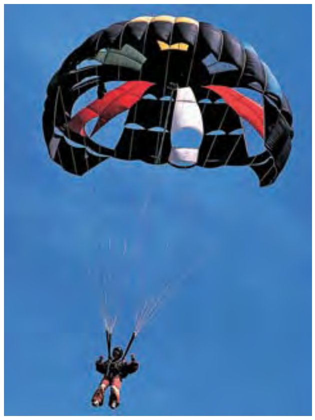
The speed is zero at $t = 0$ (the instant the object is released), so at $t = 0$ the drag force is zero and the acceleration is g downward. As the speed of the object increases, the drag force increases so the acceleration decreases. Eventually, the speed is great enough for the magnitude of the drag force bv^n to approach the force of gravity mg. In this limit, the acceleration approaches zero and the speed approaches the **terminal speed** v_T. At terminal speed, the drag force balances the weight force and the acceleration is zero. Setting v equal to v_T and a_y equal to zero in Equation 5-6, we obtain

$$bv_T^n = mg$$

Solving for the terminal speed, we get

$$v_T = \left(\frac{mg}{b}\right)^{1/n} \tag{5-8}$$

The larger the constant b, the smaller the terminal speed. Cars are designed to minimize b to reduce the effect of wind resistance. A parachute, on the other hand, is designed to maximize b so that the terminal speed will be small. For example, the terminal speed of a skydiver before release of the parachute is about 200 km/h, which is about 60 m/s. When the parachute opens, the drag force rapidly increases, becoming greater than the force of gravity. As a result, the skydiver experiences an upward acceleration while falling; that is, the speed of the descending skydiver decreases. As the speed of the skydiver decreases, the drag force decreases and the speed approaches a new terminal speed of about 20 km/h.



(Stuart Williams/Dembinsky Photo Associates.)

(Joe McBride/Stone.)

Example 5-8 Terminal Speed

A 64.0-kg skydiver falls with a terminal speed of 180 km/h with her arms and legs outspread. (*a*) What is the magnitude of the upward drag force F_d on the skydiver? (*b*) If the drag force is equal to bv^2, what is the value of b?

PICTURE We use Newton's second law to solve for the drag force in Part (*a*), and then substitute in the appropriate values to find b in Part (*b*).

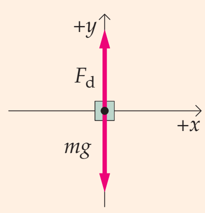


FIGURE 5-22

SOLVE

(*a*) 1. Draw a free-body diagram (Figure 5-22).

2. Apply $\Sigma F_y = ma_y$. Because the skydiver is moving with constant velocity, the acceleration is zero:

$$\Sigma F_y = ma_y \Rightarrow F_d - mg = 0$$

so $F_d = mg = (64.0\text{ kg})(9.81\text{ N/kg}) = \boxed{628\text{ N}}$

(*b*) 1. To find b we set $F_d = bv^2$:

$$F_d = mg = bv^2$$

$$\text{so} \quad b = \frac{mg}{v^2}$$

2. Convert the speed to m/s, then calculate b:

$$180\text{ km/h} = \frac{180\text{ km}}{1\text{ h}} \times \frac{1\text{ h}}{3.6\text{ ks}} = 50.0\text{ m/s}$$

$$b = \frac{(64.0\text{ kg})(9.81\text{ m/s}^2)}{(50.0\text{ m/s})^2} = \boxed{0.251\text{ kg/m}}$$

CHECK The units obtained for b are kg/m. To check that these units are correct, we multiply kg/m by $(\text{m/s})^2$ to get kg m/s^2. These units are units of force (because one newton is defined as a kg m/s)^2. We expected these units to be units of force because the drag force is given by bv^2.

TAKING IT FURTHER The conversion factor 1 h/3.6 ks appears in the last step of the solution. This conversion factor is exact because 1 h is exactly equal to 3600 s. Consequently, in converting her speed from km/h to m/s, three-figure accuracy is maintained. This is so even though we did not write the conversion factor as 1.00 h/3.60 ks.

5-3 MOTION ALONG A CURVED PATH

Objects often do not move in a straight line: a car rounding a curve is an example, as is a satellite orbiting Earth.

Consider a satellite moving in a circular orbit around Earth as shown in Figure 5-23. At an altitude of 200 km, the gravitational force on the satellite is just slightly less than at Earth's surface. Why does the satellite not fall toward Earth? Actually, the satellite does "fall." But because the surface of Earth is curved, the satellite does not get closer to the surface of Earth. If the satellite were not accelerating, it would move from point P_1 to P_2 in some time t. Instead, it arrives at point P_2' on its circular orbit. In a sense, the satellite "falls" the distance h shown in Figure 5-23. If t is small, P_2 and P_2' are nearly on a radial line. In that case, we can calculate h from the right triangle of sides vt, r, and $r + h$: Because $r + h$ is the hypotenuse of the right triangle, the Pythagorean theorem gives:

$$(r + h)^2 = (vt)^2 + r^2$$
$$r^2 + 2hr + h^2 = v^2t^2 + r^2$$

or

$$h(2r + h) = v^2t^2$$

For very short times, h will be much less than r, so we can neglect h compared with $2r$. Then

$$2rh \approx v^2t^2$$

or

$$h \approx \frac{1}{2}\left(\frac{v^2}{r}\right)t^2$$

Comparing this with the constant-acceleration expression $h = \frac{1}{2}at^2$, we see that the magnitude of the acceleration of the satellite is

$$a = \frac{v^2}{r}$$

which is the expression for centripetal acceleration established in Chapter 3. From Figure 3-24, we see this acceleration is directed toward the center of the circular orbit. By applying Newton's second law along the direction of the acceleration

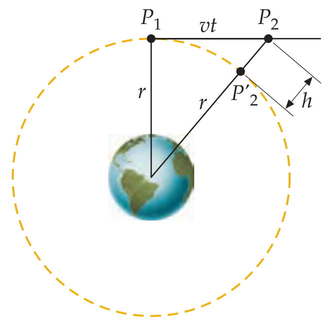

FIGURE 5-23 The satellite is moving with speed v in a circular orbit of radius r about Earth. If the satellite did not accelerate toward Earth, it would move from point P_1 to P_2 along a straight line. Because of its acceleration, it instead falls a distance h. For a sufficiently short time t, the acceleration is essentially constant, so $h = \frac{1}{2}at^2 = \frac{1}{2}(v^2/r)t^2$.

See Math Tutorial for more information on Trigonometry

vector, we find that the magnitude of the net force causing the acceleration is related to the magnitude of the acceleration by:

$$F_{\text{net}} = m\frac{v^2}{r}$$

Figure 5-24*a* shows a ball on the end of a string, the other end of which is attached to a fixed support. The ball is traveling in a horizontal circle of radius r at constant speed v. Consequently, the acceleration of the ball has magnitude v^2/r.

As we saw in Chapter 3, a particle moving with constant speed v in a circle of radius r (Figure 5-24*a*) has an acceleration of magnitude $a = v^2/r$ directed toward the center of the circle (the centripetal direction). The net force acting on an object is always in the same direction as the acceleration vector, so the net force (Figure 5-24*b*) on an object moving in a circle at constant speed is also in the centripetal direction. A net force in the centripetal direction is sometimes referred to as the **centripetal force.** It may be due to a string, spring, or other contact force such as a normal or frictional force; it may be an action-at-a-distance type of force such as a gravitational force; or it may be any combination of these. It is always directed inward—toward the center of curvature of the path.

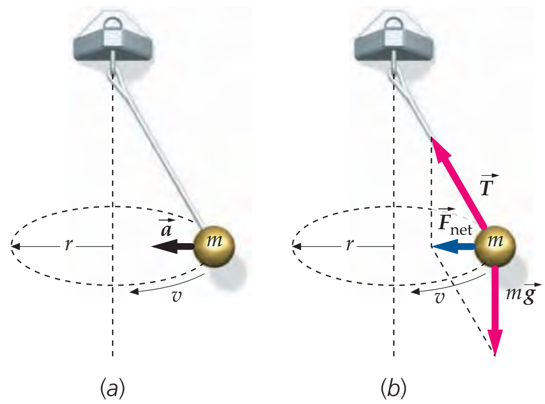

FIGURE 5-24 A ball suspended from a string moves in a horizontal circle at constant speed. (*a*) The acceleration vector is in the centripetal direction (toward the center of the circular path). Acceleration in the centripetal direction is called centripetal acceleration. (*b*) Two forces act on the ball, the tension force exerted by the string and the gravitational force. These two forces sum so that the net force is in the centripetal direction. A net force in the centripetal direction is sometimes referred to as the centripetal force.

! The centripetal force is not actually a force. It is merely a name for the component of net force toward the center of curvature of the path. Like the net force, the centripetal force does not belong on a free-body diagram. Only actual forces belong on free-body diagrams.

PROBLEM-SOLVING STRATEGY

Solving Motion Along A Curved Path Problems

PICTURE Remember that you should never label a force as a centripetal force on a free-body diagram. Instead you should label a force as a tension force, or a normal force, or a gravitational force, and so forth.

SOLVE

1. Draw a free-body diagram of the object. Include coordinate axes with the origin at a point of interest on the path. Draw one coordinate axis in the tangential direction (the direction of motion) and a second in the centripetal direction.
2. Apply $\sum F_c = ma_c$ and $\sum F_t = ma_t$ (Newton's second law in component form).
3. Substitute $a_c = v^2/r$ and $a_t = dv/dt$, where v is the speed.
4. If the object moves in a circle of radius r with constant speed v, use $v = 2\pi r/T$, where T is the time for one revolution.

CHECK Make sure that your answers are in accordance with the fact that the direction of the centripetal acceleration is always toward the center of curvature and perpendicular to the direction of the velocity vector.

Example 5-9 Swinging a Pail

You swing a pail containing mass m of water in a vertical circle of radius r (Figure 5-25). If the speed is v_{top} at the top of the circle, find (*a*) the force F_{PW} exerted by the pail on the water at the top of the circle, and (*b*) the minimum value of v_{top} for the water to remain in the pail. (*c*) What is the force exerted by the pail on the water at the bottom of the circle, where the speed of the pail is v_{bot}?

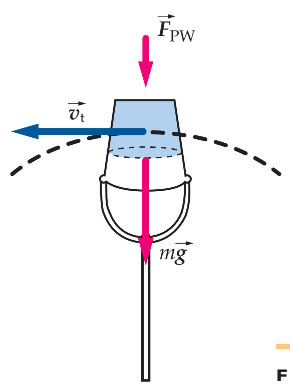

FIGURE 5-25

PICTURE When the bucket is at the top of its circle, both the force of gravity on the water and the contact force of the pail on the water are in the centripetal direction (downward). At the bottom of the circle, the contact force of the pail on the water must be greater than the force of gravity on the water to provide a net force in the centripetal direction (upward). We can apply Newton's second law to find the force exerted by the pail on the water at these points. Because the water moves in a circular path, it always has an acceleration component equal to v^2/r toward the center of the circle.

SOLVE

(*a*) 1. Draw free-body diagrams for the water at the top and bottom of the circle (Figure 5-26). Choose the $+r$ direction to be toward the center of the circle in each case.

2. Apply $\Sigma F_r = ma_r$ to the water as it passes through the top of the circle with speed v_{top}. Solve for the force F_{PW} exerted by the pail on the water:

$$\Sigma F_r = ma_r$$

$$F_{PW} + mg = m\frac{v_{top}^2}{r} \Rightarrow F_{PW} = \boxed{m\left(\frac{v_{top}^2}{r} - g\right)}$$

(*b*) The pail can push on the water, but not pull on it. The minimum force it can exert on the water is zero. Set $F_{PW} = 0$ and solve for the minimum speed:

$$0 = m\left(\frac{v_{top,min}^2}{r} - g\right) \Rightarrow v_{top,min} = \boxed{\sqrt{rg}}$$

(*c*) Apply $\Sigma F_r = ma_r$ to the water as it passes through the bottom of its path with speed v_{bot}. Solve for F_{PW}:

$$\Sigma F_r = ma_r$$

$$F_{PW} - mg = \frac{mv_{bot}^2}{r} \Rightarrow F_{PW} = \boxed{m\left(\frac{v_{bot}^2}{r} + g\right)}$$

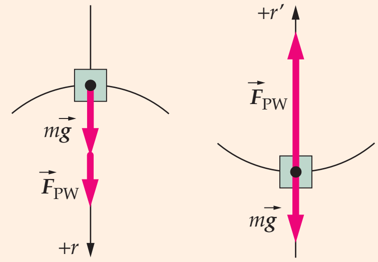

FIGURE 5-26

CHECK In the Part (*c*) result, when $v_{bot} = 0$, $F_{PW} = mg$. This is as expected.

TAKING IT FURTHER Note that there is no arrow labeled "centripetal force" in the free-body diagram. Centripetal force is not a kind of force exerted by some agent; it is just the name for the component of the resultant force in the centripetal direction.

PRACTICE PROBLEM 5-4 Estimate (*a*) the minimum speed at the top of the circle and (*b*) the maximum period of revolution that will keep you from getting wet if you swing a pail of water in a vertical circle at constant speed.

Example 5-10 Playing Ape

You step off the limb of a tree clinging to a 30-m-long vine that is attached to another limb at the same height and 30-m distant. Assuming air resistance is negligible, how fast are you gaining speed at the instant the vine makes an angle of 25° with the vertical during your descent?

PICTURE Model this situation as a rope of negligible mass with one end attached to a limb and the other to a particle of mass m. Apply Newton's second law to the mass. The tangential acceleration is the rate of change of speed, so solve for the tangential acceleration.

SOLVE

1. Sketch a free-body diagram of the object (Figure 5-27). Let the $+r$ direction be toward the center of the path and the $+t$ direction be in the direction of the velocity:

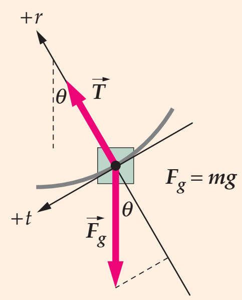

FIGURE 5-27 The $+t$ direction is in the direction of the velocity vector.

2. Apply $\Sigma F_t = ma_t$ and use the free-body diagram to find expressions for the force components:

$$\Sigma F_t = ma_t$$
$$T_t + F_{gt} = ma_t$$
$$0 + mg\sin\theta = ma_t$$

3. Solve for a_t:

$$a_t = g\sin\theta = (9.81\ \mathrm{m/s^2})\sin 25° = \boxed{4.1\ \mathrm{m/s}}$$

CHECK You expect your rate of change of speed to be positive because your speed would be increasing as long as you are descending. In addition, you expect that you will not be gaining speed at a rate equal to or greater than $g = 9.81\ \mathrm{m/s^2}$. The step-3 result meets these expectations.

PRACTICE PROBLEM 5-5 What will your rate of change of speed be at the instant the vine is vertical and you are passing through the lowest point in your arc?

Example 5-11 Tetherball — *Try It Yourself*

A tetherball of mass m is suspended from a length of rope and travels at constant speed v in a horizontal circle of radius r as shown. The rope makes an angle θ with the vertical. Find (*a*) the direction of the acceleration, (*b*) the tension in the rope, and (*c*) the speed of the ball.

PICTURE Two forces act on the ball; the gravitational force and the tension in the rope (Figure 5-28). The vector sum of these forces is in the direction of the acceleration vector.

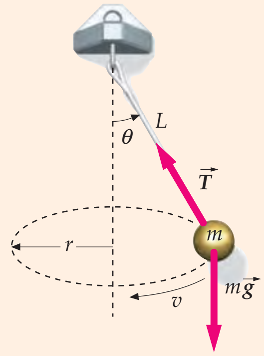

FIGURE 5-28

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
(*a*) 1. The ball is moving in a horizontal circle at constant speed. The acceleration is in the centripetal direction.	The acceleration is horizontal and directed from the ball toward the center of the circle it is moving in.
(*b*) 1. Draw a free-body diagram for the ball (Figure 5-29). Choose as the $+x$ direction the direction of the ball's acceleration (toward the center of the circular path).	
2. Apply $\Sigma F_y = ma_y$ to the ball and solve for the tension T.	$\Sigma F_y = ma_y \Rightarrow T\cos\theta - mg = 0$ so $\boxed{T = \dfrac{mg}{\cos\theta}}$
(*c*) 1. Apply $\Sigma F_x = ma_x$ to the ball.	$\Sigma F_x = ma_x \Rightarrow T\sin\theta = m\dfrac{v^2}{r}$
2. Substitute $mg/\cos\theta$ for T and solve for v.	$\dfrac{mg}{\cos\theta}\sin\theta = m\dfrac{v^2}{r} \Rightarrow g\tan\theta = \dfrac{v^2}{r}$ so $v = \boxed{\sqrt{rg\tan\theta}}$

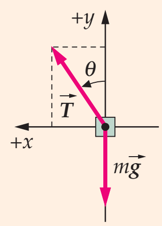

FIGURE 5-29

CHECK As $\theta \rightarrow 90°$, $\cos\theta \rightarrow 0$ and $\tan\theta \rightarrow \infty$. In the results for Parts (*b*) and (*c*), the expressions T and v both approach infinity as $\theta \rightarrow 90°$. This is what anyone who has played tetherball would expect. For θ to even approach 90°, the ball would have to move very fast.

TAKING IT FURTHER An object attached to a string and moving in a horizontal circle so that the string makes an angle θ with the vertical is called a *conical pendulum*.

UNBANKED AND BANKED CURVES

When a car rounds a curve on a horizontal road, the force components in both the centripetal and the tangential (forward) directions are provided by the force of static friction exerted by the road on the tires of the car. If the car travels at constant speed, then the forward component of the frictional force is balanced by the rearward-directed forces of air drag and rolling friction. The forward component of the static frictional force remains zero if air drag and rolling friction are both negligible and if the speed of the car remains constant.

If a curved road is not horizontal but banked, the normal force of the road will have a component in the centripetal direction. The *banking angle* is usually chosen so that no friction is needed for a car to complete the curve at the specified speed.

As a car rounds the curve, the tire is distorted by the frictional force exerted by the road. *(David Allio/Icon SMI/Corbis.)*

In 1993 a descent probe containing instruments went deep into the Jovian atmosphere—to the surface of Jupiter. The fully assembled probe was tested at accelerations up to 200*g*s in this large centrifuge at Sandia National Laboratories. *(Sandia National Laboratory.)*

Example 5-12 Rounding a Banked Curve

A curve of radius 30.0 m is banked at an angle θ. That is, the normal to the road surface makes an angle of 30.0° with the vertical. Find θ such that a car can round the curve at 40.0 km/h even if the road is coated with ice, making the road essentially frictionless.

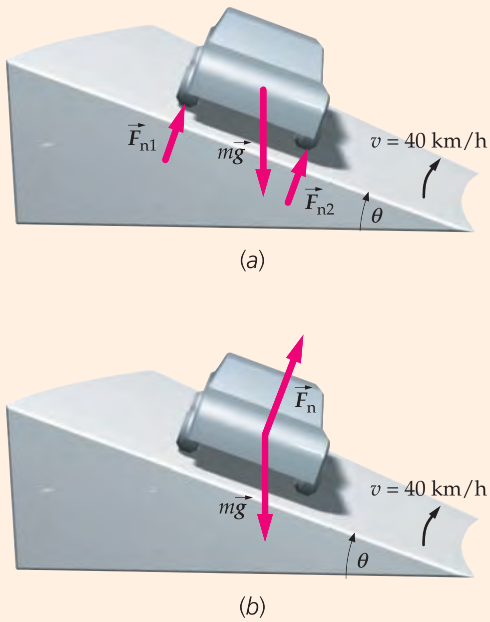

FIGURE 5-30

PICTURE In this case, only two forces act on the car: the force of gravity and the normal force $\vec{F}_n$ (Figure 5-30). Because the road is banked, the normal force has a horizontal component that causes the car's centripetal acceleration. The vector sum of the two force vectors is in the direction of the acceleration. We can apply Newton's second law and then solve for θ.

SOLVE

1. Draw a free-body diagram for the car (Figure 5-31)

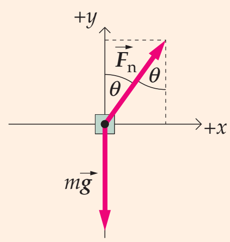

FIGURE 5-31

2. Apply $\Sigma F_y = ma_y$ to the car:

$$\Sigma F_y = ma_y$$
$$F_n \cos\theta - mg = 0 \;\Rightarrow\; F_n \cos\theta = mg$$

3. Apply $\Sigma F_x = ma_x$ to the car.

$$\Sigma F_x = ma_x \;\Rightarrow\; F_n \sin\theta = m\frac{v^2}{r}$$

4. Divide the step-3 result by the step-2 result, then solve for θ:

$$\frac{\sin\theta}{\cos\theta} = \frac{mv^2}{rmg} \;\Rightarrow\; \tan\theta = \frac{v^2}{rg}$$
$$\theta = \tan^{-1}\frac{[(40.0\text{ km/h})(1\text{ h}/3.6\text{ ks})]^2}{(30.0\text{ m})(9.81\text{ m/s}^2)}$$
$$= \boxed{22.8°}$$

CHECK The banking angle is 22.8°. It is plausible because 30.0 m is a very small radius for a highway turn. For comparison, the turns at the Daytona International Speedway have a radius of 300 m and a banking angle of 31°.

TAKING IT FURTHER The banking angle θ depends on v and r, but not the mass m; θ increases with increasing v, and decreases with increasing r. When the banking angle, speed, and radius satisfy $\tan\theta = v^2/rg$, the car rounds the curve smoothly, with no tendency to slide either inward or outward. If the car speed is greater than $\sqrt{rg\tan\theta}$, the road must exert a static frictional force down the incline if the car is stay on the road. This force has a horizontal component, which provides the additional centripetal force needed to keep r from increasing. If the car speed is less than $\sqrt{rg\tan\theta}$, the road must exert a frictional force up the incline for the car is to stay on the road.

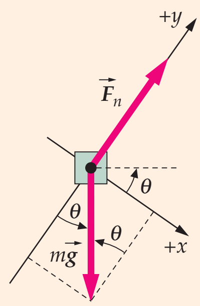

FIGURE 5-32

ALTERNATIVE SOLUTION In the preceding solution, we followed the guidelines to choose one of the coordinate axis directions to be the direction of the acceleration vector, the centripetal direction. However, the solution is no more difficult if we choose one of the axis directions to be down the incline. This choice is taken in the following solution.

1. Draw a free-body diagram for the car (Figure 5-32). The $+x$ direction is down the incline and the $+y$ direction is the normal direction.

2. Apply $\Sigma F_x = ma_x$ to the car:

$$\Sigma F_x = ma_x \;\Rightarrow\; mg\sin\theta = ma_x$$

3. Draw a sketch and use trigonometry to obtain an expression for a_x in terms of a and θ (Figure 5-33):

$$a_x = a\cos\theta$$

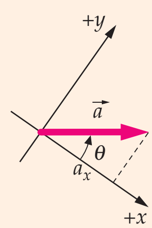

FIGURE 5-33

4. Substitute the step-3 result into the step-2 result. Then substitute v^2/r for a and solve for θ:

$$mg\sin\theta = ma\cos\theta$$
$$g\sin\theta = \frac{v^2}{r}\cos\theta$$
$$\tan\theta = \frac{v^2}{rg} \;\Rightarrow\; \theta = \boxed{\tan^{-1}\frac{v^2}{rg}}$$

PRACTICE PROBLEM 5-6 Find the component of the acceleration normal to the road surface.

Example 5-13 A Road Test

Context-Rich

You have a summer job with NASCAR as part of an automobile tire testing team. You are testing a new model of racing tires to see whether or not the coefficient of static friction between the tires and dry concrete pavement is 0.90 as claimed by the manufacturer. In a skidpad test, a racecar is able to travel at constant speed in a circle of radius 45.7 m in 15.2 s without skidding. Assume air drag and rolling friction are negligible and assume that the road surface is horizontal. In a skidpad test a car travels in a circle on a flat, horizontal surface (a skidpad) at the maximum possible speed v without skidding. (*a*) What was its speed v? (*b*) What was the acceleration? (*c*) What was the minimum value for the coefficient of static friction between the tires and the road?

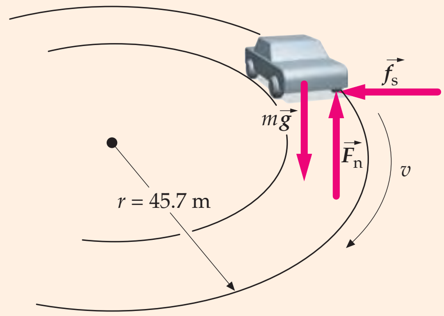

FIGURE 5-34

PICTURE Figure 5-34 shows the forces acting on the car. The normal force $\vec{F}_n$ balances the downward force due to gravity $\vec{F}_g = m\vec{g}$. The horizontal force is the force of static friction, which provides the centripetal acceleration. The faster the car travels, the greater the centripetal acceleration. The speed can be found from the circumference of the circle and the period T. This speed puts a lower limit on the maximum value of the coefficient of static friction.

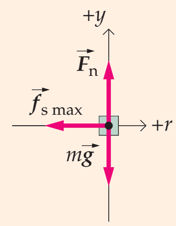

FIGURE 5-35

SOLVE

(*a*) 1. Draw a free-body diagram for the car (Figure 5-35). The $+r$ direction is away from the center of curvature.

2. The speed v is the circumference of the circle divided by the time required for one revolution:

$$v = \frac{2\pi r}{T} = \frac{2\pi(45.7\text{ m})}{15.2\text{ s}} = \boxed{18.9\text{ m/s}}$$

(*b*) Use v to calculate the centripetal and tangential accelerations:

$$a_c = \frac{v^2}{r} = \frac{(18.9\text{ m/s})^2}{(45.7\text{ m})} = \boxed{7.81\text{ m/s}^2}$$

$$a_t = \frac{dv}{dt} = \boxed{0}$$

The acceleration is 7.81 m/s² in the centripetal direction.

(*c*) 1. Apply $\sum F_y = ma_y$ to the car. Solve for the normal and maximum frictional force:

$$\sum F_y = ma_y$$

$$F_n - mg = 0 \quad \text{so} \quad F_n = mg$$

$$\text{and} \quad f_{s\,max} = \mu_s F_n = \mu_s mg$$

2. Apply $\sum F_r = ma_r$ to the car:

$$\sum F_r = ma_r$$

$$-f_{s\,max} = m\left(-\frac{v^2}{r}\right) \Rightarrow f_{s\,max} = m\frac{v^2}{r}$$

3. Substitute from step 1 of Part (*c*) and solve for μ_s:

$$\mu_s mg = m\frac{v^2}{r} \Rightarrow \mu_s g = \frac{v^2}{r}$$

$$\mu_s = \frac{v^2}{rg} = \frac{(18.9\text{ m/s})^2}{(45.7\text{ m})(9.81\text{ m/s}^2)} = \boxed{0.796}$$

CHECK If μ_s were equal to 1.00, the inward force would be equal to mg and the centripetal acceleration would be g. Here μ_s is about 0.80 and the centripetal acceleration is about $0.80g$.

TAKING IT FURTHER Does the result of the skidpad test support the manufacturer's claim that the coefficient of static friction is 0.90? It does support the manufacturer's claim. In calculating the magnitude of the frictional force, we accounted for the frictional force needed to accelerate the car toward the center of curvature, but we neglected to account for the frictional force required to counter the effects of air drag and rolling friction. A speed of 18.9 m/s equals 42.3 mi/h, a speed at which air drag is definitely significant.

* 5-4 NUMERICAL INTEGRATION: EULER'S METHOD

If a particle moves under the influence of a *constant* force, its acceleration is constant and we can find its velocity and position from the constant-acceleration kinematic formulas in Chapter 2. But consider a particle moving through space where the force on it, and therefore its acceleration, depends on its position and its velocity. The position, velocity, and acceleration of the particle at one instant determine the position and velocity the next instant, which then determines its acceleration at that instant. The actual position, velocity, and acceleration of an object all change continuously with time. We can approximate this by replacing the continuous time variations with small time steps of duration Δt. The simplest approximation is to assume constant acceleration during each step. This approximation is called **Euler's method.** If the time interval is sufficiently short, the change in acceleration during the interval will be small and can be neglected.

Let x_0, v_{0x}, and a_{0x} be the known position, velocity, and acceleration of a particle at some initial time t_0. If we neglect any change in velocity during the time interval, the new position is given by

$$x_1 = x_0 + v_{0x}\,\Delta t$$

Similarly, if we assume constant acceleration during Δt, the velocity at time $t_1 = t_0 + \Delta t$ is given by

$$v_1 = v_{0x} + a_{0x}\,\Delta t$$

We can use the values x_1 and v_{1x} to compute the new acceleration a_{1x} using Newton's second law, and then use x_1, v_{1x}, and a_{1x} to compute x_2 and v_{2x}.

$$x_2 = x_1 + v_{1x}\,\Delta t$$
$$v_2 = v_1 + a_{1x}\,\Delta t$$

The connection between the position and velocity at time t_n and time $t_{n+1} = t_n + \Delta t$ is given by

$$x_{n+1} = x_n + v_{nx}\,\Delta t \qquad \text{5-9}$$

and

$$v_{n+1} = v_{nx} + a_{nx}\,\Delta t \qquad \text{5-10}$$

To find the velocity and position at some time t, we therefore divide the time interval $t - t_0$ into a large number of smaller intervals Δt and apply Equations 5-9 and 5-10, beginning at the initial time t_0. This involves a large number of simple, repetitive calculations that are most easily done on a computer. The technique of breaking the time interval into small steps and computing the acceleration, velocity, and position at each step using the values from the previous step is called *numerical integration*.

To illustrate the use of numerical integration, let us consider a problem in which a skydiver is dropped from rest at some height under the influences of both gravity and a drag force that is proportional to the square of the speed. We will find the velocity v_x and the distance traveled x as functions of time.

The equation describing the motion of an object of mass m dropped from rest is Equation 5-6 with $n = 2$:

$$mg - bv^2 = ma_x$$

where down is the positive direction. The acceleration is thus

$$a_x = g - \frac{b}{m}v^2 \qquad \text{5-11}$$

(b)

FIGURE 5-36 (*a*) Spreadsheet to compute the position and speed of a skydiver with air drag proportional to v^2. (*b*) The same Excel spreadsheet displaying the formulas rather than the values.

It is convenient to write the constant b/m in terms of the terminal speed v_{T}. Setting $a_x = 0$ in Equation 5-11, we obtain

$$0 = g - \frac{b}{m}v_{\mathrm{T}}^2$$

$$\frac{b}{m} = \frac{g}{v_{\mathrm{T}}^2}$$

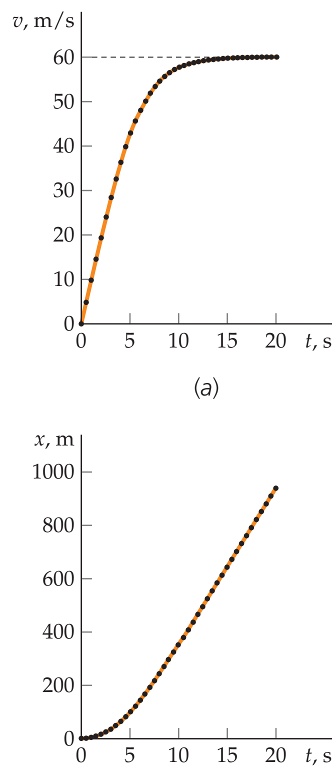
Substituting g/v_{T}^2 for b/m in Equation 5-11 gives

$$a_x = g\left(1 - \frac{v^2}{v_{\mathrm{T}}^2}\right) \qquad \text{5-12}$$

The acceleration at time t_n is calculated using the values x_n and v_{nx}.

To solve Equation 5-12 numerically, we need to use numerical values for g and v_{t}. A reasonable terminal speed for a skydiver is 60.0 m/s. If we choose $x_0 = 0$ for the initial position, the initial values are $x_0 = 0$, $v_0 = 0$, and $a_{0x} = g = 9.81\ \mathrm{m/s^2}$. To find the velocity v_x and position x after some time, say, $t = 20.0$ s, we divide the time interval $0 < t < 20.0$ s into many small intervals Δt and apply Equations 5-9, 5-10, and 5-12. We do this by using a computer spreadsheet (or by writing a computer program) as shown in Figure 5-36. This spreadsheet has $\Delta t = 0.5$ s, and the computed values at $t = 20$ s are $v = 59.89$ m/s and $x = 939.9$ m. Figure 5-37 shows graphs of v_x versus t and x versus t plotted from these data.

But how accurate are our computations? We can estimate the accuracy by running the program again using a smaller time interval. If we use $\Delta t = 0.25$ s, one-half of the value we originally used, we obtain $v = 59.86$ m/s and $x = 943.1$ m at $t = 20$ s. The difference in v is about 0.05 percent and that in x is about 0.3 percent. These are our estimates of the accuracy of the original computations.



(b)

FIGURE 5-37 (*a*) Graph of v versus t for a skydiver, found by numerical integration using $\Delta t = 0.5$ s. The horizontal dashed line is the terminal speed $v_{\mathrm{t}} = 60$ m/s. (*b*) Graph of x versus t using $\Delta t = 0.5$ s.

Because the difference between the value of $a_{\mathrm{av}x}$ for some time interval Δt and the value of a_x at the beginning of the interval becomes smaller as the time interval becomes shorter, we might expect that it would be better to use very short time intervals, say, $\Delta t = 0.000\,000\,001$ s. But there are two reasons for not using extremely short intervals. First, the shorter the time interval, the larger the number of calculations that are required and the longer the program takes to run. Second, the computer keeps only a fixed number of digits at each step of the calculation, so that at each step there is a round-off error. These round-off errors add up. The larger the number of calculations, the more significant the total round-off errors become. When we first decrease the time interval, the accuracy improves because a_{i} more nearly approximates a_{av} for the interval. However, as the time interval is decreased further, the round-off errors build up and the accuracy of the computation decreases. A good rule of thumb to follow is to use no more than about 10^5 time intervals for the typical numerical integration.

5-5 THE CENTER OF MASS

If you throw a ball into the air, the ball follows a smooth parabolic path. But if you toss a baton in the air (Figure 5-38), the motion of the baton is more complicated. Each end of the baton moves in a different direction, and both ends move in a different way than the middle. However, if you look at the motion of the baton more closely, you will see that there is one point on the baton that moves in a parabolic path, even though the rest of the baton does not. This point, called the **center of mass,** moves as if all the baton's mass were concentrated at that point and all external forces were applied there.

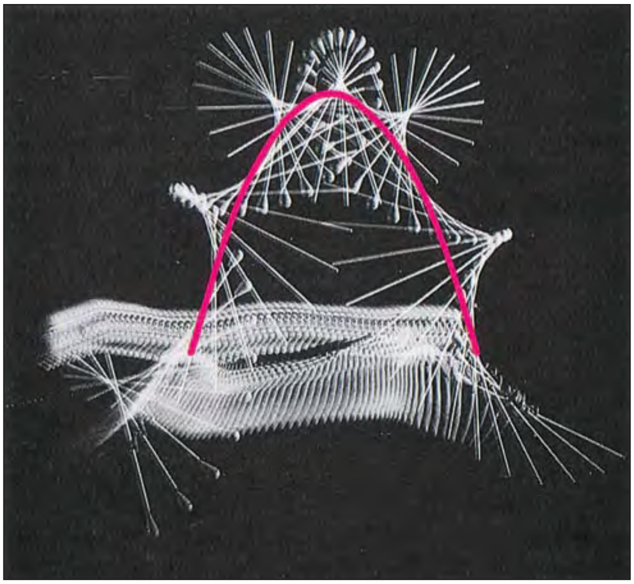


FIGURE 5-38 A multiflash photo of a baton thrown into the air. *(Estate of Harold E. Edgerton/Palm Press.)*

To determine the center of mass of an object, it is helpful to think of the object as a system of particles. Consider, for example, a simple system that consists of two point particles located on the x axis at positions x_1 and x_2 (Figure 5-39). If the particles have masses m_1 and m_2, then the center-of-mass is located on the x axis at position x_{cm}, defined by

$$Mx_{\mathrm{cm}} = m_1x_1 + m_2x_2 \qquad 5\text{-}13$$

where $M = m_1 + m_2$ is the total mass of the system. If we choose the position of the origin and the $+x$ direction such that the position of m_1 is at the origin and that of m_2 is on the positive x axis, then $x_1 = 0$ and $x_2 = d$, where d is the distance between the particles. The center of mass is then given by

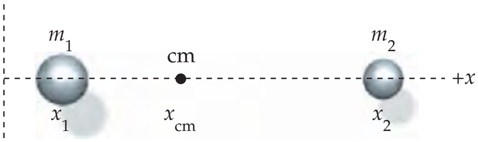

FIGURE 5-39

$$Mx_{\mathrm{cm}} = m_1x_1 + m_2x_2 = m_1(0) + m_2d$$

$$x_{\mathrm{cm}} = \frac{m_2}{M}d = \frac{m_2}{m_1 + m_2}d \qquad 5\text{-}14$$

In the case of just two particles, the center of mass lies at some point on the line between the particles; if the particles have equal masses, then the center of mass is midway between them (Figure 5-40*a*). If the two particles are of unequal mass, then the center of mass is closer to the more massive particle (Figure 5-40*b*).

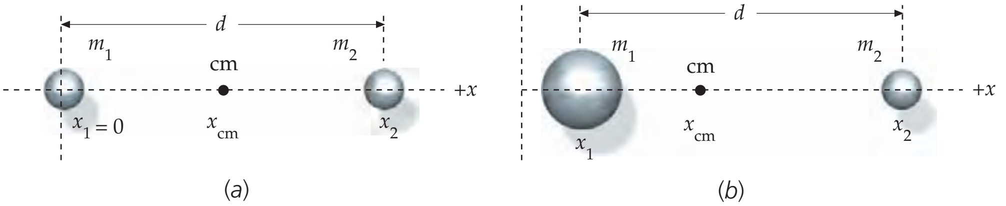

FIGURE 5-40

PRACTICE PROBLEM 5-7

A 4.0-kg mass is at the origin and a 2.0-kg mass is on the x axis at $x = 6.0$ cm. Find x_{cm}.

We can generalize from two particles in one dimension to a system of many particles in three dimensions. For N particles in three dimensions,

$$Mx_{\text{cm}} = m_1x_1 + m_2x_2 + m_3x_3 + \cdots + m_Nx_N$$

Using more concise notation, this is written

$$Mx_{\text{cm}} = \sum_i m_ix_i \qquad \text{5-15}$$

where again $M = \sum_i m_i$ is the total mass of the system. Similarly, in the y and z directions,

$$My_{\text{cm}} = \sum_i m_iy_i \qquad \text{5-16}$$

and

$$Mz_{\text{cm}} = \sum_i m_iz_i \qquad \text{5-17}$$

In vector notation, $\vec{r}_i = x_i\hat{i} + y_i\hat{j} + z_i\hat{k}$ is the position vector of the ith particle. The **position of the center of mass, $\vec{r}_{\text{cm}}$**, is defined by

$$M\vec{r}_{\text{cm}} = m_1\vec{r}_1 + m_2\vec{r}_2 + \cdots = \sum_i m_i\vec{r}_i \qquad \text{5-18}$$

DEFINITION: CENTER OF MASS

where $\vec{r}_{\text{cm}} = x_{\text{cm}}\hat{i} + y_{\text{cm}}\hat{j} + z_{\text{cm}}\hat{k}$.

Now let us consider extended objects, such as balls, baseball bats, and even cars. We can think of objects such as these as a system containing a very large number of particles, with a continuous distribution of mass. For highly symmetric objects, the center of mass is at the *center of symmetry*. For example, the center of mass of a uniform sphere or a uniform cylinder is located at its *geometric center*. For an object with a line or plane of symmetry, the center of mass lies somewhere along that line or plane. To find the position center of mass of an object, we replace the sum in Equation 5-18 with an integral:

$$M\vec{r}_{\text{cm}} = \int \vec{r}\,dm \qquad \text{5-19}$$

CENTER OF MASS, CONTINUOUS OBJECT

where dm is a small element of mass located at position $\vec{r}$, as shown in Figure 5-41. (We will examine in detail how this integral is set up after Example 5-15.)

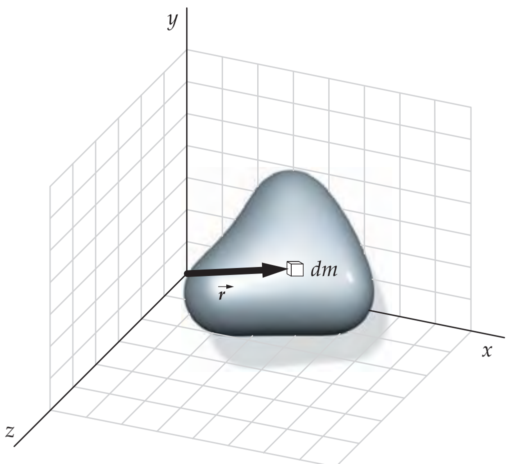

FIGURE 5-41 A mass element dm located at position $\vec{r}$ is used for finding the center of mass by integration.

PROBLEM-SOLVING STRATEGY

Solving Center-of-Mass Problems

PICTURE Determining centers of mass often simplifies determinations of the motions of an object or system of objects. Drawing a sketch of the object or system of objects is useful when trying to determine a center of mass.

SOLVE

1. Check the mass distribution for symmetry axes. If there are symmetry axes, the center of mass will be located on them. Use existing symmetry axes as coordinate axes where feasible.

2. Check to see if the mass distribution is composed of highly symmetric subsystems. If so, then calculate the centers of mass of the individual subsystems, and then calculate the center of mass of the system by treating each subsystem as a point particle at its center of mass.
3. If the system contains one or more point particles, place the origin at the location of a point particle. (If the i^{th} particle is at the origin, then $\vec{r}_i = 0$.)

CHECK Make sure your center-of-mass determinations make sense. In many cases, the center of mass of an object is located near the more massive and larger part of the object. The center of mass of a multi-object system or an object such as a hoop may not be located within or on any object.

Example 5-14 The Center of Mass of a Water Molecule

A water molecule consists of an oxygen atom and two hydrogen atoms. An oxygen atom has a mass of 16.0 unified mass units (u), and each hydrogen atom has a mass of 1.00 u. The hydrogen atoms are each at an average distance of 96.0 pm (96.0×10^{-12} m) from the oxygen atom, and are separated from one another by an angle of 104.5°. Find the center of mass of a water molecule.

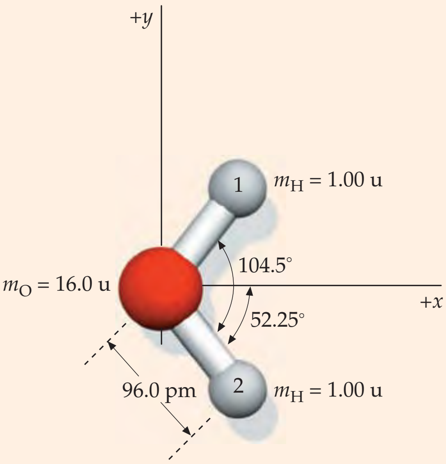

FIGURE 5-42

PICTURE We can simplify the calculation by selecting a coordinate system such that the origin is located at the oxygen atom, with the x axis bisecting the angle between the hydrogen atoms (Figure 5-42). Then, given the symmetries of the molecule, the center of mass will be on the x axis, and the line from the oxygen atom to each hydrogen atom will make an angle of 52.25°.

SOLVE

1. The location of the center of mass is given by its coordinates, x_{cm} and y_{cm} (Equations 5-15 and 5-16):

$$x_{cm} = \frac{\sum m_i x_i}{M}, \quad y_{cm} = \frac{\sum m_i y_i}{M}$$

2. Writing these out explicitly gives:

$$x_{cm} = \frac{m_{H1}x_{H1} + m_{H2}x_{H2} + m_O x_O}{m_{H1} + m_{H2} + m_O}$$

$$y_{cm} = \frac{m_{H1}y_{H1} + m_{H2}y_{H2} + m_O y_O}{m_{H1} + m_{H2} + m_O}$$

3. We have chosen the origin to be the location of the oxygen atom, so both the x and y coordinates of the oxygen atom are zero. The x and y coordinates of the hydrogen atoms are calculated from the 52.25° angle each hydrogen makes with the x axis:

$$x_O = y_O = 0$$

$$x_{H1} = 96.0 \text{ pm} \cos 52.25° = 58.8 \text{ pm}$$

$$x_{H2} = 96.0 \text{ pm} \cos(-52.25°) = 58.8 \text{ pm}$$

$$y_{H1} = 96.0 \text{ pm} \sin 52.25° = 75.9 \text{ pm}$$

$$y_{H2} = 96.0 \text{ pm} \sin(-52.25°) = -75.9 \text{ pm}$$

4. Substituting the coordinate and mass values into step 2 gives x_{cm}:

$$x_{cm} = \frac{(1.00 \text{ u})(58.8 \text{ pm}) + (1.00 \text{ u})(58.8 \text{ pm}) + (16.0 \text{ u})(0)}{1.00 \text{ u} + 1.00 \text{ u} + 16.0 \text{ u}} = 6.53 \text{ pm}$$

$$x_{cm} = \frac{(1.00 \text{ u})(75.9 \text{ pm}) + (1.00 \text{ u})(-75.9 \text{ pm}) + (16.0 \text{ u})(0)}{1.00 \text{ u} + 1.00 \text{ u} + 16.0 \text{ u}} = 0.00 \text{ pm}$$

5. The center of mass is on the x axis:

$$\vec{r}_{cm} = x_{cm}\hat{i} + y_{cm}\hat{j} = \boxed{6.53 \text{ pm } \hat{i} + 0.00\hat{j}}$$

CHECK That $y_{cm} = 0$ can be seen from the symmetry of the mass distribution. Also, the center of mass is very close to the relatively massive oxygen atom, as expected.

TAKING IT FURTHER The distance 96 pm is read "ninety six picometers," where pico is the prefix for 10^{-12}.

Note that we could also have solved Example 5-14 by first finding the center of mass of just the two hydrogen atoms. For a system of three particles Equation 5-18 is

$$M\vec{r}_{\rm cm} = m_1\vec{r}_1 + m_2\vec{r}_2 + m_3\vec{r}_3$$

The first two terms on the right side of this equation are related to the center of mass of the first two particles $\vec{r}\,'_{\rm cm}$:

$$m_1\vec{r}_1 + m_2\vec{r}_2 = (m_1 + m_2)\vec{r}\,'_{\rm cm}$$

The center of mass of the three-particle system can then be written

$$M\vec{r}_{\rm cm} = (m_1 + m_2)\vec{r}\,'_{\rm cm} + m_3\vec{r}_3$$

So we can first find the center of mass for two of the particles, the hydrogen atoms, for example, and then replace them with a single particle of total mass $m_1 + m_2$ at that center of mass (Figure 5-43).

The same technique enables us to calculate centers of mass for more complex systems, for instance, two uniform rods (Figure 5-44). The center of mass of each rod separately is at the center of the rod. The center of mass of the two-rod system can be found by modeling each rod as a point particle at its individual center of mass.

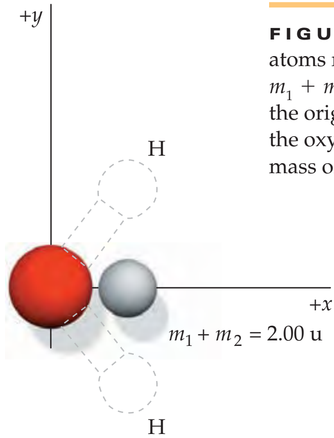

FIGURE 5-43 Example 5-14 with the two hydrogen atoms replaced by a single particle of mass $m_1 + m_2 = 2.00\,$u on the x axis at the center of mass of the original atoms. The center of mass then falls between the oxygen atom at the origin and the calculated center of mass of the two hydrogen atoms.

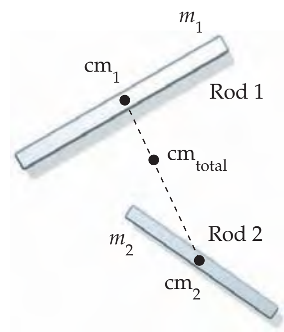

FIGURE 5-44

Example 5-15 The Center of Mass of a Plywood Sheet

Find the center of mass of the uniform sheet of plywood shown in Figure 5-45*a*.

PICTURE The sheet can be divided into two symmetrical parts (Figure 5-45*b*). The center of mass of each part is at that part's geometric center. Let m_1 be the mass of part 1 and m_2 be the mass of part 2. The total mass is $M = m_1 + m_2$. The masses are proportional to the areas, where A_1, A_2, and A are the areas of the pieces of mass m_1, m_2, and M, respectively.

SOLVE

Steps

1. Write the x and y coordinates of the center of mass in terms of m_1 and m_2.
$$x_{\rm cm} = \frac{1}{M}(m_1x_{\rm cm1} + m_2x_{\rm cm2})$$
$$y_{\rm cm} = \frac{1}{M}(m_1y_{\rm cm1} + m_2y_{\rm cm2})$$

2. Substitute area ratios for the mass ratios.
$$x_{\rm cm} = \frac{A_1}{A}x_{\rm cm1} + \frac{A_2}{A}x_{\rm cm2}$$
$$y_{\rm cm} = \frac{A_1}{A}y_{\rm cm1} + \frac{A_2}{A}y_{\rm cm2}$$

3. Calculate the areas and the ratios of the areas, using the values from Figure 5-45*b*.
$$A_1 = 0.32\text{ m}^2; \qquad A_2 = 0.040\text{ m}^2$$
$$\frac{A_1}{A} = \frac{8.0}{9.0} \qquad \frac{A_2}{A} = \frac{1.0}{9.0}$$

4. Write the x and y coordinates of the center-of-mass coordinates for each part by inspection of the figure.
$$x_{\rm cm1} = 0.40\text{ m}, \quad y_{\rm cm1} = 0.20\text{ m}$$
$$x_{\rm cm2} = 0.70\text{ m}, \quad y_{\rm cm2} = 0.50\text{ m}$$

5. Substitute these results into the step-2 result to calculate $x_{\rm cm}$ and $y_{\rm cm}$.
$$x_{\rm cm} = \boxed{0.43\text{ m}}, \quad y_{\rm cm} = \boxed{0.23\text{ m}}$$

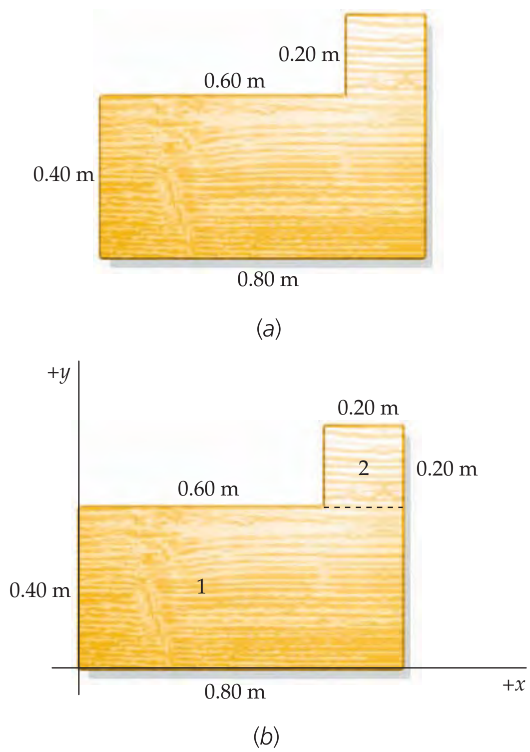

FIGURE 5-45

CHECK As expected, the center of mass of the system is very near the center of mass of part 1 (because $m_1 = 8m_2$.)

TAKING IT FURTHER Drawing an axis through the geometric centers of parts 1 and 2 and placing the origin at the geometric center of part 1, would have made locating the center of mass considerably easier.

* FINDING THE CENTER OF MASS BY INTEGRATION

In this section, we find the center of mass by integration (Equation 5-19):

$$\vec{r}_{\text{cm}} = \frac{1}{M}\int \vec{r}\,dm$$

We will start by finding the center of mass of a uniform thin rod to illustrate the technique for setting up the integration.

Uniform rod We first choose a coordinate system. A good choice for a coordinate system is one with an x axis through the length of the rod, with the origin at one end of the rod (Figure 5-46). Shown on the figure is a mass element dm of length dx a distance x from the origin. Equation 5-19 thus gives

$$\vec{r}_{\text{cm}} = \frac{1}{M}\int \vec{r}\,dm = \frac{1}{M}\int x\hat{\imath}\,dm$$

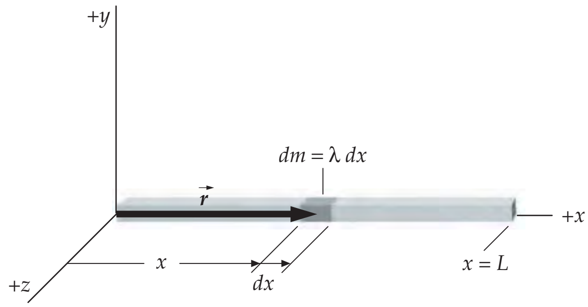

FIGURE 5-46

The mass is distributed on the x axis along the interval $0 \le x \le L$. To integrate dm along the mass distribution means the limits of the integral are 0 and L. (We integrate in the direction of increasing x.) The ratio dm/dx is the mass per unit length λ, so $dm = \lambda\,dx$:

$$\vec{r}_{\text{cm}} = \frac{1}{M}\hat{\imath}\int x\,dm = \frac{1}{M}\hat{\imath}\int_0^L x\lambda\,dx \qquad \text{5-20}$$

where

$$M = \int dm = \int_0^L \lambda\,dx \qquad \text{5-21}$$

Because the rod is uniform, λ is constant and can be factored from each of the integrals in Equations 5-20 and 5-21, giving

$$\vec{r}_{\text{cm}} = \frac{1}{M}\lambda\hat{\imath}\int_0^L x\,dx = \frac{1}{M}\lambda\hat{\imath}\frac{L^2}{2} \qquad \text{5-22}$$

and

$$M = \lambda\int_0^L dx = \lambda L \qquad \text{5-23}$$

Solving Equation 5-23 for λ gives $\lambda = M/L$. Thus, for a uniform rod the mass per unit length is equal to the total mass divided by the total length. Substituting λL for M in Equation 5-22, we complete the calculation and obtain the expected result

$$\vec{r}_{\text{cm}} = \frac{1}{\lambda L}\lambda\hat{\imath}\frac{L^2}{2} = \frac{1}{2}L\hat{\imath}$$

Semicircular hoop In calculating the center of mass of a uniform semicircular hoop of radius R, a good choice of coordinate axes is one with the origin at the center and with the y axis bisecting the semicircle (Figure 5-47). To find the center of mass, we use $M\vec{r}_{\text{cm}} = \int \vec{r}\,dm$ (Equation 5-19,) where $\vec{r} = x\hat{\imath} + y\hat{\jmath}$. The semicircular mass distribution suggests using polar coordinates,* for which $x = r\cos\theta$ and $y = r\sin\theta$. The distance of the points on the semicircle from the origin is $r = R$. With these substitutions, we have

$$\vec{r}_{\text{cm}} = \frac{1}{M}\int (x\hat{\imath} + y\hat{\jmath})\,dm = \frac{1}{M}\int R(\cos\theta\,\hat{\imath} + \sin\theta\,\hat{\jmath})\,dm$$

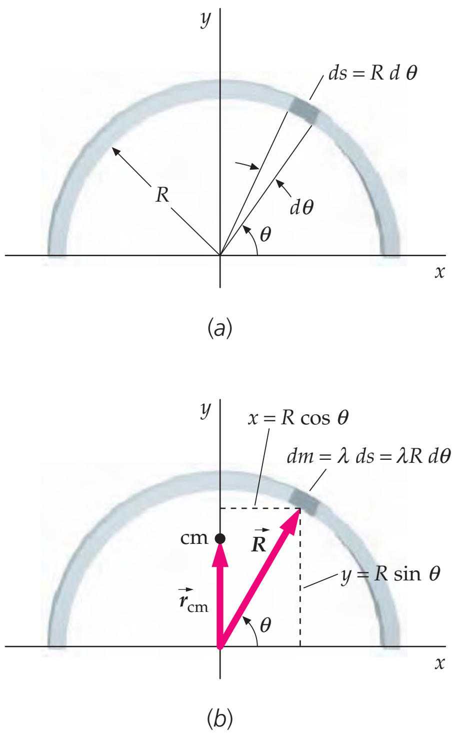

FIGURE 5-47 Geometry for calculating the center of mass of a semicircular hoop by integration.

* In polar coordinates the coordinates of a point are r and θ, were r is the magnitude of the position vector $\vec{r}$ and θ is the angle that the position vector makes with the $+x$ direction.

Next we express dm in terms of $d\theta$. First, the mass element dm has length $ds = R\,d\theta$, so

$$dm = \lambda\,ds = \lambda R\,d\theta$$

where $\lambda = dm/ds$ is the mass per unit length. Thus, we have

$$\vec{r}_{\text{cm}} = \frac{1}{M}\int R(\cos\theta\,\hat{i} + \sin\theta\,\hat{j})\lambda R\,d\theta$$

Evaluating this integral involves integrating dm along the semicircular mass distribution. This means that $0 \le \theta \le \pi$. Integrating in the direction of increasing θ, the integration limits go from 0 to π. That is,

$$\vec{r}_{\text{cm}} = \frac{1}{M}\int_0^{\pi} R(\cos\theta\hat{i} + \sin\theta\hat{j})\lambda R\,d\theta = \frac{\lambda R^2}{M}\left(\hat{i}\int_0^{\pi}\cos\theta\,d\theta + \hat{j}\int_0^{\pi}\sin\theta\,d\theta\right)$$

where we have used that an integral of a sum is the sum of the integrals. Because the hoop is uniform, we know that $M = \lambda\pi R$, where πR is the length of the semicircular arc. Substituting $M/(\pi R)$ for λ and integrating gives

$$\vec{r}_{\text{cm}} = \frac{R}{\pi}\left(\hat{i}\int_0^{\pi}\cos\theta\,d\theta + \hat{j}\int_0^{\pi}\sin\theta\,d\theta\right) = \frac{R}{\pi}\left(\hat{i}\sin\theta\Big|_0^{\pi} - \hat{j}\cos\theta\Big|_0^{\pi}\right) = \frac{2}{\pi}R\hat{j}$$

The center of mass is on the y axis a distance of $2R/\pi$ from the origin. Curiously, it is outside of the material of the semicircular hoop.

See **Math Tutorial** *for more information on* **Integrals**

MOTION OF THE CENTER OF MASS

The motion of any object or system of particles can be described in terms of the motion of the center of mass plus the motion of individual particles in the system relative to the center of mass. The multiple image photograph in Figure 5-48 shows a hammer thrown into the air. While the hammer is in the air, the center of mass follows a parabolic path, the same path that would be followed by a point particle. The other parts of the hammer rotate about this point as the hammer moves through the air.

The motion of the center of mass for a system of particles is related to the net force on the system as a whole. We can show this by examining the motion of a system of n particles of total mass M. First, we find the velocity of the center-of-mass system by differentiating both sides of Equation 5-18 ($M\vec{r}_{\text{cm}} = \sum m_i\vec{r}_i$) with respect to time:

$$M\frac{d\vec{r}_{\text{cm}}}{dt} = m_1\frac{d\vec{r}_1}{dt} + m_2\frac{d\vec{r}_2}{dt} + \cdots = \sum_i m_i\frac{d\vec{r}_i}{dt}$$

Because the time derivative of position is velocity, this gives

$$M\vec{v}_{\text{cm}} = m_1\vec{v}_1 + m_2\vec{v}_2 + \cdots = \sum_i m_i\vec{v}_i \qquad \text{5-24}$$

Differentiating both sides again, we obtain the accelerations:

$$M\vec{a}_{\text{cm}} = m_1\vec{a}_1 + m_2\vec{a}_2 + \cdots = \sum_i m_i\vec{a}_i \qquad \text{5-25}$$

where $\vec{a}_i$ is the acceleration of the ith particle and $\vec{a}_{\text{cm}}$ is the acceleration of the center of mass. From Newton's second law, $m_i\vec{a}_i$ equals the sum of the forces acting on the ith particle, so

$$\sum_i m_i\vec{a}_i = \sum_i \vec{F}_i$$

where the sum on the right is the sum of all the forces acting on each and every particle in the system. Some of these forces are *internal* forces (exerted on a particle

FIGURE 5-48 The center of mass (the black dot) of the hammer moves in a smooth parabolic path. *(Loren Winters/Visual Unlimited.)*

Throwing the hammer. If the ball moves in a horizontal circle at constant speed, its acceleration vector points in the centripetal direction (toward the center of the circle). The net force on the ball is in the direction of the acceleration vector. The centripetal component of the net force is supplied by the person pulling the handle inward. *(Pete Saloutos/Corbis.)*

in the system by some other particle in the system) and others are *external* forces (exerted on a particle in the system by something external to the system). Thus,

$$M\vec{a}_{cm} = \sum_i \vec{F}_{i\,int} + \sum_i \vec{F}_{i\,ext} \qquad 5\text{-}26$$

According to Newton's third law, forces come in equal and opposite pairs. Therefore, for each internal force acting on a particle in the system there is an equal and opposite internal force acting on some other particle in the system. When we sum all the internal forces, each third-law force pair sums to zero, so $\sum\vec{F}_{i\,int} = 0$. Equation 5-22 then becomes

$$\vec{F}_{net\,ext} = \sum_i \vec{F}_{i\,ext} = M\vec{a}_{cm} \qquad 5\text{-}27$$

NEWTON'S SECOND LAW FOR A SYSTEM

That is, the net external force acting on the system equals the total mass M times the acceleration of the center of mass $\vec{a}_{cm}$. Thus,

The center of mass of a system moves like a particle of mass $M = \sum m_i$ under the influence of the net external force acting on the system.

This theorem is important because it describes the motion of the center of mass for *any* system of particles: The center of mass moves exactly like a single point particle of mass M acted on by only the external forces. The individual motion of a particle in the system is typically much more complex and is not described by Equation 5-27. The hammer thrown into the air in Figure 5-48 is an example. The only external force acting is gravity, so the center of mass of the hammer moves in a simple parabolic path, as would a point particle. However, Equation 5-27 does not describe the rotational motion of the head of the hammer about the center of mass.

If a system has a zero net external force acting on it, then $\vec{a}_{cm} = 0$. In this case the center of mass either remains at rest or moves with constant velocity. The internal forces and motion may be complex, but the motion of the center of mass is simple. Further, if the component of the net next force in a given direction, say the x direction, remains zero, then a_{cmx} remains zero and v_{cmx} remains constant. An example of this is a projectile in the absence of air drag. The net external force on the projectile is the gravitational force. This force acts straight downward, so its component in any horizontal direction remains zero. It follows that the horizontal component of the velocity of the center of mass remains constant.

CONCEPT CHECK 5-2

A cylinder rests on a sheet of paper on a table (Figure 5-49). You pull on the paper causing the paper to slide to the right. This results in the cylinder rolling leftward *relative to the paper*. How does the center of mass of the cylinder move *relative to the table*?

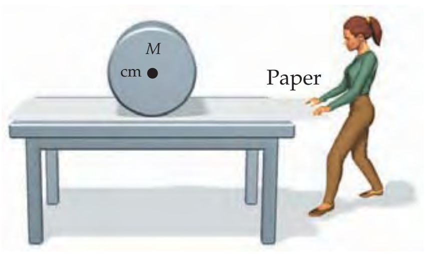

FIGURE 5-49

Example 5-16 An Exploding Projectile

A projectile is fired into the air over level ground on a trajectory that would result in it landing 55 m away. However, at its highest point it explodes into two fragments of equal mass. Immediately following the explosion one fragment has a momentary speed of zero and then falls straight down to the ground. Where does the other fragment land? Neglect air resistance.

PICTURE Let the projectile be the system. Then, the forces of the explosion are all internal forces. Because the only *external* force acting on the system is that due to gravity, the center of mass, which is midway between the two fragments, continues on its parabolic path as if there had been no explosion (Figure 5-50).

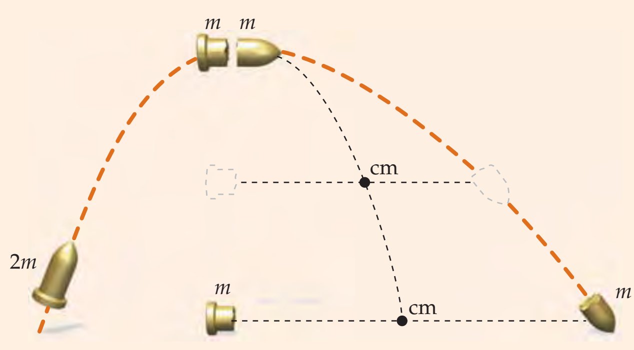

FIGURE 5-50

SOLVE

1. Let $x = 0$ be the initial position of the projectile. The landing positions x_1 and x_2 of the fragments are related to the final position of the center of mass by:

$$(2m)x_{cm} = mx_1 + mx_2$$
or $$2x_{cm} = x_1 + x_2$$

2. At impact, $x_{cm} = R$ and $x_1 = 0.5R$, where $R = 55$ m is the horizontal range for the unexploded projectile. Solve for x_2:

$$x_2 = 2x_{cm} - x_1 = 2R - 0.5R = 1.5R$$
$$= 1.5(55\text{ m}) = \boxed{83\text{ m}}$$

CHECK Fragment #1 was pushed backwards by the explosive forces, so fragment #2 was pushed forward by an equal but opposite force. As expected, fragment #2 impacts the ground at a distance farther from the launch point than the projectile would have impacted had it not exploded into two pieces.

TAKING IT FURTHER In Figure 5-51, height versus distance is plotted for exploding projectiles when fragment #1 has a horizontal velocity of half of the initial horizontal velocity. The center of mass follows a normal parabolic trajectory, as it did in the original example in which fragment #1 falls straight down. If both fragments have the same vertical component of velocity after the explosion, they land at the same time. If just after the explosion the vertical component of the velocity of one fragment is less than that of the other, the fragment with the smaller vertical-velocity component will hit the ground first. As soon as it does, the ground exerts a force on it and the net external force on the system is no longer just the gravitational force. From that instant on, our analysis is invalid.

PRACTICE PROBLEM 5-8 If the fragment that falls straight down has twice the mass of the other fragment, how far from the launch position does the lighter fragment land?

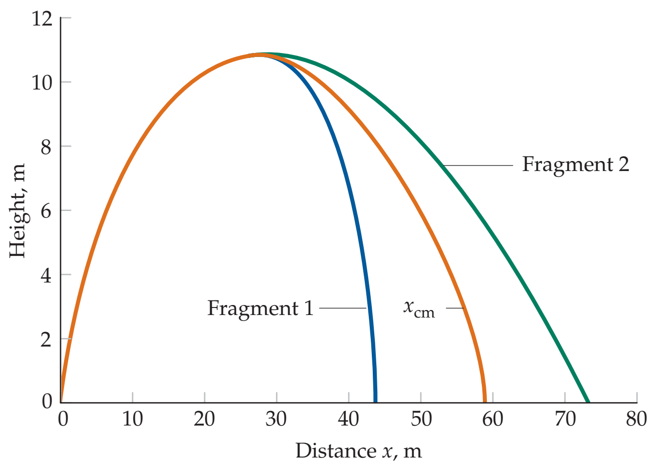

FIGURE 5-51

Example 5-17 Changing Places in a Rowboat

Pete (mass 80 kg) and Dave (mass 120 kg) are in a rowboat (mass 60 kg) on a calm lake. Dave is near the bow of the boat, rowing, and Pete is at the stern, 2.0 m from the center. Dave gets tired and stops rowing. Pete offers to row, so after the boat comes to rest they change places. How far does the boat move as Pete and Dave change places? (Neglect any horizontal force exerted by the water.)

PICTURE Let the system be Dave, Pete, and the boat. There are no *external* forces in the horizontal direction, so the center of mass does not move horizontally relative to the water. Flesh out Equation 5-15 ($Mx_{cm} = \sum m_i x_i$) both before and after Pete and Dave change places.

SOLVE

1. Make a sketch of the system in its initial and final configurations (Figure 5-52). Let $L = 2.0$ m and let $d = \Delta x_{boat}$, the distance the boat moves forward when Pete and Dave switch places:

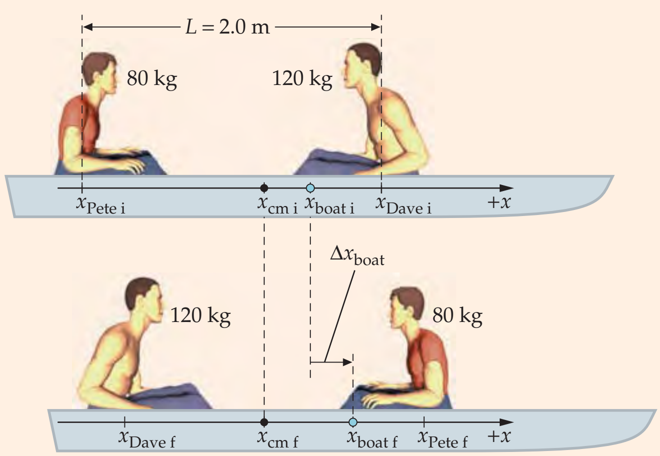

FIGURE 5-52 Pete and Dave changing places viewed from the reference frame of the water. The blue dot is the center of mass of the boat and the black dot is the center of mass of the Pete–Dave–boat system.

2. Flesh out $Mx_{\text{cm}} = \sum m_i x_i$ both before and after Pete and Dave change places. The coordinate axis measures positions in the reference frame of the water:

$$Mx_{\text{cm i}} = m_{\text{Pete}}x_{\text{Pete i}} + m_{\text{Dave}}x_{\text{Dave i}} + m_{\text{boat}}x_{\text{boat i}}$$
and
$$Mx_{\text{cm f}} = m_{\text{Pete}}x_{\text{Pete f}} + m_{\text{Dave}}x_{\text{Dave f}} + m_{\text{boat}}x_{\text{boat f}}$$

3. Subtract the third step-2 equation from the second step-2 equation. Then substitute 0 for Δx_{cm}, $d + L$ for Δx_{Pete}, $d - L$ for Δx_{Dave} and d for Δx_{boat}:

$$M\Delta x_{\text{cm}} = m_{\text{Pete}}\,\Delta x_{\text{Pete}} + m_{\text{Dave}}\,\Delta x_{\text{Dave}} + m_{\text{boat}}\,\Delta x_{\text{boat}}$$
$$0 = m_{\text{Pete}}(d + L) + m_{\text{Dave}}(d + L) + m_{\text{boat}}d$$

4. Solve for d:

$$d = \frac{(m_{\text{Dave}} - m_{\text{Pete}})}{m_{\text{Dave}} + m_{\text{Pete}} + m_{\text{boat}}}L = \frac{(120\text{ kg} - 80\text{ kg})}{120\text{ kg} + 80\text{ kg} + 60\text{ kg}}(2.0\text{ m}) = \boxed{0.31\text{ m}}$$

CHECK Dave's mass is greater than Pete's mass, so when they changed places their center of mass moved toward the stern of the boat. The boat's center of mass had to move in the opposite direction for the center of mass of the Dave–Pete–boat system to remain stationary. The step-4 result is the displacement of the boat. It is positive as expected.

Example 5-18 A Sliding Block

A wedge of mass m_2 sits at rest on a scale, as shown in Figure 5-53. A small block of mass m_1 slides down the frictionless incline of the wedge. Find the scale reading while the block slides. The wedge does not slide on the scale.

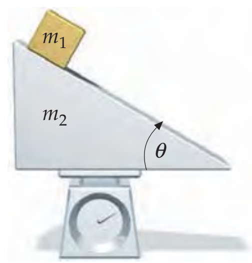

FIGURE 5-53

PICTURE We choose the wedge plus block to be the system. Because the block accelerates down the wedge, the center of mass of the system has acceleration components to the right and downward. The external forces on the system are the gravitational forces on the block and wedge, the static frictional force f_s of the scale on the wedge, and the normal force F_n exerted by the scale on the wedge. The scale reading is equal to the magnitude of F_n.

SOLVE

1. Draw a free-body diagram for the wedge–block system (Figure 5-54):

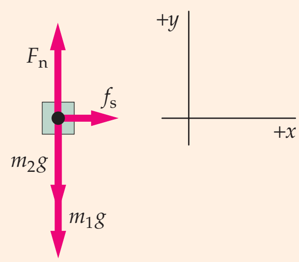

FIGURE 5-54

2. Write the vertical component of Newton's second law for the system and solve for F_n:

$$F_n - m_1g - m_2g = Ma_{\text{cm}y} = (m_1 + m_2)a_{\text{cm}y}$$
$$F_n = (m_1 + m_2)g + (m_1 + m_2)a_{\text{cm}y}$$

3. Using Equation 5-21, express $a_{\text{cm}y}$ in terms of the acceleration of the block a_{1y}:

$$Ma_{\text{cm}y} = m_1a_{1y} + m_2a_{2y}$$
$$(m_1 + m_2)a_{\text{cm}y} = m_1a_{1y} + 0$$
$$a_{\text{cm}y} = \frac{m_1}{m_1 + m_2}a_{1y}$$

4. From Example 4-7, a block sliding down a stationary frictionless incline has acceleration $g \sin\theta$ down the incline. Use trigonometry to find the y component of this acceleration and use it to find $a_{\text{cm}y}$:

so $a_{1y} = -a_1 \sin\theta$, where $a_1 = g\sin\theta$
$$a_{1y} = -(g\sin\theta)\sin\theta = -g\sin^2\theta$$

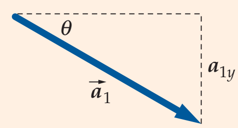

FIGURE 5-55

5. Substitute for a_{1y} in the step-3 result:

$$a_{\text{cm}y} = \frac{m_1}{m_1 + m_2}a_{1y} = -\frac{m_1}{m_1 + m_2}g\sin^2\theta$$

6. Substitute for $a_{\text{cm}y}$ in the step-2 result and solve for F_n:

$$F_n = (m_1 + m_2)g + (m_1 + m_2)a_{\text{cm}y}$$
$$= (m_1 + m_2)g - m_1g\sin^2\theta = [m_1(1 - \sin^2\theta) + m_2]g$$
$$= \boxed{(m_1\cos^2\theta + m_2)g}$$

CHECK For $\theta = 0$, $\cos\theta = 1$, the step-5 result is, as expected, equal to the sum of the two weights. For $\theta = 90°$, $\cos\theta = 0$, and the step-5 result is, as expected, equal to the weight of the wedge alone.

PRACTICE PROBLEM 5-9 Find the force component F_x exerted on the wedge by the scale.

Physics Spotlight

Accident Reconstruction—Measurements and Forces

A car being towed after an accident. *(Mikael Karlsson.)*

Four teenagers drove to a Halloween haunted house that was located out in the countryside. As their car started into a curve, the driver saw a deer in the middle of the road. Frantic swerving and braking put the car into a slide. It skidded off the edge of the gently banked curve, flew over the narrow ditch, and landed in a newly harvested field below the road, where it skidded to a stop in the loose dirt.

Thanks to airbags and safety belts, no one was killed. All were taken to the hospital. The car was towed. But the accident investigation was not finished until a question was answered—was the car speeding?

Accident reconstruction specialists investigated the scene, and used information about the physics of an accident to determine what happened before, during, and immediately after that accident.* After this accident, a police officer, a specialist hired by the driver's insurance company, and a specialist hired by the county road department all looked at the scene.

The first thing the specialists did was measure and photograph everything that might be pertinent to the accident. They measured the road, so that the curve's radius and bank angle could be calculated and compared to the information at the county roads office. They measured the tire marks on the road, and in the field. They used a *drag sled* to determine the coefficient of kinetic friction for the field.† They measured the vertical and horizontal distance from the edge of the road to the first marks in the field. They measured the angle of the road to horizontal along the path of the tire tracks.

Using the measurement information, they calculated a simplified trajectory of the car from the moment it left the road until it landed in the field. This trajectory gave the speed of the car as it left the roadway. Their calculations using the skid marks in the field confirmed that speed. Finally, they calculated the starting speed of the skid on the road. They used the coefficient of kinetic friction of the road, as it was clear that the wheels had been locked, and not spinning.

They concluded that the car had been under the speed limit for the road, but, like most cars, had been going faster than the marked advisory speed for the curve.‡ The county put up deer warning signs, and installed a guard rail along the outer edge of the curve. The driver was ticketed for failure to maintain control of the vehicle.

Not all accident reconstruction is so simple or straightforward. Many accidents involve obstacles, other cars, or tires of the wrong size for the vehicle. Others may involve looking at the physics inside the car to determine whether or not seat belts were worn, or who was driving. But all accident reconstructions start with measurements to determine the forces at work during the accident.

SUMMARY

Friction and drag forces are complex phenomena empirically approximated by simple equations. For a particle to move in a curved path at constant speed the net force is directed toward the center of curvature. The center of mass of a system moves as if the system were a single point particle with the net force on the system acting on it.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Friction	Two objects in contact exert frictional forces on each other. These forces are parallel to the contacting surfaces and directed so as to oppose sliding or tendency to slide.	
Static friction	$f_s \le \mu_s F_n$	5-2
	where F_n is the normal force of contact and μ_s is the coefficient of static friction.	
Kinetic friction	$f_k = \mu_k F_n$	5-3
	where μ_k is the coefficient of kinetic friction. The coefficient of kinetic friction is slightly less than the coefficient of static friction.	
Rolling friction	$f_r = \mu_r F_n$	5-4
	where μ_r is the coefficient of rolling friction.	
2. Drag Forces	When an object moves through a fluid, it experiences a drag force that opposes its motion. The drag force increases with increasing speed. If the body is dropped from rest, its speed increases. As it does, the magnitude of the drag force comes closer and closer to the magnitude of the force of gravity, so the net force, and thus the acceleration, approaches zero. As the acceleration approaches zero, the speed approaches a constant value called its terminal speed. The terminal speed depends on both the shape of the body and on the medium through which it falls.	
3. Motion Along a Curved Path	A particle moving along an arbitrary curve can be considered to be moving along a circular arc for a short time interval. Its instantaneous acceleration vector has a component $a_c = v^2/r$ toward the center of curvature of the arc and a component $a_t = dv/dt$ that is tangential to the arc. If the particle is moving along a circular path of radius r at constant speed v, $a_t = 0$ and the speed, radius, and period T are related by $2\pi r = vT$.	
4. *Numerical Integration: Euler's Method	To estimate the position x and velocity v at some time t, we first divide the interval from zero to t into a large number of small intervals, each of length Δt. The initial acceleration a_0 is then calculated from the initial position x_0 and velocity v_0. The position x_1 and velocity v_1 a time Δt later are estimated using the relations	
	$x_{n+1} = x_n + v_n\,\Delta t$	5-9
	and	
	$v_{n+1} = v_n + a_n\,\Delta t$	5-10
	with $n = 0$. The acceleration a_{n+1} is calculated using the values for x_{n+1} and v_{n+1} and the process is repeated. This continues until estimations for the position and velocity at time t are calculated.	
5. Center of Mass		
Center of mass for a system of particles	The center of mass of a system of particles is defined to be the point whose coordinates are given by:	
	$Mx_{cm} = \sum_i m_i x_i$	5-15
	$My_{cm} = \sum_i m_i y_i$	5-16
	$Mz_{cm} = \sum_i m_i z_i$	5-17

TOPIC	RELEVANT EQUATIONS AND REMARKS	
Center of mass for continuous objects	If the mass is continuously distributed, the center of mass is given by: $M\vec{r}_{cm} = \int \vec{r}\, dm$	5-19
Position, velocity, and acceleration for the center of mass of a system of particles	$M\vec{r}_{cm} = m_1\vec{r}_1 + m_2\vec{r}_2 + \cdots$	5-18
	$M\vec{v}_{cm} = m_1\vec{v}_1 + m_2\vec{v}_2 + \cdots$	5-20
	$M\vec{a}_{cm} = m_1\vec{a}_1 + m_2\vec{a}_2 + \cdots$	5-21
Newton's second law for a system	$\vec{F}_{net\,ext} = \sum_i \vec{F}_{i\,ext} = M\vec{a}_{cm}$	5-23

Answers to Concept Checks

5-1 Yes, the car would slide down the incline.

5-2 It accelerates to the right, because the net external force acting on the cylinder is the frictional force to the right exerted on it by the paper. Try it. The cylinder may *appear* to move to the left, because relative to the paper it rolls leftward. However, relative to the table, which serves as an inertial reference frame, it moves to the right. If you mark the table with the original position of the cylinder, you will observe the center of mass move to the right *during the time the cylinder remains in contact with the moving paper*.

Answers to Practice Problems

5-1 35°

5-2 1.1×10^2 N

5-3 $T = m_2(g - a) = 44$ N

5-4 (*a*) Assuming $r \approx 1$ m, we find $v_{t,\,min} \approx 3$ m/s, (*b*) $T = 2\pi r/v \approx 2$ s

5-5 Zero. At that instant you are no longer gaining speed and not yet losing speed. Your rate of change of speed is momentarily zero.

5-6 $1.60\ \mathrm{m/s^2}$

5-7 $x_{cm} = 2.0$ cm

5-8 $2R = 1.1 \times 10^2$ m

5-9 $F_x = m_1 g \sin\theta \cos\theta$.

PROBLEMS

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • Various objects lie on the bed of a truck that is moving along a straight horizontal road. If the truck gradually speeds up, what force acts on the objects to cause them to speed up too? Explain why some of the objects might stay stationary on the floor while others might slip backward on the floor. SSM

2 • Blocks made of the same material but differing in size lie on the bed of a truck that is moving along a straight horizontal road. All of the blocks will slide if the truck's acceleration is sufficiently great. How does the minimum acceleration at which a small block slips compare with the minimum acceleration at which a much heavier block slips?

3 • A block of mass m rests on a plane that is inclined at an angle θ with the horizontal. It follows that the coefficient of static friction between the block and plane is (*a*) $\mu_s \geq g$, (*b*) $\mu_s = \tan\theta$, (*c*) $\mu_s \leq \tan\theta$, (*d*) $\mu_s \geq \tan\theta$.

4 • A block of mass m is at rest on a plane that is inclined at an angle of 30° with the horizontal, as shown in Figure 5-56. Which of the following statements about the magnitude of the static frictional force f_s is necessarily true? (*a*) $f_s > mg$, (*b*) $f_s > mg\cos 30°$, (*c*) $f_s = mg\cos 30°$, (*d*) $f_s = mg\sin 30°$, (*e*) None of these statements is true.

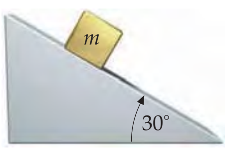

FIGURE 5-56 Problem 4

5 •• On an icy winter day, the coefficient of friction between the tires of a car and a roadway is reduced to one-quarter of its value on a dry day. As a result, the maximum speed $v_{max\,dry}$ at which the car can safely negotiate a curve of radius R is reduced. The new value for this speed is (*a*) $v_{max\,dry}$, (*b*) $0.71v_{max\,dry}$, (*c*) $0.50v_{max\,dry}$, (*d*) $0.25v_{max\,dry}$, (*e*) reduced by an unknown amount depending on the car's mass.

6 •• If it is started properly on the frictionless inside surface of a cone (Figure 5-57), a block is capable of maintaining uniform circular motion. Draw the free-body diagram of the block and identify clearly which force (or forces, or force components) is responsible for the centripetal acceleration of the block.

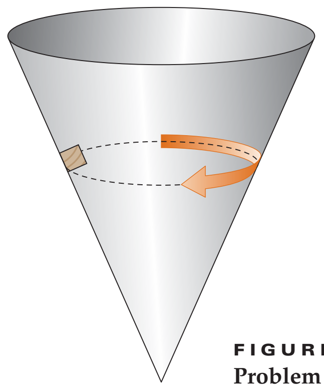

FIGURE 5-57
Problem 6

7 •• Here is an interesting experiment that you can perform at home: take a wooden block and rest it on the floor or some other flat surface. Attach a rubber band to the block and pull gently on the rubber band in the horizontal direction. Keep your hand moving at constant speed. At some point, the block will start moving, but it will not move smoothly. Instead, it will start moving, stop again, start moving again, stop again, and so on. Explain why the block moves this way. (The start-stop motion is sometimes called "stick-slip" motion.)

8 • Viewed from an inertial reference frame, an object is seen to be moving in a circle. Which, if any, of the following statements must be true. (*a*) A nonzero net force acts on the object. (*b*) The object cannot have a radially outward force acting on it. (*c*) At least one of the forces acting on the object must point directly toward the center of the circle.

9 •• A particle is traveling in a vertical circle at constant speed. One can conclude that the magnitude of its _____ is (are) constant. (*a*) velocity, (*b*) acceleration, (*c*) net force, (*d*) apparent weight.

10 •• You place a lightweight piece of iron on a table and hold a small kitchen magnet above the iron at a distance of 1.00 cm. You find that the magnet cannot lift the iron, even though there is obviously a force between the iron and the magnet. Next, holding the magnet in one hand and the piece of iron in the other, with the magnet 1.00 cm above the iron, you simultaneously drop them from rest. As they fall, the magnet and the piece of iron bang into each other before hitting the floor. (*a*) Draw free-body diagrams illustrating all of the forces on the magnet and the iron for each demonstration. (*b*) Explain why the magnet and iron move closer together while they are falling, even though the magnet cannot lift the piece of iron when it is sitting on the table.

11 ••• The following question is an excellent "braintwister," invented by Boris Korsunsky:* Two identical blocks are attached by a massless string running over a pulley, as shown in Figure 5-58.

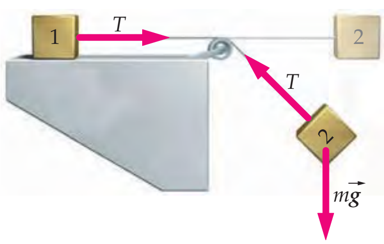

FIGURE 5-58
Problem 11

* Boris Korsunsky, "Braintwisters for Physics Students," *The Physics Teacher*, **33**, 550 (1995).

The rope initially runs over the pulley at the rope's midpoint, and the surface that block 1 rests on is frictionless. Blocks 1 and 2 are initially at rest when block 2 is released with the string taut and horizontal. Will block 1 hit the pulley before or after block 2 hits the wall? (Assume that the initial distance from block 1 to the pulley is the same as the initial distance from block 2 to the wall.) There is a very simple solution. SSM

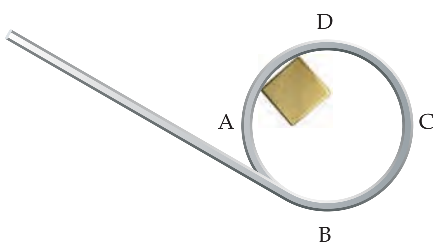
12 •• In class, most professors do the following experiment while discussing the conditions under which air drag can be neglected while analyzing free-fall. First, a flat piece of paper and a small lead weight are dropped next to each other, and clearly the paper's acceleration is less than that of the lead weight. Then, the paper is crumpled into a small wad and the experiment repeated. Over the distance of a meter or two, it is clear the acceleration of the paper is now very close to that of the lead weight. To your dismay, the professor calls on you to explain why the paper's acceleration changed so dramatically. Repeat your explanation here!

13 •• CONTEXT-RICH Jim decides to attempt to set a record for terminal speed in skydiving. Using the knowledge he has gained from a physics course, he makes the following plans. He will be dropped from as high an altitude as possible (equipping himself with oxygen), on a warm day and go into a "knife" position, in which his body is pointed vertically down and his hands are pointed ahead. He will outfit himself with a special sleek helmet and rounded protective clothing. Explain how each of these factors helps Jim attain the record. SSM

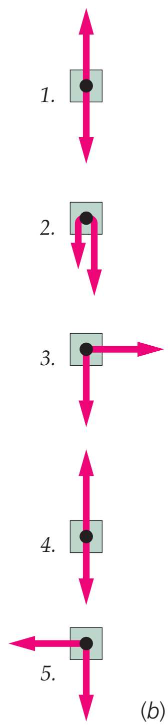
14 •• CONTEXT-RICH You are sitting in the passenger seat in a car driving around a circular, horizontal, flat racetrack at a high speed. As you sit there, you "feel" a "force" pushing you toward the outside of the track. What is the true direction of the force acting on you, and where does it come from? (Assume that you do not slide across the seat.) Explain the *sensation* of an "outward force" on you in terms of the Newtonian perspective.

15 • The mass of the moon is only about 1% of that of Earth. Therefore, the force that keeps the moon in its orbit around Earth (*a*) is much smaller than the gravitational force exerted on the moon by Earth, (*b*) is much greater than the gravitational force exerted on the moon by Earth, (*c*) actually is the gravitational force exerted on the moon by Earth, (*d*) cannot be answered yet, because we have not yet studied Newton's law of gravity. SSM

16 •• A block is sliding on a frictionless surface along a loop-the-loop, as in Figure 5-59*a*. The block is moving fast enough so that it never loses contact with the track. Match the points along the track to the appropriate free-body diagrams in Figure 5.59*b*.



(*a*)



(*b*)

FIGURE 5-59 **Problem 16**

17 •• (*a*) A rock and a feather held at the same height above the ground are simultaneously dropped. During the first few milliseconds following release, the drag force on the rock is smaller than the drag force on the feather, but later on during the fall the *opposite* is true. Explain. (*b*) In light of this result, explain how the rock's acceleration can be so obviously larger than that of the feather. *Hint: Draw a free-body diagram of each object.* SSM

18 •• Two pucks of masses m_1 and m_2 are lying on a frictionless table and are connected by a massless spring of force constant k. A horizontal force F_1 directed away from m_2 is then exerted on m_1. What is the magnitude of the resulting acceleration of the center of mass of the two-puck system? (*a*) F_1/m_1, (*b*) $F_1/(m_1 + m_2)$, (*c*) $(F_1 + kx)/(m_1 + m_2)$, where x is the amount the spring is stretched, (*d*) $(m_1 + m_2)F_1/m_1m_2$

19 •• The two pucks in Problem 18 lie unconnected on a frictionless table. A horizontal force F_1 directed away from m_2 is then exerted on m_1. How does the magnitude of the resulting acceleration of the center of mass of the two-puck system compare to the magnitude acceleration of m_1? Explain your reasoning.

20 •• If only external forces can cause the center of mass of a system of particles to accelerate, how can a car on level ground ever accelerate? We normally think of the car's engine as supplying the force needed to accelerate the car, but is this true? Where does the external force that accelerates the car come from?

21 •• When you push on the brake pedal to slow down a car, a brake pad is pressed against the rotor so that the friction of the pad slows the wheel's rotation. However, the friction of the pad against the rotor *cannot be* the force that slows the car down, because it is an internal force (both the rotor and the wheel are parts of the car, so any forces between them are purely internal to the system). What is the external force that slows down the car? Give a detailed explanation of how this force operates.

22 •• Give an example of each of the following: (*a*) a three-dimensional object that has no matter at its center of mass, (*b*) a solid object whose center of mass is outside of it, (*c*) a solid sphere whose center of mass does not lie at its geometrical center, (*d*) a long wooden stick whose center of mass does not lie at its middle.

23 •• **BIOLOGICAL APPLICATION** When you are standing upright, your center of mass is located within the volume of your body. However, as you bend over (say to pick up a package), its location changes. Approximately where is it when you are bent over at right angles and what change in your body caused the center of mass location to change? Explain. SSM

24 •• **ENGINEERING APPLICATION** Early on their three-day (one-way) trip to the moon, the Apollo team (late 1960s to early 1970s) would explosively separate the lunar ship from the third-stage booster (that provided the final "boost") while still fairly close to Earth. During the explosion, how did the velocity of each of the two pieces of the system change? How did the velocity of the center of mass of the system change?

25 •• You throw a boomerang and for a while it "flies" horizontally in a straight line at a constant speed, while spinning rapidly. Draw a series of pictures, as viewed vertically down from overhead, of the boomerang in different rotational positions as it moves parallel to the surface of Earth. On each picture, indicate the location of the boomerang's center of mass and connect the dots to trace the trajectory of its center of mass. What is the center of mass's acceleration during this part of the flight?

ESTIMATION AND APPROXIMATION

26 •• **ENGINEERING APPLICATION** To determine the aerodynamic drag on a car, automotive engineers often use the "coast-down" method. The car is driven on a long, flat road at some convenient speed (60 mi/h is typical), shifted into neutral, and allowed to coast to a stop. The time that it takes for the speed to drop by successive 5-mi/h intervals is measured and used to compute the net force slowing the car down. (*a*) One day, a group measured that a Toyota Tercel with a mass of 1020 kg coasted down from 60.0 mi/h to 55.0 mi/h in 3.92 s. Estimate the average net force slowing the car down in this speed range. (*b*) If the coefficient of rolling friction for this car is known to be 0.020, what is the force of rolling friction that is acting to slow it down? Assuming that the only two forces acting on the car are rolling friction and aerodynamic drag, what is the average drag force acting on the car? (*c*) The drag force has the form $\frac{1}{2}C\rho Av^2$, where A is the cross-sectional area of the car facing into the air, v is the car's speed, ρ is the density of air, and C is a dimensionless constant of order-of-magnitude 1. If the cross-sectional area of the car is 1.91 m^2, determine C from the data given. (The density of air is 1.21 kg/m^3; use 57.5 mi/h for the speed of the car in this computation.)

27 •• Using dimensional analysis, determine the units and dimensions of the constant b in the retarding force bv^n if (*a*) $n = 1$ and (*b*) $n = 2$. (*c*) Newton showed that the air resistance of a falling object with a circular cross section should be approximately $\frac{1}{2}\rho\pi r^2v^2$, where $\rho = 1.20$ kg/m^3, the density of air. Show that this is consistent with your dimensional analysis for part (*b*). (*d*) Find the terminal speed for a 56.0-kg skydiver; approximate his cross-sectional area as a disk of radius 0.30 m. The density of air near the surface of Earth is 1.20 kg/m^3. (*e*) The density of the atmosphere decreases with height above the surface of Earth; at a height of 8.0 km, the density is only 0.514 kg/m^3. What is the terminal velocity at this height? SSM

28 •• Estimate the terminal velocity of an average sized raindrop and a golf-ball-sized hailstone. *Hint: See Problems 26 and 27.*

29 •• Estimate the minimum coefficient of static friction needed between a car's tires and the pavement in order to complete a left turn at a city street intersection at the posted straight-ahead speed limit of 25 mph and on narrow inner-city streets. Comment on the wisdom of attempting such a turn at that speed.

30 •• Estimate the widest stance you can take when standing on a dry, icy surface. That is, how wide can you safely place your feet and not slip into an undesired "split"? Let the coefficient of static friction of rubber on ice be roughly 0.25.

FRICTION

31 • A block of mass m slides at constant speed down a plane inclined at an angle of θ with the horizontal. It follows that (*a*) $\mu_k = mg\sin\theta$, (*b*) $\mu_k = \tan\theta$, (*c*) $\mu_k = 1 - \cos\theta$, (*d*) $\mu_k = \cos\theta - \sin\theta$. SSM

32 • A block of wood is pulled at constant velocity by a horizontal string across a horizontal surface with a force of 20 N. The coefficient of kinetic friction between the surfaces is 0.3. The force of friction is (*a*) impossible to determine without knowing the mass of the block, (*b*) impossible to determine without knowing the speed of the block, (*c*) 0.30 N, (*d*) 6.0 N, (*e*) 20 N.

33 • A block weighing 20-N rests on a horizontal surface. The coefficients of static and kinetic friction between the surface and the

block are $\mu_s = 0.80$ and $\mu_k = 0.60$. A horizontal string is then attached to the block and a constant tension T is maintained in the string. What is the magnitude of the force of friction acting on the block if (*a*) $T = 15$ N, (*b*) $T = 20$ N? SSM

34 • A block of mass m is pulled at a constant velocity across a horizontal surface by a string as shown in Figure 5-60. The magnitude of the frictional force is (*a*) $\mu_k mg$, (*b*) $T\cos\theta$, (*c*) $\mu_k(T - mg)$, (*d*) $\mu_k T\sin\theta$, or (*e*) $\mu_k(mg - T\sin\theta)$.

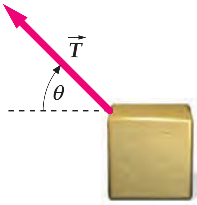


FIGURE 5-60 Problem 34

35 • A 100-kg crate rests on a thick-pile carpet. A weary worker then pushes on the crate with a horizontal force of 500 N. The coefficients of static and kinetic friction between the crate and the carpet are 0.600 and 0.400, respectively. Find the magnitude of the frictional force exerted by the carpet on the crate. SSM

36 • A box weighing 600 N is pushed along a horizontal floor at constant velocity with a force of 250 N parallel to the floor. What is the coefficient of kinetic friction between the box and the floor?

37 • The coefficient of static friction between the tires of a car and a horizontal road is 0.60. Neglecting air resistance and rolling friction, (*a*) what is the magnitude of the maximum acceleration of the car when it is braked? (*b*) What is the shortest distance in which the car can stop if it is initially traveling at 30 m/s? SSM

38 • The force that accelerates a car along a flat road is the frictional force exerted by the road on the car's tires. (*a*) Explain why the acceleration can be greater when the wheels do not slip. (*b*) If a car is to accelerate from 0 to 90 km/h in 12 s, what is the minimum coefficient of friction needed between the road and tires? Assume that the drive wheels support exactly half the weight of the car.

39 •• A 5.00-kg block is held at rest against a vertical wall by a horizontal force of 100 N. (*a*) What is the frictional force exerted by the wall on the block? (*b*) What is the minimum horizontal force needed to prevent the block from falling if the static coefficient of friction between the wall and the block is 0.400?

40 •• A tired and overloaded student is attempting to hold a large physics textbook wedged under his arm, as shown in Figure 5-61.

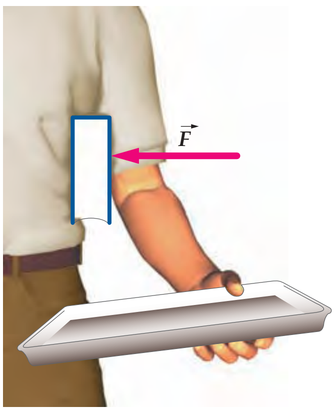

FIGURE 5-61 Problem 40

The textbook has a mass of 3.2 kg, while the coefficient of static friction of the textbook against the student's underarm is 0.320 and the coefficient of static friction of the book against the student's shirt is 0.160. (*a*) What is the minimum horizontal force that the student must apply to the textbook to prevent it from falling? (*b*) If the student can only exert a force of 61 N, what is the acceleration of the textbook as it slides from under his arm? The coefficient of kinetic friction of arm against textbook is 0.200, while that of shirt against textbook is 0.090.

41 •• **ENGINEERING APPLICATION** You are racing in a rally on a snowy day when the temperature is near the freezing point. The coefficient of static friction between a car's tires and an icy road is 0.080. Your crew boss is concerned about some of the hills on the course and wants you to think about switching to studded tires. To address the issue, he wants to compare the actual hill angles on the course to see which of them your car can negotiate. (*a*) What is the angle of the steepest incline that a vehicle with four-wheel drive can climb at constant speed? (*b*) Given that the hills are icy, what is the steepest possible hill angle for the same four-wheel drive car to descend at constant speed?

42 •• A 50-kg box that is resting on a level floor must be moved. The coefficient of static friction between the box and the floor is 0.60. One way to move the box is to push down on the box at an angle θ below the horizontal. Another method is to pull up on the box at an angle θ above the horizontal. (*a*) Explain why one method requires less force than the other. (*b*) Calculate the minimum force needed to move the box by each method if $\theta = 30°$ and compare the answer with the results when $\theta = 0°$.

43 •• A block of mass $m_1 = 250$ g is at rest on a plane that makes an angle of $\theta = 30°$ with the horizontal. The coefficient of kinetic friction between the block and the plane is 0.100. The block is attached to a second block of mass $m_2 = 200$ g that hangs freely by a string that passes over a frictionless, massless pulley (Figure 5-62). When the second block has fallen 30.0 cm, what will be its speed? SSM

FIGURE 5-62 Problems 43, 44, 45

44 •• In Figure 5-62, $m_1 = 4.0$ kg and the coefficient of static friction between the block and the incline is 0.40. (*a*) Find the range of possible values for m_2 for which the system will be in static equilibrium. (*b*) Find the frictional force on the 4.0-kg block if $m_2 = 1.0$ kg.

45 •• In Figure 5-62, $m_1 = 4.0$ kg, $m_2 = 5.0$ kg, and the coefficient of kinetic friction between the inclined plane and the 4.0-kg block is $\mu_k = 0.24$. Find the magnitude of the acceleration of the masses and the tension in the cord.

46 •• A 12-kg turtle rests on the bed of a zookeeper's truck, which is traveling down a country road at 55 mi/h. The zookeeper spots a deer in the road, and slows to a stop in 12 s. Assuming constant acceleration, what is the minimum coefficient of static friction between the turtle and the truck bed surface that is needed to prevent the turtle from sliding?

47 •• A 150-g block is projected up a ramp with an initial speed of 7.0 m/s. The coefficient of kinetic friction between the ramp and the block is 0.23. (*a*) If the ramp is inclined 25° with the horizontal, how far along the surface of the ramp does the block slide before coming to a stop? (*b*) The block then slides back down the ramp. What is the minimum coefficient of static friction between the block and the ramp if the block is not to slide back down the ramp? SSM

48 •• An automobile is going up a 15° grade at a speed of 30 m/s. The coefficient of static friction between the tires and the road is 0.70. (*a*) What minimum distance does it take to stop the car? (*b*) What minimum distance would it take to stop if the car were going down the grade?

49 •• **ENGINEERING APPLICATION** A rear-wheel-drive car supports 40 percent of its weight on its two drive wheels and has a coefficient of static friction of 0.70 with a horizontal straight road. (*a*) Find the vehicle's maximum acceleration. (*b*) What is the shortest possible time in which this car can achieve a speed of 100 km/h? (Assume the engine can provide unlimited power.)

50 •• You and your best pal make a friendly bet that you can place a 2.0-kg box against the side of a cart, as in Figure 5-63, and that the box will not fall to the ground, even though you guarantee to use no hooks, ropes, fasteners, magnets, glue, or adhesives of any kind. When your friend accepts the bet, you begin pushing the cart in the direction shown in the figure. The coefficient of static friction between the box and the cart is 0.60. (*a*) Find the minimum acceleration for which you will win the bet. (*b*) What is the magnitude of the frictional force in this case? (*c*) Find the force of friction on the box if the acceleration is twice the minimum needed for the box not to fall. (*d*) Show that, for a box of any mass, the box will not fall if the magnitude of the forward acceleration is $a \geq g/\mu_s$, where μ_s is the coefficient of static friction.

FIGURE 5-63 Problem 50

51 •• Two blocks attached by a string (Figure 5-64) slide down a 10° incline. Block 1 has mass $m_1 = 0.80$ kg and block 2 has mass $m_2 = 0.25$ kg. In addition, the kinetic coefficients of friction between the blocks and the incline are 0.30 for block 1 and 0.20 for block 2. Find (*a*) the magnitude of the acceleration of the blocks, and (*b*) the tension in the string.

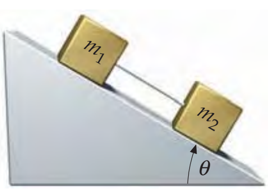

FIGURE 5-64 Problems 51 and 52

52 •• Two blocks of masses m_1 and m_2 are sliding down an incline as shown in Figure 5-64. They are connected by a massless *rod*. The coefficients of kinetic friction between the block and the surface are μ_1 for block 1 and μ_2 for block 2. (*a*) Determine the acceleration of the two blocks. (*b*) Determine the force that the rod exerts on each of the two blocks. Show that these forces are both 0 when $\mu_1 = \mu_2$ and give a simple, nonmathematical argument why this is true.

53 •• A block of mass m rests on a horizontal table (Figure 5-65). The block is pulled by a massless rope with a force $\vec{F}$ at an angle θ. The coefficient of static friction is 0.60. The minimum value of the force needed to move the block depends on the angle θ. (*a*) Discuss qualitatively how you would expect the magnitude of this force to depend on θ. (*b*) Compute the force for the angles $\theta = 0°, 10°, 20°, 30°, 40°, 50°$, and $60°$, and make a plot of F versus θ for $mg = 400$ N. From your plot, at what angle is it most efficient to apply the force to move the block? SSM

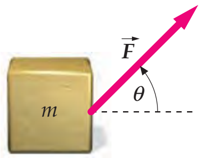

FIGURE 5-65 Problems 53 and 54

54 •• Consider the block in Figure 5-65. Show that, in general, the following results hold for a block of mass m resting on a horizontal surface whose coefficient of static friction is μ_s. (*a*) If you want to apply the *minimum* possible force to move the block, you should apply it with the force pulling upward at an angle $\theta = \tan^{-1}\mu_s$. (*b*) The minimum force necessary to start the block moving is $F_{min} = (\mu_s/\sqrt{1+\mu_s^2})mg$. (*c*) Once the block starts moving, if you want to apply the least possible force to keep it moving, should you keep the angle at which you are pulling the same, increase it, or decrease it?

55 •• Answer the questions in Problem 54, but for a force $\vec{F}$ that pushes down on the block at an angle θ *below* the horizontal.

56 •• A 100-kg mass is pulled along a frictionless surface by a horizontal force $\vec{F}$ such that its acceleration is $a_1 = 6.00\ \mathrm{m/s^2}$ (Figure 5-66). A 20.0-kg mass slides along the top of the 100-kg mass and has an acceleration of $a_2 = 4.00\ \mathrm{m/s^2}$. (It thus slides backward relative to the 100-kg mass.) (*a*) What is the frictional force exerted by the 100-kg mass on the 20.0-kg mass? (*b*) What is the net force acting on the 100-kg mass? What is the force F? (*c*) After the 20.0-kg mass falls off the 100-kg mass, what is the acceleration of the 100-kg mass? (Assume that the force F does not change.)

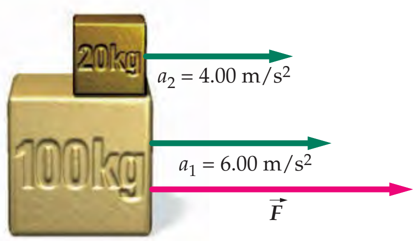

FIGURE 5-66 Problem 56

57 •• A 60-kg block slides along the top of a 100-kg block. The 60-kg block has an acceleration of 3.0 m/s² while a horizontal force of 320 N is applied to it, as shown in Figure 5-67. There is no friction between the 100-kg block and a horizontal frictionless surface, but there is friction between the two blocks. (*a*) Find the coefficient

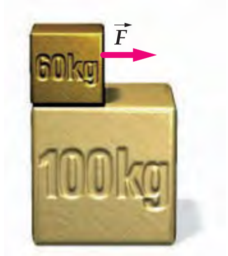

FIGURE 5-67 Problem 57

of kinetic friction between the blocks. (*b*) Find the acceleration of the 100-kg block during the time that the 60-kg block remains in contact.

58 •• The coefficient of static friction between a rubber tire and the road surface is 0.85. What is the maximum acceleration of a 1000-kg four-wheel-drive truck if the road makes an angle of 12° with the horizontal and the truck is (*a*) climbing, and (*b*) descending?

59 •• A 2.0-kg block sits on a 4.0-kg block that is on a frictionless table (Figure 5-68). The coefficients of friction between the blocks are $\mu_s = 0.30$ and $\mu_k = 0.20$. (*a*) What is the maximum horizontal force F that can be applied to the 4.0-kg block if the 2.0-kg block is not to slip? (*b*) If F has half this value, find the acceleration of each block and the force of friction acting on each block. (*c*) If F is twice the value found in (*a*), find the acceleration of each block.

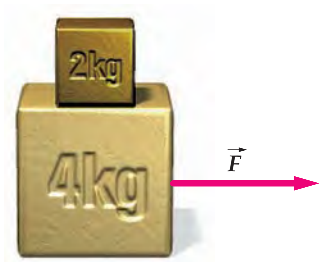

FIGURE 5-68 Problem 59

60 ••• A 10.0-kg block rests on a 5.0-kg bracket, as shown in Figure 5-69. The 5.0-kg bracket sits on a frictionless surface. The coefficients of friction between the 10.0-kg block and the bracket on which it rests are $\mu_s = 0.40$ and $\mu_k = 0.30$. (*a*) What is the maximum force F that can be applied if the 10.0-kg block is not to slide on the bracket? (*b*) What is the corresponding acceleration of the 5.0-kg bracket?

FIGURE 5-69 Problem 60

61 ••• You and your friends push a 75.0-kg greased pig up an aluminum slide at the county fair, starting from the low end of the slide. The coefficient of kinetic friction between the pig and the slide is 0.070. (*a*) All of you pushing together (parallel to the incline) manage to accelerate the pig from rest at the constant rate of 5.0 m/s^2 over a distance of 1.5 m, at which point you release the pig. The pig continues up the slide, reaching a maximum *vertical height* above its release point of 45 cm. What is the angle of inclination of the slide? (*b*) At the maximum height the pig turns around and begins to slip down the slide, how fast is it moving when it arrives at the low end of the slide?

62 ••• A 100-kg block on an inclined plane is attached to another block of mass m via a string, as in Figure 5-70. The coefficients of static and kinetic friction for the block and the incline are $\mu_s = 0.40$ and $\mu_k = 0.20$ and the plane is inclined 18° with horizontal. (*a*) Determine the range of values for m, the mass of the hanging block, for which the 100-kg block will not move unless disturbed, but if nudged, will slide down the incline. (*b*) Determine a range of values for m for which the 100-kg block will not move unless nudged, but if nudged will slide up the incline.

FIGURE 5-70 Problem 62

63 ••• A block of mass 0.50 kg rests on the inclined surface of a wedge of mass 2.0 kg, as in Figure 5-71. The wedge is acted on by a horizontal applied force $\vec{F}$ and slides on a frictionless surface. (*a*) If the coefficient of static friction between the wedge and the block is $\mu_s = 0.80$ and the wedge is inclined 35° with the horizontal, find the maximum and minimum values of the applied force for which the block does not slip. (*b*) Repeat part (*a*) with $\mu_s = 0.40$.

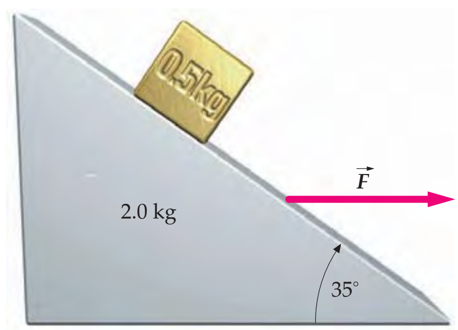

FIGURE 5-71 Problem 63

64 ••• **SPREADSHEET** In your physics lab, you and your lab partners push a block of wood with a mass of 10.0 kg (starting from rest), with a constant horizontal force of 70 N across a wooden floor. In the previous week's laboratory meeting, your group determined that the coefficient of kinetic friction was not exactly constant, but instead was found to vary with the object's speed according to $\mu_k = 0.11/(1 + 2.3 \times 10^{-4} v^2)^2$. Write a **spreadsheet** program using Euler's method to calculate and graph both the speed and the position of the block as a function of time from 0 to 10 s. Compare this result to the result you would get if you assumed the coefficient of kinetic friction had a constant value of 0.11.

65 ••• **MULTISTEP** In order to determine the coefficient of kinetic friction of a block of wood on a horizontal table surface, you are given the following assignment: Take the block of wood and give it an initial velocity across the surface of the table. Using a stopwatch, measure the time Δt it takes for the block to come to a stop and the total displacement Δx the block slides following the push. (*a*) Using Newton's laws and a free-body diagram of the block, show that the expression for the coefficient of kinetic friction is given by $\mu_k = 2\Delta x/[(\Delta t)^2 g]$. (*b*) If the block slides a distance of 1.37 m in 0.97 s, calculate μ_k. (*c*) What was the initial speed of the block?

66 •• **SPREADSHEET** (*a*) A block is sliding down an inclined plane. The coefficient of kinetic friction between the block and the plane is μ_k. Show that a graph of $a_x/\cos\theta$ versus $\tan\theta$ (where a_x is the acceleration down the incline and θ is the angle the plane is inclined with the horizontal) would be a straight line with slope g and intercept $-\mu_k g$. (*b*) The following data show the acceleration of a block sliding down an inclined plane as a function of the angle θ that the plane is inclined with the horizontal:*

θ (degrees)	Acceleration (m/s²)
25.0	1.69
27.0	2.10
29.0	2.41
31.0	2.89
33.0	3.18
35.0	3.49
37.0	3.78
39.0	4.15
41.0	4.33
43.0	4.72
45.0	5.11

Using a **spreadsheet** program, graph these data and fit a straight line to them to determine μ_k and g. What is the percentage difference between the obtained value of g and the commonly specified value of 9.81 m/s²?

DRAG FORCES

67 • A Ping-Pong ball has a mass of 2.3 g and a terminal speed of 9.0 m/s. The drag force is of the form bv^2. What is the value of b? SSM

68 • A small pollution particle settles toward Earth in still air. The terminal speed of the particle is 0.30 mm/s, the mass of the particle is 1.0×10^{-10} g and the drag force of the particle is of the form bv. What is the value of b?

69 •• A common classroom demonstration involves dropping basket-shaped coffee filters and measuring the time required for them to fall a given distance. A professor drops a single basket-shaped coffee filter from a height h above the floor, and records the time for the fall as Δt. How far will a stacked set of n identical filters fall during the same time interval Δt? Consider the filters to be so light that they instantaneously reach their terminal velocities. Assume a drag force that varies as the square of the speed and assume the filters are released oriented right-side up. SSM

70 •• A skydiver of mass 60.0 kg can slow herself to a constant speed of 90 km/h by orienting her body horizontally, looking straight down with arms and legs extended. In this position, she presents the maximum cross-sectional area and thus maximizes the air-drag force on her. (*a*) What is the magnitude of the drag force on the skydiver? (*b*) If the drag force is given by bv^2, what is the value of b? (c) At some instant she quickly flips into a "knife" position, orienting her body vertically with her arms straight down. Suppose this reduces the value of b to 55 percent of the value in Parts (*a*) and (*b*). What is her acceleration at the instant she achieves the "knife" position?

71 •• **ENGINEERING APPLICATION, CONTEXT-RICH** Your team of test engineers is to release the parking brake so an 800-kg car will roll down a very long 6.0 percent grade in preparation for a crash test at the bottom of the incline. (On a 6.0 percent grade the change in altitude is 6.0 percent of the horizontal distance traveled.) The total resistive force (air drag plus rolling friction) for this car has been previously established to be $F_d = 100\text{ N} + (1.2\text{ N}\cdot\text{s}^2/\text{m}^2)v^2$, where v is the speed of the car. What is the terminal speed for the car rolling down this grade?

72 ••• **APPROXIMATION** Small, slowly moving spherical particles experience a drag force given by Stokes' law: $F_d = 6\pi\eta r v$, where r is the radius of the particle, v is its speed, and η is the coefficient of viscosity of the fluid medium. (*a*) Estimate the terminal speed of a spherical pollution particle of radius 1.00×10^{-5} m and density of 2000 kg/m³. (*b*) Assuming that the air is still and that η is $1.80 \times 10^{-5}\text{ N}\cdot\text{s/m}^2$, estimate the time it takes for such a particle to fall from a height of 100 m.

73 ••• **ENGINEERING APPLICATION, CONTEXT-RICH** You have an environmental chemistry internship, and are in charge of a sample of air that contains pollution particles of the size and density given in Problem 72. You capture the sample in an 8.0-cm-long test tube. You then place the test tube in a centrifuge with the midpoint of the test tube 12 cm from the rotation axis of the centrifuge. You set the centrifuge to spin at 800 revolutions per minute. (*a*) Estimate the time you have to wait so that nearly all of the pollution particles settle to the end of the test tube. (*b*) Compare this to the time required for a pollution particle to fall 8.0 cm under the action of gravity and subject to the drag force given in Problem 72. SSM

MOTION ALONG A CURVED PATH

74 • A rigid rod with a 0.050-kg ball at one end rotates about the other end so the ball travels at constant speed in a vertical circle with a radius of 0.20 m. What is the maximum speed of the ball so that the force of the rod on the ball does not exceed 10 N?

75 • A 95-g stone is whirled in a horizontal circle on the end of an 85-cm-long string. The stone takes 1.2 s to make each complete revolution. Determine the angle that the string makes with the horizontal. SSM

76 •• A 0.20-kg stone is whirled in a horizontal circle on the end of an 0.80-m-long string. The string makes an angle of 20° with the horizontal. Determine the speed of the stone.

77 •• A 0.75-kg stone attached to a string is whirled in a horizontal circle of radius 35 cm as in the tetherball in Example 5-11. The string makes an angle of 30° with the vertical. (*a*) Find the speed of the stone. (*b*) Find the tension in the string.

78 •• **BIOLOGICAL APPLICATION** A pilot with a mass of 50 kg comes out of a vertical dive in a circular arc such that at the bottom of the arc her upward acceleration is $3.5g$. (*a*) How does the magnitude

* Data taken from Dennis W. Phillips, "Science Friction Adventure–Part II," *The Physics Teacher,* 553 (1990).

of the force exerted by the airplane seat on the pilot at the bottom of the arc compare to her weight? (*b*) Use Newton's laws of motion to explain why the pilot might be subject to a blackout. This means that an above normal volume of blood "pools" in her lower limbs. How would an inertial reference frame observer describe the cause of the blood pooling?

79 •• A 80.0-kg airplane pilot pulls out of a dive by following, at a constant speed of 180 km/h, the arc of a circle whose radius is 300 m. (*a*) At the bottom of the circle, what are the direction and magnitude of his acceleration? (*b*) What is the net force acting on him at the bottom of the circle? (*c*) What is the force exerted on the pilot by the airplane seat?

80 •• An small object of mass m_1 moves in a circular path of radius r on a frictionless horizontal tabletop (Figure 5-72). It is attached to a string that passes through a small frictionless hole in the center of the table. A second object with a mass of m_2 is attached to the other end of the string. Derive an expression for r in terms of m_1, m_2, and the time T for one revolution.

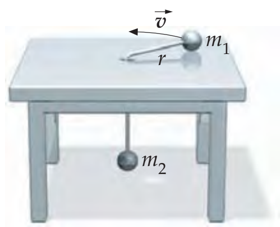

FIGURE 5-72 Problem 80

81 •• A block of mass m_1 is attached to a cord of length L_1, which is fixed at one end. The block moves in a horizontal circle on a frictionless tabletop. A second block of mass m_2 is attached to the first by a cord of length L_2 and also moves in a circle on the same frictionless tabletop, as shown in Figure 5-73. If the period of the motion is T, find the tension in each cord in terms of the given symbols. SSM

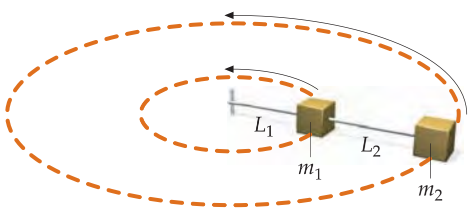

FIGURE 5-73 Problem 81

82 •• **MULTISTEP** A particle moves with constant speed in a circle of radius 4.0 cm. It takes 8.0 s to complete each revolution. (*a*) Draw the path of the particle to scale, and indicate the particle's position at 1.0-s intervals. (*b*) Sketch the displacement vectors for each interval. These vectors also indicate the directions for the average-velocity vectors for each interval. (*c*) Graphically find the magnitude of the change in the average velocity $|\Delta\vec{v}|$ for two consecutive 1-s intervals. Compare $|\Delta\vec{v}|/\Delta t$, measured in this way, with the magnitude of the instantaneous acceleration computed from $a_c = v^2/r$.

83 •• You are swinging your younger sister in a circle of radius 0.75 m, as shown in Figure 5-74. If her mass is 25 kg and you arrange it so she makes one revolution every 1.5 s, (*a*) what is the magnitude and direction of the force that must be exerted by you on her? (Model her as a point particle.) (*b*) What is the magnitude and direction of the force she exerts on you?

FIGURE 5-74 Problem 83 *(David de Lossy/The Image Bank.)*

84 •• The string of a conical pendulum is 50.0 cm long and the mass of the bob is 0.25 kg. (*a*) Find the angle between the string and the horizontal when the tension in the string is six times the weight of the bob. (*b*) Under those conditions, what is the period of the pendulum?

85 •• A 100-g coin sits on a horizontally rotating turntable. The turntable makes exactly 1.00 revolution each second. The coin is located 10 cm from the axis of rotation of the turntable. (*a*) What is the frictional force acting on the coin? (*b*) If the coin slides off the turntable when it is located more than 16.0 cm from the axis of rotation, what is the coefficient of static friction between the coin and the turntable?

86 •• A 0.25-kg tether ball is attached to a vertical pole by a 1.2-m cord. Assume the radius of the ball is negligible. If the ball moves in a horizontal circle with the cord making an angle of 20° with the vertical, (*a*) what is the tension in the cord? (*b*) What is the speed of the ball?

87 ••• A small bead with a mass of 100 g (Figure 5-75) slides without friction along a semicircular wire with a radius of 10 cm that rotates about a vertical axis at a rate of 2.0 revolutions per second. Find the value of θ for which the bead will remain stationary relative to the rotating wire.

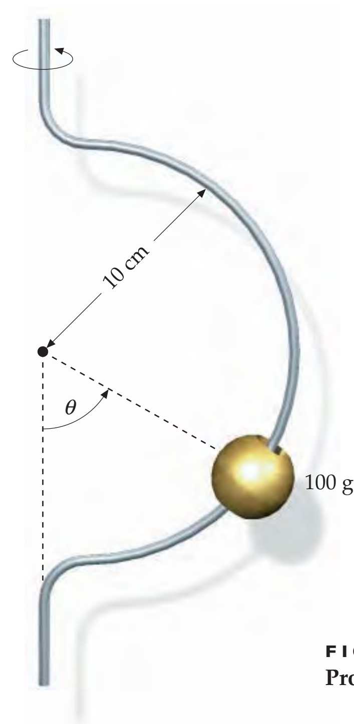

FIGURE 5-75 Problem 87

CENTRIPETAL FORCE

88 • A car speeds along the curved exit ramp of a freeway. The radius of the curve is 80.0 m. A 70.0-kg passenger holds the armrest of the car door with a 220-N force in order to keep from sliding across the front seat of the car. (Assume the exit ramp is not banked and ignore friction with the car seat.) What is the car's speed?

89 • The radius of curvature of the track at the top of a loop-the-loop on a roller-coaster ride is 12.0 m. At the top of the loop, the force that the seat exerts on a passenger of mass m is $0.40mg$. How fast is the roller-coaster car moving as it moves through the highest point of the loop. SSM

90 •• **ENGINEERING APPLICATION** On a runway of a decommissioned airport, a 2000-kg car travels at a constant speed of 100 km/h. At 100-km/h the air drag on the car is 500 N. Assume that rolling friction is negligible. (*a*) What is the force of static friction exerted on the car by the runway surface, and what is the minimum coefficient of static friction necessary for the car to sustain this speed? (*b*) The car continues to travel at 100 km/h, but now along a path with radius of curvature r. For what value of r will the angle between the static friction force vector and the velocity vector equal 45.0°, and for what value of r will it equal 88.0°? What is the minimum coefficient of static friction necessary for the car to hold this last radius of curvature without skidding?

91 •• Suppose you ride a bicycle in a 20-m-radius circle on a horizontal surface. The resultant force exerted by the surface on the bicycle (normal force plus frictional force) makes an angle of 15° with the vertical. (*a*) What is your speed? (*b*) If the frictional force on the bicycle is half its maximum possible value, what is the coefficient of static friction?

92 •• An airplane is flying in a horizontal circle at a speed of 480 km/h. The plane is banked for this turn, its wings tilted at an angle of 40° from the horizontal (Figure 5-76). Assume that a lift force acting perpendicular to the wings acts on the aircraft as it moves through the air. What is the radius of the circle in which the plane is flying?

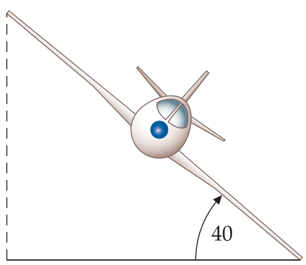

FIGURE 5-76 Problem 92

93 •• An automobile club plans to race a 750-kg car at the local racetrack. The car needs to be able to travel around several 160-m-radius curves at 90 km/h. What should the banking angle of the curves be so that the force of the pavement on the tires of the car is in the normal direction? *Hint: What does this requirement tell you about the frictional force?*

94 •• A curve of radius 150 m is banked at an angle of 10°. An 800-kg car negotiates the curve at 85 km/h without skidding. Neglect the effects of air drag and rolling friction. Find (*a*) the normal force exerted by the pavement on the tires, (*b*) the frictional force exerted by the pavement on the tires, (*c*) the minimum coefficient of static friction between the pavement and the tires.

95 •• On another occasion, the car in Problem 94 negotiates the curve at 38 km/h. Neglect the effects of air drag and rolling friction. Find (*a*) the normal force exerted on the tires by the pavement, and (*b*) the frictional force exerted on the tires by the pavement.

96 ••• **ENGINEERING APPLICATION** As a civil engineering intern during one of your summers in college, you are asked to design a curved section of roadway that meets the following conditions: When ice is on the road, and the coefficient of static friction between the road and rubber is 0.080, a car at rest must not slide into the ditch and a car traveling less than 60 km/h must not skid to the outside of the curve. Neglect the effects of air drag and rolling friction. What is the minimum radius of curvature of the curve and at what angle should the road be banked?

97 ••• **ENGINEERING APPLICATION** A curve of radius 30 m is banked so that a 950-kg car traveling at 40.0 km/h can round it even if the road is so icy that the coefficient of static friction is approximately zero. You are commissioned to tell the local police the range of speeds at which a car can travel around this curve without skidding. Neglect the effects of air drag and rolling friction. If the coefficient of static friction between the road and the tires is 0.300, what is the range of speeds you tell them?

* NUMERICAL INTEGRATION: EULER'S METHOD

* **98** •• **SPREADSHEET, APPROXIMATION** You are riding in a hovering hot air balloon when you throw a baseball straight down with an initial speed of 35.0 km/h. The baseball falls with a terminal speed of 150 km/h. Assuming air drag is proportional to the speed squared, use Euler's method (**spreadsheet**) to estimate the speed of the ball after 10.0 s. What is the uncertainty in this estimate? You drop a second baseball, this one is released from rest. How long does it take for it to reach 99 percent of its terminal speed? How far does it fall during this time?

* **99** •• **SPREADSHEET, APPROXIMATION** You throw a baseball straight up with an initial speed of 150 km/h. The ball's terminal speed when falling is also 150 km/h. (*a*) Use Euler's method (**spreadsheet**) to estimate its height 3.50 s after release. (*b*) What is the maximum height it reaches? (*c*) How long after release does it reach its maximum height? (*d*) How much later does it return to the ground? (*e*) Is the time the ball spends on the way up less than, the same as, or greater than the time it spends on the way down? SSM

* **100** ••• **SPREADSHEET, APPROXIMATION** A 0.80-kg block on a horizontal frictionless surface is held against a massless spring, compressing it 30 cm. The force constant of the spring is 50 N/m. The block is released and the spring pushes it 30 cm. Use Euler's method (**spreadsheet**) with $\Delta t = 0.0050$ s to estimate the time it takes for the spring to push the block the 30 cm. How fast is the block moving at this time? What is the uncertainty in this speed?

FINDING THE CENTER OF MASS

101 • Three point masses of 2.0 kg each are located on the x axis. One is at the origin, another at $x = 0.20$ m, and another at $x = 0.50$ m. Find the center of mass of the system.

102 • On a weekend archeological dig, you discover an old club-ax that consists of a symmetrical 8.0-kg stone attached to the end of a uniform 2.5-kg stick. You measure the dimensions of the club-ax as shown in Figure 5-77. How far is the center of mass of the club-ax from the handle end of the club-ax?

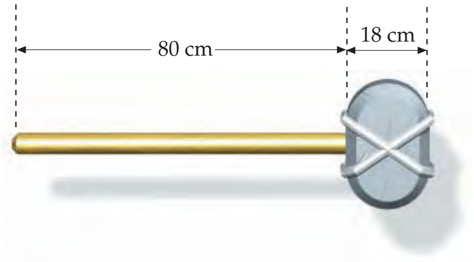

FIGURE 5-77 Problem 102

103 • Three balls A, B, and C, with masses of 3.0 kg, 1.0 kg, and 1.0 kg, respectively, are connected by massless rods, as shown in Figure 5-78. What are the coordinates of the center of mass of this system?

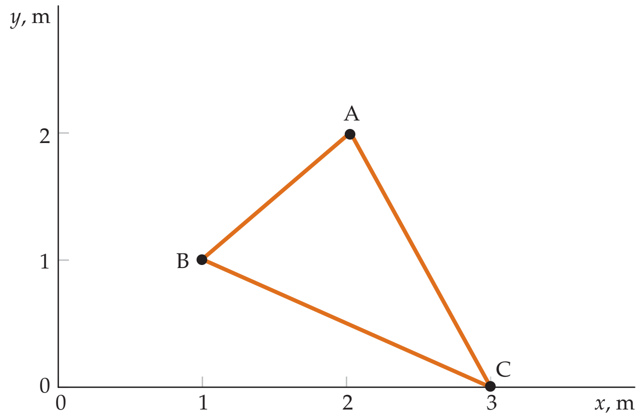

FIGURE 5-78 Problems 103 and 115

104 • By symmetry, locate the center of mass of a uniform sheet in the shape of an equilateral triangle with edges of length a. The triangle has one vertex on the y axis and the others at $(-a/2, 0)$ and $(+a/2, 0)$.

105 •• Find the center of mass of the uniform sheet of plywood in Figure 5-79. Consider this as a system of effectively two sheets, letting one have a "negative mass" to account for the cutout. Thus, one is a square sheet of 3.0-m edge length and mass m_1 and the second is a rectangular sheet measuring $1.0\ \text{m} \times 2.0\ \text{m}$ with a mass of $-m_2$. Let the coordinate origin be at the lower left corner of the sheet. SSM

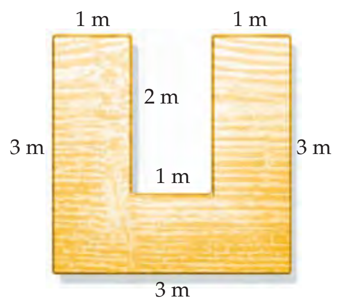

FIGURE 5-79 Problem 105

106 •• A can in the shape of a symmetrical cylinder with mass M and height H is filled with water. The initial mass of the water is M, the same mass as the can. A small hole is punched in the bottom of the can, and the water drains out. (*a*) If the height of the water in the can is x, what is the height of the center of mass of the can plus the water remaining in the can? (*b*) What is the minimum height of the center of mass as the water drains out?

107 •• Two identical thin uniform rods each of length L are glued together at the ends so that the angle at the joint is 90°. Determine the location of the center of mass (in terms of L) of this configuration relative to the origin taken to be at the joint. *Hint: You do not need the mass of the rods, but you should start by assuming a mass m and see that it cancels out.* SSM

108 ••• Repeat the analysis of Problem 107 with a general angle θ at the joint instead of 90°. Does your answer agree with the specific 90°-angle answer in Problem 107 if you set θ equal to 90°? Does your answer give plausible results for angles of zero and 180°?

* 109 •• **Finding the Center of Mass by Integration** Show that the center of mass of a uniform semicircular disk of radius R is at a point $4R/(3\pi)$ from the center of the circle.

* 110 •• Find the location of the center of mass of a nonuniform rod 0.40 m in length if its density varies linearly from 1.00 g/cm at one end to 5.00 g/cm at the other end. Specify the center-of-mass location relative to the less-massive end of the rod.

* 111 ••• You have a thin uniform wire bent into part of a circle that is described by a radius R and angle θ_m (see Figure 5-80). Show that the location of its center of mass is on the x axis and located a distance $x_{cm} = (R \sin\theta_m)/\theta_m$, where θ_m is expressed in radians. Check your answer by showing that this answer gives the physically expected limit for $\theta_m = 180°$. Verify that your answer gives you the result in the text (in the subsection Finding the Center of Mass by Integration) for the special case of $\theta_m = 90°$.

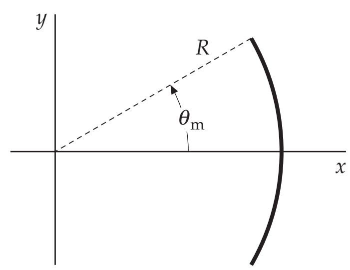

FIGURE 5-80 Problem 111

* 112 ••• A long, thin wire of length L has a linear mass density given by $A - Bx$, where A and B are positive constants and x is the distance from the more massive end. (*a*) A condition for this problem to be realistic is that $A > BL$. Explain why. (*b*) Determine x_{cm} in terms of L, A, and B. Does your answer make sense if $B = 0$? Explain.

MOTION OF THE CENTER OF MASS

113 • Two 3.0-kg particles have velocities $\vec{v}_1 = (2.0\ \text{m/s})\hat{i} + (3.0\ \text{m/s})\hat{j}$ and $\vec{v}_2 = (4.0\ \text{m/s})\hat{i} - (6.0\ \text{m/s})\hat{j}$. Find the velocity of the center of mass of the system. SSM

114 • A 1500-kg car is moving westward with a speed of 20.0 m/s, and a 3000-kg truck is traveling east with a speed of 16.0 m/s. Find the velocity of the center of mass of the car–truck system.

115 • A force $\vec{F} = 12\text{ N }\hat{i}$ is applied to the 3.0-kg ball in Figure 5-78 in Problem 103. (No forces act on the other two balls.) What is the acceleration of the center of mass of the three-ball system?

116 •• A block of mass m is attached to a string and suspended inside an otherwise empty box of mass M. The box rests on a scale that measures the system's weight. (*a*) If the string breaks, does the reading on the scale change? Explain your reasoning. (*b*) Assume that the string breaks and the mass m falls with constant acceleration g. Find the magnitude and direction of the acceleration of the center of mass of the box–block system. (*c*) Using the result from (*b*), determine the reading on the scale while m is in free-fall.

117 •• The bottom end of a massless, vertical spring of force constant k rests on a scale and the top end is attached to a massless cup, as in Figure 5-81. Place a ball of mass m_b gently into the cup and ease it down into an equilibrium position where it sits at rest in the cup. (*a*) Draw the separate free-body diagrams for the ball and the spring. (*b*) Show that in this situation, the spring compression d is given by $d = m_b g/k$. (*c*) What is the scale reading under these conditions? SSM

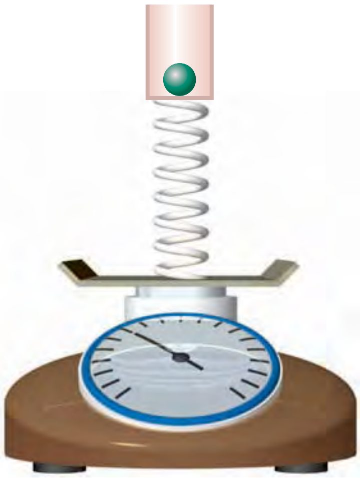

FIGURE 5-81 Problem 117

118 ••• In the Atwood's machine in Figure 5-82 the string passes over a fixed cylinder of mass m_c. The cylinder does not rotate. Instead, the string slides on its frictionless surface. (*a*) Find the acceleration of the center of mass of the two-block–cylinder-string system. (*b*) Use Newton's second law for systems to find the force F exerted by the support. (*c*) Find the tension T in the string connecting the blocks and show that $F = m_c g + 2T$.

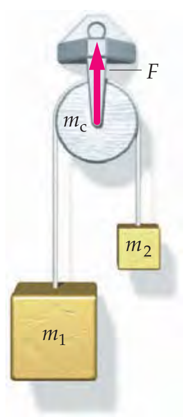

FIGURE 5-82 Problem 118

119 ••• Starting with the equilibrium situation in Problem 117, the whole system (scale, spring, cup, and ball) is now subjected to an upward acceleration of magnitude a (for example, in an elevator). Repeat the free-body diagrams and calculations in Problem 117?

GENERAL PROBLEMS

120 • In designing your new house in California, you are prepared for it to withstand a maximum horizontal acceleration of $0.50g$. What is the minimum coefficient of static friction between the floor and your prized Tuscan vase so that the vase does not slip on the floor under these conditions?

121 • A 4.5-kg block slides down an inclined plane that makes an angle of 28° with the horizontal. Starting from rest, the block slides a distance of 2.4 m in 5.2 s. Find the coefficient of kinetic friction between the block and plane.

122 •• You plan to fly a model airplane of mass 0.400 kg that is attached to a horizontal string. The plane will travel in a horizontal circle of radius 5.70 m. (Assume the weight of the plane is balanced by the upward "lift" force of the air on the wings of the plane.) The plane will make 1.20 revolutions every 4.00 s. (*a*) Find the speed at which you must fly the plane. (*b*) Find the force exerted on your hand as you hold the string (assume the string is massless).

123 •• **CONTEXT-RICH** Your moving company is to load a crate of books on a truck with the help of some planks that slope upward at 30°. The mass of the crate is 100 kg, and the coefficient of sliding friction between it and the planks is 0.500. You and your employees push *horizontally* with a combined net force $\vec{F}$. Once the crate has started to move, how large must F be in order to keep the crate moving at constant speed?

124 •• Three forces act on an object in static equilibrium (Figure 5-83). (*a*) If F_1, F_2, and F_3 represent the magnitudes of the forces acting on the object, show that $F_1/\sin\theta_{23} = F_2/\sin\theta_{31} = F_3/\sin\theta_{12}$. (*b*) Show that $F_1^2 = F_2^2 + F_3^2 + 2F_2F_3\cos\theta_{23}$.

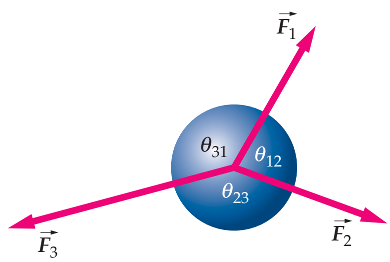

FIGURE 5-83 Problem 124

125 •• In a carnival ride, you sit on a seat in a compartment that rotates with constant speed in a vertical circle of radius 5.0 m. The ride is designed so your head always points toward the center of the circle. (*a*) If the ride completes one full circle in 2.0 s, find the direction and magnitude of your acceleration. (*b*) Find the slowest rate of rotation (in other words, the longest time T_m to complete one full circle) if the seat belt is to exert no force on you at the top of the ride.

126 •• A flat-topped toy cart moves on frictionless wheels, pulled by a rope under tension T. The mass of the cart is m_1. A load of mass m_2 rests on top of the cart with the coefficient of static friction μ_s between the cart and the load. The cart is pulled up a ramp that is inclined at angle θ above the horizontal. The rope is parallel to the ramp. What is the maximum tension T that can be applied without causing the load to slip?

127 ••• A sled weighing 200 N that is held in place by static friction, rests on a 15° incline. The coefficient of static friction between the sled and the incline is 0.50. (*a*) What is the magnitude of the normal force on the sled? (*b*) What is the magnitude of the static frictional force on the sled? (*c*) The sled is now pulled up the incline (Figure 5-84) at constant speed by a child walking up the incline ahead of the sled. The child weighs 500 N and pulls on the rope with a constant force of 100 N. The rope makes an angle of 30° with the incline and has negligible mass. What is the magnitude of the kinetic frictional force on the sled? (*d*) What is the coefficient of kinetic friction between the sled and the incline? (*e*) What is the magnitude of the force exerted on the child by the incline?

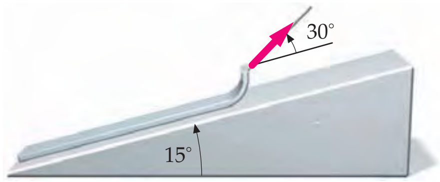

FIGURE 5-84 Problem 127

128 •• **ENGINEERING APPLICATION** In 1976, Gerard O'Neill proposed that large space stations be built for human habitation in orbit around Earth and the moon. Because prolonged free-fall has adverse medical effects, he proposed making the stations in the form of long cylinders and spinning them around the cylinder axis to provide the inhabitants with the sensation of gravity. One such O'Neill colony is to be built 5.0 miles long, with a diameter of 0.60 mi. A worker on the inside of the colony would experience a sense of "gravity," because he would be in an accelerated frame of reference due to the rotation. (*a*) Show that the "acceleration of gravity" experienced by the worker in the O'Neill colony is equal to his centripetal acceleration. *Hint: Consider someone "looking in" from outside the colony.* (*b*) If we assume that the space station is composed of several decks that are at varying distances (radii) from the axis of rotation, show that the "acceleration of gravity" becomes weaker the closer the worker gets to the axis. (*c*) How many revolutions per minute would this space station have to make to give an "acceleration of gravity" of $9.8\,\mathrm{m/s^2}$ at the outermost edge of the station?

129 •• A child of mass m slides down a slide inclined at 30° in time t_1. The coefficient of kinetic friction between her and the slide is μ_k. She finds that if she sits on a small sled (also of mass m) with frictionless runners, she slides down the same slide in time $\frac{1}{2}t_1$. Find μ_k.

130 ••• The position of a particle of mass $m = 0.80$ kg as a function of time is given by $\vec{r} = x\hat{i} + y\hat{j} = (R\sin\omega t)\,\hat{i} + (R\cos\omega t)\,\hat{j}$, where $R = 4.0$ m and $\omega = 2\pi\ \mathrm{s^{-1}}$. (*a*) Show that the path of this particle is a circle of radius R, with its center at the origin of the xy plane. (*b*) Compute the velocity vector. Show that $v_x/v_y = -y/x$. (*c*) Compute the acceleration vector and show that it is directed toward the origin and has the magnitude v^2/R. (*d*) Find the magnitude and direction of the net force acting on the particle.

131 ••• **MULTISTEP** You are on an amusement park ride with your back against the wall of a spinning vertical cylinder. The floor falls away and you are held up by static friction. Assume your mass is 75 kg. (*a*) Draw a free-body diagram of yourself. (*b*) Use this diagram with Newton's laws to determine the force of friction on you. (*c*) If the radius of the cylinder is 4.0 m and the coefficient of static friction between you and the wall is 0.55. What is the minimum number of revolutions per minute necessary to prevent you from sliding down the wall? Does this answer hold only for you? Will other, more massive, patrons fall downward? Explain.

132 ••• An block of mass m_1 is on a horizontal table. The block is attached to a 2.5-kg block (m_2) by a light string that passes over a pulley at the edge of the table. The block of mass m_2 dangles 1.5 m above the ground (Figure 5-85). The string that connects them passes over a frictionless, massless pulley. This system is released from rest at $t = 0$ and the 2.5-kg block strikes the ground at $t = 0.82$ s. The system is now placed in its initial configuration and a 1.2-kg block is placed on top of the block of mass m_1. Released from rest, the 2.5-kg block now strikes the ground 1.3 s later. Determine the mass m_1 and the coefficient of kinetic friction between the block whose mass is m_1 and the table.

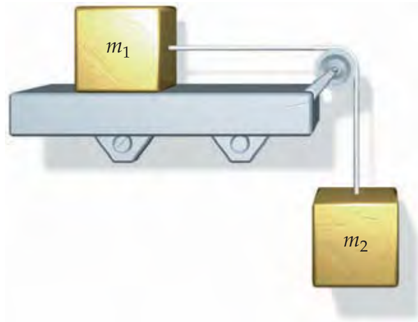

FIGURE 5-85 Problem 132

133 ••• Sally claims flying squirrels do not really fly; they jump and use the folds of skin that connect their forelegs and their back legs like a parachute to allow them to glide from tree to tree. Liz decides to test Sally's hypothesis by calculating the terminal speed of a falling outstretched flying squirrel. If the constant b in the drag force is proportional to the area of the object facing the air flow, use the results of Example 5-12 and some assumptions about the size of the squirrel to estimate its terminal (downward) speed. Is Sally's claim supported by Liz's calculation?

134 •• **BIOLOGICAL APPLICATION** After a parachutist jumps from an airplane (but before he pulls the rip cord to open his parachute), a downward speed of up to 180 km/h can be reached. When the parachute is finally opened, the drag force is increased by about a factor of 10, and this can create a large jolt on the jumper. Suppose this jumper falls at 180 km/h before opening his chute. (*a*) Determine the parachutist's acceleration when the chute is just opened, assuming his mass is 60 kg. (*b*) If rapid accelerations greater than 5.0g can harm the structure of the human body, is this a safe practice?

135 • Find the location of the center of mass of the Earth–moon system relative to the center of Earth. Is it inside or outside the surface of Earth?

136 •• A circular plate of radius R has a circular hole of radius $R/2$ cut out of it (Figure 5-86). Find the center of mass of the plate after the hole has been cut. *Hint: The plate can be modeled as two disks superimposed, with the hole modeled as a disk negative mass.*

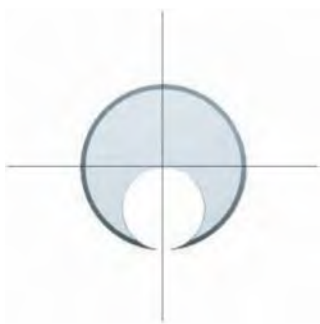

FIGURE 5-86 Problem 136

137 •• An unbalanced baton consists of a 50-cm-long uniform rod of mass 200 g. At one end there is a 10-cm-diameter uniform solid sphere of mass 500 g, and at the other end there is a 8.0-cm-diameter uniform solid sphere of mass 750 g. (The center-to-center distance between the spheres is 59 cm.) (*a*) Where, relative to the center of the light sphere, is the center of mass of this baton? (*b*) If this baton is tossed straight up (but spinning) so that its initial center of mass speed is 10.0 m/s, what is the velocity of the center of mass 1.5 s later? (*c*) What is the net external force on the baton while in the air? (*d*) What is the acceleration of the baton's center of mass 1.5 s following its release?

138 •• You are standing at the very rear of a 6.0-m-long, 120-kg raft that is at rest in a lake with its prow only 0.50 m from the end of the pier (Figure 5-87). Your mass is 60 kg. Neglect frictional forces between the raft and the water. (*a*) How far from the end of the pier is the center of mass of the you–raft system? (*b*) You walk to the front of the raft and then stop. How far from the end of the pier is the center of mass now? (*c*) When you are at the front of the raft, how far are you from the end of the pier?

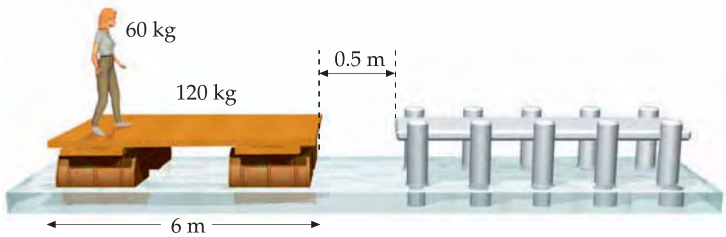

FIGURE 5-87 Problem 138

139 •• An Atwood's machine that has a frictionless massless pulley and massless strings has a 2.00-kg object hanging from one side and 4.00-kg object hanging from the other side. (*a*) What is the speed of each object 1.50 s after they are simultaneously released from rest? (*b*) At that time, what is the velocity of the center of mass of the two objects? (*c*) At that moment, what is the acceleration of the center of mass of the two objects?

CHAPTER 6

THE SNOW MELTS UNDER THE SKIES DUE TO THE KINETIC FRICTION BETWEEN THE SKIS AND THE SNOW. THE SKIER IS GLIDING DOWN THE MOUNTAIN ON A THIN LAYER OF LIQUID WATER. *(Courtesy of Rossignol Ski Company.)*

Work and Kinetic Energy

? How does the shape of the hill or the length of the path affect a skier's final speed at the finish line? (See Example 6-12.)

Thus far, we have analyzed motion by using concepts such as position, velocity, acceleration, and force. However, some types of motion are difficult to describe using Newton's laws directly. (A speed skier sliding down a curved slope is an example of this type of motion.) In this chapter and Chapter 7, we look at alternative methods for analyzing motion that involve two central concepts in science: energy and work. Unlike force, which is a vector physical quantity, energy and work are scalar physical quantities associated with particles and with systems of particles. As you will see, these new concepts provide powerful methods for solving a wide class of problems.

In this chapter, we explore the concept of work and how work is related to kinetic energy—the energy associated with the motion of objects. We also discuss the related concepts of power and center-of-mass work.

6-1 WORK DONE BY A CONSTANT FORCE

You may be used to thinking of work as anything that requires physical or mental exertion, such as studying for an exam, carrying a backpack, or riding a bike. But in physics, work is the transfer of energy by a force. If you stretch a spring by pulling on it with your hand (Figure 6-1), energy is transferred from you to the spring, and the energy transferred from you to the spring is equal to the work done by the force of your hand on the spring. The energy transferred to the spring can be evidenced if you let go of the spring and watch it rapidly contract and vibrate.

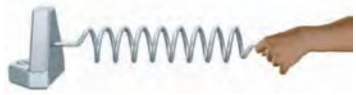

FIGURE 6-1 Energy is transferred from the person to the spring as the spring lengthens. The energy transferred is equal to the work done by the person on the spring.

Work is a scalar quantity that can be positive, negative, or zero. The work done by object A on object B is positive if energy is transferred from A to B, and is negative if energy is transferred from B to A. If no energy is transferred, the work done is zero. In the case of you stretching a spring, the work done by you on the spring is positive because energy is transferred from you to the spring. However, suppose you move your hand so the spring slowly contracts to its unstressed state. During the contraction the spring loses energy—energy is transferred from the spring to you—and the work you do on the spring is negative.

CONCEPT CHECK 6-1

For the contraction of the spring described immediately before this concept check, is the work done by the spring on the person positive or negative?

It is commonly said that work is force times distance. Unfortunately, the statement "work is force times distance" is misleadingly simple. Work is done on an object by a force when the point of application of the force moves through a displacement. For a constant force, the work done equals the force component in the direction of the displacement times the magnitude of the displacement. For example, suppose you push a box along the ground with a constant horizontal force $\vec{F}$ in the direction of displacement $\Delta x\,\hat{i}$ (Figure 6-2a). Because the force acts on the box in the same direction as the displacement, the work W done by the force on the box is

$$W = F\,|\Delta x|$$

Now suppose you pull on a string attached to the box, such that force acts at an angle to the displacement, as shown in Figure 6-2b. In this case, the work done on the box by the force is given by the force component *in the direction* of the displacement times the magnitude of the displacement:

$$W = F_x \Delta x = F\cos\theta\,|\Delta x| \qquad 6\text{-}1$$

WORK BY A CONSTANT FORCE

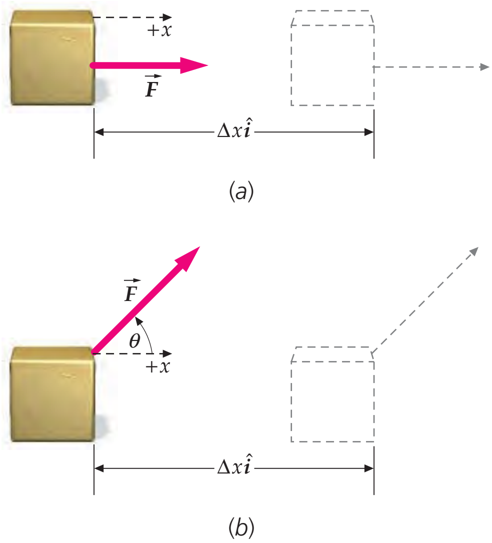

FIGURE 6-2

where F is the magnitude of the constant force, $|\Delta x|$ is the magnitude of the displacement of the point of application of the force, and θ is the angle between the directions of the force and displacement vectors. The displacement of the point of application of the force is identical to the displacement of any other point on the box because the box is rigid and moves without rotating. If you raise or lower a box by exerting a force $\vec{F}$ on it, you are doing work on the box. Let up be the positive y direction and let $\Delta y\,\hat{j}$ be the displacement of the box. The work done by you on the box is positive if Δy and F_y have the same signs and negative if they have opposite signs. But if you are simply holding the box in a fixed position then, according to the definition of work, you are not doing work *on the box* because the Δy is zero (Figure 6-3). In this case, the work you do on the box is zero, even though you are applying a force.

FIGURE 6-3

The SI unit of work is the **joule** (J), which equals the product of a newton and a meter:

$$1\text{ J} = 1\text{ N}\cdot\text{m} \qquad 6\text{-}2$$

In the U.S. customary system, the unit of work is the foot-pound: $1\text{ ft}\cdot\text{lb} = 1.356\text{ J}$. Another convenient unit of work in atomic and nuclear physics is the **electron volt** (eV):

$$1\text{ eV} = 1.602\times10^{-19}\text{ J} \qquad 6\text{-}3$$

Commonly used multiples of eV are keV (10^3 eV) and MeV (10^6 eV). The work required to remove an electron from an atom is of the order of a few eV, whereas the work needed to remove a proton or a neutron from an atomic nucleus is of the order of several MeV.

PRACTICE PROBLEM 6-1

A force of 12 N is exerted on a box at an angle of $\theta = 20°$, as in Figure 6-2*b*. How much work is done by the force on the box as the box moves along the table a distance of 3.0 m?

If there are several forces that do work on *a system*, the total work is found by computing the work done by each force and adding each individual work together.

$$W_{\text{total}} = F_{1x}\,\Delta x_1 + F_{2x}\,\Delta x_2 + F_{3x}\,\Delta x_3 + \cdots \qquad 6\text{-}4$$

We model the system as a *particle* if the system moves so all the parts of the system undergo identical displacements. When several forces do work on such a *particle*, the displacements of the points of application of these forces are identical. Let the displacement of the point of application of any one of the forces be Δx. Then

$$W_{\text{total}} = F_{1x}\,\Delta x + F_{2x}\,\Delta x + \cdots = (F_{1x} + F_{2x} + \cdots)\Delta x = F_{\text{net}\,x}\,\Delta x \qquad 6\text{-}5$$

For a particle constrained to move along the x axis, the net force has only an x component. That is, $\vec{F}_{\text{net}} = F_{\text{net}\,x}\hat{i}$. Thus, for a particle, the x component of the net force times the displacement of any part of the object is equal to the total work done on the object.

Example 6-1 Loading with a Crane

A 3000-kg truck is to be loaded onto a ship by a crane that exerts an upward force of 31 kN on the truck. This force, which is strong enough to overcome the gravitational force and keep the truck moving upward, is applied over a distance of 2.0 m. Find (*a*) the work done on the truck by the crane, (*b*) the work done on the truck by gravity, and (*c*) the net work done on the truck.

PICTURE In Parts (*a*) and (*b*), the force acting on the truck is constant and the displacement is in a straight line, so we can use Equation 6-1, choosing the $+y$ direction as the direction of the displacement:

SOLVE

(*a*) 1. Sketch the truck at its initial and final positions, and choose the $+y$ direction to be the direction of the displacement (Figure 6-4):

2. Calculate the work done by the applied force:

$$W_{\text{app}} = F_{\text{app}\,y}\,\Delta y = (31\text{ kN})(2.0\text{ m}) = \boxed{62\text{ kJ}}$$

(*b*) Calculate the work done by the force of gravity:
(*Note*: The vector $\vec{g}$ is directed downward and the $+y$ direction is upward. Consequently, $g_y = g\cos 180° = -g$.)

$$W_g = mg_y\,\Delta y = (3000\text{ kg})(-9.81\text{ N/kg})(2.0\text{ m}) = \boxed{-59\text{ kJ}}$$

(*c*) The net work done on the truck is the sum of the work done by each force:

$$W_{net} = W_{\text{app}\,y} + W_g = 62\text{ kJ} + (-59\text{ kJ}) = \boxed{3\text{ kJ}}$$

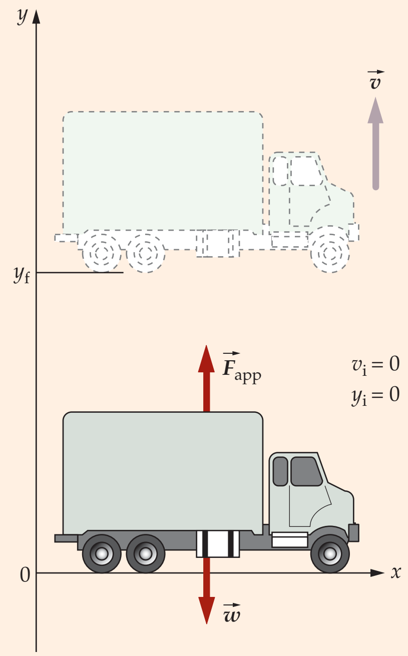

FIGURE 6-4

CHECK In Part (*a*), the force is applied in the same direction as the displacement, so we expect the work done on the truck to be positive. In Part (*b*), the force is applied in a direction opposite the displacement, so we expect the work done on the truck to be negative. Our results match these expectations.

TAKING IT FURTHER In Part (*c*), we also could have found the total work by first calculating the net force on the truck and then using Equation 6-5.

THE WORK–KINETIC-ENERGY THEOREM

Energy is one of the most important unifying concepts in science. All physical processes involve energy. The **energy** of a system is a measure of its ability to do work.

Different terms are used to describe the energy associated with different conditions or states. **Kinetic energy** is energy associated with motion. *Potential energy* is energy associated with the configuration of a system, such as the separation distance between two objects that attract each other. *Thermal energy* is associated with the random motion of the atoms, molecules, or ions within a system and is closely connected with the temperature of the system. In this chapter, we focus on kinetic energy. Potential energy and thermal energy are discussed in Chapter 7.

When forces do work on a particle, the result is a change in the energy associated with the motion of the particle—the kinetic energy. To evaluate the relationship between kinetic energy and work, let us look at what happens if a constant net force $\vec{F}_{\text{net}}$ acts on a particle of mass m that moves along the x axis. Applying Newton's second law, we see that

$$F_{\text{net}\,x} = ma_x$$

If the net force is constant, the acceleration is constant, and we can relate the displacement to the initial speed v_{i} and final speed v_{f} by using the constant-acceleration kinematic equation (Equation 2-16)

$$v_{\text{f}}^2 = v_{\text{i}}^2 + 2a_x\,\Delta x$$

Solving this for a_x gives

$$a_x = \frac{1}{2\Delta x}(v_{\text{f}}^2 - v_{\text{i}}^2)$$

Substituting for a_x in $F_{\text{net}\,x} = ma_x$ and then multiplying both sides by Δx, gives

$$F_{\text{net}\,x}\,\Delta x = \tfrac{1}{2}mv_{\text{f}}^2 - \tfrac{1}{2}mv_{\text{i}}^2$$

The term on the left $F_{\text{net}\,x}\,\Delta x$ is the total work done on the particle. Thus

$$W_{\text{total}} = \tfrac{1}{2}mv_{\text{f}}^2 - \tfrac{1}{2}mv_{\text{i}}^2 \qquad 6\text{-}6$$

The quantity $\frac{1}{2}mv^2$ is a scalar quantity that represents the energy associated with the motion of the particle, and is called the **kinetic energy** K of the particle:

$$K = \tfrac{1}{2}mv^2 \qquad 6\text{-}7$$

DEFINITION—KINETIC ENERGY

Note that the kinetic energy depends on only the particle's speed and mass, not its direction of motion. In addition, kinetic energy can never be negative, and is zero only when the particle is at rest.

The quantity on the right side of Equation 6-6 is the change in the kinetic energy of the particle. Thus, Equation 6-6 gives us a relationship between the total work done on a particle and the kinetic energy of the particle. The total work done on a particle is equal to the change in kinetic energy of the particle:

$$W_{\text{total}} = \Delta K \qquad 6\text{-}8$$

WORK–KINETIC-ENERGY THEOREM

This result is known as the **work–kinetic-energy theorem.** This theorem tells us that when W_{total} is positive, the kinetic energy increases, which means the particle is moving faster at the end of the displacement than at the beginning. When W_{total} is negative, the kinetic energy decreases. When W_{total} is zero, the kinetic energy does not change, which means the particle's speed is unchanged.

Because total work on a particle is equal to its change in kinetic energy, we can see that the units of energy are the same as those of work. Three commonly used units of energy are the joule (J), the foot-pound (ft-lb), and the electron volt (eV).

The derivation of the work–kinetic-energy theorem presented here is valid only if the net force remains constant. However, as you will see later in this chapter, this theorem is valid even when the net force varies and the motion is not along a straight line.

! Note that kinetic energy depends on the *speed* of the particle, not the velocity. If the velocity changes direction, but not magnitude, the kinetic energy remains the same.

PROBLEM-SOLVING STRATEGY

Solving Problems Involving Work and Kinetic Energy

PICTURE The way you choose the $+y$ direction or $+x$ direction can help you to easily solve a problem that involves work and kinetic energy.

SOLVE

1. Draw the particle first at its initial position and second at its final position. For convenience, the object can be represented as a dot or a box. Label the initial and final positions of the object.
2. Put one or more coordinate axes on the drawing.
3. Draw arrows for the initial and final velocities, and label them appropriately.
4. On the initial-position drawing of the particle, place a vector for each force acting on it. Accompany each vector with a suitable label.
5. Calculate the total work done on the particle by the forces and equate this total to the change in the particle's kinetic energy.

CHECK Make sure you pay attention to negative signs during your calculations. For example, values for work done can be positive or negative, depending on the direction of the displacement relative to the direction of the force.

Example 6-2 Force on an Electron

In a television picture tube*, electrons are accelerated by an electron gun. The force that accelerates the electron is an electric force due to the electric field in the gun. An electron is accelerated from rest by an electron gun to a kinetic energy of 2.5 keV over a distance of 2.5 cm. Find the force on the electron, assuming it to be both constant and in the direction of the electron's motion.

PICTURE The electron can be modeled as a particle. Its initial and final kinetic energies are both given, and the electric force is the only force acting on it. Apply the work–kinetic-energy theorem and solve for the force.

* A television picture tube is a type of cathode-ray tube.

SOLVE

1. Make a drawing of the electron in its initial and final positions. Include the displacement, the initial and final speeds, and the force (Figure 6-5):

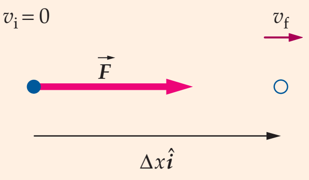

FIGURE 6-5

2. Set the work done equal to the change in kinetic energy:

$$W_{total} = \Delta K$$
$$F_x\,\Delta x = K_f - K_i$$

3. Solve for the force using the conversion factor $1.6 \times 10^{-19}\,J = 1.0\,eV$:

$$F_x = \frac{K_f - K_i}{\Delta x} = \frac{2500\,eV - 0}{0.025\,m} \times \frac{1.6 \times 10^{-19}\,J}{1.0\,eV}$$
$$= \boxed{1.6 \times 10^{-14}\,N}$$

CHECK The mass of an electron is only 9.1×10^{-31} kg. Thus, it is no surprise that such a small force would give it a large speed and thus a noticeable change in kinetic energy.

TAKING IT FURTHER (*a*) $1\,J = 1\,N \cdot m$, so $1\,J/m = 1\,N$. (*b*) 1 eV is the kinetic energy acquired by a particle of charge $-e$ (an electron, for example) when it is accelerated from the $-$ terminal to the $+$ terminal of a 1-V battery through a vacuum.

Example 6-3 A "Dogsled" Race

During your winter break you enter a "dogsled" race across a frozen lake. This is a race where each sled is pulled by a person, not by dogs. To get started you pull the sled (total mass 80 kg) with a force of 180 N at 40° above the horizontal. Find (*a*) the work you do, and (*b*) the final speed of the sled after it moves $\Delta x = 5.0$ m, assuming that it starts from rest and there is no friction.

PICTURE The work done by you is $F_x\,\Delta x$, where we choose the direction of the displacement as the positive x direction. This is also the *total* work done on the sled because the other forces, mg and F_n, have no x components. The final speed of the sled can be found by applying the work–kinetic-energy theorem to the sled. Calculate the work done by each force on the sled (Figure 6-6) and equate the total work to the change in kinetic energy of the sled.

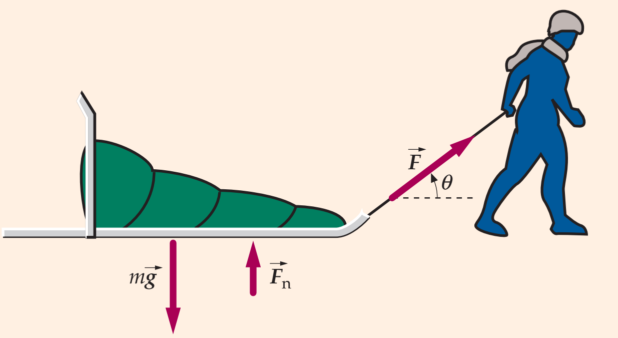

FIGURE 6-6

SOLVE

(*a*) 1. Sketch the sled both in its initial position and in its position after moving the 5.0 m. Draw the x axis in the direction of the motion (Figure 6-7).

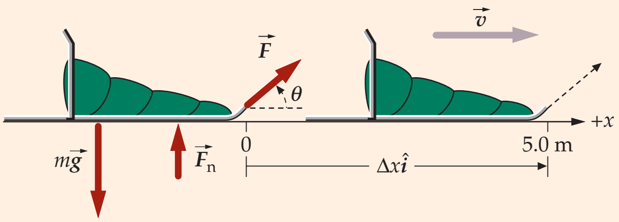

FIGURE 6-7

2. The work done by you on the sled is $F_x\,\Delta x$. This is the total work done on the sled. The other two forces each act perpendicular to the x direction (see Figure 6-7), so they do zero work:

$$W_{total} = W_{you} = F_x\,\Delta x = F\cos\theta\,\Delta x$$
$$= (180\,N)(\cos 40°)(5.0\,m) = 689\,J$$
$$= \boxed{6.9 \times 10^2\,J}$$

(*b*) Apply the work–kinetic-energy theorem to the sled and solve for the final speed:

$$W_{total} = \tfrac{1}{2}mv_f^2 - \tfrac{1}{2}mv_i^2$$
$$v_f^2 = v_i^2 + \frac{2W_{total}}{m}$$
$$= 0 + \frac{2(689\,J)}{80\,kg} = 17.2\,m^2/s^2$$
$$v_f = \sqrt{17.2\,m^2/s^2} = 4.151\,m/s = \boxed{4.2\,m/s}$$

CHECK In Part (*b*) we used that 1 J/kg = 1 m²/s². This is correct because

$$1\text{ J/kg} = 1\text{ N}\cdot\text{m/kg} = (1\text{ kg}\cdot\text{m/s}^2)\cdot\text{m/kg} = 1\text{ m}^2/\text{s}^2$$

TAKING IT FURTHER The square root of 17.2 is 4.147, which rounds off to 4.1. However, the correct answer to Part (*b*) is 4.2 m/s. It is correct because it is calculated by taking the square root of 17.235 999 970 178 (the value stored in my calculator after executing the calculation of v_f).

PRACTICE PROBLEM 6-2 What is the magnitude of the force you exert if the 80-kg sled starts with a speed of 2.0 m/s and its final speed is 4.5 m/s after you pull it through a distance of 5.0 m while keeping the angle at 40°?

See **Math Tutorial** *for more information on*
Integrals

6-2 WORK DONE BY A VARIABLE FORCE–STRAIGHT-LINE MOTION

Many forces vary with position. For example, a stretched spring exerts a force proportional to the distance it is stretched. In addition, the gravitational force Earth exerts on a spaceship varies inversely with the square of the center-to-center distance between the two bodies. How can we calculate the work done by forces like these?

Figure 6-8 shows the plot of a *constant* force F_x as a function of position x. Notice that the work done by the force on a particle whose displacement is Δx is represented by the area under the force-versus-position curve—indicated by the shading in Figure 6-8. We can approximate a variable force by a series of essentially constant forces (Figure 6-9). For each small displacement interval Δx_i, the force is approximately constant. Therefore the work done is approximately equal to the *area* of the rectangle of height F_{xi} and width Δx_i. The work W done by a variable force is then equal to the sum of the areas of an increasingly large number of these rectangles in the limit that the width of each individual rectangle approaches zero:

$$W = \lim_{\Delta x_i \to 0} \sum_i F_{xi}\,\Delta x_i = \text{area under the } F_x\text{-versus-}x \text{ curve} \qquad 6\text{-}9$$

This limit is the integral of $F_x dx$ over the interval from x_1 to x_2. So the work done by a variable force F_x acting on a particle as it moves from x_1 to x_2 is

$$W = \int_{x_1}^{x_2} F_x\,dx = \text{area under the } F_x\text{-versus-}x \text{ curve} \qquad 6\text{-}10$$

WORK BY A VARIABLE FORCE—STRAIGHT-LINE MOTION

If the force plotted in Figure 6-9 is the net force on the particle, then each term $F_{xi}\,\Delta x_i$ in the sum in Equation 6-9 represents the total work done on the particle by a constant force as the particle undergoes the incremental displacement Δx_i. Thus, $F_{xi}\,\Delta x_i$ is equal to the change in kinetic energy ΔK_i of the particle during incremental displacement Δx_i (see Equation 6-8). In addition, the total change in the kinetic energy ΔK of the particle during the total displacement is equal to the sum of the incremental changes in kinetic energy. It follows that the total work W_{total} done on the particle for the total displacement equals the change in kinetic energy for the total displacement. Therefore, $W_{\text{total}} = \Delta K$ (Equation 6-8) holds for variable forces as well as for constant forces.

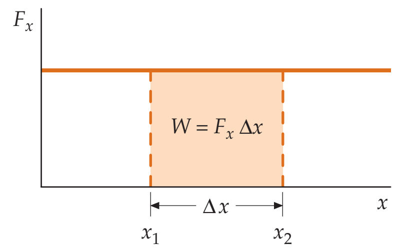

FIGURE 6-8 The work done by a constant force is represented graphically as the area under the F_x-versus-x curve.

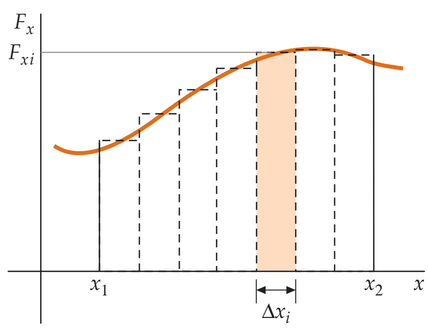

FIGURE 6-9 A variable force can be approximated by a series of constant forces over small intervals. The work done by the constant force in each interval is the area of the rectangle beneath the force curve. The sum of these rectangular areas is the sum of the work done by the set of constant forces that approximates the varying force. In the limit of infinitesimally small Δx_i, the sum of the areas of the rectangles equals the area under the complete force curve.

Example 6-4 Work Done by a Varying Force

A force $\vec{F} = F_x\hat{i}$ varies with x, as shown in Figure 6-10. Find the work done by the force on a particle as the particle moves from $x = 0.0$ m to $x = 6.0$ m.

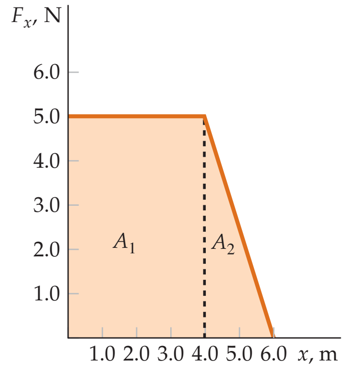

FIGURE 6-10

PICTURE The work done is the area under the curve from $x = 0.0$ m to $x = 6.0$ m. Because the curve consists of straight-line segments, the easiest approach is to break the area into two segments, one consisting of a rectangle (area A_1) and the other consisting of a right triangle (A_2), and then use the geometric formulas for area to find the work. (The alternative approach is to set up and execute an integration, as is done in Example 6-5.)

SOLVE

1. We find the work done by calculating the area under the F_x-versus-x curve: $W = A_{\text{total}}$

2. This area is the sum of the two areas shown. The area of a triangle is one half the altitude times the base:

$$W = A_{\text{total}} = A_1 + A_2$$
$$= (5.0\text{ N})(4.0\text{ m}) + \tfrac{1}{2}(5.0\text{ N})(2.0\text{ m})$$
$$= 20\text{ J} + 5.0\text{ J} = \boxed{25\text{ J}}$$

CHECK If the force were a constant 5.0 N over the entire 6.0 m, the work would be (5.0 N)(6.0 m) = 30 J. The step-2 result of 25 J is slightly less than the 30 J, as expected.

PRACTICE PROBLEM 6-3 The force shown is the only force that acts on a particle of mass 3.0 kg. If the particle starts from rest at $x = 0.0$ m, how fast is it moving when it reaches $x = 6.0$ m?

WORK DONE BY A SPRING THAT OBEYS HOOKE'S LAW

Figure 6-11 shows a block on a horizontal frictionless surface connected to a spring. If the spring is stretched or compressed, the spring exerts a force on the block. Recall from Equation 4-7 that the force exerted by the spring on the block is given by

$$F_x = -kx \qquad \text{(Hooke's law)} \qquad 6\text{-}11$$

where the k is a positive constant and x is the extension of the spring. If the spring is extended, then x is positive and the force component F_x is negative. If the spring is compressed, then x is negative and the force component F_x is positive.

Because the force varies with x, we can use Equation 6-10 to calculate the work done by the spring force on the block as the block undergoes a displacement from $x = x_i$ to $x = x_f$. (Besides the spring force, two other forces act on the block; the force of gravity, $m\vec{g}$, and the normal force of the table, $\vec{F}_n$. However, each of these forces does no work because neither has a component in the direction of the displacement. The only force that does work on the block is the spring force.) Substituting F_x from Equation 6-11 into Equation 6-10, we get

$$W_{\text{by spring}} = \int_{x_i}^{x_f} F_x\,dx = \int_{x_i}^{x_f} (-kx)\,dx = -k\int_{x_i}^{x_f} x\,dx = -k\left(\frac{x_f^2}{2} - \frac{x_i^2}{2}\right) \qquad 6\text{-}12$$

Rearranging this gives:

$$W_{\text{by spring}} = \tfrac{1}{2}kx_i^2 - \tfrac{1}{2}kx_f^2 \qquad 6\text{-}13$$

WORK BY A SPRING FORCE

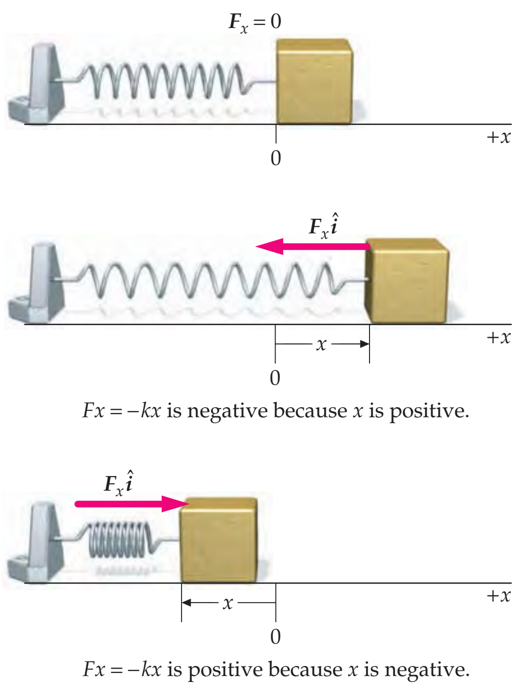

FIGURE 6-11 A horizontal spring. (*a*) When the spring is unstretched, it exerts no force on the block. (*b*) When the spring is stretched so that x is positive, it exerts a force of magnitude kx in the $-x$ direction. (*c*) When the spring is compressed so that x is negative, the spring exerts a force of magnitude $k|x|$ in the $+x$ direction.

The integral in Equation 6-12 can also be computed using geometry to calculate the area under the curve (Figure 6-12*a*). This gives

$$W_{\text{by spring}} = A_1 + A_2 = |A_1| - |A_2| = \tfrac{1}{2}kx_1^2 - \tfrac{1}{2}kx_2^2$$

which is identical to Equation 6-13.

PRACTICE PROBLEM 6-4

Using geometry, calculate the area under the curve shown in Figure 6-12*b* and show you get an expression identical to that shown in Equation 6-13.

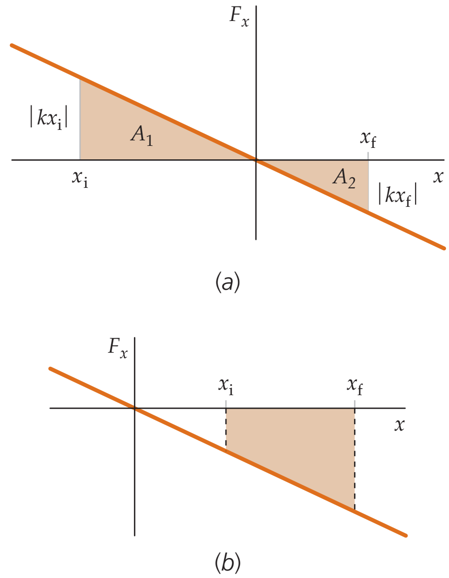

FIGURE 6-12

Suppose you pull on an initially relaxed spring (Figure 6-13), stretching it to a final extension x_f. How much work does the force exerted on the spring by your hand $\vec{F}_{SH}$ do? The force by your hand on the spring is equal to kx. (It is equal and opposite to the force by the spring on your hand.) As x increases from 0 to x_f, the force on the spring increases linearly from $F_{SHx} = 0$ to $F_{SHx} = kx_f$, and so has an average value* of $\frac{1}{2}kx_f$. The work done by this force is equal to the product of this average value and x_f. Thus, the work W done on the spring by your hand is given by

$$W = \tfrac{1}{2}kx_f^2$$

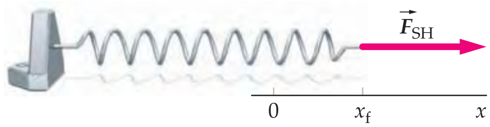

FIGURE 6-13

Example 6-5 Work Done on a Block by a Spring

A 4.0-kg block on a frictionless table is attached to a horizontal spring with $k = 400$ N/m. The spring is initially compressed 5.0 cm (Figure 6-14). Find (*a*) the work done on the block by the spring as the block moves from $x = x_1 = -5.0$ cm to its equilibrium position $x = x_2 = 0.0$ cm, and (*b*) the speed of the block at $x_2 = 0.0$ cm.

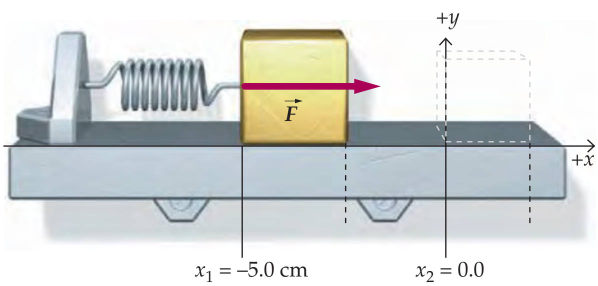

FIGURE 6-14

PICTURE Make a graph of F_x versus x. The work done on the block as it moves from x_1 to x_2 equals the area under the F_x-versus-x curve between these limits, shaded in Figure 6-15, which can be calculated by integrating the force over the distance. The work done equals the change in kinetic energy, which is simply its final kinetic energy because the initial kinetic energy is zero. The speed of the block at $x = 0.0$ cm is found from the kinetic energy of the block.

SOLVE

(*a*) The work W done on the block by the spring is the integral of $F_x dx$ from x_1 to x_2:

$$W = \int_{x_1}^{x_2} F_x\,dx = \int_{x_1}^{x_2} -kx\,dx = -k\int_{x_1}^{x_2} x\,dx$$

$$= -\tfrac{1}{2}kx^2\Big|_{x_1}^{x_2} = -\tfrac{1}{2}k(x_2^2 - x_1^2)$$

$$= -\tfrac{1}{2}(400\text{ N/m})[(0.000\text{ m})^2 - (0.050\text{ m})^2]$$

$$= \boxed{0.50\text{ J}}$$

(*b*) Apply the work–kinetic-energy theorem to the block and solve for v_2:

$$W_{\text{total}} = \tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2$$

so

$$v_2^2 = v_1^2 + \frac{2W_{\text{total}}}{m} = 0 + \frac{2(0.50\text{ J})}{4.0\text{ kg}} = 0.25\text{ m}^2/\text{s}^2$$

$$v_2 = \boxed{0.50\text{ m/s}}$$

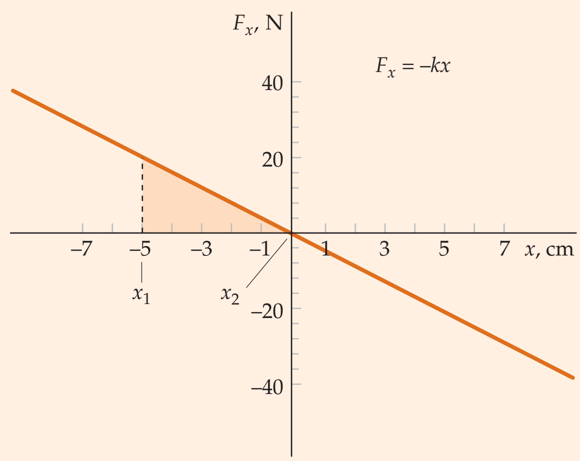

FIGURE 6-15

*Typically, an average value refers to an average over time. In this case, it refers to an average over position.

CHECK The work done is positive. The force and displacement are in the same direction, so this is as expected. The work is positive, so we expect the kinetic energy, and thus the speed, to increase. Our results fulfill this expectation.

TAKING IT FURTHER Note that we could *not* have solved this example by first applying Newton's second law to find the acceleration, and then using the constant-acceleration kinematic equations. This is so because the force exerted by the spring on the block, $F_x = -kx$, varies with position. Thus, the acceleration also varies with position. Therefore, the constant-acceleration kinematic equations are not in play.

PRACTICE PROBLEM 6-5 Find the speed of the 4.0-kg block when it reaches $x = 3.0$ cm if it starts from $x = 0.0$ cm with velocity $v_x = 0.50$ m/s.

6-3 THE SCALAR PRODUCT

Work is based on the component of force in the direction of an object's displacement. For straight-line motion, it is easy to calculate the component of the force in the direction of the displacement. However, in situations involving motion along a curved path, the force and the displacement can point in any direction. For these situations we can use a mathematical operation known as the *scalar* or *dot product* to determine the component of a given force in the direction of the displacement. The scalar product involves multiplying one vector by a second vector to produce a scalar.

Consider the particle moving along the arbitrary curve shown in Figure 6-16*a*. The component $F_{\|}$ in Figure 6-16*b* is related to the angle ϕ between the directions of $\vec{F}$ and $d\vec{\ell}$ by $F_{\|} = F\cos\phi$, so the work dW done by $\vec{F}$ for the displacement $d\vec{\ell}$ is

$$dW = F_{\|}d\ell = F\cos\phi\, d\ell$$

This combination of two vectors and the cosine of the angle between their directions is called the **scalar product** of the vectors. The scalar product of two general vectors $\vec{A}$ and $\vec{B}$ is written $\vec{A}\cdot\vec{B}$ and defined by

$$\vec{A}\cdot\vec{B} = AB\cos\phi \qquad \text{6-14}$$

DEFINITION—SCALAR PRODUCT

where A and B are the magnitudes of the vectors and ϕ is the angle between $\vec{A}$ and $\vec{B}$. (The "angle between two vectors" means the angle between their directions in space.) Because of the notation, the scalar product is also known as the **dot product.**

The scalar product $\vec{A}\cdot\vec{B}$ can be thought of either as A times the component of $\vec{B}$ in the direction of $\vec{A}$ ($A \times B\cos\phi$), or as B times the component of $\vec{A}$ in the direction of $\vec{B}$ ($B \times A\cos\phi$) (Figure 6-17). Properties of the scalar product are summarized in Table 6-1. We can use unit vectors to write the scalar product in terms of the rectangular components of the two vectors:

$$\vec{A}\cdot\vec{B} = (A_x\hat{i} + A_y\hat{j} + A_z\hat{k})\cdot(B_x\hat{i} + B_y\hat{j} + B_z\hat{k})$$

The scalar product of any rectangular unit vector with itself, such as $\hat{i}\cdot\hat{i}$, is equal to 1. (This is because $\hat{i}\cdot\hat{i} = |\hat{i}||\hat{i}|\cos(0) = 1 \times 1 \times \cos(0) = 1$.) Thus, a term like $A_x\hat{i}\cdot B_x\hat{i} = A_xB_x\hat{i}\cdot\hat{i}$ is equal to A_xB_x. Also, because the unit vectors $\hat{i}$, $\hat{j}$, and $\hat{k}$ are mutually perpendicular, the scalar product of one of them

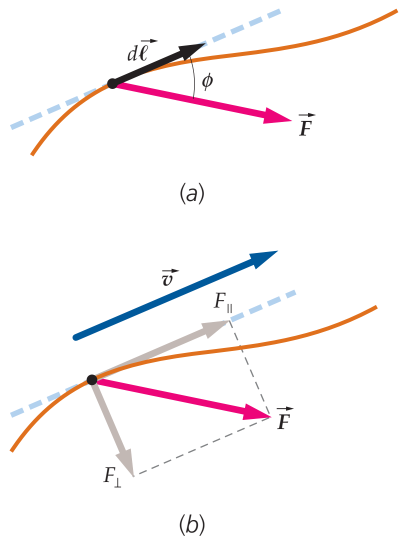

FIGURE 6-16 (*a*) A particle moving along an arbitrary curve in space. (*b*) The perpendicular component of the force $F_{\perp}$ changes the direction of the particle's motion, but not its speed. The tangential, or parallel, component $F_{\|}$ changes the particle's speed, but not its direction of motion. $F_{\|}$ is equal to the mass m times the tangential acceleration dv/dt. The parallel component of the force does work $F_{\|}d\ell$ and the perpendicular component does no work.

Table 6-1 Properties of Scalar Products

If	Then
$\vec{A}$ and $\vec{B}$ are perpendicular,	$\vec{A}\cdot\vec{B} = 0$ (because $\phi = 90°$, $\cos\phi = 0$)
$\vec{A}$ and $\vec{B}$ are parallel,	$\vec{A}\cdot\vec{B} = AB$ (because $\phi = 0°$, $\cos\phi = 1$)
$\vec{A}\cdot\vec{B} = 0$,	Either $\vec{A} = 0$ or $\vec{B} = 0$ or $\vec{A}\perp\vec{B}$
Furthermore,	
$\vec{A}\cdot\vec{A} = A^2$	Because $\vec{A}$ is parallel to itself
$\vec{A}\cdot\vec{B} = \vec{B}\cdot\vec{A}$	Commutative rule of multiplication
$(\vec{A} + \vec{B})\cdot\vec{C} = \vec{A}\cdot\vec{C} + \vec{B}\cdot\vec{C}$	Distributive rule of multiplication

with any other one of them, such as $\hat{i}\cdot\hat{j}$, is zero. (This is because $\hat{i}\cdot\hat{j} = |\hat{i}||\hat{j}|\cos(90°) = 1 \times 1 \times \cos(90°) = 0$.) Thus, any term like $A_x\hat{i}\cdot B_y\hat{j}$ (called a *cross term*) is equal to zero. The result is

$$\vec{A}\cdot\vec{B} = A_xB_x + A_yB_y + A_zB_z \qquad 6\text{-}15$$

The component of a vector in a specific direction can be written as the scalar product of the vector and the unit vector in that direction. For example, the component A_x is found from

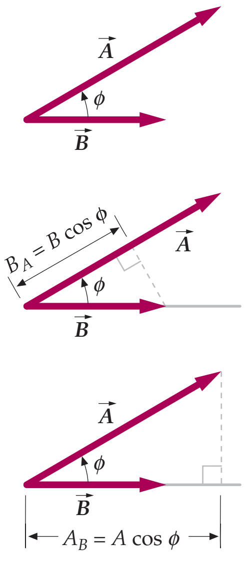
$$\vec{A}\cdot\hat{i} = (A_x\hat{i} + A_y\hat{j} + A_z\hat{k})\cdot\hat{i} = A_x \qquad 6\text{-}16$$

This result provides an algebraic procedure for obtaining a component equation, given a vector equation. That is, multiplying both sides of the vector equation $\vec{A} + \vec{B} = \vec{C}$ by $\hat{i}$ gives $(\vec{A} + \vec{B})\cdot\hat{i} = \vec{C}\cdot\hat{i}$, which in turn gives $A_x + B_x = C_x$.

The rule for differentiating a dot product is

$$\frac{d}{dt}(\vec{A}\cdot\vec{B}) = \frac{d\vec{A}}{dt}\cdot\vec{B} + \vec{A}\cdot\frac{d\vec{B}}{dt} \qquad 6\text{-}17$$

This rule is analogous with the rule for differentiating the product of two scalars. The rule for differentiating a dot product can be obtained by differentiating both sides of Equation 6-15.



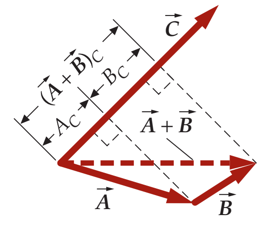


FIGURE 6-17 (*a*) The scalar product $\vec{A}\cdot\vec{B}$ is the product of A and the projection of $\vec{B}$ on $\vec{A}$, or the product of B and the projection of $\vec{A}$ on $\vec{B}$. That is, $\vec{A}\cdot\vec{B} = AB\cos\phi = AB_A = BA_B$. (*b*) $(\vec{A} + \vec{B})\cdot\vec{C}$ equals $(\vec{A} + \vec{B})_C C$ (the projection of $\vec{A} + \vec{B}$ in the direction of $\vec{C}$ times C). However, $(\vec{A} + \vec{B})_C = A_C + B_C$, so $(\vec{A} + \vec{B})\cdot\vec{C} = (A_C + B_C)C = A_CC + B_CC = \vec{A}\cdot\vec{C} + \vec{B}\cdot\vec{C}$. That is, for the scalar product, multiplication is distributive over addition.

Example 6-6 Using the Scalar Product

(*a*) Find the angle between the vectors $\vec{A} = (3.00\hat{i} + 2.00\hat{j})$ m and $\vec{B} = (4.00\hat{i} - 3.00\hat{j})$ m (Figure 6-18). (*b*) Find the component of $\vec{A}$ in the direction of $\vec{B}$.

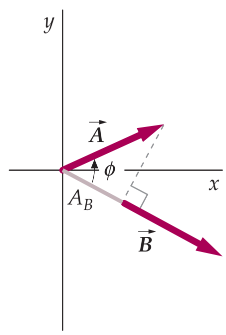

FIGURE 6-18

PICTURE For Part (a), we find the angle ϕ from the definition of the scalar product. Because we are given the components of the vectors, we first determine the scalar product and the values of A and B. Then, we use these values to determine the angle ϕ. For Part (*b*), the component of $\vec{A}$ in the direction of $\vec{B}$ is found from the scalar product $\vec{A}\cdot\hat{B}$, where $\hat{B} = \vec{B}/B$.

SOLVE

(*a*) 1. Write the scalar product of $\vec{A}$ and $\vec{B}$ in terms of A, B, and $\cos\phi$ and solve for $\cos\phi$:

$$\vec{A}\cdot\vec{B} = AB\cos\phi, \text{ so}$$

$$\cos\phi = \frac{\vec{A}\cdot\vec{B}}{AB}$$

2. Find $\vec{A}\cdot\vec{B}$ from the components of $\vec{A}$ and $\vec{B}$:

$$\vec{A}\cdot\vec{B} = A_xB_x + A_yB_y = (3.00\text{ m})(4.00\text{ m}) + (2.00\text{ m})(-3.00\text{ m})$$
$$= 12.0\text{ m}^2 - 6.00\text{ m}^2 = 6.0\text{ m}^2$$

3. The magnitudes of the vectors are obtained from the scalar product of the vector with itself:

$$\vec{A}\cdot\vec{A} = A^2 = A_x^2 + A_y^2 = (3.00\text{ m})^2 + (2.00\text{ m})^2 = 13.0\text{ m}^2$$

so $A = \sqrt{13.0}$ m

and

$$\vec{B}\cdot\vec{B} = B^2 = B_x^2 + B_y^2 = (4.00\text{ m})^2 + (-3.00\text{ m})^2 = 25.0\text{ m}^2$$

so $B = 5.00$ m

4. Substitute these values into the equation in step 1 for $\cos\phi$ to find ϕ:

$$\cos\phi = \frac{\vec{A}\cdot\vec{B}}{AB} = \frac{6.0\text{ m}^2}{(\sqrt{13}\text{ m})(5.00\text{ m})} = 0.333$$

$$\phi = \boxed{71°}$$

(*b*) The component of $\vec{A}$ in the direction of $\vec{B}$ is the scalar product of $\vec{A}$ with the unit vector $\hat{B} = \vec{B}/B$:

$$A_B = \vec{A}\cdot\hat{B} = \vec{A}\cdot\frac{\vec{B}}{B} = \frac{\vec{A}\cdot\vec{B}}{B} = \frac{6.0\text{ m}^2}{5.00\text{ m}} = \boxed{1.2\text{ m}}$$

CHECK The component of $\vec{A}$ in the direction of $\vec{B}$ is $A\cos\phi = (\sqrt{13}\text{ m})\cos 71° = 1.2\text{ m}$. This answer verifies our Part (*b*) result.

PRACTICE PROBLEM 6-6 (*a*) Find $\vec{A}\cdot\vec{B}$ for $\vec{A} = (3.0\hat{i} + 4.0\hat{j})\text{m}$ and $\vec{B} = (2.0\hat{i} + 8.0\hat{j})\text{m}$. (*b*) Find A, B, and the angle between $\vec{A}$ and $\vec{B}$ for these vectors.

WORK IN SCALAR-PRODUCT NOTATION

In scalar-product notation, the work dW done by a force $\vec{F}$ on a particle over an infinitesimal displacement $d\vec{\ell}$ is

$$dW = F_{\|}d\ell = F\cos\phi\, d\ell = \vec{F}\cdot d\vec{\ell} \qquad 6\text{-}18$$

INCREMENTAL WORK

where $d\ell$ is the magnitude of $d\vec{\ell}$ and $F_{\|}$ is the component of $\vec{F}$ in the direction of $d\vec{\ell}$. The work done on the particle as it moves from point 1 to point 2 is

$$W = \int_1^2 \vec{F}\cdot d\vec{\ell} \qquad 6\text{-}19$$

THE DEFINITION OF WORK

(If the force remains constant, the work can be expressed $W = \vec{F}\cdot\vec{\ell}$, where $\vec{\ell}$ is the displacement. In Chapter 3, the displacement is denoted $\Delta\vec{r} = \Delta x\hat{i} + \Delta y\hat{j}$; $\vec{\ell}$ and $\Delta\vec{r}$ are different symbols for the same quantity.)

When several forces $\vec{F}_i$ act on a particle whose displacement is $d\vec{\ell}$, the total work done on it is

$$dW_{\text{total}} = \vec{F}_1\cdot d\vec{\ell} + \vec{F}_2\cdot d\vec{\ell} + \cdots = (\vec{F}_1 + \vec{F}_2 + \cdots)\cdot d\vec{\ell} = (\Sigma\vec{F}_i)\cdot d\vec{\ell} \qquad 6\text{-}20$$

Example 6-7 Pushing a Box

You push a box up a ramp using a constant horizontal 100-N force $\vec{F}$. For each distance of 5.00 m along the ramp, the box gains 3.00 m of height. Find the work done by $\vec{F}$ for each 5.00 m the box moves along the ramp (*a*) by directly computing the scalar product from the components of $\vec{F}$ and $\vec{\ell}$, where $\vec{\ell}$ is the displacement, (*b*) by multiplying the product of the magnitudes of $\vec{F}$ and $\vec{\ell}$ by $\cos\phi$, where ϕ is the angle between the direction of $\vec{F}$ and the direction of $\vec{\ell}$, (*c*) by finding $F_{\|}$ (the component of $\vec{F}$ in the direction of $\vec{\ell}$) and multiplying it by ℓ (the magnitude of $\vec{\ell}$), and (*d*) by finding $\ell_{\|}$ (the component of $\vec{\ell}$ in the direction of $\vec{F}$) and multiplying it by the magnitude of the force.

PICTURE Draw a sketch of the box in its initial and final positions. Place coordinate axes on the sketch with the x axis horizontal. Express the force and displacement vectors in component form and take the scalar product. Then find the component of the force in the direction of the displacement, and vice versa.

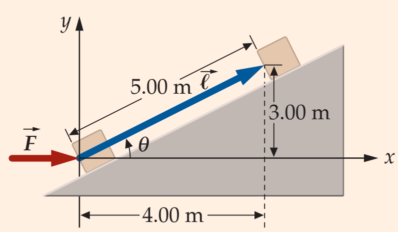

FIGURE 6-19

SOLVE

(*a*) 1. Draw a sketch of the situation (Figure 6-19).

2. Express $\vec{F}$ and $\vec{\ell}$ in component form and take the scalar product:

$$\vec{F} = (100\hat{i} + 0\hat{j})\text{N}$$
$$\vec{\ell} = (4.00\hat{i} + 3.00\hat{j})\text{m}$$
$$W = \vec{F}\cdot\vec{\ell} = F_x\Delta x + F_y\Delta y = (100\text{ N})(4.00\text{ m}) + 0(3.00\text{ m})$$
$$= \boxed{4.00\times 10^2\text{ J}}$$

(*b*) Calculate $F\ell\cos\phi$, where ϕ is the angle between the directions of the two vectors as shown. Equate this expression with the Part-(*a*) result and solve for $\cos\phi$. Then solve for the work:

$\vec{F}\cdot\vec{\ell} = F\ell\cos\phi$ and $\vec{F}\cdot\vec{\ell} = F_x\Delta x + F_y\Delta y$

so

$$\cos\phi = \frac{F_x\Delta x + F_y\Delta y}{F\ell} = \frac{(100\text{ N})(4.00\text{ m}) + 0}{(100\text{ N})(5.00\text{ m})} = 0.800$$

and

$$W = F\ell\cos\phi = (100\text{ N})(5.00\text{ m})0.800 = \boxed{4.00\times10^2\text{ J}}$$

(*c*) Find $F_{||}$ and multiply it by ℓ:

$$F_{||} = F\cos\phi = (100\text{ N})0.800 = 80.0\text{ N}$$

$$W = F_{||}\ell = (80.0\text{ N})(5.00\text{ m}) = \boxed{4.00\times10^2\text{ J}}$$

(*d*) Multiply F and $\ell_{||}$, where $\ell_{||}$ is the component of $\vec{\ell}$ in the direction of $\vec{F}$:

$$\ell_{||} = \ell\cos\phi = (5.00\text{ m})0.800 = 4.00\text{ m}$$

$$W = F\ell_{||} = (100\text{ N})(4.00\text{ m}) = \boxed{4.00\times10^2\text{ J}}$$

CHECK The four distinct calculations give the same result for the work.

TAKING IT FURTHER For this problem, computing the work is easiest using the procedure in Part (*a*). For other problems, the procedure in Part (*b*), Part (*c*), or Part (*d*) may be the easiest. You need to be competent in using all four procedures. (The more problem-solving tools you have at your disposal, the better.)

Example 6-8 A Displaced Particle

Try It Yourself

A particle undergoes a displacement $\vec{\ell} = (2.00\hat{i} - 5.00\hat{j})$ m. During this displacement a constant force $\vec{F} = (3.00\hat{i} + 4.00\hat{j})$ N acts on the particle. Find (*a*) the work done by the force, and (*b*) the component of the force in the direction of the displacement.

PICTURE The force is constant, so the work W can be found by computing $W = \vec{F}\cdot\vec{\ell} = F_x\Delta x + F_y\Delta y$. Combining this with the relation $\vec{F}\cdot\vec{\ell} = F_{||}\ell$, we can find the component of $\vec{F}$ in the direction of the displacement.

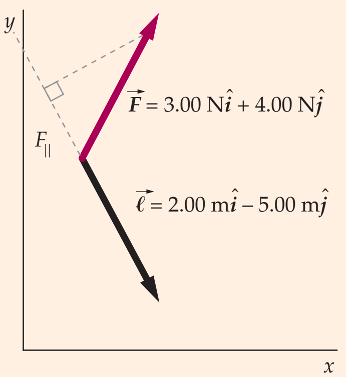

FIGURE 6-20

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
(*a*) 1. Make a sketch showing $\vec{F}$, $\vec{\ell}$, and $F_{\|\|}$ (Figure 6-20).	
2. Compute the work done W.	$W = \vec{F}\cdot\vec{\ell} = \boxed{-14.0\text{ J}}$
(*b*) 1. Compute $\vec{\ell}\cdot\vec{\ell}$ and use your result to find ℓ.	$\vec{\ell}\cdot\vec{\ell} = 29.0\text{ m}^2$, so $\ell = \sqrt{29.0}$ m
2. Using $\vec{F}\cdot\vec{\ell} = F_{\|\|}\ell$, solve for $F_{\|\|}$.	$F_{\|\|} = \vec{F}\cdot\vec{\ell}/\ell = \boxed{-2.60\text{ N}}$

CHECK From Figure 6-20, we see that the angle between $\vec{F}$ and $\vec{\ell}$ is between 90° and 180°, so we expect both $F_{||}$ and the work to be negative. Our results are in agreement with this expectation.

TAKING IT FURTHER Nowhere in the wording of either the problem statement or the solution of Example 6-8 does it say that the motion of the particle is along any particular path. Because the force is constant, the solution depends on the net displacement $\vec{\ell}$, but not on the path taken. The path could be a straight-line path or a curved path (Figure 6-21) and not a word in the solution would have to be changed.

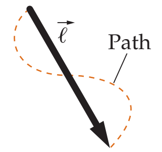

FIGURE 6-21

PRACTICE PROBLEM 6-7 Find the magnitude of $\vec{F}$ and the angle ϕ between $\vec{F}$ and $\vec{\ell}$.

Example 6-9 Differentiating a Scalar Product

Show that $\vec{a} \cdot \vec{v} = \frac{1}{2}d(v^2)/dt$, where $\vec{a}$ the acceleration, $\vec{v}$ the velocity, and v the speed.

PICTURE Note that $v^2 = \vec{v} \cdot \vec{v}$, so the rule for differentiating scalar products can be used here.

SOLVE

Apply the rule for differentiating scalar products (Equation 6-17) to the scalar product $\vec{v} \cdot \vec{v}$:

$$\frac{d}{dt}v^2 = \frac{d}{dt}(\vec{v} \cdot \vec{v}) = \frac{d\vec{v}}{dt} \cdot \vec{v} + \vec{v} \cdot \frac{d\vec{v}}{dt} = 2\frac{d\vec{v}}{dt} \cdot \vec{v} = 2\vec{a} \cdot \vec{v}$$

$$\text{so} \quad \vec{a} \cdot \vec{v} = \frac{1}{2}\frac{d}{dt}v^2$$

CHECK Speed v has dimensions of length over time, so dv^2/dt has dimensions of length squared over time cubed. Acceleration $\vec{a}$ has dimensions of length over time squared, so $\vec{a} \cdot \vec{v}$ has dimensions of length squared over time cubed. Thus, both sides of $\vec{a} \cdot \vec{v} = \frac{1}{2}d(v^2)/dt$ have the same dimensions (length squared over time cubed).

TAKING IT FURTHER This example involves only kinematic parameters, so the resulting relation is a strictly kinematic relation. The equation $\vec{a} \cdot \vec{v} = \frac{1}{2}d(v^2)/dt$ has unrestricted validity (unlike some kinematic equations we have studied that are valid only if the acceleration remains constant).

From Example 6-9 we have the kinematic relation

$$\vec{a} \cdot \vec{v} = \frac{1}{2}\frac{d}{dt}v^2 = \frac{d}{dt}\left(\frac{1}{2}v^2\right) \qquad \text{6-21}$$

In Section 6-4, this equation is used to derive the work–kinetic-energy theorem for particles moving along curved paths under the influence of forces that are not necessarily constant.

POWER

The definition of work says nothing about how long it takes to do the work. For example, if you push a box a certain distance up a hill with a constant velocity, you do the same amount of work on the box regardless of how long it takes you to push the box that distance. In physics, the rate at which a force does work is called the **power** P. Because work is the measure of energy transferred by a force, power is the rate of transfer of energy.

Consider a particle moving with instantaneous velocity $\vec{v}$. In a short time interval dt, the particle undergoes the displacement $d\vec{\ell} = \vec{v}\,dt$. The work done by a force $\vec{F}$ acting on the particle during this time interval is

$$dW = \vec{F} \cdot d\vec{\ell} = \vec{F} \cdot \vec{v}\,dt$$

The power is then

$$P = \frac{dW}{dt} = \vec{F} \cdot \vec{v} \qquad \text{6-22}$$

POWER BY A FORCE

Note the difference between power and work. Two motors that lift a given load a given distance expend the same amount of energy, but the power is greater for the force that does the work in the least time.

Like work and energy, power is a scalar quantity. The SI unit of power, one joule per second, is called a **watt** (W):

$$1\text{ W} = 1\text{ J/s}$$

In the U.S. customary system, the unit of energy is the foot-pound and the unit of power is the foot-pound per second. A commonly used multiple of this unit, called a horsepower (hp), is defined as

$$1\ \text{hp} = 550\ \text{ft}\cdot\text{lb/s} \approx 746\ \text{W}$$

The product of a unit of power and a unit of time is a unit of energy. Electric companies charge for energy, not power, usually by the kilowatt-hour (kW · h). A kilowatt-hour of energy is the energy transferred in 1 hour at the constant rate of 1 kilowatt, or

$$1\ \text{kW}\cdot\text{h} = (10^3\ \text{W})(3600\ \text{s}) = 3.6 \times 10^6\ \text{W}\cdot\text{s} = 3.6\ \text{MJ}$$

Example 6-10 The Power of a Motor

A small motor is used to operate a lift that raises a load of bricks weighing 500 N to a height of 10 m in 20 s (Figure 6-22) at constant speed. The lift weighs 300 N. What is the power output of the motor?

PICTURE Because the acceleration is zero, the magnitude of the upward force $\vec{F}$ exerted by the motor is equal to the weight of the lift plus the weight of the bricks. The rate the motor does work is the power.

SOLVE

The power is given by $\vec{F}\cdot\vec{v}$:

$$P = \vec{F}\cdot\vec{v} = Fv\cos\phi = Fv\cos(0) = Fv$$

$$= (800\ \text{N})\frac{10\ \text{m}}{20\ \text{s}} = \boxed{4.0 \times 10^2\ \text{W}}$$

CHECK The work done by the force is (800 N)(10 m) = 8000 J. This work took 20 s to do, so we expect the power to be the 8000 J/20 s = 4.0×10^2 W. Our result is in perfect agreement with this.

TAKING IT FURTHER (1) The lift could not actually operate at constant speed. The bricks and lift will have to initially be brought up to speed (because they are starting from rest.) The power output will exceed 400 W during this speedup interval. In addition, the power output will be less than 400 W as the lift slows to a stop at the top. The average power output of the motor during the lift is 400 W (and the power provided by the force of gravity is −400 W). (2) A power of 400 W is slightly more than $\frac{1}{2}$ hp.

PRACTICE PROBLEM 6-8 Find the average power output of the motor needed to raise the bricks and lift to a height of 10 m in 40 s. What is the work done by the force of the motor? What is the work done by the force of gravity?

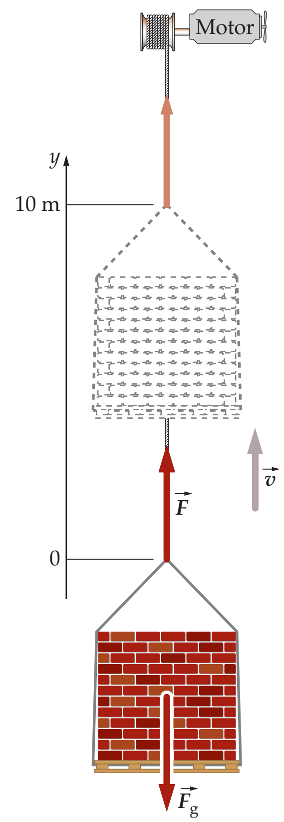

FIGURE 6-22

Example 6-11 Power and Kinetic Energy

Show that the power delivered by the net force acting on a particle equals the rate at which the kinetic energy of the particle is changing.

PICTURE The power delivered by the net force P_{net} equals $\vec{F}_{net}\cdot\vec{v}$. Show that $\vec{F}_{net}\cdot\vec{v} = dK/dt$, where $K = \frac{1}{2}mv^2$.

SOLVE

1. Substitute for $\vec{F}_{net}$ using Newton's second law:

$$\vec{F}_{net}\cdot\vec{v} = m\vec{a}\cdot\vec{v}$$

2. The product $\vec{a}\cdot\vec{v}$ is related to the time derivative of v^2 by $2\vec{a}\cdot\vec{v} = d(v^2)/dt$ (Equation 6–21):

$$\frac{d}{dt}v^2 = \frac{d}{dt}(\vec{v}\cdot\vec{v}) = 2\vec{a}\cdot\vec{v}$$

3. Substitute the step-2 result into the step-1 result: $\vec{F}_{\text{net}} \cdot \vec{v} = m\vec{a} \cdot \vec{v} = m\frac{1}{2}\frac{d}{dt}v^2$
4. The mass m is constant, so it and the fraction $\frac{1}{2}$ can be moved inside the argument of the derivative: $\vec{F}_{\text{net}} \cdot \vec{v} = \frac{d}{dt}\left(\frac{1}{2}mv^2\right)$
5. The argument of the derivative is the kinetic energy K: $\boxed{P_{\text{net}} = \vec{F}_{\text{net}} \cdot \vec{v} = \frac{dK}{dt}}$

CHECK The joule is the unit for energy, so dK/dt has units of joules per second, or watts. The watt is the unit for power, so $P_{\text{net}} = dK/dt$ is dimensionally consistent.

From Example 6-11 we have

$$P_{\text{net}} = \vec{F}_{\text{net}} \cdot \vec{v} = \frac{dK}{dt} \qquad \text{6-23}$$

which relates the power delivered by the net force to the rate of change of kinetic energy of any object that can be modeled as a particle.

6-4 WORK–KINETIC-ENERGY THEOREM—CURVED PATHS

The work–energy theorem for motion along a curved path can be established by integrating both sides of $\vec{F}_{\text{net}} \cdot \vec{v} = dK/dt$ (Equation 6-23). Integrating both sides over time gives

$$\int_1^2 \vec{F}_{\text{net}} \cdot \vec{v}\, dt = \int_1^2 \frac{dK}{dt} dt \qquad \text{6-24}$$

Because $d\vec{\ell} = \vec{v}\,dt$, where $d\vec{\ell}$ is the displacement during time dt, and because $(dK/dt)\,dt = dK$, Equation 6-24 can be expressed

$$\int_1^2 \vec{F}_{\text{net}} \cdot d\vec{\ell} = \int_1^2 dK$$

The integral on the left is the total work, W_{total}, done on the particle. The integral on the right can be evaluated, giving

$$\int_1^2 \vec{F}_{\text{net}} \cdot d\vec{\ell} = K_2 - K_1 \quad (\text{or } W_{\text{total}} = \Delta K) \qquad \text{6-25}$$

WORK–KINETIC-ENERGY THEOREM

Equation 6-25 follows directly from Newton's second law of motion.

Example 6-12 Work Done on a Skier — *Context-Rich*

You and your friend are at a ski resort with two ski runs, a beginner's run and an expert's run. Both runs begin at the top of the ski lift and end at a finish line at the bottom of the same lift. Let h be the vertical descent for both runs. The beginner's run is longer and less steep than the expert's run. You and your friend, who is a much better skier than you, are testing some experimental frictionless skis. To make things interesting, you offer a wager that if she takes the expert's run and you take the beginner's run, her speed at the finish line will not be greater than your speed at the finish line. Forgetting that you are studying physics, she accepts the bet. The conditions are that you both start from rest at the top of the lift and both of you coast for the entire trip. Who wins the bet? (Assume air drag is negligible.)

(PhotoDisc/Getty.)

PICTURE Because you and your friend are coasting on the skis, you both can be modeled as particles. (The work–kinetic-energy theorem works only for particles.) Two forces act on each of you, a weight force and a normal force.

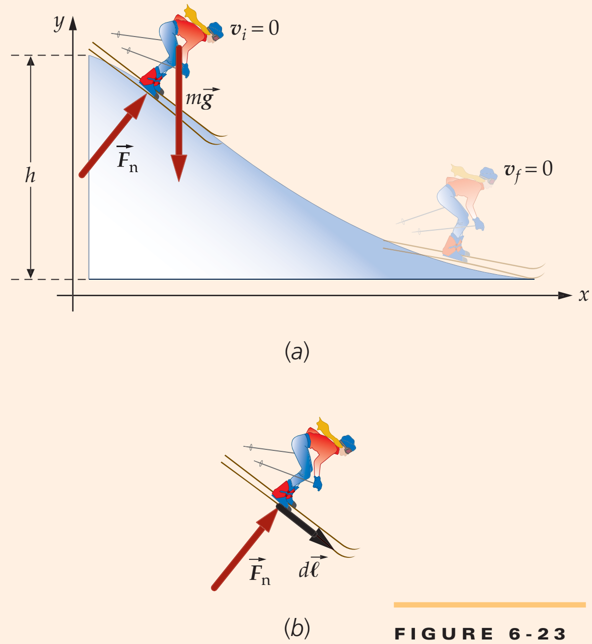

FIGURE 6-23

SOLVE

1. Make a sketch of yourself and draw the two force vectors on the sketch (Figure 6-23*a*). Also include coordinate axes. The work–kinetic-energy theorem, with $v_1 = 0$, relates the final speed v_f to the total work.

2. The final speed is related to the final kinetic energy, which in turn is related to the total work by the work–kinetic-energy theorem:
   $W_{total} = \frac{1}{2}mv_f^2 - \frac{1}{2}mv_i^2$

3. For each of you, the total work is the work done by the normal force plus the work done by the gravitational force:
   $W_{total} = W_n + W_g$

4. The force $m\vec{g}$ on you is constant, but the force $\vec{F}_n$ is not constant. First we calculate the work done by $\vec{F}_n$. Calculate the work dW_n done on you by $\vec{F}_n$ for an infinitesimal displacement $d\vec{\ell}$ (Figure 6-23*b*) at an arbitrary location along the run:
   $dW_n = \vec{F}_n \cdot d\vec{\ell} = F_n \cos\phi \, d\ell$

5. Find the angle ϕ between the directions of $\vec{F}_n$ and $d\vec{\ell}$. The displacement $d\vec{\ell}$ is tangent to the slope:
   $\phi = 90°$

6. Calculate the work done by $\vec{F}_n$ for the entire run:
   $W_n = \int F_n \cos 90° \, d\ell = \int (0) \, d\ell = 0$

7. The force of gravity $\vec{F}_g$ is constant, so the work done by gravity is $W_g = \vec{F}_g \cdot \vec{\ell}$, where $\vec{\ell}$ (Figure 6-24) is the net displacement from the top to the bottom of the lift:
   $$W_g = m\vec{g} \cdot \vec{\ell} = -mg\,\hat{j} \cdot (\Delta x\,\hat{i} + \Delta y\,\hat{j}) = -mg\,\Delta y$$

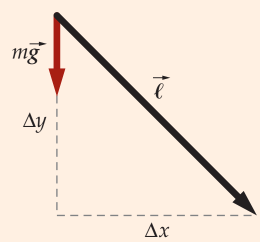

FIGURE 6-24

8. The skier is descending the hill, so Δy is negative. From Figure 6-23*a*, we see that $\Delta y = -h$:
   $\Delta y = -h$

9. Substituting gives:
   $W_g = mgh$

10. Apply the work–kinetic-energy theorem to find v_f:
    $W_n + W_g = \Delta K$

11. The final speed depends only on h, which is the same for both runs. Both of you will have the same final speeds.
    $0 + mgh = \frac{1}{2}mv_f^2 - 0 \quad \text{so} \quad v_f = \sqrt{2gh}$
    $\boxed{\text{YOU WIN!}}$ (The bet was that she would not be going faster than you.)

CHECK The force driving your motion is the gravitational force. This force is proportional to the mass, so the work done by it is proportional to the mass. Because the kinetic energy is also proportional to the mass, the mass cancels out of the work–kinetic-energy equation. Thus, we expect the final speed to be independent of mass. Our result is independent of mass as expected.

TAKING IT FURTHER Your friend on the steeper trail will cross the finish line in less time, but that was not the bet. What was shown here is that the work done by the gravitational force equals mgh. It does not depend upon the shape of the hill or upon the length of the path taken. It depends only upon the mass m and the vertical drop h between the starting point and the finishing point.

* 6-5 CENTER-OF-MASS WORK

Here we present a work–kinetic-energy relation that works for systems that cannot be modeled as a particle. (A particle is a system for which all parts undergo identical displacements.) In Chapter 5 we found (Equation 5-23) that for a system of particles

$$\vec{F}_{\text{net ext}} = \sum \vec{F}_{i\,\text{ext}} = M\vec{a}_{\text{cm}} \tag{6-26}$$

where $M = \Sigma m_i$ is the mass of the system and $\vec{a}_{\text{cm}}$ is the acceleration of the center of mass. Equation 6-26 can be integrated to obtain a useful equation involving work and kinetic energy that can be applied to systems that cannot be modeled as a particle. First, we take the scalar product of both sides of Equation 6-26 with $\vec{v}_{\text{cm}}$ to obtain

$$\vec{F}_{\text{net ext}} \cdot \vec{v}_{\text{cm}} = M\vec{a}_{\text{cm}} \cdot \vec{v}_{\text{cm}} = \frac{d}{dt}\left(\tfrac{1}{2}Mv_{\text{cm}}^2\right) = \frac{dK_{\text{trans}}}{dt} \tag{6-27}$$

where $K_{\text{trans}} = \frac{1}{2}Mv_{\text{cm}}^2$, called the **translational kinetic energy**, is the kinetic energy associated with the motion of the center of mass. Multiplying both sides of Equation 6-27 by dt and then integrating gives

$$\int_1^2 \vec{F}_{\text{net ext}} \cdot d\vec{\ell}_{\text{cm}} = \Delta K_{\text{trans}} \tag{6-28}$$

CENTER-OF-MASS WORK–TRANSLATIONAL-KINETIC-ENERGY RELATION

where $d\vec{\ell}_{\text{cm}} = \vec{v}_{\text{cm}}dt$. The integral $\int_1^2 \vec{F}_{\text{net ext}} \cdot d\vec{\ell}_{\text{cm}}$ is referred to as the **center-of-mass work*** done by the net force on a system of particles, and $d\vec{\ell}_{\text{cm}} = \vec{v}_{\text{cm}}dt$ is the incremental displacement of the center of mass. Equation 6-28 is the **center-of-mass work–translational-kinetic-energy relation.** Stated in words "The center-of-mass work done by the net external force on a system equals the change in the translational kinetic energy of the system. Although Equation 6-28 looks like the equation for the work–kinetic-energy theorem (Equation 6-25), there are some important differences. The center-of-mass work–translational-kinetic-energy relation deals only with the displacement and speed of the center of mass of the system, so when using this relation, we ignore the motion of any part of the system relative to the center-of-mass reference frame. (A center-of-mass reference frame is a nonrotating reference frame† that moves with the center of mass.) This allows us to calculate the bulk motion of the system without knowing all the internal details of the system.

For a system that moves as a particle (with all parts having the same velocity) the center-of-mass work–translational-kinetic-energy relation reduces to the work–kinetic-energy theorem (Equation 6-25).

It is also sometimes useful to refer to the center-of-mass work done by a single force. The center-of-mass work W_{cm} done by any particular force $\vec{F}$ is given by

$$W_{\text{cm}} = \int_1^2 \vec{F} \cdot d\vec{\ell}_{\text{cm}} \tag{6-29}$$

---

* Center-of-mass work is also called pseudowork.

† A nonrotating reference frame is a frame that is not rotating relative to an inertial reference frame.

Example 6-13 Two Pucks and a String

Two identical pucks on an air table are connected by a length of string (see Figure 6-25). The pucks, each of mass m, are initially at rest in the configuration shown. A constant force of magnitude F accelerates the system toward the right. After the point of application P of the force has moved a distance d, the pucks collide and stick together. What is the speed of the pucks immediately following the collision?

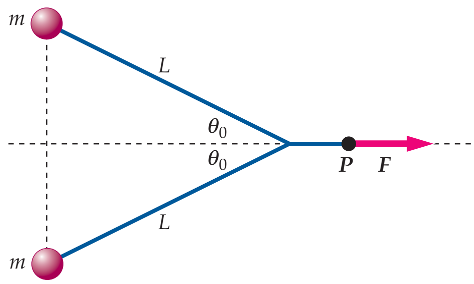

FIGURE 6-25

PICTURE Let the system be the two pucks and the string. Apply the center-of-mass work–kinetic-energy relation to the system. Following the collision the speed of each puck equals the speed of the center of mass. (The pucks can move without friction on the air table.)

SOLVE

1. Make a drawing showing the system initially, and after it has moved distance d (Figure 6-26):

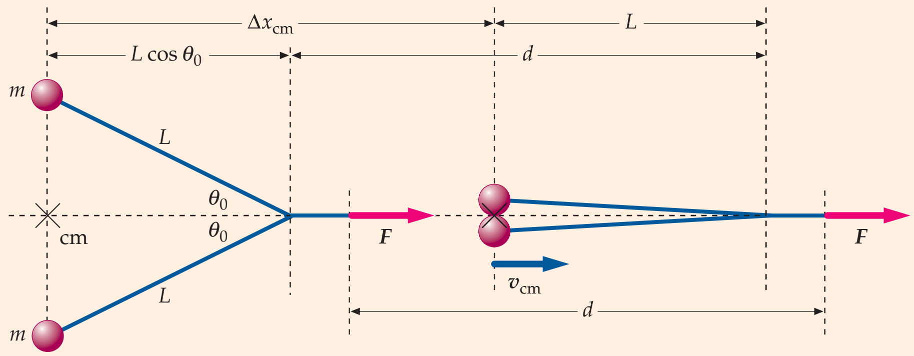

FIGURE 6-26 As the center of mass moves the distance Δx_{cm}, the point of application of the force $\vec{F}$ moves the distance d.

2. Apply the center-of-mass-work–translational-kinetic-energy relation to the system. The net force on the system is $\vec{F} = F\hat{i}$:

$$\int_i^f \vec{F}_{\text{net ext}} \cdot d\vec{\ell}_{cm} = \Delta K_{\text{trans}}$$

$$\int_i^f F\hat{i} \cdot dx_{cm}\hat{i} = K_{\text{trans f}} - K_{\text{trans i}}$$

$$F\int_i^f dx_{cm} = K_{\text{trans f}} - 0$$

$$F\Delta x_{cm} = \tfrac{1}{2}(2m)v_{cm}^2 = mv_{cm}^2$$

3. Find Δx_{cm} in terms of d and L. Figure 6-26 makes the calculation of Δx_{cm} fairly straightforward:

$$\Delta x_{cm} + L = L\cos\theta_0 + d$$

$$\text{so} \quad \Delta x_{cm} = d - L(1 - \cos\theta_0)$$

4. Substitute the step-3 result into the step-2 result and solve for v_{cm}:

$$F\Delta x_{cm} = mv_{cm}^2$$

$$F[d - L(1 - \cos\theta_0)] = mv_{cm}^2$$

$$\text{so} \quad v_{cm} = \boxed{\sqrt{\frac{F[d - L(1 - \cos\theta_0)]}{m}}}$$

CHECK If the initial angle θ_0 is zero, the system can be modeled as a particle and the work–kinetic-energy theorem can be used. This would give $Fd = \frac{1}{2}(2m)v^2 = mv^2$, or $v = \sqrt{Fd/m}$. Our step-4 result gives the very same expression for the speed if $\theta_0 = 0$.

TAKING IT FURTHER (1) In this example, the displacement of the center of mass Δx_{cm} is less than the displacement d of the point of application of the force $\vec{F}$. As a result, the center-of-mass work done by the force is less than the work Fd done by the force. (2) The pucks lose kinetic energy when they collide and stick together. This energy appears as some other form of energy, such as thermal energy. The conservation of energy is discussed further in Chapter 7.

Example 6-14 Stopping Distance

To avoid an accident, the driver of a 1000-kg car moving at 90 km/h on a straight horizontal road steps on the brakes with maximum force. The antilock braking system (ABS) is not working, so the wheels lock and the tires skid as the car comes to a stop. The kinetic coefficient of friction between the road and the tires is 0.80. How far does the car travel during the skid?

PICTURE The car cannot be modeled as a particle. The points of application of the kinetic frictional forces are the parts of the tires in contact with the road surface. The high points of the contacting surfaces alternatively stick and slip. Therefore, the car cannot be modeled as a particle during the skid. The center-of-mass work–translational-kinetic-energy relation applied to the car enables us to calculate the stopping distance.

SOLVE

1. Write the center-of-mass work–translational-kinetic-energy relation. We need to solve for the displacement of the center of mass of the car:

$$\int_1^2 \vec{F}_{\text{net ext}} \cdot d\vec{\ell}_{\text{cm}} = \Delta K_{\text{trans}}$$

2. Draw a free-body diagram of the car during the skid (Figure 6-27):

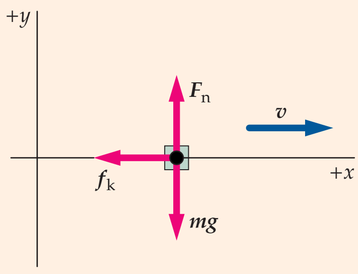

FIGURE 6-27

3. The vertical acceleration is zero, so the normal force and the gravitational force sum to zero. The net external force on the car is equal to the frictional force. Solve for the net force on the car:

$$\vec{F}_{\text{net}} = \vec{F}_n + m\vec{g} + \vec{f}_k = \vec{f}_k$$

so

$$F_{\text{net}} = f_k = \mu_k F_n = \mu_k mg$$

$$\vec{F}_{\text{net}} = -\mu_k mg\,\hat{\boldsymbol{i}}$$

4. Apply the center-of-mass work–translational-kinetic-energy relation to the car:

$$\int_1^2 \vec{F}_{\text{net}} \cdot d\vec{\ell}_{\text{cm}} = \Delta K_{\text{trans}}$$

$$\int_1^2 -\mu_s mg\,\hat{\boldsymbol{i}} \cdot dx_{\text{cm}}\,\hat{\boldsymbol{i}} = K_{\text{trans}\,2} - K_{\text{trans}\,1}$$

$$-\mu_s mg \int_1^2 dx_{\text{cm}} = 0 - K_{\text{trans}\,1}$$

$$-\mu_s mg\,(x_{\text{cm}\,2} - x_{\text{cm}\,1}) = -\tfrac{1}{2}mv_{\text{cm}\,1}^2$$

5. Solve for the displacement, but first convert the initial speed from km/h to m/s:

$$v_{\text{cm}\,1} = 90\ \text{km/h} \cdot \frac{1\ \text{h}}{(3.6\ \text{ks})} = 25\ \text{m/s}$$

so

$$\Delta x_{\text{cm}} = x_{\text{cm}\,2} - x_{\text{cm}\,1} = \frac{v_{\text{cm}\,1}^2}{2\mu_k g}$$

$$\Delta x_{\text{cm}} = \frac{(25\ \text{m/s})^2}{2 \cdot (0.80)(9.81\ \text{m/s}^2)} = \boxed{40\ \text{m}}$$

CHECK We would expect the stopping distance to increase with initial speed, and to decrease with increasing coefficient of friction. The step-5 expression for Δx_{cm} meets these expectations.

TAKING IT FURTHER The translational kinetic energy of the car is dissipated as thermal energy of the tires and of the pavement. The dissipation of kinetic energy into thermal energy by kinetic friction is discussed further in Chapter 7.

Physics Spotlight

Coasters and Baggage and Work (Oh My!)

Baggage transfer methods at some major airports have a lot in common with roller coasters. High rates of change of acceleration for long periods of time are bad for both coaster passengers and baggage items. Both must move swiftly without unwanted jerking and halting.

Some roller coaster cars (and some baggage carriers) gain kinetic energy because of the work done on them by constant forces exerted on them by banks of *linear induction motors* (LIMs). A LIM is an electromagnetic method of providing force without moving parts.* The main reason for the use of linear induction motors is the flexibility of applying force at calculated locations during the travel of the coaster train or the baggage buggy. The roller coaster and the baggage buggies run on tracks that use sensors to determine the speed of the vehicles, and communicate that speed to the controllers for the motors. The LIMs can be turned off when the vehicle has reached the right speed. In both cases, some LIMs are also wired to act as brakes on the vehicles, exerting forces on them in opposition to their direction of travel.

Speed—The Ride is a roller coaster launched from the NASCAR Café in the Sahara Hotel and Casino in Las Vegas. The design firm, Ingenieurbuero Stengel GmbH, specified 88 motors in three locations along the track. The first bank of motors launches the coaster train. The 6-car, 24-passenger coaster train is smoothly accelerated to 45 mi/h in 2.0 s. It swoops around a corner and plunges 25 ft underground before rising and going through a clothoid loop-the-loop.† After it goes through the loop-the-loop, forces exerted on it by the second bank of LIMs quadruple its kinetic energy in 2.0 s.‡ The roller coaster glides along Las Vegas Boulevard, and races two hundred feet up a near-vertical incline. For safety's sake, a series of LIMs near the top of the incline can slow the train, if necessary. The coaster train then runs backward through the entire coaster route. As it returns to the station, the LIMs in the station act as brakes, and bring the train to a stop.

Other than the forces from the LIMs, the forces acting on the coaster train are gravity, friction, and the normal force. Each of the cars in the coaster train travels over the same path, although the starting and ending points for each car are not the same. The maximum acceleration of any passenger is 3.5 g. This is not excessive—the momentary acceleration caused by being hit on the head with a pillow can go above 20 g.§

Heathrow International Airport often transfers luggage between Terminals One and Four. The terminals are more than 1.0 km apart and are separated by a runway. Each piece of luggage is loaded onto a small buggy that rides on rails. (The speeds of the buggies are controlled by LIMs mounted on the tracks.) The buggy goes down a steep incline to reach the level of a tunnel, 20 m underground. It travels through the tunnel at 30 km/h, and is kept at that speed by regularly spaced LIMs. At the end of the tunnel, the buggy climbs up into the appropriate floor of the other terminal. When you transfer between flights at a large airport, remember that your luggage may well be going on its own special ride.

The speeds of the buggies transporting luggage between terminals at Heathrow International Airport are controlled by LIMs. *(Vanderlande Industries.)*

SUMMARY

1. Work, kinetic energy, and power are important derived dynamic quantities.
2. The work–kinetic-energy theorem is an important relation derived from Newton's laws applied to a particle. (In this context, a particle is a perfectly rigid object that moves without rotating.)
3. The scalar product of vectors is a mathematical definition that is useful throughout physics.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Work	$W = \int_1^2 \vec{F} \cdot d\vec{\ell} = \int_1^2 F_{\parallel} d\ell$ (definition)	
Constant force	$W = \vec{F} \cdot \vec{\ell} = F_{\parallel}\ell = F\ell_{\parallel} = F\ell \cos\theta$	
Constant force—straight-line motion	$W = F_x \Delta x = F\lvert\Delta x\rvert \cos\theta$	
Variable force—straight-line motion	$W = \int_{x_1}^{x_2} F_x dx =$ area under the F_x-versus-x curve	
2. Kinetic Energy	$K = \frac{1}{2}mv^2$ (definition)	
3. Work–Kinetic-Energy Theorem	$W_{\text{total}} = \Delta K = \frac{1}{2}mv_f^2 - \frac{1}{2}mv_i^2$	
4. Scalar or Dot Product	$\vec{A} \cdot \vec{B} = AB\cos\phi$ (definition)	
In terms of components	$\vec{A} \cdot \vec{B} = A_xB_x + A_yB_y + A_zB_z$	
Unit vector times vector	$\vec{A} \cdot \hat{i} = A_x$	
Derivative product rule	$\frac{d}{dt}(\vec{A} \cdot \vec{B}) = \frac{d\vec{A}}{dt} \cdot \vec{B} + \vec{A} \cdot \frac{d\vec{B}}{dt}$	
5. Power	$P = \frac{dW}{dt} = \vec{F} \cdot \vec{v}$	
6. Center-of-Mass Work–Translational-Kinetic-Energy Relation	$\int_1^2 \vec{F}_{\text{net ext}} \cdot d\vec{\ell}_{\text{cm}} = \Delta K_{\text{trans}}$ This relation is a useful problem-solving tool if for systems that cannot be modeled as a particle.	6-2
Center-of-Mass Work	$W_{\text{cm}} = \int_1^2 \vec{F} \cdot d\vec{\ell}_{\text{cm}}$	6-3
Translational Kinetic Energy	$K_{\text{trans}} = \frac{1}{2}Mv_{\text{cm}}^2$, where $M = \Sigma m_i$	

Answers to Concept Checks

6-1 The work being done by the force is negative.

Answers to Practice Problems

6-1 34 J

6-2 1.7×10^2 N

6-3 4.1 m/s

6-4 The region of interest is below the x axis, so the "area under the curve" is negative. The "area under the curve" is $-(\lvert A_1\rvert - \lvert A_2\rvert)$, where A_1 and A_2 are shown in Figure 6-28. The work done by the spring is equal to

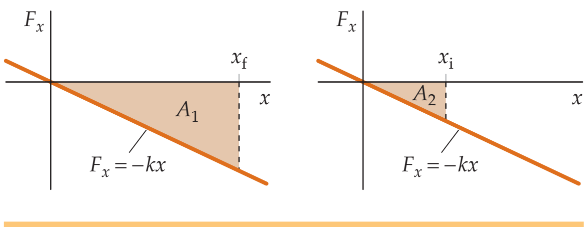

FIGURE 6-28

the "area under the curve," and the area of a triangle is one-half the altitude times the base. Thus,

$$W_{\text{by spring}} = -(|A_1| - |A_2|) = -(\tfrac{1}{2} \cdot kx_f \cdot x_f - \tfrac{1}{2} \cdot kx_i \cdot x_i) = \boxed{\tfrac{1}{2}kx_i^2 - \tfrac{1}{2}kx_f^2}$$

which is identical to Equation 6-13.

6-5 0.40 m/s

6-6 (*a*) 38 m^2, (*b*) $A = 5.0$ m, $B = 8.2$ m, $\phi = 23°$

6-7 $F = 5.00$ N, $\phi = 121°$

6-8 $P = 2.0 \times 10^2$ W, $W = 8.0 \times 10^3$ J, $W = -8.0 \times 10^3$ J

PROBLEMS

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimates.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

For all problems, use g = 9.81 m/s^2 for the free-fall acceleration due to gravity and neglect friction and air resistance unless instructed to do otherwise.

• Single-concept, single-step, relatively easy

•• Intermediate-level, may require synthesis of concepts

••• Challenging

SSM Solution is in the *Student Solutions Manual*

Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • True or false: (*a*) If the net or total work done on a particle was not zero, then its speed must have changed. (*b*) If the net or total work done on a particle was not zero, then its velocity must have changed. (*c*) If the net or total work done on a particle was not zero, then its direction of motion could not have changed. (*d*) No work is done by the forces acting on a particle if it remains at rest. (*e*) A force that is always perpendicular to the velocity of a particle never does work on the particle.

2 • You push a heavy box in a straight line along the top of a rough horizontal table. The box starts at rest and ends at rest. Describe the work done on it (including sign) by each force acting on it and the net work done on it.

3 • You are riding on a Ferris wheel that is rotating at constant speed. True or false: During any fraction of a revolution: (*a*) None of the forces acting on you does work on you. (*b*) The total work done by all forces acting on you is zero. (*c*) There is zero net force on you. (*d*) You are accelerating.

4 • By what factor does the kinetic energy of a particle change if its speed is doubled but its mass is cut in half?

5 • Give an example of a particle that has constant kinetic energy but is accelerating. Can a non-accelerating particle have a changing kinetic energy? If so, give an example.

6 • An particle initially has kinetic energy *K*. Later it is found to be moving in the opposite direction with three times its initial speed. What is the kinetic energy now? (*a*) *K*, (*b*) 3*K*, (*c*) 23*K*, (*d*) 9*K*, (*e*) −9*K*

7 • How does the work required to stretch a spring 2.0 cm from its unstressed length compare with the work required to stretch it 1.0 cm from its unstressed length? SSM

8 • A spring is first stretched 2.0 cm from its unstressed length. It is then stretched an additional 2.0 cm. How does the work required for the second stretch compare to the work required for the first stretch (give a ratio of second to first)?

9 • The dimension of power is (*a*) M·L^2·T^2, (*b*) M·L^2/T, (*c*) M·L^2/T^2, (*d*) M·L^2/T^3.

10 • Show that the SI units of the force constant of a spring can be written as kg/s^2.

11 • True or false: (*a*) The gravitational force cannot do work on an object, because it is not a contact force. (*b*) Static friction can never do work on an object. (*c*) As a negatively charged electron is removed from a positively charged nucleus, the force on the electron does work that as a positive value. (*d*) If a particle is moving along a circular path, the total work being done on it is necessarily zero.

12 •• A hockey puck has an initial velocity in the $+x$ direction on a horizontal sheet of ice. Qualitatively sketch the force-versus-position graph for the (constant) horizontal force that would need to act on the puck to bring it to rest. Assume that the puck is located at $x = 0$ when the force begins to act. Show that the sign of the area under the curve agrees with the sign of the change in the puck's kinetic energy and interpret this in terms of the work–kinetic-energy theorem.

13 •• True or false: (*a*) The scalar product cannot have units. (*b*) If the scalar product of two nonzero vectors is zero, then they are parallel. (*c*) If the scalar product of two nonzero vectors is equal to the product of their magnitudes, then the two vectors are parallel. (*d*) As an object slides up an incline, the sign of the scalar product of the force of gravity on it and its displacement is negative. SSM

14 •• (*a*) Must the scalar product of two perpendicular unit vectors always be zero? If not, give an example. (*b*) An object has a velocity $\vec{v}$ at some instant. Interpret $\sqrt{\vec{v} \cdot \vec{v}}$ physically. (*c*) A ball rolls off a horizontal table. What is the scalar product between its velocity and its acceleration the instant after it leaves the table? Explain. (*d*) In Part (*c*), what is the sign of the scalar product of its velocity and acceleration the instant before it impacts the floor?

15 •• You lift a package vertically upward a distance L in time Δt. You then lift a second package that has twice the mass of the first package vertically upward the same distance while providing the same power as required for the first package. How much time does lifting the second package take (answer in terms of Δt)?

16 •• There are lasers that output more than 1.0 GW of power. A typical large modern electric generation plant typically outputs 1.0 GW of electrical power. Does this mean the laser outputs a huge amount of energy? Explain. *Hint: These high-power lasers are pulsed on and off, so they are not outputting power for very long time intervals.*

17 •• You are driving a car that accelerates from rest on a level road without spinning its wheels. Use the center-of-mass work–translational-kinetic-energy relation and free-body diagrams to clearly explain which force (or forces) is (are) directly responsible for the gain in translational kinetic energy of both you and the car. *Hint: The relation refers to external forces only, so the car's engine is not the answer. Pick your "system" correctly for each case.* SSM

ESTIMATION AND APPROXIMATION

18 •• (*a*) Estimate the work done on you by gravity as you take an elevator from the ground floor to the top of the Empire State Building, a building 102 stories high. (*b*) Estimate the amount of work the normal force of the floor did on you. *Hint: The answer is not zero.* (*c*) Estimate the average power of the force of gravity.

19 •• **Engineering Application, Context-Rich** The nearest stars, apart from the Sun, are light-years away from Earth. If we are to investigate these stars, our space ships will have to travel at an appreciable fraction of the speed of light. (*a*) You are in charge of estimating the energy required to accelerate a 10,000-kg capsule from rest to 10 percent of the speed of light in one year. What is the minimum amount of energy that is required? Note that at velocities approaching the speed of light, the kinetic energy formula $\frac{1}{2}mv^2$ is not correct. However, it gives a value that is within 1% of the correct value for speeds up to 10% of the speed of light. (*b*) Compare your estimate to the amount of energy that the United States uses in a year (about 5×10^{20} J). (*c*) Estimate the minimum average power required of the propulsion system.

20 •• The mass of the Space Shuttle orbiter is about 8×10^4 kg and the period of its orbit is 90 min. Estimate the kinetic energy of the orbiter and the work done on it by gravity between launch and orbit. (Although the force of gravity decreases with altitude, this effect is small in low-Earth orbit. Use this fact to make the necessary approximation; you do not need to do an integral.) The orbits are about 250 miles above the surface of Earth.

21 • **Context-Rich** Ten inches of snow have fallen during the night, and you must shovel out your 50-ft-long driveway (Figure 6-29). Estimate how much work you do on the snow by completing this task. Make a plausible guess of any value(s) needed (the width of the driveway, for example), and state the basis for each guess.

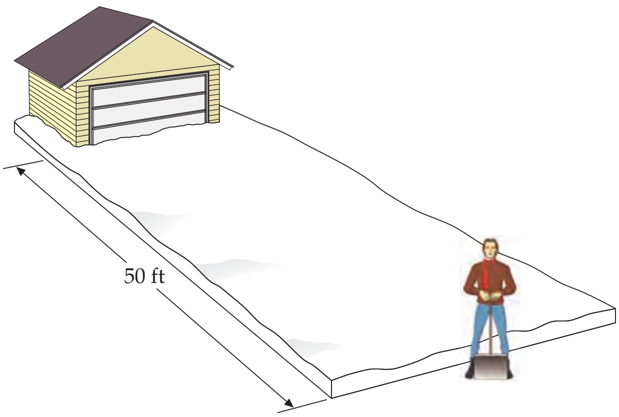

FIGURE 6-29 Problem 21

WORK, KINETIC ENERGY, AND APPLICATIONS

22 • A 15-g piece of space junk has a speed of 1.2 km/s. (*a*) What is its kinetic energy? (*b*) What is its kinetic energy if its speed is halved? (*c*) What is its kinetic energy if its speed is doubled?

23 • Find the kinetic energy of (*a*) a 0.145-kg baseball moving with a speed of 45.0 m/s, and (*b*) a 60.0-kg jogger running at a steady pace of 9.00 min/mi.

24 • A 6.0-kg box is raised a distance of 3.0 m from rest by a vertical applied force of 80 N. Find (*a*) the work done on the box by the applied force, (*b*) the work done on the box by gravity, and (*c*) the final kinetic energy of the box.

25 • A constant 80-N force acts on a 5.0 kg box. The box initially is moving at 20 m/s in the direction of the force, and 3.0 s later the box is moving at 68 m/s. Determine both the work done by this force and the average power delivered by the force during the 3.0-s interval.

26 •• You run a race with a friend. At first you each have the same kinetic energy, but she is running faster than you are. When you increase your speed by 25 percent, you are running at the same speed she is. If your mass is 85 kg, what is her mass?

27 •• A 3.0-kg particle moving along the x axis has a velocity of $+2.0$ m/s as it passes through the origin. It is subjected to a single force, F_x, that varies with position, as shown in Figure 6-30. (*a*) What is the kinetic energy of the particle as it passes through the origin? (*b*) How much work is done by the force as the particle moves from $x = 0.0$ m to $x = 4.0$ m? (*c*) What is the speed of the particle when it is at $x = 4.0$ m? SSM

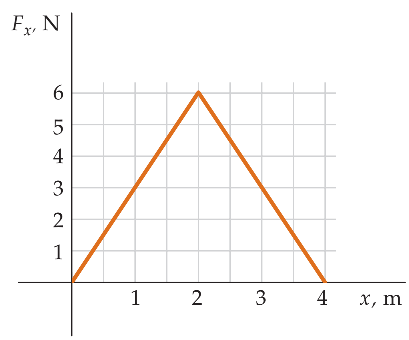

FIGURE 6-30 Problem 27

28 •• A 3.0-kg object moving along the x axis has a velocity of 2.4 m/s as it passes through the origin. It is acted on by a single force, F_x, that varies with x, as shown in Figure 6-31. (*a*) Find the work done by the force from $x = 0.0$ m to $x = 2.0$ m. (*b*) What is the kinetic energy of the object at $x = 2.0$ m? (*c*) What is the speed of the object at $x = 2.0$ m? (*d*) What is the work done on the object from $x = 0.0$ to $x = 4.0$ m? (*e*) What is the speed of the object at $x = 4.0$ m?

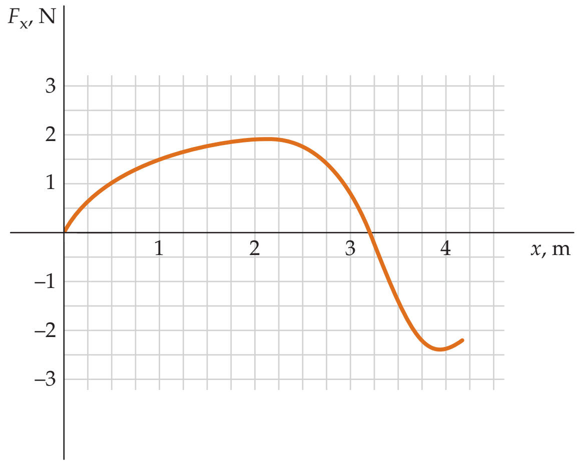

FIGURE 6-31 Problem 28

29 •• One end of a light spring (force constant k) is attached to the ceiling, the other end is attached to an object of mass m. The spring initially is vertical and unstressed. You then "ease the object down" to an equilibrium position a distance h below its initial position. Next, you repeat this experiment, but instead of easing the object down, you release it, with the result that it falls a distance H below the initial position before momentarily stopping. (*a*) Show that $h = mg/k$. (*b*) Use the work–kinetic-energy theorem to show that $H = 2h$. Try this experiment on your own.

30 •• A force F_x acts on a particle that has a mass of 1.5 kg. The force is related to the position x of the particle by the formula $F_x = Cx^3$, where $C = 0.50$ if x is in meters and F_x is in newtons. (*a*) What are the SI units of C? (*b*) Find the work done by this force as the particle moves from $x = 3.0$ m to $x = 1.5$ m. (*c*) At $x = 3.0$ m, the force points opposite the direction of the particle's velocity (speed is 12.0 m/s). What is its speed at $x = 1.5$ m? Can you tell its direction of motion at $x = 1.5$ m using only the work–kinetic-energy theorem? Explain.

31 •• You have a vacation cabin that has a nearby solar (black) water container used to provide a warm outdoor shower. For a few days last summer, your pump went out and you had to personally haul the water up the 4.0 m from the pond to the tank. Suppose your bucket has a mass of 5.0 kg and holds 15.0 kg of water when it is full. However, the bucket has a hole in it, and as you moved it vertically at a constant speed v, water leaked out at a constant rate. By the time you reached the top, only 5.0 kg of water remained. (*a*) Write an expression for the mass of the bucket plus water as a function of the height above the pond surface. (*b*) Find the work done by you on the bucket for each 5.0 kg of water delivered to the tank.

32 •• A 6.0-kg block slides 1.5 m down a frictionless incline that makes an angle of 60° with the horizontal. (*a*) Draw the free-body diagram of the block, and find the work done by each force when the block slides 1.5 m (measured along the incline). (*b*) What is the total work done on the block? (*c*) What is the speed of the block after it has slid 1.5 m, if it starts from rest? (*d*) What is its speed after 1.5 m, if it starts with an initial speed of 2.0 m/s?

33 •• **ENGINEERING APPLICATION** You are designing a jungle-vine–swinging sequence for the latest Tarzan movie. To determine his speed at the low point of the swing and to make sure it does not exceed mandatory safety limits, you decide to model the system of Tarzan + vine as a pendulum. Assume your model consists of a particle (Tarzan, mass 100 kg) hanging from a light string (the vine) of length ℓ attached to a support. The angle between the vertical and the string is written as ϕ. (*a*) Draw a free-body diagram for the object on the end of the string (Tarzan on the vine). (*b*) An infinitesimal distance along the arc (along which the object travels) is $\ell d\phi$. Write an expression for the total work dW_{total} done on the particle as it traverses that distance for an arbitrary angle ϕ. (*c*) If the $\ell = 7.0$ m, and if the particle starts from rest at an angle 50°, determine the particle's kinetic energy and speed at the low point of the swing using the work–kinetic-energy theorem. SSM

34 •• *Simple machines* are frequently used for reducing the amount of force that must be supplied to perform a task such as lifting a heavy weight. Such machines include the screw, block-and-tackle systems, and levers, but the simplest of the simple machines is the inclined plane. In Figure 6-32, you are raising a heavy box to the height of the truck bed by pushing it up an inclined plane (a ramp). (*a*) The *mechanical advantage MA* of the inclined plane is defined as the ratio of the magnitude of the force it would take to lift the block straight up (at constant speed) to the magnitude of the force it would take to push it up the ramp (at constant speed). If the plane is frictionless, show that $MA = 1/\sin\theta = L/H$, where H is the height of the truck bed and L is the length of the ramp. (*b*) Show that the work you do by moving the block into the truck is the same whether you lift it straight up or push it up the frictionless ramp.

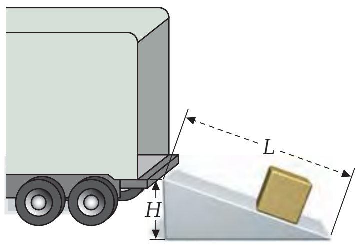

FIGURE 6-32 Problem 34

35 •• Particle a has mass m, is initially located on the positive x axis at $x = x_0$ and is subject to a repulsive force F_x from particle b. The location of particle b is fixed at the origin. The force F_x is inversely proportional to the square of the distance x between the particles. That is, $F_x = A/x^2$, where *A is a positive constant*. Particle a is released from rest and allowed to move under the influence of the force. Find an expression for the work done by the force on a as a function of x. Find both the kinetic energy and speed of a as x approaches infinity.

36 • You exert a force of magnitude F on the free end of the rope. (*a*) If the load moves up a distance h, through what distance does the point of application of the force move? (*b*) How much work is done by the rope on the load? (*c*) How much work do you do on the rope? (*d*) The mechanical advantage (defined in Problem 34) of this system is the ratio F/F_g, where F_g is the weight of the load. What is this mechanical advantage?

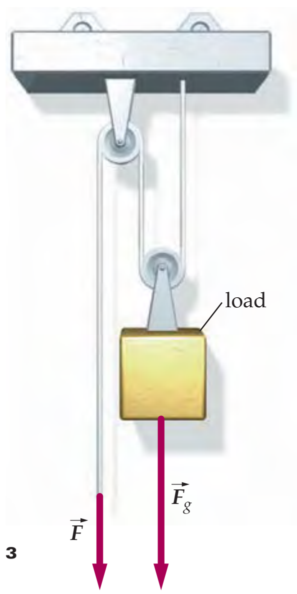

FIGURE 6-33
Problem 36

SCALAR (DOT) PRODUCTS

37 • What is the angle between the vectors $\vec{A}$ and $\vec{B}$ if $\vec{A}\cdot\vec{B} = -AB$?

38 • Two vectors $\vec{A}$ and $\vec{B}$ each have magnitudes of 6.0 m and the angle between their directions is 60°. Find $\vec{A}\cdot\vec{B}$.

39 • Find $\vec{A}\cdot\vec{B}$ for the following vectors: (*a*) $\vec{A} = 3\hat{i} - 6\hat{j}$, $\vec{B} = -4\hat{i} + 2\hat{j}$; (*b*) $\vec{A} = 5\hat{i} + 5\hat{j}$, $\vec{B} = 2\hat{i} - 4\hat{j}$; and (*c*) $\vec{A} = 6\hat{i} + 4\hat{j}$, $\vec{B} = 4\hat{i} - 6\hat{j}$.

40 • Find the angles between the vectors $\vec{A}$ and $\vec{B}$ given: (*a*) $\vec{A} = 3\hat{i} - 6\hat{j}$, $\vec{B} = -4\hat{i} + 2\hat{j}$; (*b*) $\vec{A} = 5\hat{i} + 5\hat{j}$, $\vec{B} = 2\hat{i} - 4\hat{j}$; and (*c*) $\vec{A} = 6\hat{i} + 4\hat{j}$, $\vec{B} = 4\hat{i} - 6\hat{j}$.

41 • A 2.0-kg particle is given a displacement of $\Delta\vec{r} = (3.0\text{ m})\hat{i} + (3.0\text{ m})\hat{j} + (-2.0\text{ m})\hat{k}$. During the displacement, a constant force $\vec{F} = (2.0\text{ N})\hat{i} - (1.0\text{ N})\hat{j} + (1.0\text{ N})\hat{k}$ acts on the particle. (*a*) Find the work done by $\vec{F}$ for this displacement. (*b*) Find the component of $\vec{F}$ in the direction of this displacement.

42 •• (*a*) Find the unit vector that is in the same direction as the vector $\vec{A} = 2.0\hat{i} - 1.0\hat{j} - 1.0\hat{k}$. (*b*) Find the component of the vector $\vec{A} = 2.0\hat{i} - 1.0\hat{j} - 1.0\hat{k}$ in the direction of the vector $\vec{B} = 3.0\hat{i} + 4.0\hat{j}$.

43 •• (*a*) Given two nonzero vectors $\vec{A}$ and $\vec{B}$, show that if $|\vec{A} + \vec{B}| = |\vec{A} - \vec{B}|$, then $\vec{A} \perp \vec{B}$. (*b*) Given a vector $\vec{A} = 4\hat{i} - 3\hat{j}$, find a vector in the *xy* plane that is perpendicular to $\vec{A}$ and has a magnitude of 10. Is this the only vector that satisfies the specified requirements? Explain. SSM

44 •• Unit vectors $\hat{A}$ and $\hat{B}$ are in the *xy* plane. They make angles of θ_1 and θ_2, respectively, with the $+x$ axis. (*a*) Use trigonometry to find the *x* and *y* components of the two vectors directly. (Your answer should be in terms of the angles.) (*b*) By considering the scalar product of $\hat{A}$ and $\hat{B}$, show that $\cos(\theta_1 - \theta_2) = \cos\theta_1\cos\theta_2 + \sin\theta_1\sin\theta_2$.

45 •• In Chapter 8, we shall introduce a new vector for a particle, called its *linear momentum*, symbolized by $\vec{p}$. Mathematically, it is related to the mass *m* and velocity $\vec{v}$ of the particle by $\vec{p} = m\vec{v}$. (*a*) Show that the particle's kinetic energy *K* can be expressed as $K = \dfrac{\vec{p}\cdot\vec{p}}{2m}$. (*b*) Compute the linear momentum of a particle of mass 2.5 kg that is moving at a speed of 15 m/s at an angle of 25° clockwise from the $+x$ axis in the *xy* plane. (*c*) Compute its kinetic energy using both $K = \frac{1}{2}mv^2$ and $K = \dfrac{\vec{p}\cdot\vec{p}}{2m}$ and verify that they give the same result.

46 ••• (*a*) Let $\vec{A}$ be a constant vector in the *xy* plane with its tail at the origin. Let $\vec{r} = x\hat{i} + y\hat{j}$ be a vector in the *xy* plane that satisfies the relation $\vec{A}\cdot\vec{r} = 1$. Show that the points with coordinates (x, y) lie on a straight line. (*b*) If $\vec{A} = 2\hat{i} - 3\hat{j}$, find the slope and *y* intercept of the line. (*c*) If we now let $\vec{A}$ and $\vec{r}$ be vectors in three-dimensional space, show that the relation $\vec{A}\cdot\vec{r} = 1$ specifies a plane.

47 ••• A particle moves in a circle that is centered at the origin and the magnitude of its position vector $\vec{r}$ is constant. (*a*) Differentiate $\vec{r}\cdot\vec{r} = r^2 =$ constant with respect to time to show that $\vec{v}\cdot\vec{r} = 0$, and therefore $\vec{v} \perp \vec{r}$. (*b*) Differentiate $\vec{v}\cdot\vec{r} = 0$ with respect to time and show that $\vec{a}\cdot\vec{r} + v^2 = 0$, and therefore $a_r = -v^2/r$. (*c*) Differentiate $\vec{v}\cdot\vec{v} = v^2$ with respect to time to show that $\vec{a}\cdot\hat{v} = dv/dt$, and therefore $a_t = dv/dt$. SSM

WORK AND POWER

48 • Force A does 5.0 J of work in 10 s. Force B does 3.0 J of work in 5.0 s. Which force delivers greater power, A or B? Explain.

49 • MULTISTEP A single force of 5.0 N in the $+x$ direction acts on an 8.0-kg object. (*a*) If the object starts from rest at $x = 0$ at time $t = 0$, write an expression for the power delivered by this force as a function of time. (*b*) What is the power delivered by this force at time $t = 3.0$ s?

50 • Find the power delivered by a force $\vec{F}$ acting on a particle that moves with a velocity $\vec{v}$, where (*a*) $\vec{F} = (4.0\text{ N})\hat{i} + (3.0\text{ N})\hat{k}$ and $\vec{v} = (6.0\text{ m/s})\hat{i}$; (*b*) $\vec{F} = (6.0\text{ N})\hat{i} - (5.0\text{ N})\hat{j}$ and $\vec{v} = -(5.0\text{ m/s})\hat{i} + (4.0\text{ m/s})\hat{j}$; and (*c*) $\vec{F} = (3.0\text{ N})\hat{i} + (6.0\text{ N})\hat{j}$ and $\vec{v} = (2.0\text{ m/s})\hat{i} + (3.0\text{ m/s})\hat{j}$.

51 •• ENGINEERING APPLICATION You are in charge of installing a small food-service elevator (called a *dumbwaiter* in the food industry) in a campus cafeteria. The elevator is connected by a pulley system to a motor, as shown in Figure 6-34. The motor raises and lowers the dumbwaiter. The mass of the dumbwaiter is 35 kg. In operation, it moves at a speed of 0.35 m/s upward, without accelerating (except for a brief initial period, which we can neglect, just after the motor is turned on). Electric motors typically have an efficiency of 78%. If you purchase a motor with an efficiency of 78%, what minimum power rating should the motor have? Assume that the pulleys are frictionless. SSM

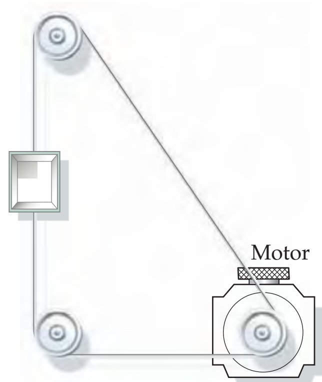

FIGURE 6-34 Problem 51

52 •• A cannon placed at the edge of a cliff of height *H* fires a cannonball directly upward with an initial speed v_0. The cannonball rises, falls back down (missing the cannon by a small margin), and lands at the foot of the cliff. Neglecting air resistance, calculate the velocity $\vec{v}$ as a function of time, and show explicitly that the integral of $\vec{F}_{\text{net}}\cdot\vec{v}$ over the time that the cannonball spends in flight is equal to the change in the kinetic energy of the cannonball over the same time.

53 •• A particle of mass *m* moves from rest at $t = 0$ under the influence of a single constant force $\vec{F}$. Show that the power delivered by the force at any time *t* is $P = F^2t/m$.

54 •• A 7.5-kg box is being lifted by means of a light rope that is threaded through a single, light, frictionless pulley that is attached to the ceiling. (*a*) If the box is being lifted at a *constant speed* of 2.0 m/s, what is the power delivered by the person pulling on the rope? (*b*) If the box is lifted, at *constant acceleration*, from rest on the floor to a height of 1.5 m above the floor in 0.42 s, what average power is delivered by the person pulling on the rope?

* CENTER OF MASS WORK AND CENTER OF MASS TRANSLATIONAL KINETIC ENERGY

55 ••• ENGINEERING APPLICATION, CONTEXT-RICH, SPREADSHEET You have been asked to test drive a car and study its actual performance relative to its specifications. This particular car's engine is rated at 164 hp. This value is the *peak* rating, which means that it is capable, at most, of providing energy at the rate of 164 hp to the drive wheels. You determine that the car's mass (including test equipment and driver on board) is 1220 kg. (*a*) When cruising at a constant 55.0 mi/h, your onboard engine-monitoring computer determines that the engine is producing 13.5 hp. From previous coasting experiments, it has been determined that the coefficient of rolling friction on the car is 0.0150. Assume that the drag force on the car varies as the square of the car's speed. That is, $F_d = Cv^2$. (*a*) What is the value of the constant, *C*? (*b*) Considering the peak power, what is the maximum speed (to the nearest 1 mi/h) that you would expect the car could attain? (This problem can be done by hand analytically, but it can be done more easily and quickly using a **graphing calculator** or **spreadsheet.**)

56 •• **CONTEXT-RICH, CONCEPTUAL** As you drive your car along a country road at night, a deer jumps out of the woods and stands in the middle of the road ahead of you. This occurs just as you are passing from a 55-mi/h zone to a 50-mi/h zone. At the 50-mi/h speed-limit sign, you slam on the car's brakes, causing them to lock up, and skid to a stop inches from the startled deer. As you breathe a sigh of relief, you hear the sound of a police siren. The policeman proceeds to write you a ticket for driving 56 mi/h in 50-mi/h zone. Because of your preparation in physics, you are able to use the 25-m-long skid marks that your car left behind as evidence that you were not speeding. What evidence do you present? In formulating your answer, you will need to know the coefficient of kinetic friction between automobile tires and dry concrete (see Table 5-1).

GENERAL PROBLEMS

57 • **APPROXIMATION** In February 2002, a total of 60.7 billion kW·h of electrical energy was generated by nuclear power plants in the United States. At that time, the population of the United States was about 287 million people. If the average American has a mass of 60 kg, and if 25% of the entire energy output of all nuclear power plants was diverted to supplying energy for a single giant elevator, estimate the height *h* to which the entire population of the country could be lifted by the elevator. In your calculations, assume also that *g* is constant over the entire height *h*.

58 • **ENGINEERING APPLICATION** One of the most powerful cranes in the world operates in Switzerland. It can slowly raise a 6000-t load to a height of 12.0 m. (Note that 1 t = one tonne is sometimes called a metric ton. It is a unit of mass, not force, and is equal to 1000 kg.) (*a*) How much work is done by the crane during this lift? (*b*) If it takes 1.00 min to lift this load to this height at constant velocity, and the crane is 20 percent efficient, find the total (gross) power rating of the crane.

59 • In Austria, there once was a 5.6-km-long ski lift. It took about 60 min for a gondola to travel up its length. If there were 12 gondolas going up, each with a cargo of mass 550 kg, and if there were 12 empty gondolas going down, and the angle of ascent was 30°, estimate the power *P* the engine needed to deliver in order to operate the ski lift.

60 •• **ENGINEERING APPLICATION** To complete your master's degree in physics, your advisor has you design a small, linear accelerator capable of emitting protons, each with a kinetic energy of 10.0 keV. (The mass of a single proton is 1.67×10^{-27} kg.) In addition, 1.00×10^9 protons per second must reach the target at the end of the 1.50-m-long accelerator. (*a*) What the average power must be delivered to the stream of protons? (*b*) What force (assumed constant) must be applied to each proton? (*c*) What speed does each proton attain just before it strikes the target, assuming the protons start from rest?

61 ••• The four strings pass over the bridge of a violin, as shown in Figure 6-35. The strings make and angle of 72.0° with the normal to the plane of the instrument on either side of the bridge. The resulting total normal force pressing the bridge into the violin is 1.00×10^3 N. The length of the strings from the bridge to the peg to which each is attached is 32.6 cm. (*a*) Determine the tension in the strings, assuming the tension is the same for each string. (*b*) One of the strings is plucked out a distance of 4.00 mm, as shown. Make a free-body diagram showing all of the forces acting on the segment of the string in contact with the finger (not shown), and determine the force pulling the segment back to its equilibrium position. Assume the tension in the string remains constant during the pluck. (*c*) Determine the work done on the string in plucking it out that distance. Remember that the net force pulling the string back to its equilibrium position is changing as the string is being pulled out, but assume that the magnitudes of the tension forces remain constant.

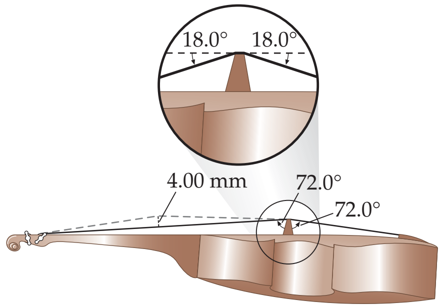

FIGURE 6-35 Problem 61

62 •• The magnitude of the single force acting on a particle of mass *m* is given by $F = bx^2$, where *b* is a constant. The particle starts from rest. After it travels a distance *L*, determine its (*a*) kinetic energy and (*b*) speed.

63 •• A single horizontal force in the $+x$ direction acts on a cart of mass *m*. The cart starts from rest at $x = 0$, and the speed of the cart increases with *x* as $v = Cx$, where *C* is a constant. (*a*) Find the force acting on the cart as a function of *x*. (*b*) Find the work done by the force in moving the cart from $x = 0$ to $x = x_1$. SSM

64 ••• A force $\vec{F} = (2.0\ \mathrm{N/m^2})x^2\hat{i}$ is applied to a particle initially at rest in the *xy* plane. Find the work done by this force on the particle and the final speed of the particle as it moves along a path that is (*a*) in a straight line from point (2.0 m, 2.0 m) to point (2.0 m, 7.0 m) and (*b*) in a straight line from point (2.0 m, 2.0 m) to point (5.0 m, 6.0 m). The given force is the only force doing work on the particle.

65 •• A particle of mass *m* moves along the *x* axis. Its position varies with time according to $x = 2t^3 - 4t^2$, where *x* is in meters and *t* is in seconds. Find (*a*) the velocity and acceleration of the particle as functions of *t*, (*b*) the power delivered to the particle as a function of *t*, and (*c*) the work done by the net force from $t = 0$ to $t = t_1$.

66 •• A 3.0-kg particle starts from rest at $x = 0.050$ m and moves along the *x* axis under the influence of a single force $F_x = 6.0 + 4.0x - 3.0x^2$, where F_x is in newtons and *x* is in meters. (*a*) Find the work done by the force as the particle moves from $x = 0.050$ m to $x = 3.0$ m. (*b*) Find the power delivered to the particle as it passes through the point $x = 3.0$ m.

67 •• The initial kinetic energy imparted to a 0.0200-kg bullet is 1200 J. (*a*) Assuming it accelerated down a 1.00-m-long rifle barrel, estimate the average power delivered to it during the firing. (*b*) Neglecting air resistance, find the range of this projectile when it is fired at an angle such that the range equals the maximum height attained.

68 •• The force F_x acting on a 0.500-kg particle is shown as a function of *x* in Figure 6-36. (*a*) From the graph, calculate the work done by the force when the particle moves from $x = 0.00$ to the following values of *x*: −4.00, −3.00, −2.00, −1.00, +1.00, +2.00,

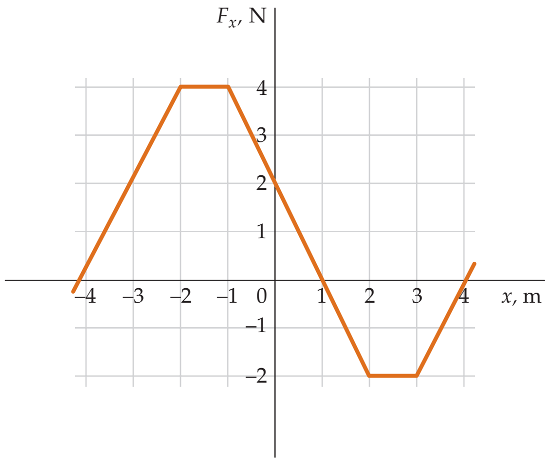

FIGURE 6-36 Problem 68

+3.00, and +4.00 m. (b) If it starts with a velocity of 2.00 m/s in the $+x$ direction, how far will the particle go in that direction before stopping?

69 •• (a) Repeat Problem 68(a) for the force F_x shown in Figure 6-37. (b) If the object starts at the origin moving to the right with a kinetic energy of 25.0 J, how much kinetic energy does it have at x = 4.00 m.

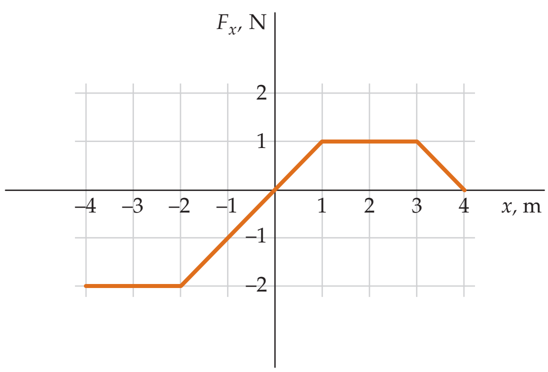

FIGURE 6-37 Problem 69

70 •• A box of mass M is at rest at the bottom of a frictionless inclined plane (Figure 6-38). The box is attached to a string that pulls with a constant tension T. (a) Find the work done by the tension T as the box moves through a distance x along the plane. (b) Find the speed of the box as a function of x. (c) Determine the power delivered by the tension in the string as a function of x.

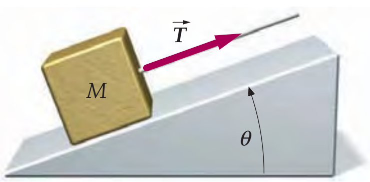

FIGURE 6-38 Problem 70

71 ••• A force acting on a particle in the xy plane at coordinates (x, y) is given by $\vec{F} = (F_0/r)(y\hat{i} - x\hat{j})$, where F_0 is a positive constant and r is the distance of the particle from the origin. (a) Show that the magnitude of this force is F_0 and that its direction is perpendicular to $\vec{r} = x\hat{i} + y\hat{j}$. ($b$) Find the work done by this force on a particle that moves once around a circle of radius 5.0 m that is centered at the origin. SSM

72 ••• A force acting on a 2.0-kg particle in the xy plane at coordinates (x, y) is given by $\vec{F} = -(b/r^3)(x\hat{i} + y\hat{j})$, where b is a positive constant and r is the distance from the origin. (a) Show that the magnitude of the force is inversely proportional to r^2, and that its direction is antiparallel (opposite) to the radius vector $\vec{r} = x\hat{i} + y\hat{j}$. ($b$) If $b = 3.0\ \text{N}\cdot\text{m}^2$, find the work done by this force as the particle moves from (2.0 m, 0.0 m), to (5.0 m, 0.0 m) along a straight-line path. (c) Find the work done by this force on a particle moving once around a circle of radius r = 7.0 m that is centered at the origin.

73 ••• A block of mass m on a horizontal frictionless tabletop is attached by a swivel to a spring that is attached to the ceiling (Figure 6-39). The vertical distance between the top of the block and the ceiling is y_0, and the horizontal position is x. When the block is at $x = 0$, the spring, which has force constant k, is completely unstressed. (a) What is F_x, the x component of the force on the block due to the spring, as a function of x? (b) Show that F_x is proportional to x^3 for sufficiently small values of $|x|$. (c) If the block is released from rest at $x = x_0$, where $|x_0| \ll y_0$, what is its speed when it reaches $x = 0$?

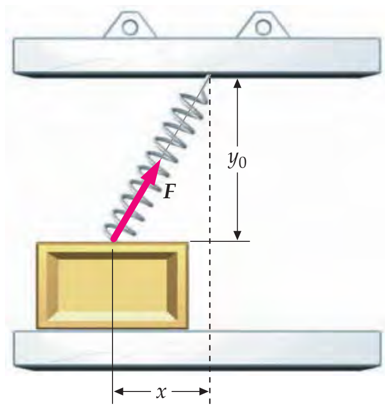

FIGURE 6-39 Problem 73

74 •• Two horses pull a large crate at constant speed across a barn floor by means of two light steel cables. A large box of mass 250 kg sits on the crate (Figure 6-40). As the horses pull, the cables are parallel to the horizontal floor. The coefficient of friction between the crate and the barn floor is 0.25. (a) What is the work done by each horse if the box is moved a distance of 25 m? (b) What is the tension in each cable if the angle between each cable and the direction the crate moves is 15°?

FIGURE 6-40 Problem 74

CHAPTER 7

AS A ROLLER COASTER RUSHES THROUGH ITS TWISTS AND TURNS, ENERGY IS TRANSFERRED IN DIFFERENT WAYS. ELECTRICAL POTENTIAL ENERGY PURCHASED FROM THE POWER COMPANY IS TRANSFORMED INTO GRAVITATIONAL POTENTIAL ENERGY AS THE CARS AND PASSENGERS ARE RAISED TO THE HIGHEST POINT OF THE RIDE. AS THE ROLLER-COASTER CARS PLUMMET DOWN THE STEEP INCLINE, THIS GRAVITATIONAL POTENTIAL ENERGY IS TRANSFORMED INTO KINETIC ENERGY AND THERMAL ENERGY — INCREASING THE TEMPERATURE OF BOTH THE CARS AND THEIR SURROUNDINGS BY A SMALL AMOUNT. *(Michael S. Lewis/Corbis.)*

Conservation of Energy

When work is done by one system on another, energy is transferred between the two systems. For example, when you pull a sled, energy from you goes partly into the kinetic energy of the sled and partly into the thermal energy that arises from the friction between the sled and the snow. At the same time, the internal chemical energy of your body decreases. The net result is the transfer of the internal chemical energy of your body to the external kinetic energy of the sled plus the thermal energy of the sled and the snow. This transfer of energy highlights one of the most important principles in science, *the law of conservation of energy*, which states that the total energy of a system and its surroundings does not change. Whenever the energy of a system changes, we can account for the change by the appearance or disappearance of energy somewhere else.

In this chapter, we continue the study of energy begun in Chapter 6 by describing and applying the law of conservation of energy and examining the energy associated with several different states, including potential energy and thermal energy. We also discuss that energy changes for a system are often not continuous, but occur in discrete "bundles" or "lumps" called quanta. *Although a quantum of energy in a macroscopic system typically is so small that it goes unnoticed, its presence has profound consequences for microscopic systems such as atoms and molecules.*

? How can we use the concept of energy transformation to determine how high the cars must be when they start their descent for them to complete the loop-the-loop? (See Example 7-8.)

7-1 POTENTIAL ENERGY

In Chapter 6, we showed that the total work done on a *particle* equals the change in its kinetic energy. However, sometimes a particle is part of a *system* consisting of two or more particles, and we need to examine the external work done on the system.* Often, the energy transferred to such a system by the work done by external forces on the system does not go into increasing the total kinetic energy *of the system*. Instead, the energy transferred is stored as **potential energy—**energy associated with the relative positions of different parts of the system. The configuration of a system is the way the different parts of the system are positioned relative to each other. Potential energy is an energy associated with system configuration, whereas kinetic energy is an energy associated with motion.

For example, consider a pile driver whose driver is suspended some distance h above a pile (a long, slender column). When the driver is released, it falls—gaining kinetic energy until it smashes into the pile, driving the pile into the ground. The driver is then raised back up to its initial height and released again. Each time the driver is raised from its lowest to its highest position, a gravitational force does work on it given by $-mgh$, where m is the mass of the driver. A second force, the force provided by the lifting agent, acts on the driver. As the driver is raised, the force exerted by the lifting agent does work on the driver that has a positive value. During the raising of the driver, these two work values sum to zero. We know they sum to zero because during the lift, the driver can be modeled as a particle, so the work–kinetic-energy theorem (Equation 6-8) tells us that the total work done on the driver is equal to the change in its kinetic energy—which is zero.

Consider lifting a barbell of mass m to a height h. The barbell starts at rest and ends at rest, so the net change in the kinetic energy of the barbell is zero. The barbell can be modeled as a particle during the lift, so the work–kinetic-energy theorem tells us that the total work done on the barbell is zero. There are two forces on the barbell, the force of gravity and the force of your hands. The gravitational force on the barbell is $m\vec{g}$, and the work done on the barbell by this force during the lift is $-mgh$. Because we know that the total work done on the barbell is zero, it follows that the work done on the barbell by the force of your hands is $+mgh$.

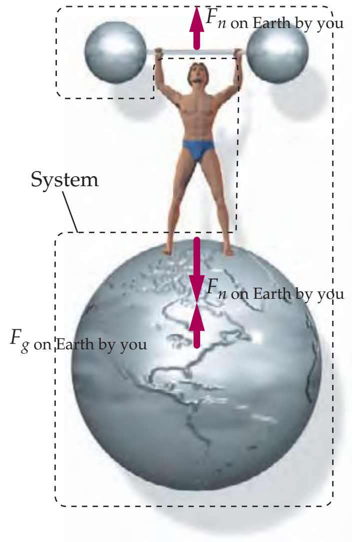

FIGURE 7-1

Consider the barbell and planet Earth to be a *system* of two particles (Figure 7-1). (You are not part of this system.) The external forces acting *on the Earth–barbell system* are the three forces exerted on it by you. These forces are the contact force by your hands *on the barbell*, the contact force by your feet *on the floor*, and the gravitational force by you *on Earth*. The gravitational force on Earth by you is equal and opposite to the gravitational force on you by Earth. (The gravitational forces you and the barbell attract each other with are negligible.) The barbell moves through a displacement of one or two meters, but displacements of the floor and planet Earth are negligibly small, so the force exerted on the barbell by your hands is the only one of the three external forces that does work on the Earth–barbell system. Thus, the total work done on this system by all three external forces is $+mgh$ (the work done on the barbell by your hands). The energy transferred to the system by this work is stored as *gravitational potential energy*, energy associated with the position of the barbell relative to Earth (energy associated with the height of the barbell above the floor).

Another system that stores energy associated with its configuration is a spring. If you stretch or compress a spring, energy associated with the length of the spring is stored as *elastic potential energy*. Consider the spring shown in Figure 7-2 as the system. You compress the spring, pushing it with equal and opposite forces $\vec{F}_1$ and $\vec{F}_2$. These forces sum to zero, so the net force on the spring remains zero. Thus, there is no change in the kinetic energy of the spring. The energy transfer associated with the work you do on the spring is stored not as kinetic energy, but as

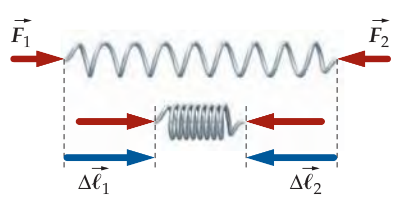

FIGURE 7-2 The spring is compressed by external forces $\vec{F}_1$ and $\vec{F}_2$. Both forces do work on the spring as they compress it. These work values are positive, so the elastic potential energy of the spring increases as it is compressed.

* Systems of particles are discussed more thoroughly in Chapter 8.

elastic potential energy. The configuration of this system has been changed, as evidenced by the change in the length of the spring. The total work done on the spring is positive because both $\vec{F}_1$ and $\vec{F}_2$ do positive work. (The work done by $\vec{F}_1$ is positive because both $\vec{F}_1$ and the displacement $\Delta\vec{\ell}_1$ are in the same direction. The same can be said for $\vec{F}_2$ and $\Delta\vec{\ell}_2$.)

CONSERVATIVE AND NONCONSERVATIVE FORCES

When you ride a ski lift to the top of a hill of height h, the work done on you by gravity is $-mgh$, where m is your mass. When you ski down the hill to the bottom, the work done by gravity is $+mgh$, independent of the shape of the hill (as you saw in Example 6-12). The total work done on you by gravity during the round-trip up and down the hill is zero and is independent of the path you take. In a situation such as this, where the total work done on an object by a force depends on only the initial and final positions of the object, and not the path taken, the force doing the work is called a **conservative force.**

> The work done by a conservative force on a particle is independent of the path taken as the particle moves from one point to another.
>
> DEFINITION—CONSERVATIVE FORCE

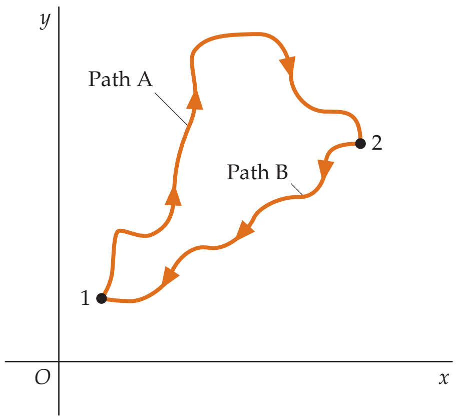

FIGURE 7-3 Two paths in space connecting the points 1 and 2. If the work done by a conservative force along path A from 1 to 2 is $+W$, the work done on the return trip along path B must be $-W$, because the roundtrip work is zero. When traversing path B from 1 to 2, the force is the same at each point, but the displacement is opposite to that when going on path B from 2 to 1. Thus, the work done along path B from 1 to 2 must also be W. It follows that the work done as a particle goes from point 1 to 2 is the same along any path connecting the two points.

From Figure 7-3 we see that this definition implies that:

> A force is conservative if the work it does on a particle is zero when the particle moves around *any* closed path, returning to its initial position.
>
> ALTERNATIVE DEFINITION—CONSERVATIVE FORCE

In the ski-lift example, the force of gravity, exerted by Earth on you, is a conservative force, because the total work done by gravity on you during the round-trip is zero, independent of the path you take. Both the gravitational force on an object and the force exerted by a spring of negligible mass on an object are conservative forces. (If a spring's mass is negligible then its kinetic energy is also negligible.) Any spring in this book has negligible mass unless otherwise stated.

Not all forces are conservative. A force is said to be **nonconservative** if it does not meet the definition for conservative forces. Suppose, for example, that you push a block across a table along a straight line from point A to point B and back again, so that the block ends up at A, its original position. Friction opposes the block's motion, so the force you push on the block with is in the direction of motion and the value of the work done by the push is positive on both legs of the round-trip. The total work done by the push does *not* equal zero. Thus, the push is an example of a nonconservative force.

As another example, consider the force $\vec{F}$ a donkey exerts on a pole as the donkey pulls the pole around the circle at constant speed. As the donkey walks, $\vec{F}$ is continuously doing work whose value is positive. The point of application (point P) of $\vec{F}$ returns to the same position each time the donkey completes one pass around the circle, so the work done by $\vec{F}$ is not equal to zero each time P completes one trip around a closed path (the circle). We can thus conclude that $\vec{F}$ is a nonconservative force.

A machine for pumping water. The donkey exerts force $\vec{F}$ on the pole at P, the point of application of the force. *(O. Alamany and E. Vicens/Corbis.)*

If the work done around *any* particular closed path is not zero, we can conclude that the force is nonconservative. However, we can conclude the force is conservative only if the work is zero around *all* possible closed paths. Because there are infinitely many possible closed paths, it is impossible to calculate the work done for each one. Therefore, finding a single closed path along which the work done by a particular force *is not zero* is sufficient for showing that the force is nonconservative, but is of limited use when investigating whether a given force is conservative. In more advanced physics courses, more sophisticated mathematical methods for evaluating whether a force is conservative are studied.

Example 7-1 Integral Around a Closed Path

To calculate the work done by a force $\vec{F}$ around a closed curve (path) C, we evaluate $\oint_C \vec{F}\cdot d\vec{\ell}$, where the circle on the integral sign means that the integration is evaluated for one complete trip around C. For $\vec{F} = Ax\hat{i}$, calculate $\oint_C \vec{F}\cdot d\vec{\ell}$ for the path C shown in Figure 7-4.

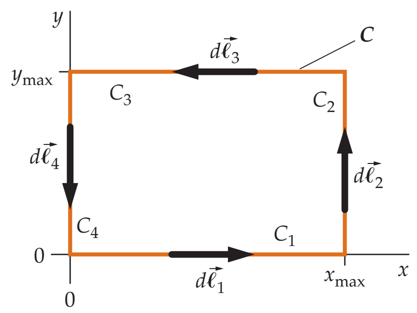

FIGURE 7-4

PICTURE The path C consists of four straight segments. Evaluate $d\vec{\ell} = dx\hat{i} + dy\hat{j}$ on each segment and calculate $\int \vec{F}\cdot d\vec{\ell}$ separately for each of the four segments.

SOLVE

1. The integral around C is equal to the sum of the integrals along the segments that make up C:
$$\oint_C \vec{F}\cdot d\vec{\ell} = \int_{C_1} \vec{F}\cdot d\vec{\ell}_1 + \int_{C_2} \vec{F}\cdot d\vec{\ell}_2 + \int_{C_3} \vec{F}\cdot d\vec{\ell}_3 + \int_{C_4} \vec{F}\cdot d\vec{\ell}_4$$

2. On C_1, $dy = 0$, so $d\vec{\ell}_1 = dx\hat{i}$:
$$\int_{C_1} \vec{F}\cdot d\vec{\ell}_1 = \int_0^{x_{max}} Ax\hat{i}\cdot dx\hat{i} = A\int_0^{x_{max}} x\,dx = \tfrac{1}{2}Ax_{max}^2$$

3. On C_2, $dx = 0$ and $x = x_{max}$, so $d\vec{\ell}_2 = dy\hat{j}$ and $\vec{F} = Ax_{max}\hat{i}$:
$$\int_{C_2} \vec{F}\cdot d\vec{\ell}_2 = \int_0^{y_{max}} Ax_{max}\hat{i}\cdot dy\hat{j} = Ax_{max}\int_0^{y_{max}} \hat{i}\cdot\hat{j}\,dy = 0$$
($\hat{i}\cdot\hat{j} = 0$ because $\hat{i}$ and $\hat{j}$ are perpendicular.)

4. On C_3, $dy = 0$, so $d\vec{\ell}_3 = dx\hat{i}$:
$$\int_{C_3} \vec{F}\cdot d\vec{\ell}_3 = \int_{x_{max}}^0 Ax\hat{i}\cdot dx\hat{i} = -A\int_0^{x_{max}} x\,dx = -\tfrac{1}{2}Ax_{max}^2$$

5. On C_4, $dx = 0$ and $x = 0$, so $d\vec{\ell}_4 = dy\hat{j}$ and $\vec{F} = 0$:
$$\int_{C_4} \vec{F}\cdot d\vec{\ell}_4 = \int_{y_{max}}^0 0\hat{i}\cdot dy\hat{j} = 0$$

6. Add the step-2, -3, -4, and -5 results:
$$\oint_C \vec{F}\cdot d\vec{\ell} = \tfrac{1}{2}Ax_{max}^2 + 0 - \tfrac{1}{2}Ax_{max}^2 + 0 = \boxed{0}$$

CHECK The force is described by Hooke's law (the force for a spring). Thus, it is conservative, so the integral of this force around any closed path is zero.

TAKING IT FURTHER The negative sign in step 4 appeared because the integration limits were reversed.

PRACTICE PROBLEM 7-1 For $\vec{F} = Bxy\hat{i}$, calculate $\oint_C \vec{F}\cdot d\vec{\ell}$ for the path C shown in Figure 7-4.

POTENTIAL-ENERGY FUNCTIONS

The work done by a conservative force on a particle does not depend on the path, but it does depend on the endpoints of the path. We can use this property to define the **potential-energy function** U that is associated with a conservative force. Let us return to the ski-lift example once again. Now consider yourself and Earth to be a *two-particle system*. (The ski lift is not part of this system.) When a ski lift raises you to the top of the hill, it does work mgh on the you–Earth system. This work is stored as the gravitational potential energy of the you–Earth system. When you ski down the hill, this potential energy is converted to the kinetic energy of your motion. Note that when you ski down the hill, the work done by gravity *decreases* the potential energy of the system. We define the potential-energy function U such that the work done by a conservative force equals the decrease in the potential-energy function:

$$W = \int_1^2 \vec{F} \cdot d\vec{\ell} = -\Delta U$$

or

$$\Delta U = U_2 - U_1 = -\int_1^2 \vec{F} \cdot d\vec{\ell} \qquad \text{7-1}a$$

DEFINITION—POTENTIAL-ENERGY FUNCTION

This equation gives the change in potential energy due to a change in the configuration of the system as an object moves from point 1 to point 2.

For an infinitesimal displacement, $d\vec{\ell}$, the change in potential energy is given by

$$dU = -\vec{F} \cdot d\vec{\ell} \qquad \text{7-1}b$$

See Math Tutorial *for more information on* Integrals

Gravitational potential energy Using Equation 7-1b we can calculate the potential-energy function associated with the gravitational force near the surface of Earth. For the force $\vec{F} = -mg\hat{j}$, we have

$$dU = -\vec{F} \cdot d\vec{\ell} = -(-mg\hat{j}) \cdot (dx\hat{i} + dy\hat{j} + dz\hat{k}) = +mg\,dy$$

where we have exploited the fact that $\hat{j} \cdot \hat{i} = \hat{j} \cdot \hat{k} = 0$ and $\hat{j} \cdot \hat{j} = 1$. Integrating, we obtain

$$U = \int mg\,dy = mgy + U_0$$

$$U = U_0 + mgy \qquad \text{7-2}$$

GRAVITATIONAL POTENTIAL ENERGY NEAR EARTH'S SURFACE

where U_0, the arbitrary constant of integration, is the value of the potential energy at $y = 0$. Because only a change in the potential energy is defined, the actual value of U is not important. For example, if the gravitational potential energy of the Earth–skier system is chosen to be zero when the skier is at the bottom of the hill, its value when the skier is at a height h above that level is mgh. Or we could choose the potential energy to be zero when the skier is at point P halfway down the ski slope, in which case its value at any other point would be mgy, where y is the height of the skier above point P. On the lower half of the slope, the potential energy would then be negative.

! We are free to choose U to be zero at any convenient reference point.

PRACTICE PROBLEM 7-2

A 55-kg window washer stands on a platform 8.0 m above the ground. What is the potential energy U of the window-washer–Earth system if (a) U is chosen to be zero on the ground, (b) U is chosen to be zero 4.0 m above the ground, and (c) U is chosen to be zero 10 m above the ground?

Example 7-2 A Falling Bottle

A 0.350-kg bottle falls from rest from a shelf that is 1.75 m above the floor. Find the potential energy of the bottle–Earth system when the bottle is on the shelf and just before impact with the floor. Find the kinetic energy of the bottle just before impact.

PICTURE The work done by Earth on the bottle as it falls equals the negative of the change in the potential energy of the bottle–Earth system. Knowing the work, we can use the work–kinetic-energy theorem to find the kinetic energy.

SOLVE

1. Make a sketch showing the bottle on the shelf and again when it is about to impact the floor (Figure 7-5). Choose the potential energy of the bottle–Earth system to be zero when the bottle is on the floor, and place a y axis on the sketch with the origin at floor level:

2. The only force doing work on the falling bottle is the force of gravity, so $W_{\text{total}} = W_g$. Apply the work–kinetic-energy theorem to the falling bottle:
$$W_{\text{total}} = W_g = \Delta K$$

3. The gravitational force exerted by Earth on the falling bottle is internal to the bottle–Earth system. It is also a conservative force, so the work done by it equals the negative of the change in the potential energy of the system:
$$W_g = -\Delta U = -(U_{\text{f}} - U_{\text{i}}) = -(mgy_{\text{f}} - mgy_{\text{i}})$$
$$= mg(y_{\text{i}} - y_{\text{f}}) = mg(h - 0) = mgh$$

4. Substitute the step-3 result into the step-2 result and solve for the final kinetic energy. The original kinetic energy is zero:
$$mgh = \Delta K$$
$$mgh = K_{\text{f}} - K_{\text{i}}$$
$$K_{\text{f}} = K_{\text{i}} + mgh$$
$$= 0 + (0.350\text{ kg})(9.81\text{ N/kg})(1.75\text{ m})$$
$$= 6.01\text{ N}\cdot\text{m} = \boxed{6.01\text{ J}}$$

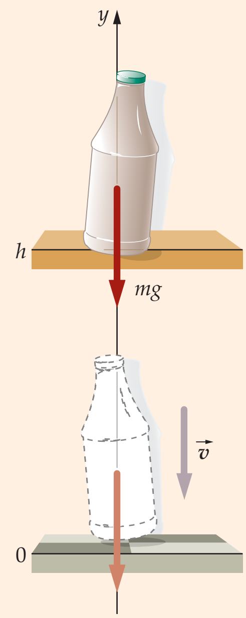

FIGURE 7-5

CHECK The units of the answer in step 4 are units of energy, because $1\text{ N}\cdot\text{m} = 1\text{ J}$.

TAKING IT FURTHER Potential energy is associated with the configuration of a *system of particles*, but we sometimes have systems, such as the bottle–Earth system in this example, in which only one particle moves (Earth's motion is negligible). For brevity, then, we sometimes refer to the potential energy of the bottle–Earth system as simply the potential energy of the bottle.

The gravitational potential energy of a system of particles in a uniform gravitational field is the same as if the entire mass of the system were concentrated at the system's center of mass. For such a system, let h_i be the height of the ith particle above some reference level. The gravitational potential energy of the system is then

$$U_g = \sum_i m_i g h_i = g \sum_i m_i h_i$$

where the sum is over all the particles in the system. By definition of the center of mass, the height of the center of mass of the system is given by

$$Mh_{\text{cm}} = \sum_i m_i h_i, \qquad \text{where } M = \sum_i m_i$$

Substituting Mh_{cm} for $\Sigma m_i h_i$ gives

$$U_g = Mgh_{cm} \tag{7-3}$$

GRAVITATIONAL POTENTIAL ENERGY OF A SYSTEM

Elastic potential energy Another example of a conservative force is that of a stretched (or compressed) spring of negligible mass. Suppose you pull a block attached to a spring from its equilibrium position at $x = 0$ to a new position at $x = x_1$ (Figure 7-6). The work done by the spring on the block is negative because the force exerted by the spring on the block and the displacement of the block are oppositely directed. If we then release the block, the force of the spring does positive work on the block as the block accelerates back toward its initial position. The total work done on the block by the spring as the block moves from $x = 0$ to $x = x_1$, and then back to $x = 0$, is zero. This result is independent of the size of x_1 (as long as the stretching is not so great as to exceed the elastic limit of the spring). The force exerted by the spring is therefore a conservative force. We can calculate the potential-energy function associated with this force from Equation 7-1*b*:

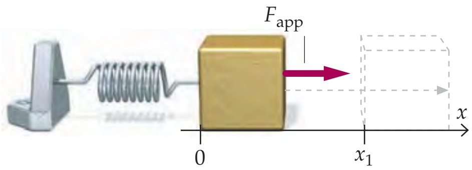

FIGURE 7-6 The applied force F_{app} pulls the block to the right, stretching the spring by x_1.

$$dU = -\vec{F} \cdot d\vec{\ell} = -F_x\,dx = -(-kx)dx = +kx\,dx$$

Then

$$U = \int kx\,dx = \frac{1}{2}kx^2 + U_0$$

where U_0 is the potential energy when $x = 0$, that is, when the spring is unstressed. Choosing U_0 to be zero gives

$$U = \tfrac{1}{2}kx^2 \tag{7-4}$$

POTENTIAL ENERGY OF A SPRING

The formula $U = \frac{1}{2}kx^2$ for the potential energy of a spring requires that the spring is relaxed if $x = 0$. Thus, the location of the point where $x = 0$ is not arbitrary when using the potential energy function $U = \frac{1}{2}kx^2$.

When we pull the block from $x = 0$ to $x = x_1$, the agent doing the pulling must exert an applied force on the block. If the block starts from rest at $x = 0$ and ends at rest at $x = x_1$, the change in its kinetic energy is zero. The work–energy theorem then tells us that the total work done on the block is zero. That is, $W_{app} + W_{spring} = 0$, or

$$W_{app} = -W_{spring} = \Delta U_{spring} = \tfrac{1}{2}kx_1^2 - 0 = \tfrac{1}{2}kx_1^2$$

The energy transferred from the agent doing the pulling to the block–spring system is equal to W_{app} and is stored as potential energy in the spring.

PRACTICE PROBLEM 7-3

A suspension spring on a Toyota Prius has a force constant of 11,000 N/m. How much energy is transferred to one of these springs when, starting from its relaxed length, it is compressed 30.0 cm?

Example 7-3 Potential Energy of a Basketball Player

A system consists of a 110-kg basketball player, the rim of a basketball hoop, and Earth. Assume that the potential energy of this system is zero when the player is standing on the floor and the rim is horizontal. Find the total potential energy of this system when the player is hanging on the front of the rim (much like that shown in Figure 7-7). Also, assume that the center of mass of the player is 0.80 m above the floor when he is standing and 1.30 m above the floor when he is hanging. The force constant of the rim is 7.2 kN/m and the front of the rim is displaced downward a distance of 15 cm. Assume the mass of the rim is negligible.

FIGURE 7-7 *(Elio Castoria/APF/Getty Images.)*

PICTURE When the player changes position from standing on the floor to hanging on the rim, the total change in potential energy is the change in gravitational potential energy plus the change in elastic potential energy stored in the stressed rim, whose potential energy can be measured just as if it were a spring: $U_s = \frac{1}{2}kx^2$. Choose 0.80 m above the floor as the reference point where $U_g = 0$.

SOLVE

1. Sketch the system, first in the initial configuration and again in the final configuration (Figure 7-8):

2. The gravitational potential energy reference point where $U_g = 0$ is 0.80 m above the floor. Thus, $U_{gi} = 0$. The initial total potential energy equals zero:

$$U_{gi} = mgy_{\text{cm i}} = mg(0) = 0$$
$$U_{si} = \tfrac{1}{2}kx_i^2 = \tfrac{1}{2}k(0)^2 = 0$$
$$U_i = U_{gi} + U_{si} = 0$$

3. The total final potential energy is the sum of final gravitational potential energy and the final elastic potential energy of the rim:

$$\begin{aligned} U_f = U_{gf} + U_{sf} &= mgy_{\text{cm f}} + \tfrac{1}{2}kx_f^2 \\ &= (110\text{ kg})(9.81\text{ N/kg})(0.50\text{ m}) \\ &\quad + \tfrac{1}{2}(7.2\text{ kN/m})(0.15\text{ m})^2 \\ &= 540\text{ N}\cdot\text{m} + 81\text{ N}\cdot\text{m} = \boxed{6.2 \times 10^2\text{ J}} \end{aligned}$$

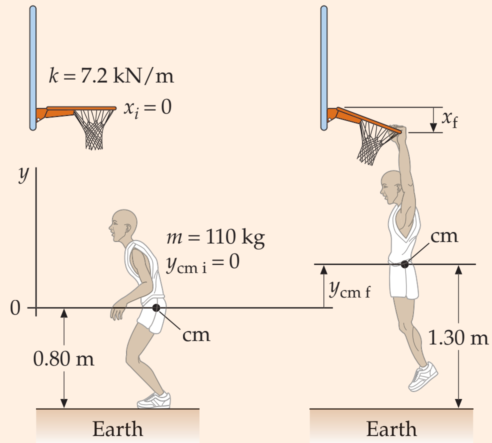

FIGURE 7-8 A basketball player jumps, grabs hold of the rim, and dangles from it.

CHECK The units check out if we use the definition of the joule. That definition is 1 J = 1 N·m.

TAKING IT FURTHER The front of the rim and player oscillate vertically immediately after the player grabs. However, they eventually come to rest with the front of the rim 15 cm below its initial position. The total potential energy is a minimum when the system is in equilibrium (Figure 7-9). Why this is so is explained near the end of Section 7-2.

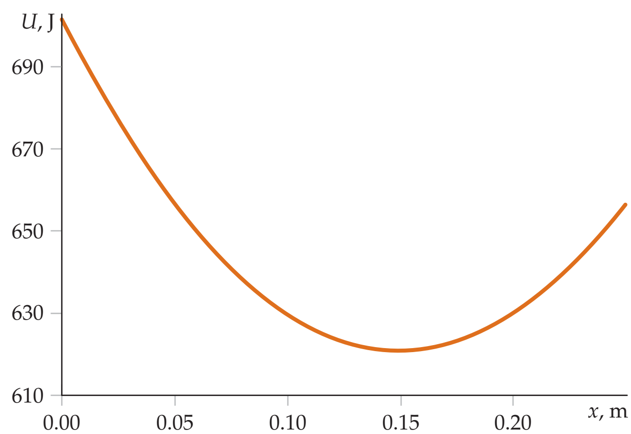

FIGURE 7-9 The graph shows the total potential energy $U = U_g + U_s$ as a function of the downward displacement of the rim.

PRACTICE PROBLEM 7-4 A 3.0-kg block is hung vertically from a spring with a force constant of 600 N/m. (*a*) By how much is the spring stretched? (*b*) How much potential energy is stored in the spring?

7-2 THE CONSERVATION OF MECHANICAL ENERGY

We are now ready to look at the relationship between kinetic energy and potential energy. Recall that the total work done on each particle in a system equals the change in the kinetic energy ΔK_i of that particle, so the total work done by all the forces W_{total} equals the change in the total kinetic energy of the system ΔK_{sys}:

$$W_{total} = \sum \Delta K_i = \Delta K_{sys} \tag{7-5}$$

Two sets of forces do work on a particle in a system: the external forces and the internal forces. Each internal force is either conservative or nonconservative. The total work done by all forces equals the work done by all external forces W_{ext}, plus the work done by all internal nonconservative forces W_{nc}, plus that done by all internal conservative forces W_c:

$$W_{total} = W_{ext} + W_{nc} + W_c$$

Rearranging gives

$$W_{ext} + W_{nc} = W_{total} - W_c$$

The negative of the total work done by all the conservative internal forces $-W_c$ equals the change in the potential energy of the system ΔU_{sys}

$$-W_c = \Delta U_{sys} \tag{7-6}$$

Substituting from Equations 7-5 and 7-6, we have

$$W_{ext} + W_{nc} = \Delta K_{sys} + \Delta U_{sys} \tag{7-7}$$

The right side of this equation can be simplified as

$$\Delta K_{sys} + \Delta U_{sys} = \Delta(K_{sys} + U_{sys}) \tag{7-8}$$

The sum of the kinetic energy K_{sys} and the potential energy U_{sys} is called the **total mechanical energy** E_{mech}:

$$E_{mech} = K_{sys} + U_{sys} \tag{7-9}$$

DEFINITION—TOTAL MECHANICAL ENERGY

Combining Equations 7-8 and 7-9, and then substituting into Equation 7-7 gives

$$W_{ext} = \Delta E_{mech} - W_{nc} \tag{7-10}$$

WORK-ENERGY THEOREM FOR SYSTEMS

The mechanical energy of a system of particles is conserved (E_{mech} = constant) if the total work done by all external forces and by all internal nonconservative forces is zero.

$$E_{mech} = K_{sys} + U_{sys} = \text{constant} \tag{7-11}$$

CONSERVATION OF MECHANICAL ENERGY

This is **conservation of mechanical energy,** and is the origin of the expression "conservative force."

If $E_{\text{mech i}} = K_i + U_i$ is the initial mechanical energy of the system and $E_{\text{mech f}} = K_f + U_f$ is the final mechanical energy of the system, conservation of mechanical energy implies that

$$E_{\text{mech f}} = E_{\text{mech i}} \quad (\text{or } K_f + U_f = K_i + U_i) \qquad \text{7-12}$$

In other words, when the mechanical energy of a system is conserved, we can relate the final mechanical energy of the system to the initial mechanical energy of the system without considering the intermediate motion and the work done by the forces involved. Therefore, conservation of mechanical energy allows us to solve problems that might be difficult to solve using Newton's laws directly.

APPLICATIONS

Suppose that you are on skis and, starting at rest from a height h_i above the bottom of a hill, you coast down the hill. Assuming that friction and air drag are negligible, what is your speed as you pass by a marker on the hill a height h above the bottom of the hill?

The mechanical energy of the Earth–skier system is conserved because the only force doing work is the internal, conservative force of gravity. If we choose $U = 0$ at the bottom of the hill, the initial potential energy is mgh_i. This energy is also the total mechanical energy because the initial kinetic energy is zero. Thus,

$$E_{\text{mech i}} = K_i + U_i = 0 + mgh_i$$

As you pass the marker, the potential energy is mgh and the speed is v. Hence,

$$E_{\text{mech f}} = K_f + U_f = \tfrac{1}{2}mv^2 + mgh$$

Setting $E_{\text{mech f}} = E_{\text{mech i}}$, we find

$$\tfrac{1}{2}mv^2 + mgh = mgh_i$$

Solving for v gives

$$v = \sqrt{2g(h_i - h)}$$

Your speed is the same as if you had undergone free-fall, falling straight down through a distance $h_i - h$. However, by skiing down the hill, you travel a greater distance and take more time than you would if you were in free-fall and falling straight down.

PROBLEM-SOLVING STRATEGY

Solving Problems Involving Mechanical Energy

PICTURE Identify a system that includes the object (or objects) of interest and any other objects that interact with the object of interest by either a conservative or a kinetic-frictional force.

SOLVE

1. Make a sketch of the system and include labels. Include a coordinate axis (or axes) and show the system in its initial and final configurations. (Showing an intermediate configuration is often helpful also.) Objects may be represented as dots, just as is done in free-body diagrams.
2. Identify any external forces acting on the system that do work, and any internal nonconservative forces that do work. Also identify any internal conservative forces that do work.
3. Apply Equation 7-10 (the work–energy theorem for systems). For each internal conservative force doing work use a potential-energy function to represent the work done.

CHECK Make sure that you have accounted for the work done by all conservative and nonconservative forces in determining your answer.

Example 7-4 Kicking a Ball

Standing near the edge of the roof of a 12-m-high building, you kick a ball with an initial speed of $v_i = 16$ m/s at an angle of 60° above the horizontal. Neglecting effects due to air resistance, find (*a*) how high above the height of the building the ball rises, and (*b*) its speed just before it hits the ground.

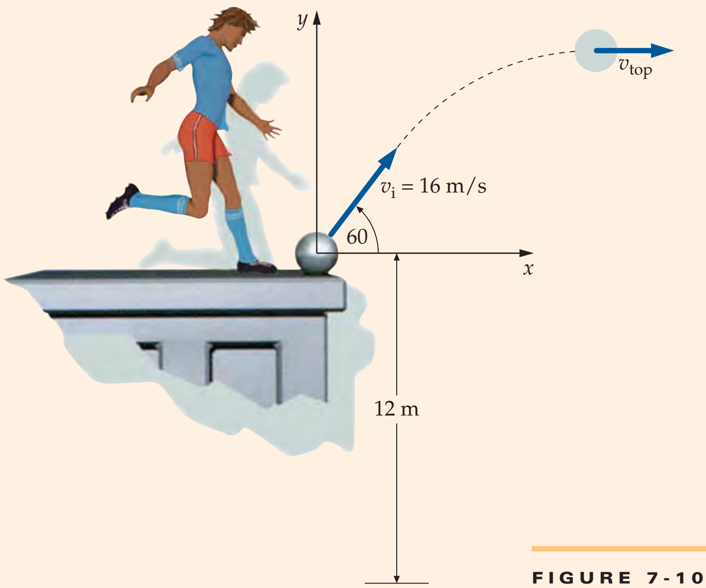

FIGURE 7-10

PICTURE We choose the ball and Earth as the system. We consider this system during the interval from just after the kick to just before impact with the ground. No external forces do work on the system, and no internal nonconservative forces do work, so the mechanical energy of the system is conserved. At the top of its flight, the ball is moving horizontally with a speed v_{top}, equal to the horizontal component of its initial velocity v_{ix}. We choose $y = 0$ at the roof of the building.

SOLVE

(*a*) 1. Make a sketch (Figure 7-10) of the trajectory. Include coordinate axes and show the initial position of the ball and its position at the top of its flight. Choose $y = 0$ at the roof of the building:

2. Apply the work–energy equation for systems. Choose the ball and Earth as the system. Following the kick and before impact with the ground no external forces do work and no nonconservative forces do work (we are neglecting the effects of air resistance):

$$W_{ext} = \Delta E_{mech} - W_{nc}$$
$$0 = \Delta E_{mech} - 0$$
$$\therefore E_{mech\,f} = E_{mech\,i}$$

3. The gravitational force does work on the system. We account for this work using the gravitational potential energy function mgy:

$$E_{mech\,top} = E_{mech\,i}$$
$$\tfrac{1}{2}mv_{top}^2 + mgy_{top} = \tfrac{1}{2}mv_i^2 + mgy_i$$
$$\tfrac{1}{2}mv_{top}^2 + mgh_{top} = \tfrac{1}{2}mv_i^2 + 0$$

4. Conservation of mechanical energy relates the height y_{top} above the roof of the building to the initial speed v_i and the speed at the top of its flight v_{top}:

$$E_{mech\,top} = E_{mech\,i}$$
$$\tfrac{1}{2}mv_{top}^2 + mgy_{top} = \tfrac{1}{2}mv_i^2 + mgy_i$$
$$\tfrac{1}{2}mv_{top}^2 + mgy_{top} = \tfrac{1}{2}mv_i^2 + 0$$

5. Solve for y_{top}:

$$y_{top} = \frac{v_i^2 - v_{top}^2}{2g}$$

6. The velocity at the top of its flight equals the x component of its initial velocity:

$$v_{top} = v_{ix} = v_i \cos\theta$$

7. Substitute the step-3 result into the step-2 result and solve for y_{top}:

$$y_{top} = \frac{v_i^2 - v_{top}^2}{2g} = \frac{v_i^2 - v_i^2\cos^2\theta}{2g} = \frac{v_i^2(1 - \cos^2\theta)}{2g}$$
$$= \frac{(16\text{ m/s})^2(1 - \cos^2 60°)}{2(9.81\text{ m s}^2)} = \boxed{9.8\text{ m}}$$

(*b*) 1. If v_f is the speed of the ball just before it hits the ground (where $y = y_f = -12$ m), its energy is expressed:

$$E_{mech\,f} = \tfrac{1}{2}mv_f^2 + mgy_f$$

2. Set the final mechanical energy equal to the initial mechanical energy:

$$\tfrac{1}{2}mv_f^2 + mgy_f = \tfrac{1}{2}mv_i^2 + 0$$

3. Solve for v_f, and set $y_f = -12$ m to find the final velocity:

$$v_f = \sqrt{v_i^2 - 2gy_f}$$
$$= \sqrt{(16\text{ m/s})^2 - 2(9.81\text{ m/s}^2)(-12\text{ m})}$$
$$= \boxed{22\text{ m/s}}$$

CHECK We would expect that the higher the building, the greater the speed at impact. The expression for v_f in step 3 of Part (*b*) reflects this expectation.

Example 7-5 A Pendulum

A pendulum consists of a bob of mass m attached to a string of length L. The bob is pulled aside so that the string makes an angle θ_0 with the vertical, and is released from rest. As it passes through the lowest point of the arc, find expressions for (*a*) the speed of the bob, and (*b*) the tension in the string. Effects due to air resistance are negligible.

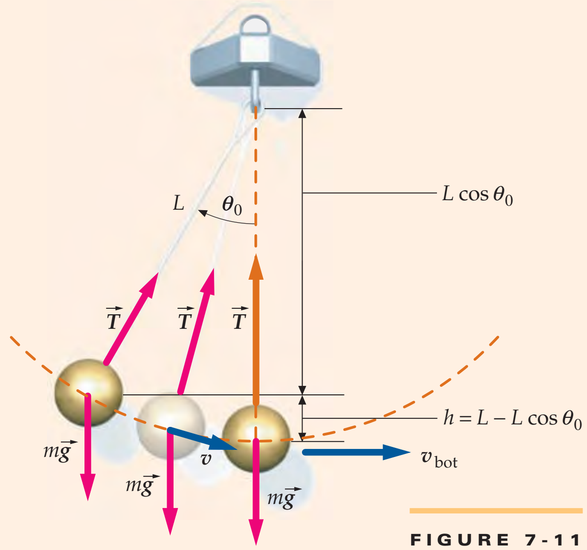

FIGURE 7-11

PICTURE Let the system be the pendulum and Earth. The tension force $\vec{T}$ is an internal nonconservative force acting on the bob. The rate at which $\vec{T}$ does work is $\vec{T}\cdot\vec{v}$. The other force acting on the bob is the gravitational force $m\vec{g}$, which is an internal conservative force. Use the work–energy theorem for systems (Equation 7-10) to find the speed at the bottom of the arc. The tension in the string is obtained using Newton's second law.

SOLVE

(*a*) 1. Make a sketch of the system in its initial and final configurations (Figure 7-11). We choose $y = 0$ at the bottom of the swing and $y = h$ at the initial position:

2. The external work done on the system equals the change in its mechanical energy minus the work done by internal nonconservative forces (Equation 7-10):

$$W_{\text{ext}} = \Delta E_{\text{mech}} - W_{\text{nc}}$$

3. There are no external forces acting on the system. The tension force is an internal nonconservative force:

$$W_{\text{ext}} = 0$$

$$W_{\text{nc}} = \int_1^2 \vec{T}\cdot d\vec{\ell}$$

4. The displacement increment $d\vec{\ell}$ equals the velocity times the time increment dt. Substitute into the step-3 result. The tension is perpendicular to the velocity, so $\vec{T}\cdot\vec{v} = 0$:

$$d\vec{\ell} = \vec{v}\,dt$$

$$\text{so}\quad W_{\text{nc}} = \int_1^2 \vec{T}\cdot d\vec{\ell} = \int_1^2 \vec{T}\cdot\vec{v}\,dt = 0$$

5. Substitute for W_{ext} and W_{nc} in the step-2 result. The bob initially is at rest:

$$W_{\text{ext}} = \Delta E_{\text{mech}} - W_{\text{nc}}$$
$$0 = \Delta E_{\text{mech}} - 0$$
$$\Delta E_{\text{mech}} = 0$$

6. Apply conservation of mechanical energy. The bob initially is at rest:

$$E_{\text{mech f}} = E_{\text{mech i}}$$
$$\tfrac{1}{2}mv_{\text{f}}^2 + mgy_{\text{f}} = \tfrac{1}{2}mv_{\text{i}}^2 + mgy_{\text{i}}$$
$$\tfrac{1}{2}mv_{\text{bot}}^2 + 0 = 0 + mgh$$

7. Conservation of mechanical energy thus relates the speed v_{bot} to the initial height $y_{\text{i}} = h$:

$$\tfrac{1}{2}mv_{\text{bot}}^2 = mgh$$

8. Solve for the speed v_{bot}:

$$v_{\text{bot}} = \sqrt{2gh}$$

9. To express speed in terms of the initial angle θ_0, we need to relate h to θ_0. This relation is illustrated in Figure 7-11:

$$L = L\cos\theta_0 + h$$
$$\text{so}\quad h = L - L\cos\theta_0 = L(1 - \cos\theta_0)$$

10. Substitute this value for h to express the speed at the bottom in terms of θ_0:

$$v_{\text{bot}} = \boxed{\sqrt{2gL(1 - \cos\theta_0)}}$$

(*b*) 1. When the bob is at the bottom of the circle, the forces on it are $m\vec{g}$ and $\vec{T}$. Apply $\Sigma F_y = ma_y$:

$$T - mg = ma_y$$

2. At the bottom, the bob has an acceleration v_{bot}^2/L in the centripetal direction (toward the center of the circle), which is upward:

$$a_y = \frac{v_{\text{bot}}^2}{L} = \frac{2gL(1 - \cos\theta_0)}{L} = 2g(1 - \cos\theta_0)$$

3. Substitute for a_y in the Part-(*b*), step-1 result and solve for T:

$$T = mg + ma_y = m(g + a_y) = m[g + 2g(1 - \cos\theta_0)]$$
$$= \boxed{(3 - 2\cos\theta_0)mg}$$

CHECK (1) The tension at the bottom is greater than the weight of the bob because the bob is accelerating upward. (2) Step 3 in Part (*b*) shows that for $\theta_0 = 0$, $T = mg$, the expected result for a stationary bob hanging from a string.

TAKING IT FURTHER (1) The rate at which a force does work is given by $\vec{F} \cdot \vec{v}$ (Equation 6-22). Step 4 of Part (*a*) reveals that the rate at which the tension force is doing work is zero. *Any* force that remains perpendicular to the velocity does zero work. (2) Step 8 of Part (*a*) shows that the speed at the bottom is the same as if the bob had dropped in free-fall from a height h. (3) The speed of the bob at the bottom of the arc can also be found using Newton's laws directly, but such a solution is more challenging because the tangential acceleration a_t varies with position, and therefore with time, so the constant-acceleration formulas do not apply. (4) If the string had not been included in the system then the W_{ext} would equal the work done by the tension force and W_{nc} would equal zero because there would be no internal nonconservative forces. The results would be identical.

Example 7-6 A Block Pushing a Spring

Try It Yourself

A 2.0-kg block on a frictionless horizontal surface is pushed against a spring that has a force constant of 500 N/m, compressing the spring by 20 cm. The block is then released, and the force of the spring accelerates the block as the spring decompresses. The block then glides along the surface and then up a frictionless incline of angle 45°. How far up the incline does the block travel before momentarily coming to rest?

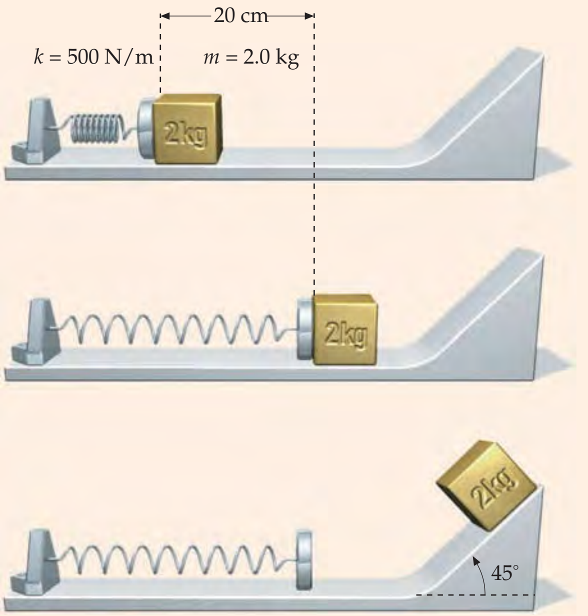

FIGURE 7-12

PICTURE Let the system include the block, the spring, Earth, the horizontal surface, the ramp, and the wall to which the spring is attached. After the block is released there are no external forces on this system. The only forces that do work are the force exerted by the spring on the block and the force of gravity, both of which are conservative. Thus, the total mechanical energy of the system is conserved. Find the maximum height h from the conservation of mechanical energy, and then the maximum distance up the incline s from $\sin 45° = h/s$.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. Choose the block, the spring, Earth, the horizontal surface, the ramp, and the wall to which the spring is attached. Sketch the system with both the initial and final configurations (Figure 7-12).	
2. Apply the work-energy theorem for systems. Following release no external forces act on the system and no internal nonconservative forces do work on the system:	$W_{ext} = \Delta E_{mech} - W_{nc}$ $0 = \Delta E_{mech} - 0$ $\therefore E_{mech\,f} = E_{mech\,i}$
3. Write the initial mechanical energy in terms of the compression distance x_i.	$E_{mech\,i} = U_{s\,i} + U_{g\,i} + K_i = \frac{1}{2}kx_i^2 + 0 + 0$
4. Write the final mechanical energy in terms of the height h.	$E_{mech\,f} = U_{s\,f} + U_{g\,f} + K_f = 0 + mgh + 0$
5. Substitute into the step-3 result and solve for h.	$mgh = \frac{1}{2}kx_i^2$ $h = \dfrac{kx_i^2}{2mg} = 0.51\text{ m}$
6. Find the distance s from h and the angle of inclination (Figure 7-13).	$h = s \times \sin\theta$ $s = \boxed{0.72\text{ m}}$

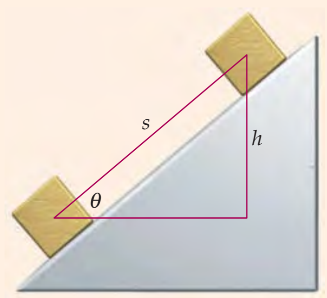

FIGURE 7-13

CHECK The expression for h in step 5 is plausible. It tells us by inspection that increasing x_i results in a larger maximum height, and using a larger mass results in a smaller maximum height.

TAKING IT FURTHER (1) In this problem, the initial mechanical energy of the system is the potential energy of the spring. This energy is transformed first into kinetic energy and then into gravitational potential energy. (2) The normal force $\vec{F}_n$ on the block always acts at right angles to the velocity, so $\vec{F}_n \cdot \vec{v} = 0$ at all times.

PRACTICE PROBLEM 7-5 Find the speed of the block just as it leaves the spring.

PRACTICE PROBLEM 7-6 How much work did the normal force on the block do?

Example 7-7 Bungee Jumping *Context-Rich*

You jump off a platform 134 m above the Nevis River. After you have free-fallen for the first 40 m, the bungee cord attached to your ankles starts to stretch. (The unstretched length of the cord is 40 m.) You continue to descend another 80 m before coming to rest. Assume that your mass is 100 kg, the cord follows Hooke's law, and the cord has negligible mass. What is your acceleration when you are momentarily at rest at the lowest point in the jump? (Neglect air drag.)

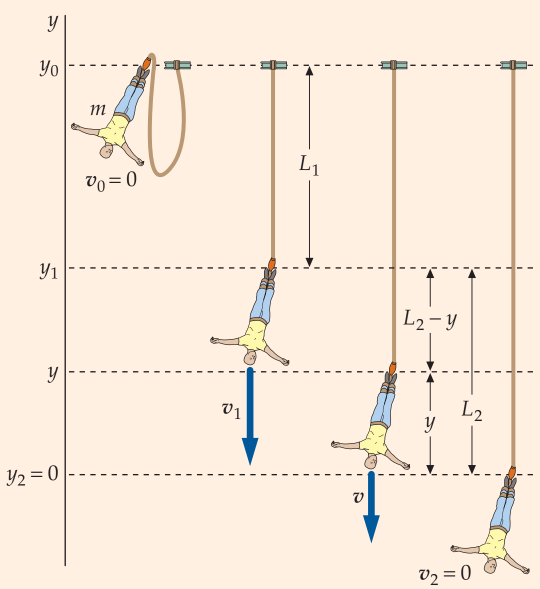

FIGURE 7-14

PICTURE Choose as the system everything mentioned in the problem statement, plus Earth. As you fall, your speed first increases, then reaches some maximum value, and then decreases until it is again zero when you are at your lowest point. Apply the work–energy theorem for systems. To find your acceleration at the bottom we use Newton's second law ($\Sigma F_x = ma_x$) and Hooke's law ($F_x = -kx$).

SOLVE

1. The system includes you, Earth and the cord. Sketch the system showing the initial and final positions of the first 40 m of descent, and again for the next 80 m of descent (Figure 7-14). Include a y axis with up as the positive y direction and with the origin at your final position (lowest). Let $L_1 = 40\text{ m}$ be the length of the unstressed cord and let $L_2 = 80\text{ m}$ be the maximum extension of the cord.

2. Apply the work–energy theorem for systems. There are no external forces and no internal nonconservative forces doing work:

$$W_{\text{ext}} = \Delta E_{\text{mech}} - W_{\text{nc}}$$
$$0 = \Delta E_{\text{mech}} - 0$$
$$\therefore E_{\text{mech f}} = E_{\text{mech i}}$$

3. Apply the step-2 result to the part of the descent that the cord is stretching. The extension of the cord is $L_2 - y$:

$$E_{\text{mech 3}} = E_{\text{mech 2}}$$
$$U_{g3} + U_{s3} + K_3 = U_{g2} + U_{s2} + K_2$$
$$mgy_3 + \tfrac{1}{2}k(L_2 - y_3)^2 + \tfrac{1}{2}mv_3^2 = mgy_2 + \tfrac{1}{2}ky_2^2 + \tfrac{1}{2}mv_2^2$$
$$0 + \tfrac{1}{2}kL_2^2 + 0 = mgL_2 + 0 + \tfrac{1}{2}mv_2^2$$
$$\tfrac{1}{2}kL_2^2 = mgL_2 + \tfrac{1}{2}mv_2^2$$

4. To solve for k, we need to find the kinetic energy at the end of the free-fall region. Apply the step-2 result again and solve for the kinetic energy:

$$E_{\text{mech 2}} = E_{\text{mech 1}}$$
$$U_{g2} + K_2 = U_{g1} + K_1$$
$$mgy_2 + \tfrac{1}{2}mv_2^2 = mgy_1 + \tfrac{1}{2}mv_1^2$$
$$mgL_2 + \tfrac{1}{2}mv_2^2 = mg(L_1 + L_2) + 0$$
$$\tfrac{1}{2}mv_2^2 = mgL_1$$

5. Substitute the step-4 result into the step-3 result and solve for k:

$$\frac{1}{2}kL_2^2 = mgL_2 + mgL_1$$

$$k = \frac{2mg(L_2 + L_1)}{L_2^2}$$

6. Apply Newton's second law when you are at the lowest point. First we construct a free-body diagram (Figure 7-15):

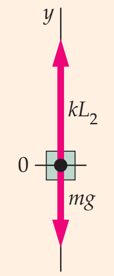

FIGURE 7-15

7. Apply Newton's second law and solve for the acceleration. Use the expression for k from step 5:

$$\Sigma F_y = ma_y$$

$$-mg + kL_2 = ma_y$$

$$a_y = -g + k\frac{L_2}{m} = -g + \frac{2mg(L_2 + L_1)}{L_2^2}\frac{L_2}{m}$$

$$= g\left(1 + 2\frac{L_1}{L_2}\right) = g\left(1 + 2\frac{40}{80}\right) = \boxed{2.0g}$$

CHECK We expect the acceleration at the bottom to be upward (the $+y$ direction) and our result is in agreement with that. Any time the velocity reverses directions, immediately following the reversal the velocity vector and the acceleration vector are in the same direction.

PRACTICE PROBLEM 7-7 As you fall, you gain speed until the upward pull of the cord equals the downward pull of gravity. What is your height above the lowest point when you achieve maximum speed?

Example 7-8 Back to the Future *Context-Rich*

Imagine that you have time-traveled back to the late 1800s and are watching your great-great-great-grandparents on their honeymoon taking a ride on the Flip Flap Railway, a Coney Island roller coaster with a circular loop-the-loop. The car they are in is about to enter the loop-the-loop when a 100-lb sack of sand falls from a construction-site platform and lands in the back seat of the car. No one is hurt, but the impact causes the car to lose 25 percent of its speed. The car started from rest at a point 2 times as high as the top of the circular loop. Neglect losses due to friction or air drag. Will their car make it over the top of the loop-the-loop without falling off?

PICTURE Let the system be the car, its contents, the track (including the loop-the-loop), and Earth. The car has to have enough speed at the top of the loop to maintain contact with the track. We can use the work-energy theorem for systems to determine the speed just before the sandbag hits the car, and we can use it again to determine the speed the car has at the top of the loop. Then we can use Newton's second law to determine the magnitude of the normal force, if any, exerted on the car by the track.

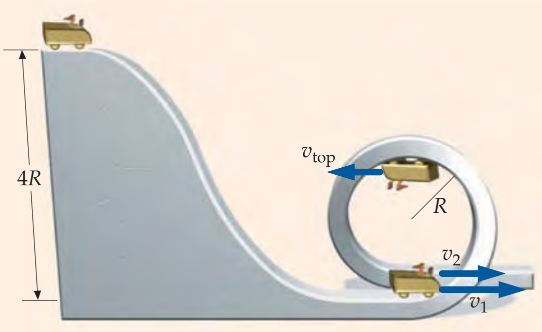

FIGURE 7-16

SOLVE

1. Choose the system to be the car, its contents, the track, and Earth. Draw a picture of the car and track, with the car at the starting point, at the bottom of the track, and again at the top of the loop (Figure 7-16):

2. Apply Newton's second law to relate the speed at the top of the loop to the normal force:

$$F_n + mg = m\frac{v_{top}^2}{R}$$

3. Apply the work–energy theorem to the interval prior to impact. There are no external forces and no internal nonconservative forces do work. Find the speed just prior to impact. Measuring heights from the bottom of the loop, the initial height of $4R$, where R is the radius of the loop, is two times the height of the top of the loop:

$$W_{ext} = \Delta E_{mech} - W_{nc}$$
$$0 = \Delta E_{mech} - 0$$
$$\therefore E_{mech\,f} = E_{mech\,i}$$
$$U_0 + K_0 = U_1 + K_1$$
$$mg\,4R + 0 = 0 + \tfrac{1}{2}mv_1^2$$
$$\text{so} \quad v_1 = \sqrt{8Rg}$$

4. The impact with the sandbag results in a 25 percent decrease in speed. Find the speed after impact:

$$v_2 = 0.75v_1 = 0.75\sqrt{8Rg}$$

5. Apply the work–energy theorem to the interval following impact. Find the speed at the top of the loop-the-loop:

$$U_{top} + K_{top} = U_2 + K_2$$
$$mg\,2R + \tfrac{1}{2}mv_{top}^2 = 0 + \tfrac{1}{2}m(0.75^2 \cdot 8Rg)$$
$$\text{so} \quad v_{top}^2 = (0.75^2 \cdot 8 - 4)Rg = 0.5Rg$$

6. Substituting for v_{top}^2 in the step-2 result gives:

$$F_n + mg = m\frac{0.5Rg}{R}$$
$$F_n + mg = 0.5mg$$

7. Solve for F_n:

$$F_n = -0.5mg$$

8. F_n is the magnitude of the normal force. It cannot be negative:

$$\boxed{\text{Oops! The car has left the track.}}$$

CHECK A loss of 25 percent of your speed means losing almost 44 percent of your kinetic energy. The speed is the same as would be attained if the car started from rest at a height of $0.56 \times 4R = 1.12 \times 2R$ (12 percent higher than the height of the top of the loop). We should not be too surprised to find that the car left the track.

TAKING IT FURTHER Fortunately, there were safety devices to prevent the cars from falling, so your ancestors likely would have survived. The biggest concern for riders on the Flip Flap Railway was a broken neck. The Flip Flap Railway subjected riders to accelerations of up to 12g's during the loop-the-loop and was the last of the circular loop-the-loop roller coasters. Loop-the-loops on modern rides are higher than they are wide.

POTENTIAL ENERGY AND EQUILIBRIUM

We can gain insight into the motion of a system by looking at a graph of its potential energy versus the position of a particle in that system. For simplicity, we restrict our consideration to a particle constrained to move along a straight line—the x axis. To create such a graph, we first must find the relationship between the potential energy function and the force acting on the particle. Consider a conservative force $\vec{F} = F_x\hat{i}$ acting on the particle. Substituting this into Equation 7-1b gives

$$dU = -\vec{F} \cdot d\vec{\ell} = -F_x\,dx$$

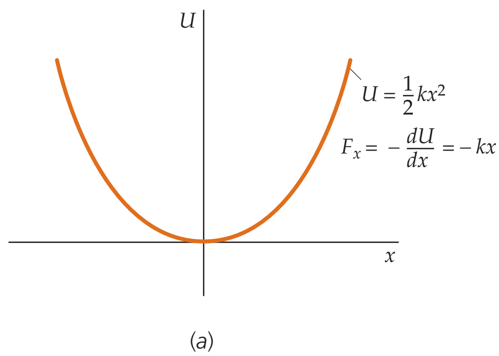
The force component F_x is therefore the negative of the derivative* of the potential-energy function:

$$F_x = -\frac{dU}{dx} \qquad 7\text{-}13$$

We can illustrate this general relation for a block–spring system by differentiating the function $U = \frac{1}{2}kx^2$. We obtain

$$F_x = -\frac{dU}{dx} = -\frac{d}{dx}\left(\frac{1}{2}kx^2\right) = -kx$$

Figure 7-17 shows a plot of $U = \frac{1}{2}kx^2$ versus x for a block and spring. The derivative of this function is represented graphically as the slope of the tangent line



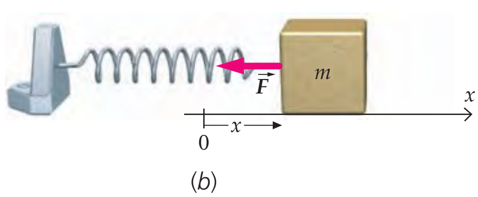


FIGURE 7-17 (a) Plot of the potential-energy function U versus x for an object on a spring. A minimum in the potential-energy curve is a point of stable equilibrium. Displacement in either direction results in a force directed toward the equilibrium position. (b) The applied force $\vec{F}_{app}$ pulls the block to the right, stretching the spring by x_1.

* The derivative in Equation 7-13 is replaced by the partial derivative with respect to x if the motion is not restricted to the x axis.

to the curve. The force is thus equal to the negative of the slope of the tangent line to the curve. At $x = 0$, the force $F_x = -dU/dx$ is zero and the block is in *equilibrium*, assuming no other forces are acting on it.

When x is positive in Figure 7-17*a*, the slope is positive and the force F_x is negative. When x is negative, the slope is negative and the force F_x is positive. In either case, the force is in the direction that will accelerate the block in the direction of decreasing potential energy. If the block is displaced slightly from $x = 0$, the force is directed back toward $x = 0$. The equilibrium at $x = 0$ is thus **stable equilibrium,** because a small displacement results in a restoring force that accelerates the particle back toward its equilibrium position.

! The potential energy function is a minimum at a point of stable equilibrium.

In stable equilibrium, a small displacement in any direction results in a restoring force that accelerates the particle back toward its equilibrium position.

CONDITION FOR STABLE EQUILIBRIUM

Figure 7-18 shows a potential-energy curve with a maximum rather than a minimum at the equilibrium point $x = 0$. Such a curve could represent the potential energy of a space ship at the point between Earth and the moon where the gravitational pull on the ship by Earth is equal to the gravitational pull on the ship by the moon. (We are neglecting any gravitational pull from the Sun.) For this curve, when x is positive, the slope is negative and the force F_x is positive, and when x is negative, the slope is positive and the force F_x is negative. Again, the force is in the direction that will accelerate the particle toward lower potential energy, but this time the force is away from the equilibrium position. The maximum at $x = 0$ in Figure 7-18 is a point of **unstable equilibrium** because a small displacement results in a force that accelerates the particle away from its equilibrium position.

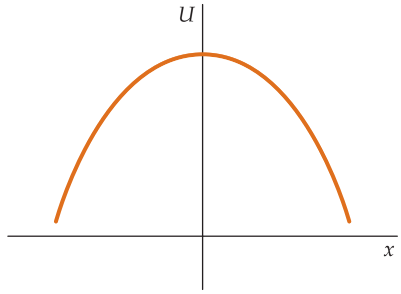

FIGURE 7-18 A particle with a potential energy shown by this potential-energy curve will be in unstable equilibrium at $x = 0$ because a displacement from $x = 0$ results in a force directed away from the equilibrium position.

In unstable equilibrium, a small displacement results in a force that accelerates the particle away from its equilibrium position.

CONDITION FOR UNSTABLE EQUILIBRIUM

Figure 7-19 shows a potential-energy curve that is flat in the region near $x = 0$. No force acts on a particle at $x = 0$, and hence the particle is at equilibrium; furthermore, there will be no resulting force if the particle is displaced slightly in either direction. This is an example of **neutral equilibrium.**

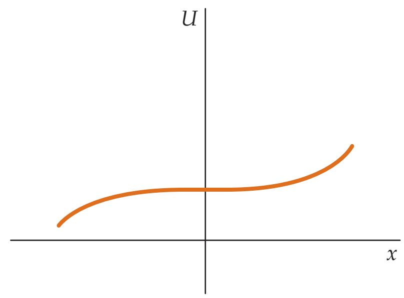

FIGURE 7-19 Neutral equilibrium. The force $F_x = -dU/dx$ is zero at $x = 0$ and at neighboring points, so displacement away from $x = 0$ results in no force, and the system remains in equilibrium.

In neutral equilibrium, a small displacement in any direction results in zero force and the particle remains in equilibrium.

CONDITION FOR NEUTRAL EQUILIBRIUM

Example 7-9 Force and the Potential-Energy Function

In the region $-a < x < a$ the force on a particle is represented by the potential-energy function

$$U = -b\left(\frac{1}{a+x} + \frac{1}{a-x}\right)$$

where a and b are positive constants. (*a*) Find the force F_x in the region $-a < x < a$. (*b*) At what value of x is the force zero? (*c*) At the location where the force equals zero, is the equilibrium stable or unstable?

PICTURE The force is the negative of the derivative of the potential-energy function. The equilibrium is stable where the potential-energy function is a minimum and it is unstable where the potential-energy function is a maximum.

SOLVE

(*a*) Compute $F_x = -dU/dx$.

$$F_x = -\frac{d}{dx}\left[-b\left(\frac{1}{(a+x)} + \frac{1}{(a-x)}\right)\right] = \boxed{-b\left(\frac{1}{(a+x)^2} - \frac{1}{(a-x)^2}\right)}$$

(*b*) Set F_x equal to zero and solve for x.

$F_x = 0$ at $\boxed{x = 0}$

(*c*) Compute d^2U/dx^2. If it is positive at the equilibrium position, then U is a minimum and the equilibrium is stable. If it is negative, then U is a maximum and the equilibrium is unstable.

$$\frac{d^2U}{dx^2} = -2b\left(\frac{1}{(a+x)^3} + \frac{1}{(a-x)^3}\right)$$

At $x = 0$, $\dfrac{d^2U}{dx^2} = \dfrac{-4b}{a^3} < 0$

Thus, $\boxed{\text{unstable}}$ equilibrium.

CHECK If U is expressed in joules and x and a are expressed in meters, then b must be expressed in joule·meters and F_x must be expressed in newtons. Our Part-(*a*) result shows that F_x has the same units as those of Part (*b*) divided by m^2. That is, our expression for F_x has units of $\text{J}\cdot\text{m}/\text{m}^2 = \text{J/m}$. Because $1\,\text{J} = 1\,\text{N}\cdot\text{m}$, our expression for F_x has units of newtons. Consequently, our Part-(*a*) result is dimensionally correct, and therefore is plausible.

TAKING IT FURTHER The potential-energy function in this example is for a particle under the influence of the gravitational forces exerted by two identical fixed-point masses, one at $x = -a$, the other at $x = +a$. The particle is located on the line joining the masses. Midway between the two masses the net force on the particle is zero. Otherwise, it is toward the closest mass.

We can use the result that a position of stable equilibrium is a potential-energy minimum to locate the center of mass experimentally. For example, two objects connected by a light rod will balance if the pivot is at the center of mass (Figure 7-20). If we pivot the system at any other point, the system will rotate until the gravitational potential energy is at a minimum, which occurs when the center of mass is at its lowest possible point directly below the pivot (Figure 7-21). (The gravitational potential energy of a system is given by $U_g = mgh_{\text{cm}}$ [Equation 7-3].)

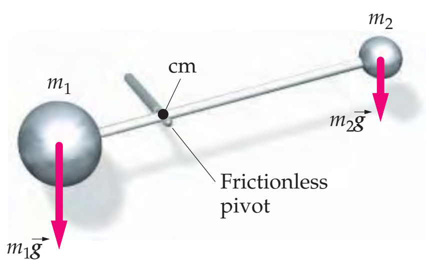

FIGURE 7-20

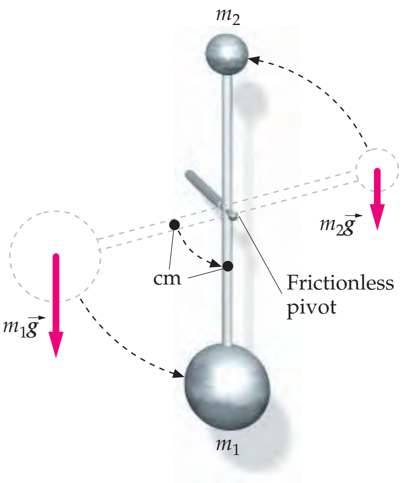

FIGURE 7-21

If we suspend any irregular object from a pivot, the object will hang so that its center of mass lies somewhere on the vertical line drawn directly downward from the pivot. Now suspend the object from another point and note where the vertical line through the pivot point now passes. The center of mass will lie at the intersection of the two lines (Figure 7-22).

FIGURE 7-22 The center of mass of an irregular object can be found by suspending it first from one point and then from a second point.

For a system for which mechanical energy remains constant, graphs that plot both potential energy U and mechanical energy E are often useful. For example, Figure 7-23 is a plot of the potential-energy function

$$U = b\left(\frac{1}{a+x} + \frac{1}{a-x}\right)$$

which is the negative of the potential-energy function used in Example 7-9. Figure 7-23 contains plots of both this potential-energy function and the total mechanical energy E. The kinetic energy K for a specified value of x is represented by the distance that the total mechanical-energy line is above the potential-energy curve because $K = E - U$.

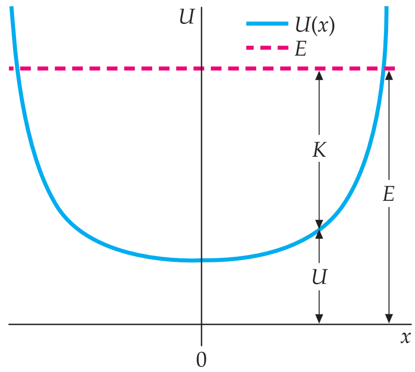

FIGURE 7-23 The potential energy U and the total mechanical energy E are plotted versus x. The sum of the kinetic energy K and the potential energy equals the total mechanical energy. That is, $K = E - U$.

7-3 THE CONSERVATION OF ENERGY

In the macroscopic world, dissipative nonconservative forces, such as kinetic friction, are always present to some extent. Such forces tend to decrease the mechanical energy of a system. However, any such decrease in mechanical energy is accompanied by a corresponding increase in thermal energy. (Consider that excessive automotive braking sometimes causes the temperature of the rotors or brake drums to increase to the point that the metal warps.) Another type of nonconservative force is that involved in the deformations of objects. When you bend a metal coat hanger back and forth, you do work on the coat hanger, but the work you do does not appear as mechanical energy. Instead, the coat hanger becomes warm. The work done in deforming the hanger is dissipated as thermal energy. Similarly, when a falling ball of modeling clay lands on the floor (thud), it becomes warmer as it deforms. The dissipated kinetic energy appears as thermal energy. For the clay–floor–Earth system, the total energy is the sum of the thermal energy and the mechanical energy. The total energy of the system is conserved even though neither the total mechanical energy nor the total thermal energy is individually conserved.

A third type of nonconservative force is associated with chemical reactions. When we include systems in which chemical reactions take place, the sum of mechanical energy plus thermal energy is not conserved. For example, suppose that you begin running from rest. You initially have no kinetic energy. When you begin to run, chemical energy stored in certain molecules in your muscles is transformed into kinetic energy and thermal energy. It is possible to identify and measure the chemical energy that is transformed into kinetic energy and thermal energy. In this case, the sum of mechanical energy, thermal energy, and chemical energy is conserved.

Even when thermal energy and chemical energy are included, the total energy of the system does not always remain constant, because energy can be converted to radiation energy, such as sound waves or electromagnetic waves. But *the increase or decrease in the total energy of a system can always be accounted for by the disappearance or appearance of energy outside the system.* This experimental result, known as the **law of conservation of energy,** is one of the most important laws in all of science. Let E_{sys} be the total energy of a given system, E_{in} be the energy that enters the system, and E_{out} be the energy that leaves the system. The law of conservation of energy then states

$$E_{in} - E_{out} = \Delta E_{sys} \qquad 7\text{-}14$$

LAW OF CONSERVATION OF ENERGY

Alternatively,

> The total energy of the universe is constant. Energy can be converted from one form to another, or transmitted from one region to another, but energy can never be created or destroyed.
>
> LAW OF CONSERVATION OF ENERGY

The total energy E of many systems from everyday life can be accounted for completely by mechanical energy E_{mech}, thermal energy E_{therm}, and chemical energy E_{chem}. To be comprehensive and include other possible forms of energy, such as electromagnetic or nuclear energy, we include E_{other}, and write

$$E_{\text{sys}} = E_{\text{mech}} + E_{\text{therm}} + E_{\text{chem}} + E_{\text{other}} \tag{7-15}$$

THE WORK–ENERGY THEOREM

One way energy is transferred into or out of a system is for work to be done on the system by agents outside the system. In situations where this is the only method of energy transfer into or out of a system, the law of conservation of energy is expressed as:

$$W_{\text{ext}} = \Delta E_{\text{sys}} = \Delta E_{\text{mech}} + \Delta E_{\text{therm}} + \Delta E_{\text{chem}} + \Delta E_{\text{other}} \tag{7-16}$$

WORK–ENERGY THEOREM

where W_{ext} is the work done on the system by external forces and ΔE_{sys} is the change in the system's total energy. This **work–energy theorem** for systems, which we call simply the work–energy theorem, is a powerful tool for studying a wide variety of systems. Note that if the system is just a single particle, its energy can only be kinetic. In that case, the work–energy theorem (Equation 7-16) reduces to the work–kinetic-energy theorem (Equation 6-8) studied in Chapter 6.

There are two methods for transferring energy into or out of a system. The second method is called heat. Heat is the transfer of energy due to a temperature difference. Exchanges of energy due to a temperature difference between a system and its surroundings are discussed in Chapter 18. In this chapter, the transfer of energy by heat is assumed to be negligible.

Example 7-10 Falling Clay *Conceptual*

A ball of modeling clay with mass m is released from rest from a height h and falls to the perfectly rigid floor (thud). Discuss the application of the law of conservation of energy to (*a*) the system consisting of the clay ball alone, and (*b*) the system consisting of Earth, the floor, and the clay ball.

PICTURE Two forces act on the clay ball following its release: the force of gravity and the contact force of the floor. Because the floor does not move (it is rigid), the contact force it exerts on the clay ball does no work. There are no chemical or other energy changes, so we can neglect ΔE_{chem} and ΔE_{other}. (We neglect the sound energy radiated when the clay ball hits the floor.) Thus, the only energy transferred to or from the clay ball is the work done by the force of gravity.

SOLVE

(*a*) 1. Write the work–energy theorem for the clay ball:

$$W_{\text{ext}} = \Delta E_{\text{sys}} = \Delta E_{\text{mech}} + \Delta E_{\text{therm}} + \Delta E_{\text{chem}} + \Delta E_{\text{other}}$$
$$W_{\text{ext}} = \Delta E_{\text{sys}} = \Delta E_{\text{mech}} + E_{\text{therm}}$$

2. The two external forces on the system (the clay ball) are the force of gravity and the normal force exerted by the floor on the clay ball. However, the part of the ball in contact with the floor does not move, so the normal force on the ball by the floor does no work. Thus, the only work done on the clay ball is done by the force of gravity on the ball:

$$W_{\text{ext}} = mgh$$

3. Because the clay ball alone is our system, its mechanical energy is entirely kinetic, which is zero both initially and finally. Thus, the change in mechanical energy is zero:

$$\Delta E_{\text{mech}} = 0$$

4. Substitute mgh for W_{ext} and 0 for ΔE_{mech} in step 1:

$$W_{\text{ext}} = \Delta E_{\text{mech}} + E_{\text{therm}}$$
$$mgh = 0 + \Delta E_{\text{therm}}$$
so $\boxed{\Delta E_{\text{therm}} = mgh}$

Note: If the floor were not perfectly rigid, the increase in thermal energy would be shared by the ball and the floor.

(*b*) 1. No external forces act on the clay ball–Earth–floor system (the force of gravity and the force of the floor are now internal to the system), so there is no external work done:

$$W_{\text{ext}} = 0$$

2. Write the work–energy theorem with $W_{\text{ext}} = 0$:

$$W_{\text{ext}} = \Delta E_{\text{sys}} = \Delta E_{\text{mech}} + \Delta E_{\text{therm}}$$
$$0 = \Delta E_{\text{mech}} + \Delta E_{\text{therm}}$$

3. The initial mechanical energy of the clay ball–Earth system is the initial gravitational potential energy. The final mechanical energy is zero:

$$E_{\text{mech i}} = mgh$$
$$E_{\text{mech f}} = 0$$

4. The change in mechanical energy of the clay ball–Earth system is thus:

$$\Delta E_{\text{mech}} = 0 - mgh = -mgh$$

5. The work–energy theorem thus gives the same result as in Part (*a*):

$$\Delta E_{\text{therm}} = \boxed{-\Delta E_{\text{mech}} = mgh}$$

CHECK The Part-(*a*) and Part-(*b*) results are the same—that the thermal energy of the system increases by mgh. This is as one would expect.

TAKING IT FURTHER In Part (*a*), energy is transferred to the ball by the work done on it by the force of gravity. This energy appears as the kinetic energy of the ball before it impacts the floor and as thermal energy after impact. The ball warms slightly and the energy is eventually transferred to the surroundings. In Part (*b*), no energy is transferred to the ball–Earth–floor system. The original potential energy of the system is converted to kinetic energy of the ball just before it hits, and then into thermal energy.

PROBLEMS INVOLVING KINETIC FRICTION

When surfaces slide across each other, kinetic friction decreases the mechanical energy of the system and increases the thermal energy. Consider a block that begins with initial velocity v_{i} and slides along a board that is on a frictionless surface (Figure 7-24). The board is initially at rest. We choose the block and board to be our system, and $\Delta E_{\text{chem}} = \Delta E_{\text{other}} = 0$. No external work is done on this system. The work–energy theorem gives

$$0 = \Delta E_{\text{mech}} + \Delta E_{\text{therm}} \tag{7-17}$$

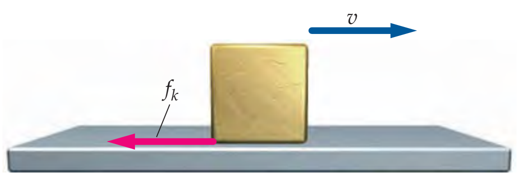

FIGURE 7-24

The change in mechanical energy is given by

$$\Delta E_{\text{mech}} = \Delta K_{\text{block}} + \Delta K_{\text{board}} = (\tfrac{1}{2}mv_{\text{f}}^2 - \tfrac{1}{2}mv_{\text{i}}^2) + (\tfrac{1}{2}MV_{\text{f}}^2 - 0) \tag{7-18}$$

where m is the mass of the block, M is the mass of the board, v is the speed of the block, and V is the speed of the board. We can relate this change in mechanical energy to the kinetic frictional force. If f_{k} is the magnitude of the frictional force on either the block or the board, Newton's second law applied to the block gives

$$-f_{\text{k}} = ma_x$$

where a_x is the acceleration of the block. Multiplying both sides by the displacement of the block Δx, we obtain

$$-f_k \Delta x = ma\Delta x \qquad 7\text{-}19$$

Solving the constant-acceleration formula $2a_x \Delta x = v_f^2 - v_i^2$ for $a_x \Delta x$ and substituting into Equation 7-19 gives

$$-f_k \Delta x = ma_x \Delta x = m(\tfrac{1}{2}v_f^2 - \tfrac{1}{2}v_i^2) = \tfrac{1}{2}mv_f^2 - \tfrac{1}{2}mv_i^2 \qquad 7\text{-}20$$

Equation 7-20 is just the center-of-mass work–translational-kinetic-energy relation (Equation 6-27) applied to the block. Applying this same relation to the board gives

$$f_k \Delta X = MA_X \Delta X = M(\tfrac{1}{2}V_f^2 - \tfrac{1}{2}V_i^2) = \tfrac{1}{2}MV_f^2 - 0 \qquad 7\text{-}21$$

where ΔX and A_x are the displacement and acceleration of the board. Adding Equations 7-20 and 7-21 gives

$$-f_k(\Delta x - \Delta X) = (\tfrac{1}{2}mv_f^2 - \tfrac{1}{2}mv_i^2) + \tfrac{1}{2}MV_f^2 \qquad 7\text{-}22$$

We note that $\Delta x - \Delta X$ is the distance s_{rel} that the block slides relative to the board, and that the right side of Equation 7-22 is the change in mechanical energy ΔE_{mech} of the block–board system. Substituting into Equation 7-22 gives

$$-f_k s_{rel} = \Delta E_{mech} \qquad 7\text{-}23$$

The decrease in mechanical energy of the block–board system is accompanied by a corresponding increase in the thermal energy of the system. This thermal energy appears both on the bottom surface of the block and on the upper surface of the board. Substituting ΔE_{therm} for $-\Delta E_{mech}$ (Equation 7-17), we obtain

$$f_k s_{rel} = \Delta E_{therm} \qquad 7\text{-}24$$

ENERGY DISSIPATED BY KINETIC FRICTION

where s_{rel} is the distance one contacting surface slides relative to the other contacting surface. Because the distance s_{rel} is the same in all frames of reference, Equation 7-24 is valid in all frames of reference, independent of whether they are inertial frames of reference or not.

Substituting this result into the work–energy theorem (with $\Delta E_{chem} = \Delta E_{other} = 0$), we obtain

$$W_{ext} = \Delta E_{mech} + \Delta E_{therm} = \Delta E_{mech} + f_k s_{rel} \qquad 7\text{-}25$$

WORK-ENERGY THEOREM WITH FRICTION

Example 7-11 Pushing a Box

A 4.0-kg box is initially at rest on a horizontal tabletop. You push the box a distance of 3.0 m along the tabletop with a horizontal force of 25 N. The coefficient of kinetic friction between the box and tabletop is 0.35. Find (*a*) the external work done on the block–table system, (*b*) the energy dissipated by friction, (*c*) the final kinetic energy of the box, and (*d*) the speed of the box.

PICTURE The box plus table is the system (Figure 7-25). You are external to this system, so the force you push with is an external force. The final speed of the box is found from its final kinetic energy, which we find using the work–energy theorem with $\Delta E_{chem} = 0$ and $\Delta E_{therm} = f_k s_{rel}$. The energy of the system is increased by the external work. Some of the energy increase is kinetic energy and some is thermal energy.

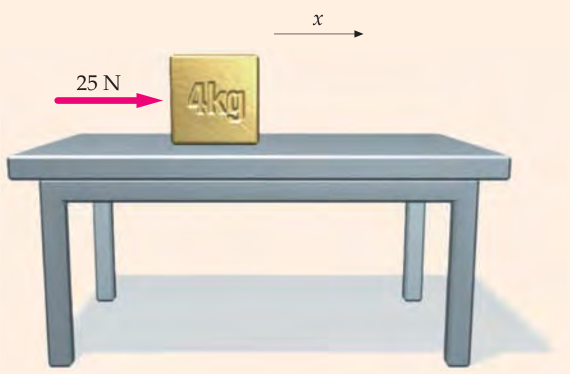

FIGURE 7-25

SOLVE

(*a*) Four external forces are acting on the system. However, only one of them does work. The total external work done is the product of the push force and the distance traveled:

$$\Sigma W_{ext} = W_{\text{by you on block}} + W_{\text{by gravity on block}} + W_{\text{by gravity on table}} + W_{\text{by floor on table}}$$
$$= F_{push}\,\Delta x + 0 + 0 + 0 = (25\,\text{N})(3.0\,\text{m})$$
$$= \boxed{75\,\text{J}}$$

(*b*) The energy dissipated by friction is $f_k\,\Delta x$ (the magnitude of the normal force equals mg):

$$\Delta E_{therm} = f_k\,\Delta x = \mu_k F_n\,\Delta x = \mu_k mg\,\Delta x$$
$$= (0.35)(4.0\,\text{kg})(9.81\,\text{N/kg})(3.0\,\text{m})$$
$$= \boxed{41\,\text{J}}$$

(*c*) 1. Apply the work–energy theorem to find the final kinetic energy:

$$W_{ext} = \Delta E_{mech} + \Delta E_{therm}$$

2. No internal conservative forces do work, so the change in potential energy ΔU is zero. Thus, the change in mechanical energy equals the change in kinetic energy:

$$\Delta E_{mech} = \Delta U + \Delta K = 0 + (K_f - 0) = K_f$$

3. Substitute this into the step-1 result, then use the values from Parts (*a*) and (*b*) to find K_f:

$$W_{ext} = K_f + \Delta E_{therm}$$
so $$K_f = W_{ext} - \Delta E_{therm}$$
$$= 75\,\text{J} - 41\,\text{J} = \boxed{34\,\text{J}}$$

(*d*) The final speed of the box is related to its kinetic energy. Solve for the final speed of the box:

$$K_f = \tfrac{1}{2}mv_f^2$$
so $$v_f = \sqrt{\frac{2K_f}{m}} = \sqrt{\frac{2(34\,\text{J})}{4.0\,\text{kg}}} = \boxed{4.1\,\text{m/s}}$$

CHECK Part of the energy transferred to the system by the pusher (you) ends up as kinetic energy and some of the energy ends up as thermal energy. As expected, the change in thermal energy (Part (*b*)) is positive and is less than the work done by the external force (Part (*a*)).

Example 7-12 A Moving Sled

Try It Yourself

A sled is coasting on a horizontal snow-covered surface with an initial speed of 4.0 m/s. If the coefficient of friction between the sled and the snow is 0.14, how far will the sled travel before coming to rest?

PICTURE We choose the sled and snow as our system and then apply the work–energy theorem.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps | **Answers**

1. Sketch the system in its initial and final configurations (Figure 7-26).

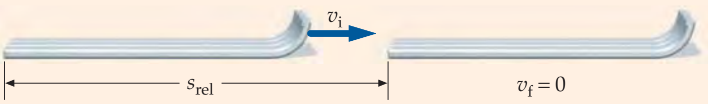

FIGURE 7-26

2. Apply the work–energy theorem. Relate the change in thermal energy to the frictional force.

$$W_{ext} = \Delta E_{mech} + \Delta E_{therm}$$
$$= (\Delta U + \Delta K) + f_k s_{rel}$$

3. Solve for f_k. The normal force is equal to mg.

$$f_k = \mu_k F_n = \mu_k mg$$

4. There are no external forces doing work on the system and there are no internal conservative forces doing work. Use these observations to eliminate two terms from the step-2 result.

$W_{ext} = 0$ and $\Delta U = 0$
so $$W_{ext} = \Delta U + \Delta K + f_k s_{rel}$$
$$0 = 0 + \Delta K + \mu_k mg\, s_{rel}$$

5. Express the change in kinetic energy in terms of the mass and the initial speed, and solve for s_{rel}.

$$s_{rel} = \frac{v^2}{2\mu_k g} = \boxed{5.8\,\text{m}}$$

CHECK The expression for the displacement in step 5 is dimensionally correct. The coefficient of friction μ_k is dimensionless, and v^2/g has the dimension of length.

Example 7-13 A Playground Slide

A child of mass 40 kg goes down an 8.0-m-long slide inclined at 30° with the horizontal. The coefficient of kinetic friction between the child and the slide is 0.35. If the child starts from rest at the top of the slide, how fast is he traveling when he reaches the bottom?

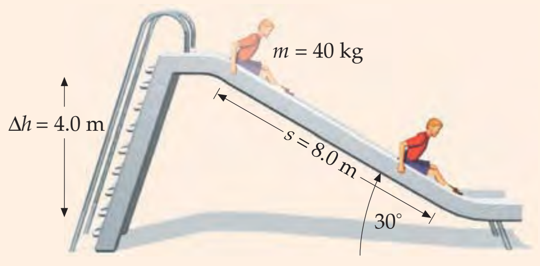

FIGURE 7-27

PICTURE As the child travels down the slide, some of his initial potential energy is converted into kinetic energy and, due to friction, some into thermal energy. We choose the child–slide–Earth as our system and apply the conservation of energy theorem.

SOLVE

1. Make a sketch of the child–slide–Earth system, showing both its initial and final configurations (Figure 7-27).
2. Write out the conservation-of-energy equation: $W_{ext} = \Delta E_{mech} + \Delta E_{therm} = (\Delta U + \Delta K) + f_k s_{rel}$
3. The initial kinetic energy is zero. The speed at the bottom is related to the final kinetic energy: $\Delta K = K_f - 0 = \frac{1}{2}mv_f^2$
4. There are no external forces acting on the system: $W_{ext} = 0$
5. The change in potential energy is related to the change in height Δh (which is negative): $\Delta U = mg\,\Delta h$
6. To find f_k we apply Newton's second law to the child. First we draw a free-body diagram (Figure 7-28):

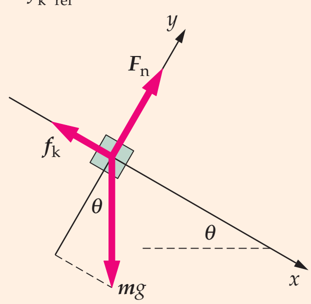

FIGURE 7-28

7. Next, we apply Newton's second law. The normal component of the acceleration is zero. To find F_n we take components in the normal direction. Then we solve for f_k using $f_k = \mu_k F_n$: $F_n - mg\cos\theta = 0$
   so $f_k = \mu_k F_n = \mu_k mg\cos\theta$
8. We use trigonometry to relate $s = s_{rel}$ to Δh: $|\Delta h| = s\sin\theta$
9. Substituting into the step-2 result gives: $0 = mg\,\Delta h + \frac{1}{2}mv_f^2 + f_k s = -mgs\sin\theta + \frac{1}{2}mv_f^2 + \mu_k mg\cos\theta\, s$
10. Solving for v_f gives:
$$v_f^2 = 2gs(\sin\theta - \mu_k\cos\theta) = 2(9.81\text{ m/s}^2)(8.0\text{ m})(\sin 30° - 0.35\cos 30°)$$
$$= 30.9\text{ m}^2/\text{s}^2$$
so $v_f = \boxed{5.6\text{ m/s}}$

CHECK Note that, as expected, the expression for v_f^2 in step 10 is independent of the mass of the child. This is expected because all forces acting on the child are proportional to the mass m.

PRACTICE PROBLEM 7-8 Use the bottom end of the slide as the reference level where the potential energy is zero. For the Earth–child–slide system, calculate (*a*) the initial mechanical energy, (*b*) the final mechanical energy, and (c) the energy dissipated by friction.

Example 7-14 Two Blocks and a Spring

A 4.0-kg block hangs by a light string that passes over a massless, frictionless pulley and is connected to a 6.0-kg block that rests on a shelf. The coefficient of kinetic friction is 0.20. The 6.0-kg block is pushed against a spring, compressing it 30 cm. The spring has a force constant of 180 N/m. Find the speed of the blocks after the 6.0-kg block is released and the 4.0-kg block has fallen a distance of 40 cm. (Assume the 6.0-kg block is initially 40 cm or more from the pulley.)

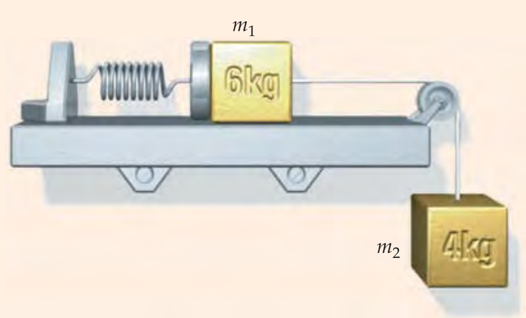

FIGURE 7-29 The system is everything shown plus Earth.

PICTURE The speed of the blocks is obtained from their final kinetic energy. Consider the system to be everything shown in Figure 7-29 plus Earth. This system has both gravitational and elastic potential energy. Apply the work–energy theorem to find the kinetic energy of the blocks. Then, use the kinetic energy of the blocks to solve for their speed.

SOLVE

1. The system is everything shown plus Earth. Write out the equation for the conservation of energy of the system.

$$W_{\text{ext}} = \Delta E_{\text{mech}} + \Delta E_{\text{therm}}$$
$$= (\Delta U_s + \Delta U_g + \Delta K) + f_k s_{\text{rel}}$$

2. Make a sketch of the system (Figure 7-30) in both the initial and final configurations:

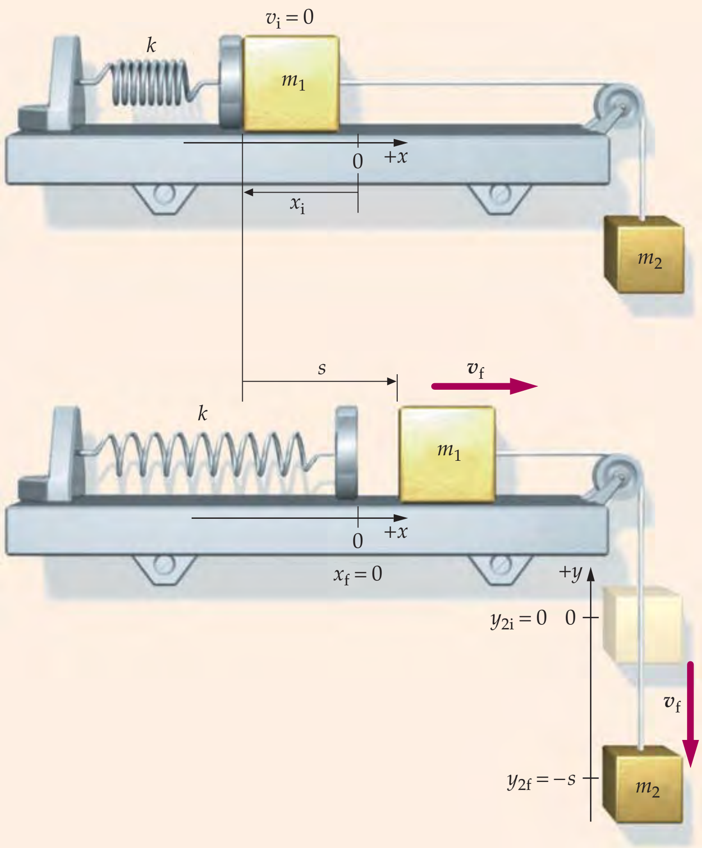

FIGURE 7-30 The system is everything shown plus Earth. The system is shown in both its initial and final configurations.

3. There are no external forces on the system.

$$W_{\text{ext}} = 0$$

4. The potential energy of the spring U_s depends on its force constant k and its extension x. (If the spring is compressed, x is negative.) The gravitational potential energy depends on the height of block 2:

$$U_s = \tfrac{1}{2}kx^2$$
$$U_s = mgy_2$$

5. Make a table of the mechanical-energy terms both initially, when the spring is compressed 30 cm, and finally, when each block has moved a distance $s = 40$ cm and the spring is unstressed. Let the gravitational potential energy of the initial configuration equal zero. Also, write down the difference (final minus initial) between each initial and final expression.

	Final	Initial	Difference
U_s	0	$\frac{1}{2}kx_i^2$	$-\frac{1}{2}kx_i^2$
U_g	$-m_2gs$	0	$-m_2gs$
K	$\frac{1}{2}(m_1 + m_2)v_f^2$	0	$\frac{1}{2}(m_1 + m_2)v_f^2$

6. Find an expression for f_k that includes μ_k.

$$f_k = \mu_k m_1 g$$

7. Substitute the results for steps 3–6 into the step-1 result.

$$0 = -\tfrac{1}{2}kx_i^2 - m_2gs + \tfrac{1}{2}(m_1 + m_2)v_f^2 + \mu_k m_1 gs$$

8. Solve the step-7 result for v_f^2, then substitute numerical values and solve for v_f:

$$v_f^2 = \frac{kx_i^2 + 2(m_2 - \mu_k m_1)gs}{m_1 + m_2}$$

so $v_f = \boxed{2.0\text{ m/s}}$

CHECK If $m_2 = \mu_k = 0$, then the final speed does not depend on either g or μ_k (see step 8). This is as expected because m_2g is the gravitational force on m_2 pulling the system forward and $\mu_k m_1 g$ is the frictional force on m_1 opposing the forward motion. If these two forces sum to zero, the effects of gravity and friction do not affect the final speed.

TAKING IT FURTHER This solution assumes that the string remains taut at all times, which will be true if the acceleration of block 1 remains less than g, that is, if the net force on block 1 is less than $m_1g = (6.0\text{ kg})(9.81\text{ N/kg}) = 59\text{ N}$. The force exerted by the spring on block 1 initially has the magnitude $kx_1 = (180\text{ N/m})(0.30\text{ m}) = 54\text{ N}$ and the frictional force initially has magnitude $f_k = \mu_k m_1 g = 0.20(59\text{ N}) = 12\text{ N}$. These forces combine to produce a net force of 42 N directed to the right. Because the spring's force decreases as block 1 moves following release, the acceleration of the 6.0-kg block will never exceed g and the string will remain taut.

PROBLEMS INVOLVING CHEMICAL ENERGY

Sometimes a system's internal chemical energy is converted into mechanical energy and thermal energy with no work being done on the system by external forces. For example, at the beginning of this section we described the energy conversions that take place when you start running. To move forward, you push back on the floor and the floor pushes forward on you with a static frictional force. This force causes you to accelerate, but it does not do work because the displacement of the point of application of the force is zero (assuming your shoes do not slip on the floor). Because no work is done, no energy is transferred from the floor to your body. The kinetic-energy increase of your body comes from the conversion of internal chemical energy derived from the food you eat. Consider the following example.

Example 7-15 Climbing Stairs *Conceptual*

Suppose that you have mass m and you run up a flight of stairs of height h. Discuss the application of energy conservation to the system consisting of you alone.

(Corbis.)

PICTURE There are two forces that act on you: the force of gravity and the force of the stair treads on your feet. Apply the work–energy theorem to the system (you).

SOLVE

1. You are the system. Write the work–energy theorem (Equation 7-16) for this system:
$$W_{ext} = \Delta E_{sys} = \Delta E_{mech} + \Delta E_{therm} + \Delta E_{chem}$$
2. There are two external forces, the gravitational force of Earth on you and the contact force of the stair treads on your feet. The force of gravity does negative work because the component of your displacement in the direction of the force is $-h$, which is negative. The force of the stair treads does no work because the points of application, the soles of your feet, do not move while this force is applied:
$$W_{ext} = -mgh$$
3. You alone are the system. Because your configuration does not change (you remain upright), any change in your mechanical energy is entirely a change in your kinetic energy, which is the same initially and finally:
$$\Delta E_{mech} = 0$$
4. Substitute these results into the work–energy theorem:
$$W_{ext} = \Delta E_{mech} + \Delta E_{therm} + \Delta E_{chem} + \Delta E_{other}$$
so $\quad -mgh = 0 + \Delta E_{therm} + \Delta E_{chem} + 0$

or $\quad \Delta E_{chem} = -(mgh + \Delta E_{therm})$

CHECK We expect your chemical energy to decrease. According to the step-4 result, the change in chemical energy is negative as expected.

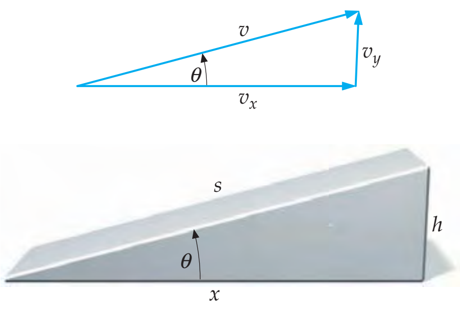
TAKING IT FURTHER If there were no change in thermal energy, then your chemical energy would decrease by mgh. Because the human body is relatively inefficient, the increase in thermal energy will be considerably greater than mgh. The decrease in stored chemical energy equals mgh plus some thermal energy. Any thermal energy is eventually transferred from your body to the surroundings.

CONCEPT CHECK 7-1

Discuss the energy conservation for the system consisting of both you and Earth.

Example 7-16 An Uphill Drive

You are driving a 1000-kg gasoline-powered car at a constant speed of 100 km/h (= 27.8 m/s = 62.2 mi/h) up a 10.0 percent grade (Figure 7-31). (A 10.0 percent grade means that the road rises 1.00 m for each 10.0 m of horizontal distance—that is, the angle of inclination θ is given by $\tan\theta = 0.100$.) (*a*) If the efficiency is 15.0 percent, what is the rate at which the chemical energy of the car–Earth–atmosphere system changes? (The efficiency is the fraction of the chemical energy consumed that appears as mechanical energy.) (*b*) What is the rate at which thermal energy is generated?



$\tan\theta = h/x \sim \sin\theta = h/s$

FIGURE 7-31

PICTURE Some of the chemical energy goes into increasing the potential energy of the car as it climbs the hill, and some goes into an increase in thermal energy, much of which is expelled by the car as exhaust. To solve this problem, we consider a system consisting of the car, the hill, the atmosphere, and Earth. We first need to find the rate of loss of the chemical energy. Then, we can apply the work–energy theorem to solve for the rate at which thermal energy is generated.

SOLVE

(*a*) 1. The rate of loss of chemical energy equals the absolute value of the change in chemical energy per unit time:

$$\text{Chemical energy loss rate} = \frac{|\Delta E_{\text{chem}}|}{\Delta t}$$

2. The increase in mechanical energy equals 15.0 percent of the decrease in chemical energy:

$$\Delta E_{\text{mech}} = 0.150|\Delta E_{\text{chem}}|$$

3. Solve for the loss rate of chemical energy:

$$\frac{|\Delta E_{\text{chem}}|}{\Delta t} = \frac{1}{0.150}\frac{\Delta E_{\text{mech}}}{\Delta t}$$

4. The car moves at constant speed, so $\Delta K = 0$ and $\Delta E_{\text{mech}} = \Delta U$. Relate the change in mechanical energy to the change in height Δh and substitute it into the step-3 result. (The chemical energy is decreasing):

$$\Delta E_{\text{mech}} = mg\,\Delta h$$

$$\text{so}\quad \frac{\Delta E_{\text{chem}}}{\Delta t} = -\frac{1}{0.150}\frac{mg\,\Delta h}{\Delta t}$$

5. Convert the changes to time derivatives. That is, take the limit of both sides as Δt approaches zero:

$$\frac{dE_{\text{chem}}}{dt} = -\frac{1}{0.150}\frac{mgdh}{dt}$$

6. The rate of change of h equals v_y, which is related to the speed v, as shown in Figure 7-31:

$$\frac{dh}{dt} = v_y = v\sin\theta$$

7. We can approximate $\sin\theta$ by $\tan\theta$ because the angle is small:

$$\sin\theta \approx \tan\theta = 0.100$$

8. Solve for the loss rate of chemical energy:

$$\frac{dE_{\text{chem}}}{dt} = -\frac{mg}{0.15}v\sin\theta \approx -\frac{(1000\text{ kg})(9.81\text{ N/kg})}{0.15}(27.8\text{ m/s})0.100$$

$$\approx -182\text{ kW}$$

$$\therefore\quad -\frac{dE_{\text{chem}}}{dt} \approx \boxed{182\text{ kW}}$$

(*b*) 1. Write out the work–energy relation:

$$W_{\text{ext}} = \Delta E_{\text{mech}} + \Delta E_{\text{therm}} + \Delta E_{\text{chem}}$$

2. Set W_{ext} equal to zero, divide both sides by Δt, convert to derivatives, and solve for dE_{therm}/dt:

$$0 = \frac{dE_{\text{mech}}}{dt} + \frac{dE_{\text{therm}}}{dt} + \frac{dE_{\text{chem}}}{dt}$$

$$\text{so}\quad \frac{dE_{\text{therm}}}{dt} = -\frac{dE_{\text{mech}}}{dt} - \frac{dE_{\text{chem}}}{dt} = 0.150\frac{dE_{\text{chem}}}{dt} - \frac{dE_{\text{chem}}}{dt}$$

$$= -0.850\frac{dE_{\text{chem}}}{dt} = 0.850(182\text{ kW}) = \boxed{154\text{ kW}}$$

CHECK The relative size of the Part (*a*) and Part (*b*) results are as expected because it was given that the efficiency was only 15 percent.

TAKING IT FURTHER Gasoline-powered cars are typically only about 15 percent efficient. About 85 percent of the chemical energy of the gasoline goes to thermal energy, most of which is expelled out the exhaust pipe. Additional thermal energy is created by rolling friction and air resistance. The energy content of gasoline is about 31.8 MJ/L.

7-4 MASS AND ENERGY

In 1905, Albert Einstein published his special theory of relativity, a result of which is the famous equation

$$E = mc^2 \tag{7-26}$$

where $c = 3.00 \times 10^8$ m/s is the speed of light in a vacuum. We will study this theory in some detail in later chapters. However, we use this equation here to present a more modern and complete view of energy conservation.

According to Equation 7-26, a particle or system of mass m has "rest" energy $E = mc^2$. This energy is intrinsic to the particle. Consider the positron—a particle emitted in a nuclear process called *beta decay.* Positrons and electrons have identical masses, but equal and opposite electrical charges. When a positron encounters an electron, electron–positron annihilation can occur. Annihilation is a process in which the electron and positron disappear and their energy appears as electromagnetic radiation. If the two particles are initially at rest, the energy of the electromagnetic radiation equals the rest energy of the electron plus the rest energy of the positron.

Energies in atomic and nuclear physics are usually expressed in units of electron volts (eV) or mega-electron-volts (1 MeV $= 10^6$ eV). A convenient unit for the masses of atomic particles is eV/c^2 or MeV/c^2. Table 7-1 lists rest energies (and therefore the masses) of some elementary particles and light nuclei. The rest energy of a positron plus the rest energy of an electron is 2(0.511 MeV), which is the energy of the electromagnetic radiation energy emitted upon annihilation of the electron and positron in a reference frame in which the electron and positron are initially at rest.

The rest energy of a *system* can consist of the potential energy of the system or other internal energies of the system, in addition to the intrinsic rest energies of the particles in the system. If the system at rest absorbs energy ΔE and remains at rest, its rest energy increases by ΔE and its mass increases by ΔM, where

$$\Delta M = \frac{\Delta E}{c^2} \tag{7-27}$$

Table 7-1 Rest Energies* of Some Elementary Particles and Light Nuclei†

Particle	Symbol	Rest Energy (MeV)	
Electron	e^-	0.5110	
Positron	e^+	0.5110	
Proton	p	938.272	
Neutron	n	939.565	
Deuteron	d	1875.613	
Triton	t	2808.921	Helion	h	2808.391	Alpha particle	α	3727.379	
* Table values are from 2002 CODATA (except for the value for the triton).

† The proton, deuteron and triton are identical with the nuclei of ^{1}H, ^{2}H, and ^{3}H, respectively, and the helion and alpha particle are identical with the nuclei of ^{3}He and ^{4}He, respectively.

Consider two 1.00-kg blocks connected by a spring of force constant k. If we stretch the spring a distance x, the potential energy of the system increases by $\Delta U = \frac{1}{2}kx^2$. According to Equation 7-27, the mass of the system has also increased by $\Delta M = \Delta U/c^2$. Because c is such a large number, this increase in mass cannot be observed in macroscopic systems. For example, suppose $k = 800\,\text{N/m}$ and $x = 10.0\,\text{cm} = 0.100\,\text{m}$. The potential energy of the spring system is then $\frac{1}{2}kx^2 = \frac{1}{2}(800\,\text{N/m})(0.100\,\text{m})^2 = 4.00\,\text{J}$. The corresponding increase in mass of the system is $\Delta M = \Delta U/c^2 = 4.00\,\text{J}/(3.00 \times 10^8\,\text{m/s})^2 = 4.44 \times 10^{-17}\,\text{kg}$. The fractional mass increase is given by

$$\frac{\Delta M}{M} = \frac{4.44 \times 10^{-17}\,\text{kg}}{2.00\,\text{kg}} = 2.22 \times 10^{-17}$$

which is much too small to be observed. However, in nuclear reactions, the energy changes are often a much, much larger fraction of the rest energy of the system. Consider the deuteron, which is the nucleus of deuterium, an isotope of hydrogen also called *heavy hydrogen.* The deuteron consists of a proton and neutron bound together. From Table 7-1 we see that the mass of the proton is $938.272\,\text{MeV}/c^2$ and the mass of the neutron is $939.565\,\text{MeV}/c^2$. The sum of these two masses is $1877.837\,\text{MeV}/c^2$. But the mass of the deuteron is $1875.613\,\text{MeV}/c^2$, which is less than the sum of the masses of the proton and neutron by $2.22\,\text{MeV}/c^2$. Note that this mass difference is much greater than any uncertainties in the measurement of these masses, and the fractional mass difference of $\Delta M/M \approx 1.2 \times 10^{-3}$ is almost 14 orders of magnitude greater than the 2.2×10^{-17} discussed for the spring–blocks system.

Heavy water (deuterium oxide) molecules are produced in the primary cooling water of a nuclear reactor when neutrons collide with the hydrogen nuclei (protons) of the water molecules. If a slow moving neutron is captured by a proton, 2.22 MeV of energy are released in the form of electromagnetic radiation. Thus, the mass of a deuterium atom is $2.22\,\text{MeV}/c^2$ less than the sum of the masses of an isolated ^1H atom and an isolated neutron. (The superscript 1 is the mass number of the isotope. So ^1H refers to protium, the isotope of hydrogen with no neutrons.)

This process can be reversed by breaking a deuteron into its constituent parts if at least 2.22 MeV of energy is transferred to the deuteron with electromagnetic radiation or by collisions with other energetic particles. Any transferred energy in excess of 2.22 MeV appears as kinetic energy of the resulting proton and neutron.

The energy needed to completely separate a nucleus into individual neutrons and protons is called the **binding energy.** The binding energy of a deuteron is 2.22 MeV. The deuteron is an example of a **bound system.** A system is bound if it does not have enough energy to spontaneously separate into separate parts. The rest energy of a bound system is less than the sum of the rest energies of its parts, so energy must be put into the system to break it apart. If the rest energy of a system is greater than the sum of the rest energies of its parts, the system is unbound. An example is uranium-236, which breaks apart or **fissions** into two smaller nuclei.* The sum of the masses of the resultant parts is less than the mass of the original nucleus. Thus, the mass of the system decreases, and energy is released.

In nuclear fusion, two very light nuclei such as a deuteron and a triton (the nucleus of the hydrogen isotope tritium) fuse together. The rest mass of the resultant nucleus is less than that of the original parts, and again energy is released. During a chemical reaction that liberates energy, such as burning coal, the mass decrease is of the order of $1\,\text{eV}/c^2$ per atom. This is more than a million times smaller than the mass changes per nucleus in many nuclear reactions, and is not readily observable.

---

* Uranium-236, written ^{236}U, is made in a nuclear reactor when the stable isotope ^{235}U absorbs a neutron. This reaction is discussed in Chapter 34.

Example 7-17 Binding Energy

A hydrogen atom consisting of a proton and an electron has a binding energy of 13.6 eV. By what percentage is the mass of a proton plus the mass of an electron greater than that of the hydrogen atom?

PICTURE The mass of the proton m_p plus the mass of the electron m_e is equal to mass of the hydrogen atom plus the binding energy E_b divided by c^2. Thus, the fractional difference between $m_e + m_p$ and the mass of the hydrogen atom m_H is the ratio of E_b/c^2 to $m_e + m_p$.

SOLVE

1. The fractional difference (FD) in mass is the ratio of the binding energy E_b/c^2 to $m_e + m_p$:

$$\mathrm{FD} = \frac{(m_e + m_p) - m_H}{m_e + m_p} = \frac{E_b/c^2}{m_e + m_p} = \frac{13.6\ \mathrm{eV}/c^2}{m_e + m_p}$$

2. Obtain the rest masses of the proton and electron from Table 7-1:

$$m_p = 938.28\ \mathrm{MeV}/c^2;$$
$$m_e = 0.511\ \mathrm{MeV}/c^2$$

3. Add to find the sum of these masses:

$$m_p + m_e = 938.79\ \mathrm{MeV}/c^2$$

4. The rest mass of the hydrogen atom is less than this by 13.6 eV/c^2. The fractional difference FD is:

$$\mathrm{FD} = \frac{13.6\ \mathrm{eV}/c^2}{938.79 \times 10^6\ \mathrm{eV}/c^2} = 1.45 \times 10^{-8} = \boxed{1.45 \times 10^{-6}\,\%}$$

CHECK The units work out. If we express all masses in units of eV/c^2, we get the fractional difference as a dimensionless number.

TAKING IT FURTHER This mass difference, $\Delta m = (m_e + m_p) - m_H$, is too small to be measured directly. However, binding energies can be accurately measured, so the mass difference Δm can be found from $E_b = (\Delta m)c^2$.

Example 7-18 Nuclear Fusion — *Try It Yourself*

In a typical nuclear fusion reaction, a triton (t) and a deuteron (d) fuse together to form an alpha particle (α) plus a neutron. The reaction is written d + t $\rightarrow \alpha$ + n. How much energy is released per deuteron produced for this fusion reaction?

PICTURE Because energy is released, the total rest energy of the initial particles must be greater than that of the final particles. This difference equals the energy released.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. Write down the rest energies of d and t from Table 7-1 and add to find the total initial rest energy.	$E_{\mathrm{initial}} = 1875.613\ \mathrm{MeV} + 2808.921\ \mathrm{MeV} = 4684.534\ \mathrm{MeV}$
2. Do the same for α and n to find the final rest energy.	$E_{\mathrm{final}} = 3727.379\ \mathrm{MeV} + 939.565\ \mathrm{MeV} = 4666.944\ \mathrm{MeV}$
3. Find the energy released from $E_{\mathrm{released}} = E_{\mathrm{initial}} - E_{\mathrm{final}}$.	$E_{\mathrm{released}} = 4684.534\ \mathrm{MeV} - 4666.944\ \mathrm{MeV} = \boxed{17.59\ \mathrm{MeV} \approx 17.6\ \mathrm{MeV}}$

CHECK The energy released is a small fraction of the initial energy. This fraction is 17.6 MeV/4685 MeV = 3.76×10^{-3}, which is the same order of magnitude as the fractional mass increase during the fusion of a proton and a neutron that was discussed at the beginning of this subsection on nuclear energy. Thus, 17.6 MeV is a plausible value for the energy release when a deuteron and helion fuse to form an alpha particle.

TAKING IT FURTHER This fusion reaction and other fusion reactions occur in the Sun. The energy that is released bathes Earth and is ultimately responsible for all life on the planet. The energy continuously emitted by the Sun is accompanied by a continuous decrease in the Sun's rest mass.

NONRELATIVISTIC (NEWTONIAN) MECHANICS AND RELATIVITY

As the speed of a particle approaches a significant fraction of the speed of light, Newton's second law breaks down, and we must modify Newtonian mechanics according to Einstein's theory of relativity. The criterion for the validity of Newtonian mechanics can also be stated in terms of the energy of a particle. In nonrelativistic (Newtonian) mechanics, the kinetic energy of a particle moving with speed v is

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}mc^2\frac{v^2}{c^2} = \tfrac{1}{2}E_0\frac{v^2}{c^2}$$

where $E_0 = mc^2$ is the rest energy of the particle. Solving for v/c gives

$$\frac{v}{c} = \sqrt{\frac{2K}{E_0}}$$

Nonrelativistic mechanics is valid if the speed of the particle is much less than the speed of light, or alternatively, the kinetic energy of a particle is much less than its rest energy.

PRACTICE PROBLEM 7-9

A low-Earth-orbit satellite has an orbital speed of $v \approx 5.0$ mi/s $= 8.0$ km/s. What fraction of the speed of light c is this speed? What speed, in mi/s, is equal to one percent of c?

7-5 QUANTIZATION OF ENERGY

When energy is put into a system that remains at rest, the *internal energy* of the system increases. (Internal energy is synonymous with rest energy. It is the total energy of the system less any kinetic energy associated with the motion of the system's center of mass.) While it might seem that we could change the internal energy of a bound system, like the solar system or a hydrogen atom, by any amount, this is found not to be true. This is particularly noticeable for microscopic systems, such as molecules, atoms, and atomic nuclei. The internal energy of a bound system can increase only by discrete increments.

If we have two blocks attached to a spring (Figure 7-32) and we stretch the spring by pulling the blocks further apart, we do work on the block–spring system, and its potential energy increases. If we then release the blocks, they oscillate back and forth. The energy of oscillation E—the kinetic energy of motion of the blocks plus the potential energy (due to the stretching of the spring)—equals the initial potential energy. In time, the energy of the system decreases because of various damping effects such as friction and air resistance. *As closely as we can measure*, the energy decreases continuously. All the energy is eventually dissipated and the energy of oscillation is zero.

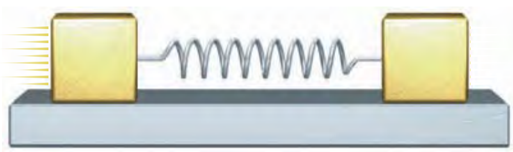

FIGURE 7-32

Now consider a diatomic molecule such as molecular oxygen, O_2. The force of attraction between the two oxygen atoms varies approximately linearly with the change in separation (for small changes), like that of two blocks connected by a spring. If a diatomic molecule is set oscillating with some energy E, the energy decreases with time as the molecule radiates or interacts with its surroundings, but careful measurements can show that the decrease is *not continuous*. The energy decreases in finite steps, and the lowest energy state, called the **ground state,** does not have zero energy. The vibrational energy of a diatomic molecule is said to be

quantized; that is, the molecule can absorb or release energies only in certain amounts, known as **quanta.**

When either blocks on a spring or diatomic molecules oscillate, the time for one oscillation is called the period T. The reciprocal of the period is the frequency of oscillation $f = 1/T$. We will see in Chapter 14 that the period and frequency of an oscillator do not depend on the energy of oscillation. As the energy decreases, the frequency remains the same. Figure 7-33 shows an **energy-level diagram** for an oscillator. The allowed energies are approximately equally spaced, and are given by*

$$E_n = (n + \tfrac{1}{2})hf \quad n = 0, 1, 2, 3, \ldots \qquad \text{7-28}$$

where f is the frequency of oscillation and h is a fundamental constant of nature called Planck's constant:†

$$h = 6.626 \times 10^{-34}\ \text{J} \cdot \text{s} = 4.136 \times 10^{-15}\ \text{eV} \cdot \text{s} \qquad \text{7-29}$$

The integer n is called a **quantum number.** The lowest possible energy is the **ground state energy** $E_0 = \frac{1}{2}hf$.

Microscopic systems often gain or lose energy by absorbing or emitting electromagnetic radiation. By conservation of energy, if E_i and E_f are the initial and final energies of a system, the energy of the radiation emitted or absorbed is

$$E_\text{rad} = |E_\text{f} - E_\text{i}|$$

Because the system energies E_i and E_f are quantized, the radiated energy is also quantized.‡ The quantum of radiation is called a **photon.** The energy of a photon is given by

$$E_\text{photon} = hf \qquad \text{7-30}$$

where f is the frequency of the electromagnetic radiation.§

As far as we know, all bound systems exhibit energy quantization. For macroscopic bound systems, the steps between energy levels are so small that they are unobservable. For example, typical oscillation frequencies for two blocks on a spring are 1 to 10 times per second. If $f = 10$ oscillations per second, the spacing between allowed levels is $hf = (6.626 \times 10^{-34}\ \text{J} \cdot \text{s})(10\ \text{s}^{-1}) \approx 7 \times 10^{-33}\ \text{J}$. Because the energy of a macroscopic system is of the order of 1 J, a quantum step of 10^{-33} J is too small to be noticed. To put it another way, if the energy of a system is 1 J, the value of n is of the order of 10^{32} and changes of one or two quantum units will not be observable.

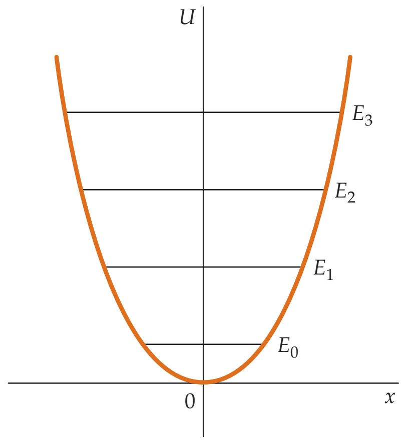

FIGURE 7-33

! A typical energy for a diatomic molecule is 10^{-19} J. Thus, changes in the energy of oscillation are of the same order of magnitude as the energy of the molecule, and quantization is definitely not negligible.

PRACTICE PROBLEM 7-10

For a diatomic molecule, a typical frequency of vibration is 10^{14} vibrations per second. Use Equation 7-28 to find the spacing between the allowed energies.

* A diatomic molecule can also have rotational energy. The rotational energy is also quantized, but the energy levels are not equally spaced, and the lowest possible energy is zero. We will study rotational energy in Chapters 9 and 10.

† In 1900, the German physicist Max Planck introduced this constant during calculations to explain discrepancies between the theoretical curves and experimental data on the spectrum of blackbody radiation. The significance of Planck's constant was not appreciated by Planck or anyone else until Einstein postulated in 1905 that the energy of electromagnetic radiation is not continuous, but occurs in packets of size hf, where f is the frequency of the radiation.

‡ Historically, the quantization of electromagnetic radiation, as proposed by Max Planck and Albert Einstein, was the first "discovery" of energy quantization.

§ Electromagnetic radiation includes light, microwaves, radio waves, television waves, X rays, and gamma rays. These differ from one another in their frequencies.

Physics Spotlight

Blowing Warmed Air

A wind farm converting the kinetic energy of the air to electrical energy. *(Image Slate.)*

Wind farms dot the Danish coast, the plains of the upper Midwest, and hills from California to Vermont. Harnessing the kinetic energy of the wind is nothing new. Windmills have been used to pump water, ventilate mines,* and grind grain for centuries.

Today, the most visible wind turbines run electrical generators. These turbines transform kinetic energy into electromagnetic energy. Modern turbines range widely in size, cost, and output. Some are very small, simple machines that cost under \$500/turbine, and put out less than 100 watts of power.† Others are complex behemoths that cost over \$2 million and put out as much as 2.5 MW/turbine.‡ All of these turbines take advantage of a widely available energy source—the wind.

The theory behind the windmill's conversion of kinetic energy to electromagnetic energy is straightforward. The moving air molecules push on the turbine blades, driving their rotational motion. The rotating blades then turn a series of gears. The gears, in turn, step up the rotation rate, and drive the rotation of a generator rotor. The generator sends the electromagnetic energy out along power lines.

But the conversion of the wind's kinetic energy to electromagnetic energy is not 100 percent efficient. The most important thing to remember is that it *cannot* be 100 percent efficient. If turbines converted 100 percent of the kinetic energy of the air into electrical energy, the air would leave the turbines with zero kinetic energy. That is, the turbines would stop the air. If the air were completely stopped by the turbine, it would flow around the turbine, rather than through the turbine.

So the theoretical efficiency of a wind turbine is a trade-off between capturing the kinetic energy of the moving air, and preventing most of the wind from flowing around the turbine. Propeller-style turbines are the most common, and their theoretical efficiency at transforming the kinetic energy of the air into electromagnetic energy varies from 30 percent to 59 percent.§ (The predicted efficiencies vary because of assumptions made about the way the air behaves as it flows through and around the propellers of the turbine.)

So even the most efficient turbine cannot convert 100 percent of the theoretically available energy. What happens? Upstream from the turbine, the air moves along straight streamlines. After the turbine, the air rotates and is turbulent. The rotational component of the air's movement beyond the turbine takes energy. Some dissipation of energy occurs because of the viscosity of air. When some of the air slows, there is friction between it and the faster moving air flowing by it. The turbine blades heat up, and the air itself heats up.° The gears within the turbine also convert kinetic energy into thermal energy through friction. All this thermal energy needs to be accounted for. The blades of the turbine vibrate individually—the energy associated with those vibrations cannot be used. Finally, the turbine uses some of the electricity it generates to run pumps for gear lubrication, and to run the yaw motor that moves the turbine blades into the most favorable position to catch the wind.

In the end, most wind turbines operate at between 10 and 20 percent efficiency.# They are still attractive power sources, because of the free fuel. One turbine owner explains, "The bottom line is we did it for our business to help control our future."**

Summary

1. The work–energy theorem and the conservation of energy are fundamental laws of nature that have applications in all areas of physics.
2. The conservation of mechanical energy is an important relation derived from Newton's laws for conservative forces. It is useful in solving many problems.
3. Einstein's equation $E = mc^2$ is a fundamental relation between mass and energy.
4. Quantization of energy is a fundamental property of bound systems.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Conservative Force	A force is conservative if the total work it does on a particle is zero when the particle moves along any path that returns it to its initial position. Alternatively, the work done by a conservative force on a particle is independent of the path taken by the particle as it moves from one point to another.	
2. Potential Energy	The potential energy of a system is the energy associated with the configuration of the system. The change in the potential energy of a system is defined as the negative of the work done by all internal conservative forces acting on the system.	
Definition	$\Delta U = U_2 - U_1 = -W = -\int_1^2 \vec{F} \cdot d\vec{\ell}$ $dU = -\vec{F} \cdot d\vec{\ell}$	7-1
Gravitational	$U = U_0 + mgy$	7-2
Elastic (spring)	$U = \frac{1}{2}kx^2$	
Conservative force	$F_x = -\frac{dU}{dx}$	7-13
Potential-energy curve	At a minimum on the curve of the potential-energy function versus the displacement, the force is zero and the system is in stable equilibrium. At a maximum, the force is zero and the system is in unstable equilibrium. A conservative force always tends to accelerate a particle toward a position of lower potential energy.	
3. Mechanical Energy	The sum of the kinetic and potential energies of a system is called the total mechanical energy $E_{mech} = K_{sys} + U_{sys}$	7-9
Work–Energy Theorem for Systems	The total work done on a system by external forces equals the change in mechanical energy of the system less the total work done by internal nonconservative forces: $W_{ext} = \Delta E_{mech} - W_{nc}$	7-10
Conservation of Mechanical Energy	If no external forces do work on the system, and if no internal nonconservative forces do work, then the mechanical energy of the system is constant: $K_f + U_f = K_i + U_I$	7-12
4. Total Energy of a System	The energy of a system consists of mechanical energy E_{mech}, thermal energy E_{therm}, chemical energy E_{chem}, and other types of energy E_{other}, such as sound radiation and electromagnetic radiation: $E_{sys} = E_{mech} + E_{therm} + E_{chem} + E_{other}$	7-15
5. Conservation of Energy		
Universe	The total energy of the universe is constant. Energy can be transformed from one form to another, or transmitted from one region to another, but energy can never be created or destroyed.	

TOPIC	RELEVANT EQUATIONS AND REMARKS	
System	The energy of a system can be changed by work being done on the system and by energy transfer by heat. (These transfers include the emission or absorption of radiation.) The increase or decrease in the energy of the system can always be accounted for by the disappearance or appearance of some kind of energy somewhere else:	
	$E_{in} - E_{out} = \Delta E_{sys}$	7-14
Work–energy theorem	$W_{ext} = \Delta E_{sys} = \Delta E_{mech} + \Delta E_{therm} + \Delta E_{chem} + \Delta E_{other}$	7-16
6. Energy Dissipated by Friction	For a system that has a surface that slides on a second surface, the energy dissipated by friction on both surfaces equals the increase in thermal energy of the system and is given by	
	$f_k s_{rel} = \Delta E_{therm}$	7-24
	where s_{rel} is the distance one surface slides relative to the other.	
7. Problem Solving	The conservation of mechanical energy and the work–energy theorem can be used as an alternative to Newton's laws to solve mechanics problems that require the determination of the speed of a particle as a function of its position.	
8. Mass and Energy	A particle with mass m has an intrinsic rest energy E given by	
	$E = mc^2$	7-26
	where $c = 3 \times 10^8$ m/s is the speed of light in a vacuum. A system with mass M also has a rest energy $E = Mc^2$.If a system gains or loses internal energy ΔE, it simultaneously gains or loses mass ΔM, where $\Delta M = \Delta E/c^2$.	
Binding energy	The energy required to separate a bound system into its constituent parts is called its binding energy. The binding energy is ΔMc^2, where ΔM is the sum of the masses of the constituent parts, less the mass of the bound system.	
9. Newtonian Mechanics and Special Relativity	If the speed of a particle approaches the speed of light c (when the kinetic energy of the particle is significant in comparison to its rest energy), Newtonian mechanics breaks down, and must be replaced by Einstein's special theory of relativity.	
10. Energy Quantization	The internal energy of a bound system is found to have only a discrete set of possible values. For a system oscillating with frequency f, the allowed energy values are separated by an amount hf, where h is Planck's constant:	
	$h = 6.626 \times 10^{-34}\,\text{J}\cdot\text{s}$	7-29
Photons	Microscopic systems often exchange energy with their surroundings by emitting or absorbing electromagnetic radiation, which is also quantized. The quantum of energy of radiation is called the photon:	
	$E_{photon} = hf$	7-30
	where f is the frequency of the electromagnetic radiation.	

Answer to Concept Checks

7-1 On the you–Earth system no external work is done, so the total energy, which now includes gravitational potential energy, is conserved. The change in mechanical energy is mgh, so the work–energy theorem again gives $\Delta E_{chem} = -(mgh + \Delta E_{therm})$.

Answers to Practice Problems

7-1	$\oint_C \vec{F}\cdot d\vec{\ell} = -\frac{1}{2}Bx_{max}^2 y_{max}$
7-2	(*a*) 4.3 kJ, (b) 2.2 kJ, (*c*) −1.1 kJ
7-3	495 J
7-4	(*a*) 4.9 cm, (*b*) 0.72 J
7-5	3.16 m/s
7-6	None
7-7	53 m
7-8	(*a*) 1600 J, (*b*) 620 J, (*c*) 950 J
7-9	2.7×10^{-5}; 1.9×10^3 mi/s
7-10	$E_{n+1} - E_n = hf \approx (6.63 \times 10^{-34}\,\text{J}\cdot\text{s})(10^{14}\,\text{s}) \approx 6 \times 10^{-20}\,\text{J}$

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

For all problems, use 9.81 m/s^2 for the free-fall acceleration and neglect friction and air resistance unless instructed to do otherwise.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • Two cylinders of unequal mass are connected by a massless cord that passes over a frictionless pulley (Figure 7-34). After the system is released from rest, which of the following statements are true? (U is the gravitational potential energy and K is the kinetic energy of the system.) (*a*) $\Delta U < 0$ and $\Delta K > 0$, (*b*) $\Delta U = 0$ and $\Delta K > 0$, (*c*) $\Delta U < 0$ and $\Delta K = 0$, (*d*) $\Delta U = 0$ and $\Delta K = 0$, (*e*) $\Delta U > 0$ and $\Delta K < 0$. SSM

FIGURE 7-34
Problem 1

2 • Two stones are simultaneously thrown with the same initial speed from the roof of a building. One stone is thrown at an angle of 30° above the horizontal, the other is thrown horizontally. (Neglect effects due to air resistance.) Which statement below is true?
(*a*) The stones strike the ground at the same time and with equal speeds.
(*b*) The stones strike the ground at the same time with different speeds.
(*c*) The stones strike the ground at different times with equal speeds.
(*d*) The stones strike the ground at different times with different speeds.

3 • True or false:
(*a*) The total energy of a system cannot change.
(*b*) When you jump into the air, the floor does work on you, increasing your mechanical energy.
(*c*) Work done by frictional forces must always decrease the total mechanical energy of a system.
(*d*) Compressing a given spring 2.0 cm from its unstressed length takes more work than stretching it 2.0 cm from its unstressed length.

4 • As a novice ice hockey player (assume frictionless situation), you have not mastered the art of stopping except by coasting straight for the boards of the rink (assumed to be a rigid wall). Discuss the energy changes that occur as you use the boards to slow your motion to a stop.

5 • True or false (The particle in this question can move only along the x axis and is acted on by only one force, and $U(x)$ is the potential-energy function associated with this force.):
(*a*) The particle will be in equilibrium if it is at a location where $dU/dx = 0$.
(*b*) The particle will accelerate in the $-x$ direction if it is at a location where $dU/dx > 0$.
(*c*) The particle will both be in equilibrium and have constant speed if it is at a section of the x axis where $dU/dx = 0$ throughout the section.
(*d*) The particle will be in stable equilibrium if it is at a location where both $dU/dx = 0$ and $d^2U/dx^2 > 0$.
(*e*) The particle will be in neutral equilibrium if it is at a location where both $dU/dx = 0$ and $d^2U/dx^2 > 0$.

6 • Two knowledge seekers decide to ascend a mountain. Sal chooses a short, steep trail, while Joe, who weighs the same as Sal, chooses a long, gently sloped trail. At the top, they get into an argument about who gained more potential energy. Which of the following is true?
(*a*) Sal gains more gravitational potential energy than Joe.
(*b*) Sal gains less gravitational potential energy than Joe.
(*c*) Sal gains the same gravitational potential energy as Joe.
(*d*) To compare the gravitational potential energies, we must know the height of the mountain.
(*e*) To compare the gravitational potential energies, we must know the lengths of the two trails.

7 • True or false:
(*a*) Only conservative forces can do work.
(*b*) If only conservative forces act on a particle, the kinetic energy of the particle cannot change.
(*c*) The work done by a conservative force equals the change in the potential energy associated with that force.
(*d*) If, for a particle constrained to the x axis, the potential energy associated with a conservative force decreases as the particle moves to the right, then the force points to the left.
(*e*) If, for a particle constrained to the x axis, a conservative force points to the right, then the potential energy associated with the force increases as the particle moves to the left.

8 • Figure 7-35 shows the plot of a potential-energy function U versus x. (*a*) At each point indicated, state whether the x component of the force associated with this function is positive, negative, or zero. (*b*) At which point does the force have the greatest magnitude? (*c*) Identify any equilibrium points, and state whether the equilibrium is stable, unstable, or neutral.

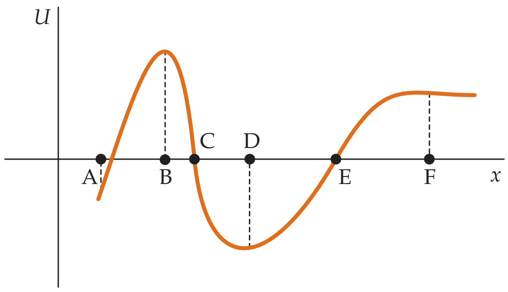

FIGURE 7-35 Problem 8

9 • Assume that, when the brakes are applied, a constant frictional force is exerted on the wheels of a car by the road. If that is so, then which of the following are necessarily true? (*a*) The distance the car travels before coming to rest is proportional to the speed of the car just as the brakes are first applied, (*b*) the car's kinetic energy diminishes at a constant rate, (*c*) the kinetic energy of the car is inversely proportional to the time that has elapsed since the application of the brakes, (*d*) none of the above.

10 •• If a rock is attached to a massless, rigid rod and swung in a vertical circle (Figure 7-36) at a constant speed, the total mechanical energy of the rock–Earth system does not remain constant. The kinetic energy of the rock remains constant, but the gravitational potential energy is continually changing. Is the total work done on the rock equal to zero during all time intervals? Does the force by the rod on the rock ever have a nonzero tangential component?

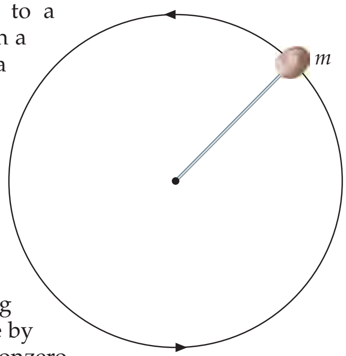

FIGURE 7-36 Problem 10

11 •• Use the rest energies given in Table 7-1 to answer the following questions. (*a*) Can the triton naturally decay into a helion? (*b*) Can the alpha particle naturally decay into helion plus a neutron? (*c*) Can the proton naturally decay into a neutron and a positron?

ESTIMATION AND APPROXIMATION

12 • Estimate (*a*) the change in your gravitational potential energy on taking an elevator from the ground floor to the top of the Empire State Building, (*b*) the average force exerted by the elevator on you during the trip, and (*c*) the average power delivered by that force. The building is 102 stories high. (You may need to estimate the time for the trip.)

13 • A tightrope walker whose mass is 50 kg walks across a tightrope held between two supports 10 m apart; the tension in the rope is 5000 N when she stands at the exact center of the rope. Estimate: (*a*) the sag in the tightrope when the acrobat stands in the exact center, and (*b*) the change in her gravitational potential energy from when she steps onto the tightrope to when she stands at its exact center.

14 •• **Biological Application** *The metabolic rate* is defined as the rate at which the body uses chemical energy to sustain its life functions. The average metabolic rate has been found to be proportional to the total skin surface area of the body. The surface area for a 5-ft, 10-in. male weighing 175 lb is about 2.0 m^2, and for a 5-ft, 4-in. female weighing 110 lb it is approximately 1.5 m^2. There is about a 1 percent change in surface area for every three pounds above or below the weights quoted here and a 1 percent change for every inch above or below the heights quoted. (*a*) Estimate your average metabolic rate over the course of a day using the following guide for metabolic rates (per square meter of skin area) for various physical activities: sleeping, 40 W/m^2; sitting, 60 W/m^2; walking, 160 W/m^2; moderate physical activity, 175 W/m^2; and moderate aerobic exercise, 300 W/m^2. How do your results compare to the power of a 100-W light bulb? (*b*) Express your average metabolic rate in terms of kcal/day (1 kcal = 4.19 kJ). (A kcal is the "food calorie" used by nutritionists.) (*c*) An estimate used by nutritionists is that each day the "average person" must eat roughly 12–15 kcal of food for each pound of body weight to maintain his or her weight. From the calculations in Part (*b*), are these estimates plausible?

15 •• **Biological Application** Assume that your maximum metabolic rate (the maximum rate at which your body uses its chemical energy) is 1500 W (about 2.7 hp). Assuming a 40 percent efficiency for the conversion of chemical energy into mechanical energy, estimate the following: (*a*) the shortest time you could run up four flights of stairs if each flight is 3.5 m high, (*b*) the shortest time you could climb the Empire State Building (102 stories high) using your Part (*a*) result. Comment on the feasibility of you actually achieving your Part (*b*) result. SSM

16 •• **Engineering Application, Context-Rich** You are in charge of determining when the uranium fuel rods in a local nuclear power plant are to be replaced with fresh ones. To make this determination, you decide to estimate how much the mass of a core of a nuclear-fueled electric-generating plant is reduced per unit of electric energy produced. (*Note:* In such a generating plant the reactor core generates thermal energy, which is then transformed to electric energy by a steam turbine. It requires 3.0 J of thermal energy for each 1.0 J of electric energy produced.) What are your results for the production of (*a*) 1.0 J of thermal energy? (*b*) enough electric energy to keep a 100-W light bulb burning for 10.0 y? (*c*) electric energy at a constant rate of 1.0 GW for a year? (This is typical of modern plants.)

17 •• **Engineering Application, Multistep** The chemical energy released by burning a gallon of gasoline is approximately 1.3×10^5 kJ. Estimate the total energy used by all of the cars in the United States during the course of one year. What fraction does this represent of the total energy use by the United States in one year (currently about 5×10^{20} J)? SSM

18 •• **Engineering Application** The maximum efficiency of a solar-energy panel in converting solar energy into useful electrical energy is currently about 12 percent. In a region such as the southwestern United States the solar intensity reaching Earth's surface is about 1.0 kW/m^2 on average during the day. Estimate the area that would have to be covered by solar panels in order to supply the energy requirements of the United States (approximately 5×10^{20} J/y) and compare it to the area of Arizona? Assume cloudless skies.

19 •• **Engineering Application** Hydroelectric power plants convert gravitational potential energy into more useful forms by flowing water downhill through a turbine system to generate electric energy. The Hoover Dam on the Colorado River is 211 m high and generates 4×10^9 kW·h/y. At what rate (in L/s) must water be flowing through the turbines to generate this power? The density of water is 1.00 kg/L. Assume a total efficiency of 90.0 percent in converting the water's potential energy into electrical energy.

FORCE, POTENTIAL ENERGY, AND EQUILIBRIUM

20 • Water flows over Victoria Falls, which is 128 m high, at a rate of 1.4×10^6 kg/s. If half the potential energy of this water were converted into electric energy, how much electric power would be produced by these falls?

21 • A 2.0-kg box slides down a long, frictionless incline of angle 30°. It starts from rest at time $t = 0$ at the top of the incline at a height of 20 m above the ground. (*a*) What is the potential energy of the box relative to the ground at $t = 0$? (*b*) Use Newton's laws to find the distance the box travels during the interval $0.0\text{ s} < t < 1.0\text{ s}$ and its speed at $t = 1.0$ s. (*c*) Find the potential energy and the kinetic energy of the box at $t = 1.0$ s. (*d*) Find the kinetic energy and the speed of the box just as it reaches the ground at the bottom of the incline.

22 • A constant force $F_x = 6.0$ N is in the $+x$ direction. (*a*) Find the potential-energy function $U(x)$ associated with this force if $U(x_0) = 0$. (*b*) Find a function $U(x)$ such that $U(4.0\text{ m}) = 0$. (*c*) Find a function $U(x)$ such that $U(6.0\text{ m}) = 14$ J.

23 • A spring has a force constant of 1.0×10^4 N/m. How far must the spring be stretched for its potential energy to equal (*a*) 50 J, and (*b*) 100 J?

24 • (*a*) Find the force F_x associated with the potential-energy function $U = Ax^4$, where A is a constant. (*b*) At what value(s) of x does the force equal zero?

25 •• The force F_x is associated with the potential-energy function $U = C/x$, where C is a positive constant. (*a*) Find the force F_x as a function of x. (*b*) Is this force directed toward the origin or away from it in the region $x > 0$? Repeat the question for the region $x < 0$? (*c*) Does the potential energy U increase or decrease as x increases in the region $x > 0$? (*d*) Answer Parts (*b*) and (*c*) where C is a negative constant. SSM

26 •• The force F_y is associated with the potential-energy function $U(y)$. On the potential-energy curve for U versus y, shown in Figure 7-37, the segments AB and CD are straight lines. Plot F_y versus y. Include numerical values, with units, on both axes. These values can be obtained from the U versus y plot.

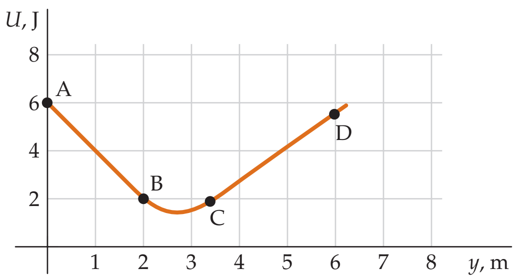

FIGURE 7-37 Problem 26

27 •• The force acting on an object is given by $F_x = a/x^2$. At $x = 5.0$ m, the force is known to point in the $-x$ direction and have a magnitude of 25 N. Determine the potential energy associated with this force as a function of x, assuming we assign a reference value of -10 J at $x = 2.0$ m for the potential energy.

28 •• The potential energy of an object constrained to the x axis is given by $U(x) = 3x^2 - 2x^3$, where U is in joules and x is in meters. (*a*) Determine the force F_x associated with this potential-energy function. (*b*) Assuming no other forces act on the object, at what positions is this object in equilibrium? (*c*) Which of these equilibrium positions are stable and which are unstable?

29 •• The potential energy of an object constrained to the x axis is given by $U(x) = 8x^2 - x^4$, where U is in joules and x is in meters. (*a*) Determine the force F_x associated with this potential-energy function. (*b*) Assuming no other forces act on the object, at what positions is this object in equilibrium? (*c*) Which of these equilibrium positions are stable and which are unstable? SSM

30 •• The net force acting on an object constrained to the x axis is given by $F_x(x) = x^3 - 4x$. (The force is in newtons and x in meters.) Locate the positions of unstable and stable equilibrium. Show that each position is stable or unstable by calculating the force one millimeter on either side of the locations.

31 •• The potential energy of a 4.0-kg object constrained to the x axis is given by $U = 3x^2 - x^3$ for $x \leq 3.0$ m and $U = 0$ for $x \geq 3.0$ m, where U is in joules and x is in meters, and the only force acting on this object is the force associated with this potential-energy function. (*a*) At what positions is this object in equilibrium? (*b*) Sketch a plot of U versus x. (*c*) Discuss the stability of the equilibrium for the values of x found in Part (*a*). (*d*) If the total mechanical energy of the particle is 12 J, what is its speed at $x = 2.0$ m?

32 •• A force is given by $F_x = Ax^{-3}$, where $A = 8.0\text{ N}\cdot\text{m}^3$. (*a*) For positive values of x, does the potential energy associated with this force increase or decrease with increasing x? (You can determine the answer to this question by imagining what happens to a particle that is placed at rest at some point x and is then released.) (*b*) Find the potential-energy function U associated with this force such that U approaches zero as x approaches infinity. (*c*) Sketch U versus x.

33 •• **MULTISTEP** A straight rod of negligible mass is mounted on a frictionless pivot, as shown in Figure 7-38. Blocks having masses m_1 and m_2 are attached to the rod at distances ℓ_1 and ℓ_2. (*a*) Write an expression for the gravitational potential energy of the blocks–Earth system as a function of the angle θ made by the rod and the horizontal. (*b*) For what angle θ is this potential energy a minimum? Is the statement "systems tend to move toward a configuration of minimum potential energy" consistent with your result? (*c*) Show that if $m_1\ell_1 = m_2\ell_2$, the potential energy is the same for all values of θ. (When this holds, the system will balance at any angle θ. This result is known as *Archimedes' law of the lever*.) SSM

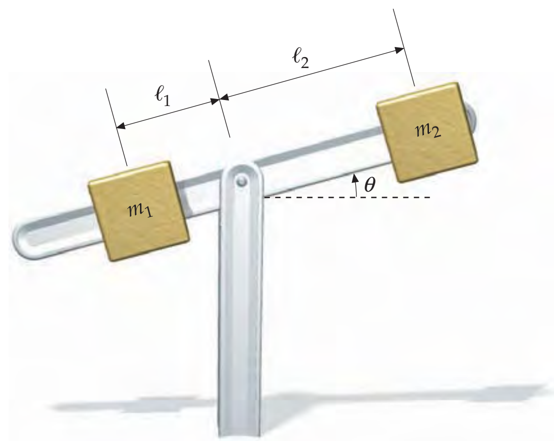

FIGURE 7-38 Problem 33

34 •• An Atwood's machine (Figure 7-39) consists of masses m_1 and m_2, and a pulley of negligible mass and friction. Starting from rest, the speed of the two masses is 4.0 m/s at the end of 3.0 s. At that time, the kinetic energy of the system is 80 J and each mass has moved a distance of 6.0 m. Determine the values of m_1 and m_2.

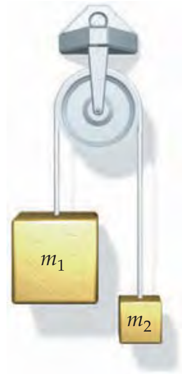

FIGURE 7-39 Problem 34

35 ••• **ENGINEERING APPLICATION, MULTISTEP** You have designed a novelty desk clock, as shown in Figure 7-40. You are worried that it is not ready for market because the clock itself might be in an unstable equilibrium configuration. You decide to apply your knowledge of potential energies and equilibrium conditions and analyze the situation. The clock (mass m) is supported by two light cables running over the two frictionless pulleys of negligible diameter, which are attached to counterweights that each have mass M. (*a*) Find the potential energy of the system as a function of the distance y. (*b*) Find the value of y for which the potential energy of the system is a minimum. (*c*) If the potential energy is a minimum, then the system is in equilibrium. Apply Newton's second law to the clock and show that it is in equilibrium (the forces on it sum to zero) for the value of y obtained for Part (*b*). (*d*) Finally, determine whether you are going to be able to market this gadget: is this a point of stable or unstable equilibrium?

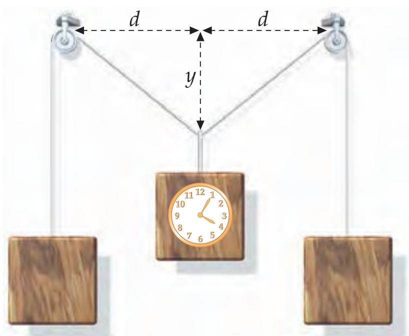

FIGURE 7-40 Problem 35

THE CONSERVATION OF MECHANICAL ENERGY

36 • A block of mass m on a horizontal frictionless tabletop is pushed against a horizontal spring, compressing it a distance x, and the block is then released. The spring propels the block along the tabletop, giving a speed v. The same spring is then used to propel a second block of mass $4m$, giving it a speed $3v$. What distance was the spring compressed in the second case? Express your answer in terms of x.

37 • A simple pendulum of length L with a bob of mass m is pulled aside until the bob is at a height $L/4$ above its equilibrium position. The bob is then released. Find the speed of the bob as it passes through the equilibrium position. Neglect any effects due to air resistance.

38 • A 3.0-kg block slides along a frictionless horizontal surface with a speed of 7.0 m/s (Figure 7-41). After sliding a distance of 2.0 m, the block makes a smooth transition to a frictionless ramp inclined at an angle of 40° to the horizontal. What distance along the ramp does the block slide before coming momentarily to rest?

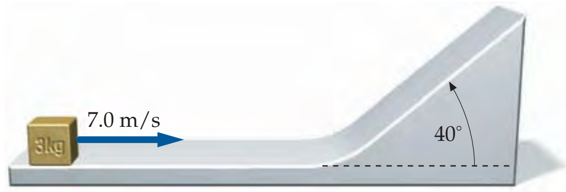

FIGURE 7-41 Problems 38 and 64

39 • The 3.00-kg object in Figure 7-42 is released from rest at a height of 5.00 m on a curved frictionless ramp. At the foot of the ramp is a spring of force constant 400 N/m. The object slides down the ramp and into the spring, compressing it a distance x before coming momentarily to rest. (*a*) Find x. (*b*) Describe the motion of the object (if any) after the block momentarily comes to rest?

FIGURE 7-42 Problem 39

40 • **ENGINEERING APPLICATION, CONTEXT-RICH** You are designing a game for small children and want to see if the ball's maximum speed is sufficient to require the use of goggles. In your game, a 15.0-g ball is to be shot from a spring gun whose spring has a force constant of 600 N/m. The spring will be compressed 5.00 cm when in use. How fast will the ball be moving as it leaves the gun and how high will the ball go if the gun is aimed vertically upward? What would be your recommendation on the use of goggles?

41 • A 16-kg child on a 6.0-m-long playground swing moves with a speed of 3.4 m/s when the swing seat passes through its lowest point. What is the angle that the swing makes with the vertical when the swing is at its highest point? Assume that the effects due to air resistance are negligible, and assume that the child is not pumping the swing. SSM

42 •• The system shown in Figure 7-43 is initially at rest when the lower string is cut. Find the speed of the objects when they are momentarily at the same height. The frictionless pulley has negligible mass.

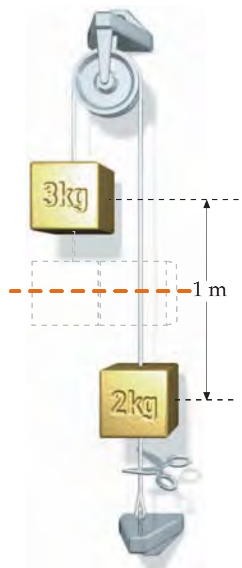

FIGURE 7-43 Problem 42

43 •• A block of mass m rests on an inclined plane (Figure 7-44). The coefficient of static friction between the block and the plane is μ_s. A gradually increasing force is pulling down on the spring (force constant k). Find the potential energy U of the spring (in terms of the given symbols) at the moment the block begins to move.

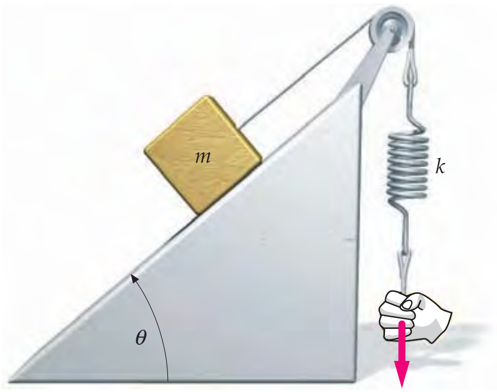

FIGURE 7-44 Problem 43

44 •• A 2.40-kg block is dropped onto a spring and platform (Figure 7-45) of negligible mass. The block is released a distance of 5.00 m above the platform. When the block is momentarily at rest, the spring is compressed by 25.0 cm. Find the speed of the block when the compression of the spring is only 15.0 cm.

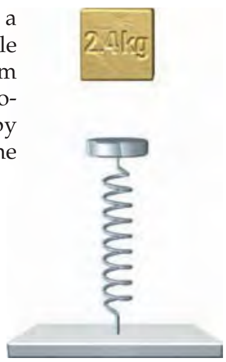

FIGURE 7-45 Problem 44

45 •• A ball at the end of a string moves in a vertical circle with constant mechanical energy E. What is the difference between the tension at the bottom of the circle and the tension at the top? SSM

46 •• A girl of mass m is taking a picnic lunch to her grandmother. She ties a rope of length R to a tree branch over a creek and starts to swing from rest at a point that is a distance $R/2$ lower than the branch. What is the minimum breaking tension for the rope if it is not to break and drop the girl into the creek?

47 •• A 1500-kg roller coaster car starts from rest at a height $H = 23.0$ m (Figure 7-46) above the bottom of a 15.0-m-diameter loop. If friction is negligible, determine the downward force of the rails on the car when the upside-down car is at the top of the loop.

FIGURE 7-46 Problem 47

48 •• A single roller-coaster car is moving with speed v_0 on the first section of track when it descends a 5.0-m-deep valley, then climbs to the top of a hill that is 4.5 m above the first section of track. Assume any effects of friction or of air resistance are negligible. (*a*) What is the minimum speed v_0 required if the car is to travel beyond the top of the hill? (*b*) Can we affect this speed by changing the depth of the valley to make the coaster pick up more speed at the bottom? Explain.

49 •• The Gravitron single-car roller coaster consists of a single loop-the-loop. The car is initially pushed, giving it just the right mechanical energy so the riders on the coaster will feel "weightless" when they pass through the top of the circular arc. How heavy will they feel when they pass through the bottom of the arc (that is, what is the normal force pressing up on them when they are at the bottom of the loop)? Express the answer as a multiple of mg (their actual weight). Assume any effects of friction or of air resistance are negligible.

50 •• A stone is thrown upward at an angle of 53° above the horizontal. Its maximum height above the release point is 24 m. What was the stone's initial speed? Assume any effects of air resistance are negligible.

51 •• A 0.17-kg baseball is launched from the roof of a building 12 m above the ground. Its initial velocity is 30 m/s at 40° above the horizontal. Assume any effects of air resistance are negligible. (*a*) What is the maximum height above the ground that the ball reaches? (*b*) What is the speed of the ball as it strikes the ground?

52 •• An 80-cm-long pendulum with a 0.60-kg bob is released from rest at an initial angle of θ_0 with the vertical. At the bottom of the swing, the speed of the bob is 2.8 m/s. (*a*) What is θ_0? (*b*) What angle does the pendulum make with the vertical when the speed of the bob is 1.4 m/s? Is this angle equal to $\frac{1}{2}\theta_0$? Explain why or why not.

53 •• The Royal Gorge bridge over the Arkansas River is 310 m above the river. A 60-kg bungee jumper has an elastic cord with an unstressed length of 50 m attached to her feet. Assume that, like an ideal spring, the cord is massless and provides a linear restoring force when stretched. The jumper leaps, and at at her lowest point she barely touches the water. After numerous ascents and descents, she comes to rest at a height h above the water. Model the jumper as a point particle and assume that any effects of air resistance are negligible. (*a*) Find h. (*b*) Find the maximum speed of the jumper.

54 •• A pendulum consists of a 2.0-kg bob attached to a light 3.0-m-long string. While hanging at rest with the string vertical, the bob is struck a sharp horizontal blow, giving it a horizonal velocity of 4.5 m/s. At the instant the string makes an angle of 30° with the vertical, what is (*a*) the speed, (*b*) the gravitational potential energy (relative to its value is at the lowest point), and (*c*) the tension in the string? (*d*) What is the angle of the string with the vertical when the bob reaches its greatest height?

55 •• A pendulum consists of a string of length L and a bob of mass m. The bob is rotated until the string is horizontal. The bob is then projected downward with the minimum initial speed needed to enable the bob to make a full revolution in the vertical plane. (*a*) What is the maximum kinetic energy of the bob? (*b*) What is the tension in the string when the kinetic energy is maximum? SSM

56 •• A child whose weight is 360 N swings out over a pool of water using a rope attached to the branch of a tree at the edge of the pool. The branch is 12 m above ground level and the surface of the water is 1.8 m below ground level. The child holds onto the rope at a point 10.6 m from the branch and moves back until the angle between the rope and the vertical is 23°. When the rope is in the vertical position, the child lets go and drops into the pool. Find the speed of the child just as he impacts the surface of the water.

(Model the child as a point particle attached to the rope 10.6 m from the branch.)

57 •• Walking by a pond, you find a rope attached to a stout tree limb that is 5.2 m above ground level. You decide to use the rope to swing out over the pond. The rope is a bit frayed, but supports your weight. You estimate that the rope might break if the tension is 80 N greater than your weight. You grab the rope at a point 4.6 m from the limb and move back to swing out over the pond. (Model yourself as a point particle attached to the rope 4.6 m from the limb.) (*a*) What is the maximum safe initial angle between the rope and the vertical at which it will not break during the swing? (*b*) If you begin at this maximum angle, and the surface of the pond is 1.2 m below the level of the ground, with what speed will you enter the water if you let go of the rope when the rope is vertical?

58 ••• A pendulum bob of mass m is attached to a light string of length L and is also attached to a spring of force constant k. With the pendulum in the position shown in Figure 7-47, the spring is at its unstressed length. If the bob is now pulled aside so that the string makes a *small* angle θ with the vertical and released, what is the speed of the bob as it passes through the equilibrium position? *Hint: Recall the small-angle approximations: if θ is expressed in radians, and if* $|\theta| \ll 1$, *then* $\sin\theta \approx \tan\theta \approx \theta$ *and* $\cos\theta \approx 1 - \frac{1}{2}\theta^2$.

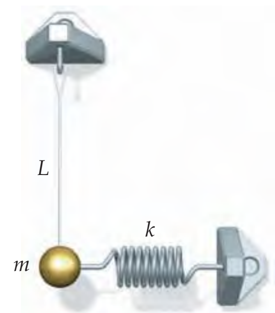

FIGURE 7-47 Problem 58

59 ••• A pendulum is suspended from the ceiling and attached to a spring fixed to the floor directly below the pendulum support (Figure 7-48). The mass of the pendulum bob is m, the length of the pendulum is L, and the force constant is k. The unstressed length of the spring is $L/2$ and the distance between the floor and ceiling is $1.5L$. The pendulum is pulled aside so that it makes an angle θ with the vertical and is then released from rest. Obtain an expression for the speed of the pendulum bob as the bob passes through a point directly below the pendulum support. SSM

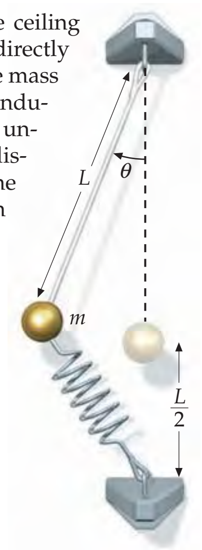

FIGURE 7-48 Problem 59

TOTAL ENERGY AND NONCONSERVATIVE FORCES

60 • In a volcanic eruption, 4.00 km^3 of mountain with an average density of 1600 kg/m^3 was raised an average height of 500 m. (*a*) What is the minimum amount of energy, in joules, that was released during this eruption? (*b*) The energy released by thermonuclear bombs is measured in megatons of TNT, where 1 megaton of TNT $= 4.2 \times 10^{15}$ J. Convert your answer for Part (*a*) to megatons of TNT.

61 • **CONTEXT-RICH** To work off a large pepperoni pizza you ate on Friday night, on Saturday morning you climb a 120-m-high hill. (*a*) Assuming a reasonable value for your mass, determine your increase in gravitational potential energy. (*b*) Where does this energy come from? (*c*) The human body is typically 20 percent efficient. How much energy was converted into thermal energy? (*d*) How much chemical energy is expended by you during the climb? Given that oxidation (burning) of a single slice of pepperoni pizza releases about 1.0 MJ (250 food calories) of energy, do you think one climb up the hill is enough?

62 • A 2000-kg car moving at an initial speed of 25 m/s along a horizontal road skids to a stop in 60 m. (*a*) Find the energy dissipated by friction. (*b*) Find the coefficient of kinetic friction between the tires and the road. (*Note*: When stopping without skidding and using conventional brakes, 100 percent of the kinetic energy is dissipated by friction within the brakes. With regenerative braking, such as that used in hybrid vehicles, only 70 percent of the kinetic energy is dissipated.)

63 • An 8.0-kg sled is initially at rest on a horizontal road. The coefficient of kinetic friction between the sled and the road is 0.40. The sled is pulled a distance of 3.0 m by a force of 40 N applied to the sled at an angle of 30° above the horizontal. (*a*) Find the work done by the applied force. (*b*) Find the energy dissipated by friction. (*c*) Find the change in the kinetic energy of the sled. (*d*) Find the speed of the sled after it has traveled 3.0 m.

64 •• Using Figure 7-41, suppose that the surfaces described are not frictionless and that the coefficient of kinetic friction between the block and the surfaces is 0.30. The block has an initial speed of 7.0 m/s and slides 2.0 m before reaching the ramp. Find (*a*) the speed of the block when it reaches the ramp, and (*b*) the distance that the block slides along the inclined surface before coming momentarily to rest. (Neglect any energy dissipated along the transition curve.)

65 •• The 2.0-kg block in Figure 7-49 slides down a frictionless curved ramp, starting from rest at a height of 3.0 m. The block then slides 9.0 m on a rough horizontal surface before coming to rest. (*a*) What is the speed of the block at the bottom of the ramp? (*b*) What is the energy dissipated by friction? (*c*) What is the coefficient of kinetic friction between the block and the horizontal surface? SSM

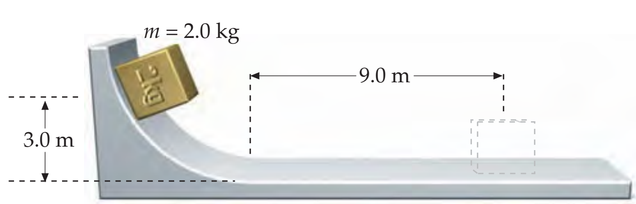

FIGURE 7-49 Problem 65

66 •• A 20-kg girl slides down a playground slide with a vertical drop of 3.2 m. When she reaches the bottom of the slide, her speed is 1.3 m/s. (*a*) How much energy was dissipated by friction? (*b*) If the slide is inclined at 20° with the horizontal, what is the coefficient of kinetic friction between the girl and the slide?

67 •• In Figure 7-50, the coefficient of kinetic friction between the 4.0-kg block and the shelf is 0.35. (*a*) Find the energy dissipated by friction when the 2.0-kg block falls a distance y. (*b*) Find the change in the mechanical energy E_{mech} of the two-block–Earth system during the time it takes the 2.0-kg block to fall a distance y. (*c*) Use your result for Part (*b*) to find the speed of either block after the 2.0-kg block falls 2.0 m.

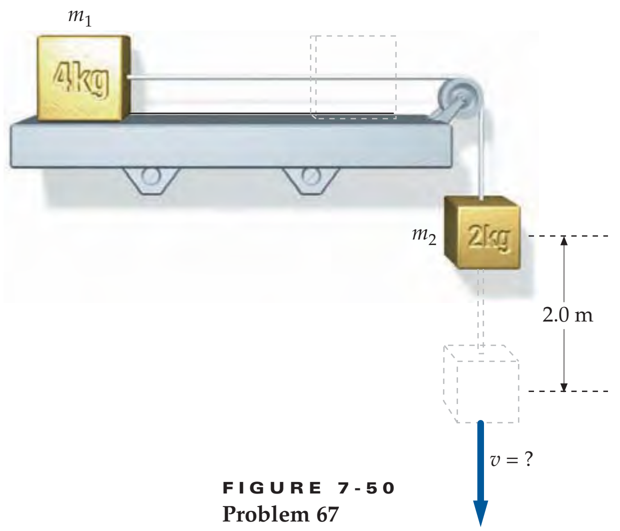

FIGURE 7-50 Problem 67

68 •• A small object of mass m moves in a horizontal circle of radius r on a rough table. It is attached to a horizontal string fixed at the center of the circle. The speed of the object is initially v_0. After completing one full trip around the circle, the speed of the object is $0.5v_0$. (*a*) Find the energy dissipated by friction during that one revolution in terms of m, v_0, and r. (*b*) What is the coefficient of kinetic friction? (*c*) How many more revolutions will the object make before coming to rest?

69 •• The initial speed of a 2.4-kg box traveling up a plane inclined 37° to the horizontal is 3.8 m/s. The coefficient of kinetic friction between the box and the plane is 0.30. (*a*) How far along the incline does the box travel before coming to a stop? (*b*) What is its speed when it has traveled half the distance found in Part (*a*)? SSM

70 ••• A block of mass m rests on a plane inclined at an angle θ with the horizontal (Figure 7-51). A spring with force constant k is attached to the block. The coefficient of static friction between the block and plane is μ_s. The spring is pulled upward along the plane very slowly. (*a*) What is the extension of the spring the instant the block begins to move? (*b*) The block stops moving just as the extension of the contracting spring reaches zero. Express μ_k (the coefficient of kinetic friction) in terms of μ_s and θ.

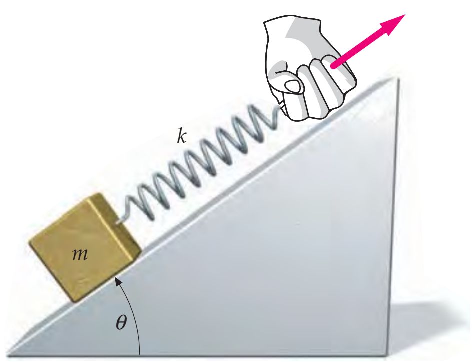

FIGURE 7-51 Problem 70

MASS AND ENERGY

71 • (*a*) Calculate the rest energy of 1.0 g of dirt. (*b*) If you could convert this energy completely into electrical energy and sell it for \$0.10/kW·h, how much money would you take in? (*c*) If you could power a 100-W light bulb with this energy, for how long could you keep the bulb lit?

72 • One kiloton of TNT, when detonated, yields an explosive energy of roughly 4×10^{12} J. How much less is the total mass of the bomb remnants after the explosion than before? If you could find and reassemble the pieces, would this loss of mass be noticeable?

73 • **CONCEPTUAL** Calculate your rest energy in both mega electron-volts and joules. If that energy could be converted completely to the kinetic energy of your car, estimate its speed. Use the nonrelativistic expression for kinetic energy and comment on whether or not your answer justifies using the nonrelativistic expression for kinetic energy.

74 • If a black hole and a "normal" star orbit each other, gases from the normal star falling into the black hole can have their temperature increased by millions of degrees due to frictional heating. When the gases are heated that much, they begin to radiate light in the X-ray region of the electromagnetic spectrum (high-energy light photons). Cygnus X-1, the second strongest known X-ray source in the sky, is thought to be one such binary system; it radiates at an estimated power of 4×10^{31} W. If we assume that 1.0 percent of the in-falling mass escapes as X ray energy, at what rate is the black hole gaining mass?

75 • **ENGINEERING APPLICATION** You are designing the fuel requirements for a small fusion electric-generating plant. Assume 33 percent conversion to electric energy. For the deuterium–tritium (D–T) fusion reaction in Example 7-18, calculate the number of reactions per second that are necessary to generate 1.00 kW of electric power. SSM

76 • Use Table 7-1 to calculate the energy needed to remove one neutron from a stationary alpha particle, leaving a stationary helion plus a neutron with a kinetic energy of 1.5 MeV.

77 • A free neutron can decay into a proton plus an electron and an electron antineutrino [an electron antineutrino (symbol $\bar{\nu}_e$) is a nearly massless elementary particle]: $n \rightarrow p + e^- + \bar{\nu}_e$. Use Table 7-1 to calculate the energy released during this reaction.

78 •• During one type of nuclear fusion reaction, two deuterons combine to produce an alpha particle. (*a*) How much energy is released during this reaction? (*b*) How many such reactions must take place per second to produce 1 kW of power?

79 •• A large nuclear power plant produces 1000 MW of electrical power by nuclear fission. (*a*) By how many kilograms does the mass of the nuclear fuel decrease in one year? (Assume an efficiency of 33 percent for a nuclear power plant.) (*b*) In a coal-burning power plant, each kilogram of coal releases 31 MJ of thermal energy when burned. How many kilograms of coal are needed each year for a 1000-MW coal-burning power plant? (Assume an efficiency of 38 percent for a coal-burning power plant.)

QUANTIZATION OF ENERGY

80 •• A mass on the end of a spring with a force constant of 1000 N/kg oscillates at a frequency of 2.5 oscillations per second. (*a*) Determine the quantum number, n, of the state it is in if it has a total energy of 10 J. (*b*) What is its ground state energy?

81 •• Repeat Problem 80, but consider instead an atom in a solid vibrating at a frequency of 1.00×10^{14} oscillations per second and having a total energy of 2.7 eV.

GENERAL PROBLEMS

82 • A block of mass m, starting from rest, is pulled up a frictionless inclined plane that makes an angle θ with the horizontal by a string parallel to the plane. The tension in the string is T. After traveling a distance L, the speed of the block is v_f. Derive an expression for work done by the tension force.

83 • A block of mass m slides with constant speed v down a plane inclined at angle θ with the horizontal. Derive an expression for the energy dissipated by friction during the time interval Δt.

84 • In particle physics, the potential energy associated with a pair of quarks bound together by the strong nuclear force is in one particular theoretical model written as the following function: $U(r) = -(\alpha/r) + kr$, where k and α are positive constants, and r is the distance of separation between the two quarks.* (*a*) Sketch the general shape of the potential-energy function. (*b*) What is a general form for the force each quark exerts on the other? (*c*) At the two extremes of very small and very large values of r, what does the force simplify to?

85 • **ENGINEERING APPLICATION, CONTEXT-RICH** You are in charge of "solar-energizing" your grandfather's farm. At the farm's location, an average of $1.0\,\mathrm{kW/m^2}$ reaches the surface during the daylight hours on a clear day. If this could be converted at 25 percent efficiency to electric energy, how large a collection area would you need to run a 4.0-hp irrigation water pump during the daylight hours? SSM

86 •• **ENGINEERING APPLICATION** The radiant energy from the Sun that reaches Earth's orbit is $1.35\,\mathrm{kW/m^2}$. (*a*) Even when the Sun is directly overhead and under dry desert conditions, 25 percent of this energy is absorbed and/or reflected by the atmosphere before it reaches Earth's surface. If the average frequency of the electromagnetic radiation from the Sun is 5.5×10^{14} Hz, how many photons per second would be incident upon a 1.0-m^2 solar panel? (*b*) Suppose the efficiency of the panels for converting the radiant energy to electrical energy and delivering it is a highly efficient 10.0 percent. How large a solar panel is needed to supply the needs of a 5.0-hp solar-powered car (assuming the car runs directly off the solar panel and not batteries) during a race in Cairo at noon on March 21? (*c*) Assuming a more-realistic efficiency of 3.3 percent and panels capable of rotating to be always perpendicular to the sunlight, how large an array of solar panels is needed to supply the power needs of the International Space Station (ISS)? The ISS requires about 110 kW of continuous electric power.

87 •• In 1964, after the 1250-kg jet-powered car *Spirit of America* lost its parachute and went out of control during a run at Bonneville Salt Flats, Utah, it left skid marks about 8.00 km long. (This earned a place in the Guinness Book of World Records for longest skid marks.) (*a*) If the car was moving initially at a speed of about 800 km/h, and was still going at about 300 km/h when it crashed into a brine pond, estimate the coefficient of kinetic friction μ_k. (*b*) What was the kinetic energy of the car 60 s after the skid began?

88 •• **ENGINEERING APPLICATION, CONTEXT-RICH** A T-bar tow is planned in a new ski area. At any one time, it will be required, to pull a maximum of 80 skiers up a 600-m slope inclined at 15° above the horizontal at a speed of 2.50 m/s. The coefficient of kinetic friction between the skiers skis and the snow is typically 0.060. As the manager of the facility, what motor power should you request of the construction contractor if the mass of the average skier is 75.0 kg. Assume you want to be ready for any emergency and will order a motor whose power rating is 50 percent larger than the bare minimum.

89 •• **MULTISTEP** A box of mass m on the floor is connected to a horizontal spring of force constant k (Figure 7-52). The coefficient of kinetic friction between the box and the floor is μ_k. The other end of the spring is connected to a wall. The spring is initially unstressed. If the box is pulled away from the wall a distance d_0 and released, the box slides toward the wall. Assume the box does not slide so far that the coils of the spring touch. (*a*) Obtain an expression for the distance d_1 the box slides before it first comes to a stop. (*b*) Assuming $d_1 > d_0$, obtain an expression for the speed of the box when it has slid a distance d_0 following the release. (*c*) Obtain the special value of μ_k such that $d_1 = d_0$.

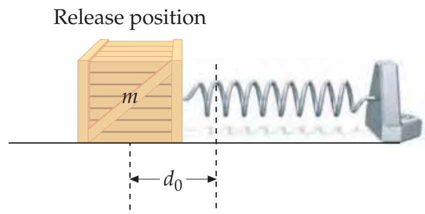

FIGURE 7-52 Problem 89

90 •• **ENGINEERING APPLICATION, CONTEXT-RICH** You operate a small grain elevator near Champaign, Illinois. One of your silos uses a bucket elevator that carries a full load of 800 kg through a vertical distance of 40 m. (A bucket elevator works with a continuous belt, like a conveyor belt.) (*a*) What is the power provided by the electric motor powering the bucket elevator when the bucket elevator ascends with a full load at a speed of 2.3 m/s? (*b*) Assuming the motor is 85 percent efficient, how much does it cost you to run this elevator, per day, assuming it runs 60 percent of the time between 7:00 a.m. and 7:00 p.m. with an average load of 85 percent of a full load? Assume the cost of electric energy in your location is 15 cents per kilowatt hour.

91 •• **ENGINEERING APPLICATION** To reduce the power requirement of elevator motors, elevators are counterbalanced with weights connected to the elevator by a cable that runs over a pulley at the top of the elevator shaft. Neglect any effects of friction in the pulley. If a 1200-kg elevator that carries a maximum load of 800 kg is counterbalanced with a mass of 1500 kg, (*a*) what is the power provided by the motor when the elevator ascends fully loaded at a speed of 2.3 m/s? (*b*) How much power is provided by the motor when the elevator ascends at 2.3 m/s without a load?

92 •• In old science fiction movies, writers attempted to come up with novel ways of launching spacecraft toward the moon. In one hypothetical case, a screenwriter envisioned launching a moon probe from a deep, smooth tunnel, inclined at 65.0° above the horizontal. At the bottom of the tunnel a very stiff spring designed to launch the craft was anchored. The top of the spring, when the spring is unstressed, is 30.0 m from the upper end of the tunnel. The screenwriter knew from his research that to reach the moon, the 318-kg probe should have a speed of at least 11.2 km/s when it exits the tunnel. If the spring is compressed by 95.0 m just before launch, what is the minimum value for its force constant to achieve a successful launch? Neglect friction with the tunnel walls and floor.

* This is known as the "Cornell potential," developed in *Physical Review Letters*. Make reference here also to the 2004 Nobel Prize to Gross, Wilczek, and Politzer.

93 •• In a volcanic eruption, a 2-kg piece of porous volcanic rock is thrown straight upward with an initial speed of 40 m/s. It travels upward a distance of 50 m before it begins to fall back to Earth. (*a*) What is the initial kinetic energy of the rock? (*b*) What is the increase in thermal energy due to air resistance during ascent? (*c*) If the increase in thermal energy due to air resistance on the way down is 70 percent of that on the way up, what is the speed of the rock when it returns to its initial position? SSM

94 •• A block of mass m starts from rest at a height h and slides down a frictionless plane inclined at angle θ with the horizontal, as shown in Figure 7-53. The block strikes a spring of force constant k. Find the distance the spring is compressed when the block momentarily stops.

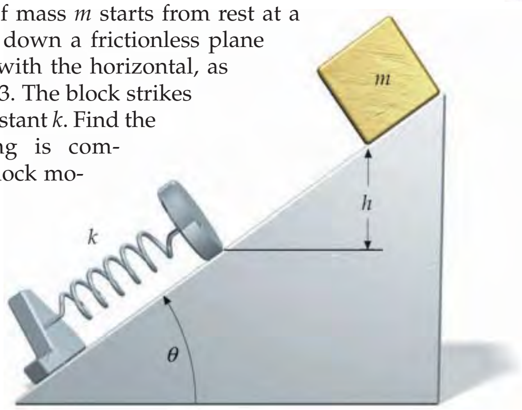

FIGURE 7-53 Problem 94

95 •• **SPREADSHEET** A block of mass m is suspended from a wall bracket by a spring and is free to move vertically (Figure 7-54). The $+y$ direction is downward and the origin is at the position of the block when the spring is unstressed. (*a*) Show that the potential energy as a function of position may be expressed as $U = \frac{1}{2}ky^2 - mgy$. (*b*) Using a **spreadsheet** program or graphing calculator, make a graph of U as a function of y, with $k = 2\text{ N/m}$ and $mg = 1\text{ N}$. (*c*) Explain how this graph shows that there is a position of stable equilibrium for a positive value of y. Using the Part (*a*) expression for U, determine (symbolically) the value of y when the block is at its equilibrium position. (*d*) From the expression for U, find the net force acting on m at any position y. (*e*) The block is released from rest with the spring unstressed; if there is no friction, what is the maximum value of y that will be reached by the mass? Indicate y_{max} on your graph/spreadsheet. SSM

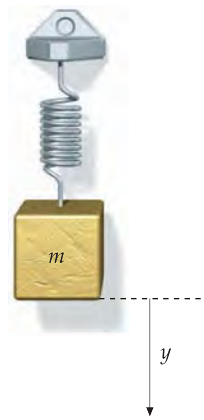

FIGURE 7-54 Problem 95

96 •• A spring-loaded gun is cocked by compressing a short, strong spring by a distance d. It fires a signal flare of mass m directly upward. The flare has speed v_0 as it leaves the spring and is observed to rise to a maximum height h above the point where it leaves the spring. After it leaves the spring, effects of drag force by the air on the flare are significant. (Express answers in terms of m, v_0, d, h, and g.) (*a*) How much work is done on the spring during the compression? (*b*) What is the value of the force constant k? (*c*) Between the time of firing and the time at which maximum elevation is reached, how much mechanical energy is dissipated into thermal energy?

97 •• **ENGINEERING APPLICATION, CONTEXT-RICH** Your firm is designing a new roller-coaster ride. The permit process requires the calculation of forces and accelerations at various important locations on the ride. Each roller-coaster car will have a total mass (including passengers) of 500 kg and will travel freely along the winding frictionless track shown in Figure 7-55. Points A, E, and G are on horizontal straight sections, all at the same height of 10 m above the ground. Point C is at a height of 10 m above the ground on an inclined section of slope angle 30°. Point B is at the crest of a hill, while point D is at ground level at the bottom of a valley; the radius of curvature at both of these points is 20 m. Point F is at the middle of a banked horizontal curve with a radius of curvature of 30 m, and at the same height as points A, E, and G. At point A the speed of the car is 12 m/s. (*a*) If the car is just barely to make it over the hill at point B, what must be the height of point B above the ground? (*b*) If the car is to just barely make it over the hill at point B, what should be the magnitude of the force exerted by the track on the car at that point? (*c*) What will be the acceleration of the car at point C? (*d*) What will be the magnitude and direction of the force exerted by the track on the car at point D? (*e*) What will be the magnitude and direction of the force exerted by the track on the car at point F? (*f*) At point G a constant braking force is to be applied to the car, bringing it to a halt in a distance of 25 m. What is the magnitude of this required braking force?

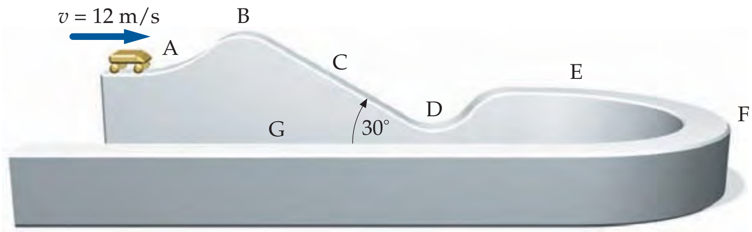

FIGURE 7-55 Problem 97

98 •• **ENGINEERING APPLICATION** The cable of a 2000-kg elevator has broken, and the elevator is moving downward at a steady speed of 1.5 m/s. A safety braking system that works on friction prevents the downward speed from increasing. (*a*) At what rate is the braking system converting mechanical energy to thermal energy? (*b*) While the elevator is moving downward at 1.5 m/s, the braking system fails and the elevator is in free-fall for a distance of 5.0 m before hitting the top of a large safety spring with force constant of 1.5×10^4 N/m. After the elevator hits the top of the spring, find the distance d that the spring is compressed before the elevator is brought to rest.

99 ••• **ENGINEERING APPLICATION, CONTEXT-RICH** To measure the combined force of friction (rolling friction plus air drag) on a moving car, an automotive engineering team you are on turns off the engine and allows the car to coast down hills of known steepness. The team collects the following data: (1) On a 2.87° hill, the car can coast at a steady 20 m/s. (2) On a 5.74° hill, the steady coasting speed is 30 m/s. The total mass of the car is 1000 kg. (*a*) What is the magnitude of the combined force of friction at 20 m/s (F_{20}) and at 30 m/s (F_{30})? (*b*) How much power must the engine deliver to drive the car on a level road at steady speeds of 20 m/s (P_{20}) and 30 m/s (P_{30})? (*c*) The maximum power the engine can deliver is 40 kW. What is the angle of the steepest incline up which the car can maintain a steady 20 m/s? (*d*) Assume that the engine delivers the same total useful work from each liter of gas, no matter what the speed. At 20 m/s on a level road, the car gets 12.7 km/L. How many kilometers per liter does it get if it goes 30 m/s instead? SSM

100 •• **ENGINEERING APPLICATION** (*a*) Calculate the kinetic energy of a 1200-kg car moving at 50 km/h. (*b*) If friction (rolling friction and air drag) results in a retarding force of 300 N at a speed of 50 km/h, what is the minimum energy needed to move the car a distance of 300 m at a constant speed of 50 km/h?

101 ••• A pendulum consists of a small bob of mass m attached to a string of length L. The bob is held to the side with the string horizontal (see Figure 7-56). Then the bob is released from rest. At the lowest point of the swing, the string catches on a thin peg a distance R above the lowest point. Show that R must be smaller than $2L/5$ if the string is to remain taut as the bob swings around the peg in a full circle.

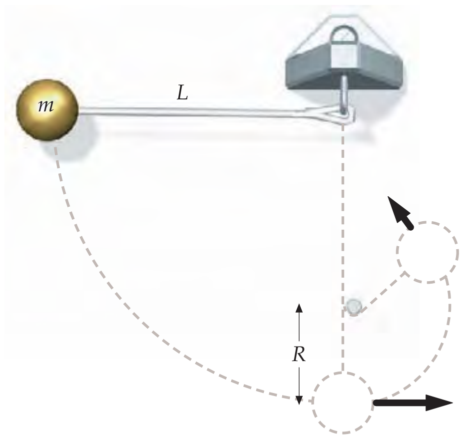

FIGURE 7-56 Problem 101

102 •• A 285-kg stunt boat is driven on the surface of a lake at a constant speed of 13.5 m/s toward a ramp, which is angled at 25.0° above the horizontal. The coefficient of friction between the boat bottom and the ramp's surface is 0.150, and the raised end of the ramp is 2.00 m above the water surface. (*a*) Assuming the engines are cut off when the boat hits the ramp, what is the speed of the boat as it leaves the ramp? (*b*) What is the speed of the boat when it strikes the water again? Neglect any effects due to air resistance.

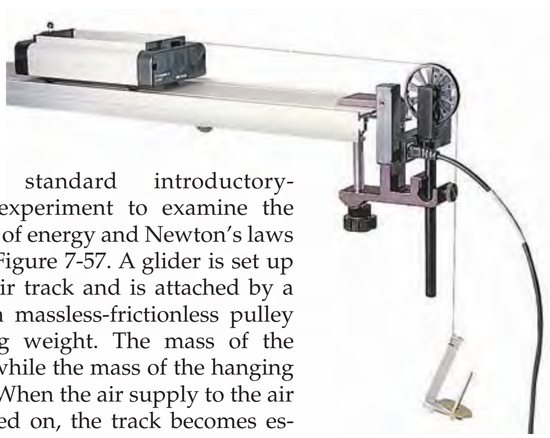

FIGURE 7-57 Problem 103

103 •• A standard introductory-physics lab-experiment to examine the conservation of energy and Newton's laws is shown in Figure 7-57. A glider is set up on a linear air track and is attached by a string over a massless-frictionless pulley to a hanging weight. The mass of the glider is M, while the mass of the hanging weight is m. When the air supply to the air track is turned on, the track becomes essentially frictionless. You then release the hanging weight and measure the speed of the glider after the weight has fallen a given distance (y). (*a*) To show that the measured speed is the speed predicted by theory, apply conservation of mechanical energy and calculate the speed as a function of y. (*b*) To verify this calculation, apply Newton's second and third laws directly by sketching a free-body diagram for each of the two masses and applying Newton's laws to find their accelerations. Then use kinematics to calculate the speed of the glider as a function of y.

104 •• **BIOLOGICAL APPLICATION** In one model of a person jogging, the energy expended is assumed to go into accelerating and decelerating the feet and the lower portions of the legs. If the jogging speed is v, then the maximum speed of the foot and lower leg is about $2v$. (From the moment a foot leaves the ground, to the moment it next contacts the ground, the foot travels nearly twice as far as the torso, so it must be going, on average, nearly twice as fast as the torso.) If the mass of the foot and lower portion of a leg is m, the energy needed to accelerate the foot and lower portion of a leg from rest to speed $2v$ is $\frac{1}{2}m(2v)^2 = 2mv^2$, and the same energy is needed to decelerate this mass back to rest for the next stride. Assume that the mass of the foot and lower portion of a man's leg is 5.0 kg and that he jogs at a speed of 3.0 m/s with 1.0 m between one footfall and the next. The energy he must provide to each leg in each 2.0 m of travel is $2mv^2$, so the energy he must provide to both legs during each second of jogging is $6mv^2$. Calculate the rate of the man's energy expenditure using this model, assuming that his muscles have an efficiency of 20 percent.

105 •• A high school teacher once suggested measuring the magnitude of free-fall acceleration by the following method: Hang a mass on a very fine thread (length L) to make a pendulum with the mass a height H above the floor when the mass is at its lowest point P. Pull the pendulum back so that the thread makes an angle θ_0 with the vertical. Just above point P, place a razor blade that is positioned to cut through the thread as the mass swings through point P. Once the thread is cut, the mass is projected horizontally, and hits the floor a horizontal distance D from point P. The idea was that the measurement of D as a function of θ_0 should somehow determine g. Apart from some obvious experimental difficulties, the experiment had one fatal flaw: D does not depend on g! Show that this is true, and that D depends only on the angle θ_0. SSM

106 ••• The bob of a pendulum of length L is pulled aside so that the string makes an angle θ_0 with the vertical, and the bob is then released. In Example 7-5, the conservation of energy was used to obtain the speed of the bob at the bottom of its swing. In this problem, you are to obtain the same result using Newton's second law. (*a*) Show that the tangential component of Newton's second law gives $dv/dt = -g\sin\theta$, where v is the speed and θ is the angle between the string and the vertical. (*b*) Show that v can be written $v = L\,d\theta/dt$. (*c*) Use this result and the chain rule for derivatives to obtain $\dfrac{dv}{dt} = \dfrac{dv}{d\theta}\dfrac{v}{L}$. (*d*) Combine the results of Parts (*a*) and (*c*) to obtain $v\,dv = -gL\sin\theta\,d\theta$. (*e*) Integrate the left side of the equation in Part (*d*) from $v = 0$ to the final speed v and the right side from $\theta = \theta_0$ to $\theta = 0$, and show that the result is equivalent to $v = \sqrt{2gh}$, where h is the original height of the bob above the bottom of its swing.

107 ••• **SPREADSHEET** A rock climber is rappelling down the face of a cliff when his hold slips and he slides down over the rock face, supported only by the bungee cord he attached to the top of the cliff. The cliff face is in the form of a smooth quarter-cylinder with height (and radius) $H = 300$ m (Figure 7-58). Treat the bungee

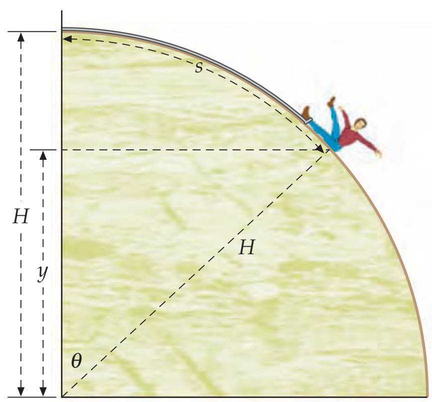

FIGURE 7-58 Problem 107

cord as a spring with force constant $k = 5.00\,\text{N/m}$ and unstressed length $L = 60.0\,\text{m}$. The climber's mass is 85.0 kg. (*a*) Using a **spreadsheet** program, make a graph of the rock climber's potential energy as a function of s, his distance from the top of the cliff *measured along the curved surface*. Use values of s between 60.0 m and 200 m. (*b*) His fall began when he was a distance $s_i = 60.0\,\text{m}$ from the top of the cliff, and ended when he was a distance $s_f = 110\,\text{m}$ from the top. Determine how much energy is dissipated by friction between the time he initially slipped and the time when he came to a stop.

108 ••• **SPREADSHEET** A block of wood (mass m) is connected to two massless springs, as shown in Figure 7-59. Each spring has unstressed length L and force constant k. (*a*) If the block is displaced a distance x, as shown, what is the change in the potential energy stored in the springs? (*b*) What is the magnitude of the force pulling the block back toward the equilibrium position? (*c*) Using a **spreadsheet** program or graphing calculator, make a graph of the potential energy U as a function of x for $0 \le x \le 0.20\,\text{m}$. Assume $k = 1.0\,\text{N/m}$, $L = 0.10\,\text{m}$, and $m = 1.0\,\text{kg}$. (*d*) If the block is displaced a distance $x = 0.10\,\text{m}$ and released, what is its speed as it passes through the equilibrium point? Assume that the block is resting on a frictionless surface.

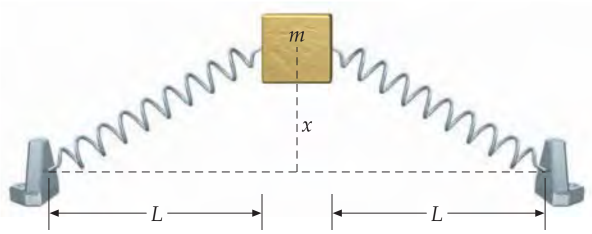

FIGURE 7-59 Problem 108

CHAPTER 8

DURING THE BRIEF PERIOD OF TIME THAT THE HEAD OF A GOLF CLUB IS IN CONTACT WITH A GOLF BALL, IT EXERTS A VERY LARGE FORCE ON THE BALL, SENDING THE BALL FLYING THROUGH THE AIR. THIS FORCE CAN BE ROUGHLY 10 000 TIMES THE WEIGHT OF THE BALL, GIVING THE BALL AN AVERAGE ACCELERATION OF APPROXIMATELY 10 000*g* FOR ABOUT ONE-HALF OF A MILLISECOND. *(Joe McNally/Getty Images.)*

Conservation of Linear Momentum

? If the golfer drives the ball 200 yards, how large a force does the clubface exert on the ball? (See Example 8-8.)

When the head of a golf club strikes a golf ball, the magnitude of the force exerted on the ball increases to a maximum value and then returns to zero as the ball leaves the club head. To describe how such a time-varying force affects the motion of an object it acts on, we need to introduce two new concepts: the impulse of a force and the momentum* of an object. Like energy, momentum is a conserved quantity. One of the most important principles in physics is *the law of conservation of momentum*, which says that the total momentum of a system and its surroundings does not change. Whenever the momentum of a system changes, we can account for the change by the appearance or disappearance of momentum somewhere else. By having these new ideas in our problem-solving toolbox, we can analyze collisions such as those that occur between golf clubs and golf balls, cars, and between subatomic particles in a nuclear reactor.

* In this chapter, the term *momentum* refers to linear momentum. (Angular momentum is developed in Chapter 10.)

In this chapter, we introduce the ideas of impulse and linear momentum, and show how integrating Newton's second law produces an important theorem known as the impulse–momentum theorem. We will also determine if the momentum of a system remains constant, and how to exploit constant momentum to solve problems involving collisions between objects. In addition, we examine a new reference frame, known as the center-of-mass reference frame, and explore situations in which a system has a continuously changing mass.

8-1 CONSERVATION OF LINEAR MOMENTUM

When Newton devised his second law, he considered the product of mass and velocity as a measure of an object's "quantity of motion." Today, we call the product of a particle's mass and velocity **linear momentum, $\vec{p}$:**

$$\vec{p} = m\vec{v} \tag{8-1}$$

DEFINITION—MOMENTUM OF A PARTICLE

The quantity $\vec{p}$ is called the *linear momentum* of a particle to distinguish linear momentum from *angular momentum*, which is presented in Chapter 10. However, when there is no need to distinguish between the two types, the adjective *linear* is often dropped and we just refer to the *momentum*. The plural of momentum is *momenta.*

Linear momentum is a vector quantity. It is the product of a vector (velocity) and a scalar (mass). Its magnitude is mv and it has the same direction as $\vec{v}$**.** The units of momentum are units of mass times speed, so the SI units of momentum are kg·m/s.

Momentum may be thought of as a measurement of the effort needed to bring a particle to rest. For example, a massive truck has more momentum than a small passenger car traveling at the same speed. It takes a greater force to stop the truck in a given time than it does to stop the car in the same time.

Using Newton's second law, we can relate the momentum of a particle to the resultant force acting on the particle. Differentiating Equation 8-1, we obtain

$$\frac{d\vec{p}}{dt} = \frac{d(m\vec{v})}{dt} = m\frac{d\vec{v}}{dt} = m\vec{a}$$

Then, substituting the force $\vec{F}_{\text{net}}$ for $m\vec{a}$,

$$\vec{F}_{\text{net}} = \frac{d\vec{p}}{dt} \tag{8-2}$$

Thus, the net force acting on a particle equals the time rate of change of the particle's momentum. (In his famous treatise *Principia* (1687), Isaac Newton presents the second law of motion in this form, rather than as $\vec{F}_{\text{net}} = m\vec{a}$.)

The total momentum $\vec{P}_{\text{sys}}$ of a system of particles is the vector sum of the momenta of the individual particles:

$$\vec{P}_{\text{sys}} = \sum_i m_i\vec{v}_i = \sum_i \vec{p}_i$$

According to Equation 5-20, $\Sigma m_i\vec{v}_i$ equals the total mass M times the velocity of the center of mass:

$$\vec{P}_{\text{sys}} = \sum_i m_i\vec{v}_i = M\vec{v}_{\text{cm}} \tag{8-3}$$

TOTAL MOMENTUM OF A SYSTEM

Differentiating this equation, we obtain

$$\frac{d\vec{P}_{\text{sys}}}{dt} = M\frac{d\vec{v}_{\text{cm}}}{dt} = M\vec{a}_{\text{cm}}$$

But according to Newton's second law for a system of particles, $M\vec{a}_{\text{cm}}$ equals the net external force acting on the system. Thus,

$$\sum_i \vec{F}_{\text{ext}} = \vec{F}_{\text{net ext}} = \frac{d\vec{P}_{\text{sys}}}{dt} \qquad 8\text{-}4$$

When the sum of the external forces acting on a system of particles remains zero, the rate of change of the total momentum remains zero and the total momentum of the system remains constant. That is,

$$\text{If } \Sigma\vec{F}_{\text{ext}} = 0, \text{ then } \vec{P}_{\text{sys}} = \sum_i m_i\vec{v}_i = M\vec{v}_{\text{cm}} = \text{constant} \qquad 8\text{-}5$$

CONSERVATION OF MOMENTUM

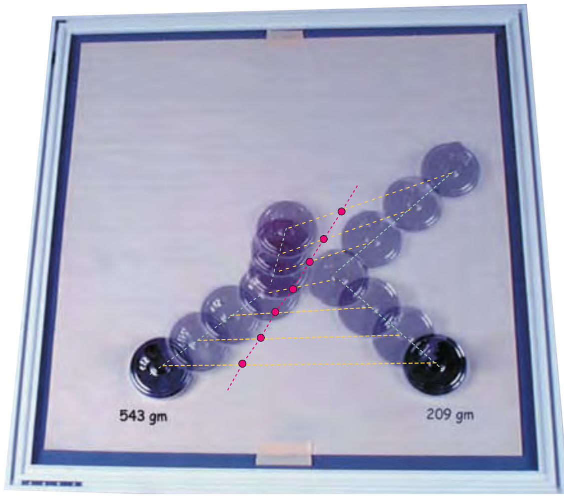
This result is known as the **law of conservation of momentum:**

If the sum of the external forces on a system remains zero, the total momentum of the system remains constant.

This law is one of the most important in physics. It is more widely applicable than the law of conservation of *mechanical* energy because internal forces exerted by one particle in a system on another are often not conservative. The nonconservative internal forces can change the total mechanical energy of the system, though they effect no change of the system's total momentum. If the total momentum of a system remains constant, then the velocity of the center of mass of the system remains constant. The law of conservation of momentum is a vector relation, so it is valid component by component. For example, if the sum of the x components of the external forces on a system remains zero, then the x component of the total momentum of the system remains constant. That is,

$$\text{If } \Sigma F_{\text{ext}\,x} = 0, \text{ then } P_{\text{sys}\,x} = \text{constant} \qquad 8\text{-}6$$

CONSERVATION OF A COMPONENT OF MOMENTUM



The two pucks are moving on an air cushion on a horizontal flat surface. (The hoses supplying the air are not shown.) The velocity of each puck changes in both magnitude and direction during the collision, but the velocity of the center of mass remains constant—unaffected by the internal forces of the collision. *(Courtesy of Daedalon Corporation.)*

PROBLEM-SOLVING STRATEGY

Finding Velocities Using Momentum Conservation (Equation 8-5)

PICTURE Determine that the net external force $\Sigma\vec{F}_{\text{ext}}$ (or $\Sigma F_{\text{ext}\,x}$) on the system is negligible for some interval of time. If the net force is determined not to be negligible, do not proceed.

SOLVE

1. Draw a sketch showing the system both before and after the time interval. Include coordinate axes and label the initial and final velocity vectors.
2. Equate the initial momentum to the final momentum. That is, write out the equation $m_1\vec{v}_{1\text{i}} + m_2\vec{v}_{2\text{i}} = m_1\vec{v}_{1\text{f}} + m_2\vec{v}_{2\text{f}}$ (or $m_1v_{1\text{i}x} + m_2v_{2\text{i}x} = m_1v_{1\text{f}x} + m_2v_{2\text{f}x}$).
3. Substitute the given information into the step-2 equation(s) and solve for the quantity of interest.

CHECK Make sure you include any minus signs that accompany velocity components because they influence your final answer.

Example 8-1 A Space Repair

During repair of the Hubble Space Telescope, an astronaut replaces a damaged solar panel during a spacewalk. Pushing the detached panel away into space, she is propelled in the opposite direction. The astronaut's mass is 60 kg and the panel's mass is 80 kg. Both the astronaut and the panel initially are at rest relative to the telescope. The astronaut then gives the panel a shove. After the shove it is moving at 0.30 m/s relative to the telescope. What is her subsequent velocity relative to the telescope? (During this operation the astronaut is tethered to the ship; for our calculations assume that the tether remains slack.)

(NASA.)

PICTURE Let us choose the system to be the astronaut and the panel, and let us choose the direction of motion of the panel to be the $-x$ direction. For this system, there are no external forces, so the momentum of the system is conserved. Because we know both the mass of the astronaut and the panel, the velocity of the astronaut can be found from the velocity of the panel using conservation of momentum. Because the total momentum of the system is initially zero, it remains zero.

SOLVE

1. Sketch a figure showing the system before and after the shove. Include velocity vectors (Figure 8-1):

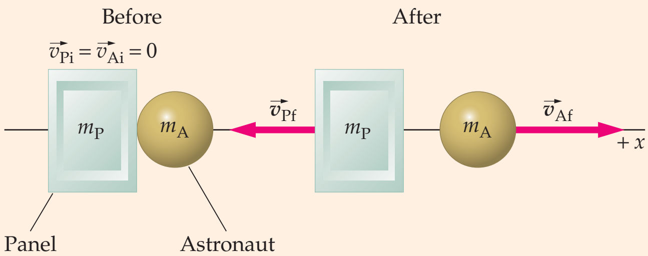


FIGURE 8-1

2. Apply Newton's second law to the system. There are no external forces on the system, so the momentum of the system remains constant:

$$\sum_i \vec{F}_{\rm ext} = \frac{d\vec{P}_{\rm sys}}{dt}$$

$$0 = \frac{d\vec{P}_{\rm sys}}{dt},$$

$$\text{so} \quad \vec{P}_{\rm sys} = \text{constant}$$

3. Equate the initial momentum of the system to the final momentum. Because the initial momentum is zero, the momentum of the system remains zero:

$$\vec{P}_{\rm sys\,i} = \vec{P}_{\rm sys\,f}$$

$$m_{\rm P}\vec{v}_{\rm Pi} + m_{\rm A}\vec{v}_{\rm Ai} = m_{\rm P}\vec{v}_{\rm Pf} + m_{\rm A}\vec{v}_{\rm Af}$$

$$0 + 0 = m_{\rm P}\vec{v}_{\rm Pf} + m_{\rm A}\vec{v}_{\rm Af}$$

4. Solve for the astronaut's velocity:

$$\vec{v}_{\rm Af} = -\frac{m_{\rm P}}{m_{\rm A}}\vec{v}_{\rm Pf} = -\frac{80\text{ kg}}{60\text{ kg}}(-0.30\text{ m/s})\hat{i} = \boxed{(0.40\text{ m/s})\hat{i}}$$

CHECK We expect the astronaut's velocity to be in the $+x$ direction because the velocity of the panel was in the $-x$ direction. Also, because her mass is less than the mass of the panel, we expect that her speed would be greater than the speed of the panel. Our result meets both these expectations.

TAKING IT FURTHER Although momentum is conserved, the mechanical energy of this system increased because chemical energy in the astronaut's muscles was transformed into kinetic energy.

PRACTICE PROBLEM 8-1 Find the final kinetic energy of the astronaut–panel system.

Example 8-2 A Runaway Railroad Car

A runaway 14,000-kg railroad car is rolling horizontally at 4.00 m/s toward a switchyard. As it passes by a grain elevator, 2000 kg of grain suddenly drops into the car. How long does it take the car to cover the 500-m distance from the elevator to the switchyard? Assume that the grain falls straight down and that slowing due to rolling friction or air drag is negligible.

PICTURE We can find the travel time we seek from the distance traveled and the speed of the car. Consider the car and the grain as our system (Figure 8-2). Let the direction of the car be the $+x$ direction. There are no external forces with nonzero x components, so the x component of the momentum is conserved. The final speed of the grain-filled car is found from its final momentum, which equals the car's initial momentum (the grain initially has zero momentum in the x direction). Let m_c and m_g be the masses of the car and grain, respectively.

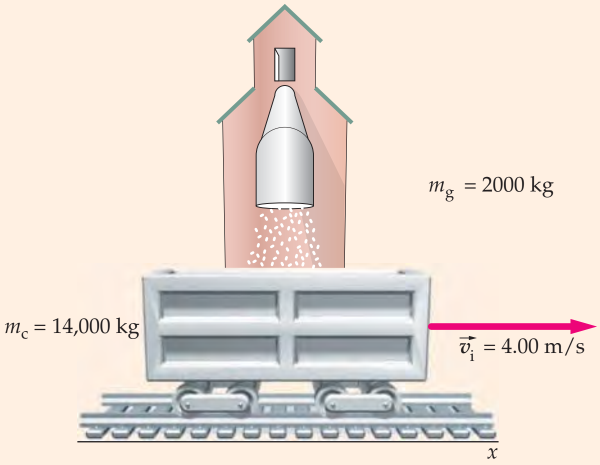

FIGURE 8-2

SOLVE

1. The time for the car to travel from the elevator to the yard is related to the distance to the yard d and the car's speed v_{fx} following the grain dump. We are looking for this time:

$$d = v_{fx}\,\Delta t$$

2. Sketch a free-body diagram (FBD) of the system consisting of the car, the grain already in the car, and the grain that is falling into the car (Figure 8-3). Include coordinate axes:

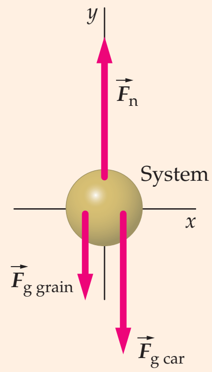

FIGURE 8-3 Three forces act on the system: the gravitational forces on the grain and the car, and the normal force of the track on the car.

3. The sum of the external forces acting on the grain–car system equals the rate of change of the momentum of the system (Equation 8-4):

$$\sum \vec{F}_{i\,\text{ext}} = \vec{F}_{\text{g grain}} + \vec{F}_{\text{g car}} + \vec{F}_n = \frac{d\vec{P}_{\text{sys}}}{dt}$$

4. Each of the external forces is vertical, so the x component of each is zero. Take the x component of each term in the step-3 result. The x component of the net external force is zero, so $P_{\text{sys}\,x}$ is constant:

$$F_{\text{g grain}\,x} + F_{\text{g car}\,x} + F_{nx} = \frac{dP_{\text{sys}\,x}}{dt}$$

$$0 + 0 + 0 = \frac{dP_{\text{sys}\,x}}{dt}$$

$$\therefore\ P_{\text{sys f}x} = P_{\text{sys i}x}$$

5. Make a sketch of the system before the collision and again after the collision (Figure 8-4):

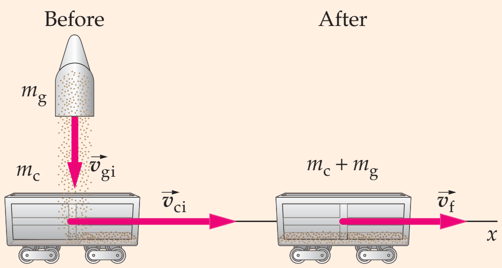

FIGURE 8-4

6. Apply conservation of momentum to relate the final velocity v_{fx} to the initial velocity v_{ix}. The x component of the system's momentum is conserved:

$$P_{\text{sys f}x} = P_{\text{sys i}}$$

$$(m_c + m_g)v_{fx} = m_c v_{ix} + m_g(0)$$

7. Solve for v_{fx}:

$$v_{fx} = \frac{m_c}{m_c + m_s} v_{ix}$$

8. Substitute the result for v_{fx} into step 1 and solve for the time:

$$\Delta t = \frac{d}{v_{fx}} = \frac{(m_c + m_s)d}{m_c v_{ix}}$$

$$= \frac{(14\,000\text{ kg} + 2000\text{ kg})(500\text{ m})}{(14\,000\text{ kg})(4.00\text{ m/s})}$$

$$= \boxed{1.43 \times 10^2\text{ s}}$$

CHECK The mass of the empty car is seven times greater than the mass of the grain, so we do not expect the grain to reduce the speed of the car by much. If the car continued at its initial speed of 4.00 m/s, the time to travel the 500 m would be (500 m)/(4.00 m/s) = 125 s. The step-8 result of 140 s is only slightly longer than 125 s, as expected.

PRACTICE PROBLEM 8-2 Suppose that there is a small vertical chute in the bottom of the car so that the grain leaks out at 10 kg/s. Now how long does it take the car to cover the 500 m?

Example 8-3 A Skateboard Workout

A 40.0-kg skateboarder on a 3.00-kg board is training with two 5.00-kg weights. Beginning from rest, she throws the weights horizontally, one at a time, from her board. The speed of each weight is 7.00 m/s relative to her after it is thrown. Assume the board rolls without friction. (*a*) How fast is she moving in the opposite direction after throwing the first weight? (*b*) After throwing the second weight?

PICTURE Let the system be the skateboard, the skateboarder, and the weights, and let the $-x$ direction be the direction she throws the first weight. Because only negligible external forces with horizontal components act along the x direction, the x component of the momentum of the system is conserved. We need to find the velocity of the skateboarder after throwing each weight (Figure 8-5). We can do this using conservation of momentum, where the mass m of each weight is 5.00 kg and the mass M of the skateboard plus skateboarder is 43.0 kg. The ground is an inertial reference frame.

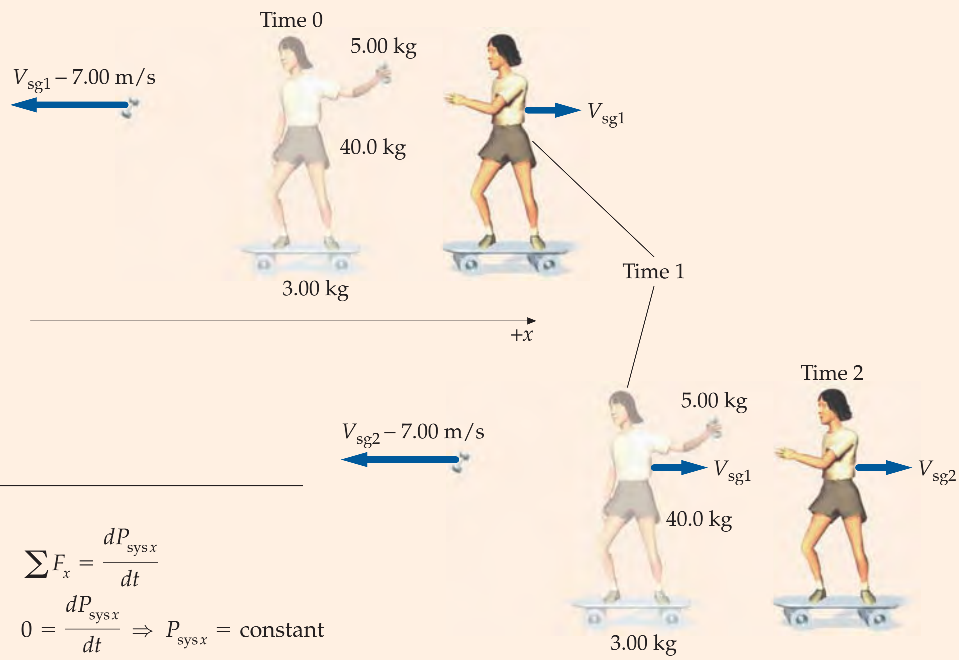

FIGURE 8-5 The numbers in the subscripts stand for times. Time 0 occurs just before the first throw, time 1 occurs between the two throws, and time 2 occurs following the second throw.

SOLVE

(*a*) 1. Let V_{sg1x} and v_{ws1x} be the x components of the velocities of the skateboarder and the thrown weight relative to the ground, respectively. Apply conservation of momentum for the first throw:

$$\sum F_x = \frac{dP_{sys\,x}}{dt}$$

$$0 = \frac{dP_{sys\,x}}{dt} \Rightarrow P_{sys\,x} = \text{constant}$$

$$\text{so} \quad P_{sys\,1x} = P_{sys\,0x}$$

$$(M + m)V_{sg1x} + mv_{wg1x} = 0$$

2. The velocity of the thrown weight relative to the ground equals the velocity of the weight relative to the skateboarder plus the velocity of the skateboarder relative to the ground:

$$v_{wg1x} = v_{ws1x} + V_{sg1x}$$

3. Substitute for v_{wg1x} into the step-1 result and solve for V_{sg1x}:

$$(M + m)V_{sg1x} + m(v_{ws1x} + V_{sg1x}) = 0$$

$$\text{so} \quad V_{sg1x} = -\frac{m}{M + 2m}v_{ws1x}$$

$$= -\frac{5.00\text{ kg}}{43.0\text{ kg} + 10.0\text{ kg}}(-7.00\text{ m/s}) = \boxed{0.660\text{ m/s}}$$

(*b*) 1. Repeat step 1 of Part (*a*) for the second throw. Let V_{sg2x} and $v_{w'g2x}$ be the x components of the respective velocities of the skateboarder and the second thrown weight relative to the ground:

$$P_{sys2x} = P_{sys1x}$$

$$MV_{sg2x} + mv_{w'g2x} = (M + m)V_{sg1x}$$

2. Repeat step 2 of Part (*a*) for the second throw.

$$v_{w'g2x} = v_{w's2x} + V_{sg2x}$$

3. Substitute for $v_{w'g2x}$ in the Part-(*b*) step-1 result and solve for V_{sg2x}:

$$MV_{sg2x} + m(v_{w's2x} + V_{sg2x}) = (M + m)V_{sg1x}$$

$$\text{so} \quad V_{sg2x} = \frac{(M + m)V_{sg1x} - mv_{w's2x}}{M + m} = V_{sg1x} - \frac{m}{M + m}v_{w's2x}$$

$$= 0.660\text{ m/s} - \frac{5.00\text{ kg}}{48.0\text{ kg}}(-7.00\text{ m/s}) = \boxed{1.39\text{ m/s}}$$

CHECK After the second throw, the mass of the skateboard and its cargo is 43.0 kg, which is 5.00 kg less than it was after the first throw. Because its mass was less for the second throw, we expect the increase in the speed of the skateboarder to be greater during the second throw. Our results show that her speed increases by 0.660 m/s during the first throw and by 1.39 m/s − 0.660 m/s = 0.73 m/s during the second throw, a small increase in the change in speed, as we expected.

TAKING IT FURTHER This example illustrates the principle of the rocket; a rocket moves forward by throwing its fuel out backward in the form of exhaust gases. As a rocket's mass lessens its acceleration increases, just as the skateboarder gains more speed with the second throw than she did with the first throw.

PRACTICE PROBLEM 8-3 How fast is the skateboarder moving if, starting from rest, she throws both weights simultaneously? The weights move at speed 7.00 m/s relative to her *after they are thrown*. Does she gain more speed by throwing them simultaneously or sequentially?

Example 8-4 Radioactive Decay

A thorium-227 nucleus (mass 227 u) at rest decays into a radium-223 nucleus (mass 223 u) by emitting an alpha particle (mass 4.00 u) (Figure 8-6). The kinetic energy of the α particle is measured to be 6.00 MeV. What is the kinetic energy of the recoiling radium nucleus?

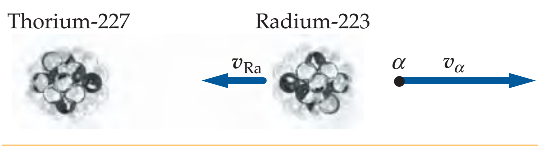

FIGURE 8-6

PICTURE A decay of a particle into two particles is like a collision run backwards in time. There are no external forces, so the momentum of the system is conserved. Recall that the kinetic energy of an object is $K = \frac{1}{2}mv^2$. Because the thorium nucleus before decay is at rest, its total momentum is zero. Therefore, we can relate the velocity of the radium nucleus to that of the alpha particle using conservation of momentum.

SOLVE

1. Write the kinetic energy of the radium nucleus K_{ra} in terms of its mass m_{ra} and speed v_{ra}.
   $$K_{ra} = \tfrac{1}{2}m_{ra}v_{ra}^2$$
2. Write the kinetic energy of the alpha particle K_α in terms of its mass m_α and speed v_α.
   $$K_\alpha = \tfrac{1}{2}m_\alpha v_\alpha^2$$
3. Use conservation of momentum to relate v_{ra} to v_α. The thorium nucleus was at rest, so the momentum of the system is zero:
   $$m_\alpha v_\alpha = m_{ra}v_{ra}$$
4. Solve the step-1 and step 2-results for the speeds v_{ra} and v_α, and substitute these expressions into the step-3 result.
   $$K_{ra} = \tfrac{1}{2}m_{ra}v_{ra}^2 \qquad K_\alpha = \tfrac{1}{2}m_\alpha v_\alpha^2$$
   $$v_{ra} = \left(\frac{2K_{ra}}{m_{ra}}\right)^{1/2} \qquad v_\alpha = \left(\frac{2K_\alpha}{m_\alpha}\right)^{1/2}$$
   $$\text{so}\quad m_\alpha\left(\frac{2K_\alpha}{m_\alpha}\right)^{1/2} = m_{ra}\left(\frac{2K_{ra}}{m_{ra}}\right)^{1/2}$$
5. Solve the step-4 result for K_{ra}.
   $$K_{ra} = \frac{m_\alpha}{m_{ra}}K_\alpha = \frac{4.00\text{ u}}{223\text{ u}}(6.00\text{ MeV}) = \boxed{0.107\text{ MeV}}$$

CHECK Let us check the step-5 result $K_{ra} = (m_\alpha/m_{ra})K_\alpha$ for several values of the ratio m_α/m_{ra}. If the two masses are equal, our result gives $K_{ra} = K_\alpha$, as expected. If $m_\alpha \ll m_{ra}$ then our result gives $K_{ra} \ll K_\alpha$, which means the kinetic energy of the alpha particle is much greater than that of the radium nuclei. This also means that the speed of the alpha particle is much greater than that of the radium nuclei, as expected.

TAKING IT FURTHER In this process, some of the rest energy of the thorium nucleus is converted into kinetic energy of the alpha particle and radium nucleus. The mass of the thorium nucleus is greater than the sum of the masses of the alpha particle and radium nucleus by $(K_\alpha + K_{ra})/c^2 = 6.11\text{ MeV}/c^2$.

8-2 KINETIC ENERGY OF A SYSTEM

If the net external force on a system of particles remains zero, then the total momentum of a system must remain constant; however, the total mechanical energy of the system can change. As we saw in the examples of the previous section, internal forces that cannot change the total momentum may be nonconservative and thus change the total mechanical energy of the system. There is an important theorem concerning the kinetic energy of a system of particles that allows us to treat the energy of complex systems more easily and gives us insight into energy changes within a system:

> The kinetic energy of a system of particles can be written as the sum of two terms: (1) the kinetic energy associated with the motion of the center of mass, $\frac{1}{2}Mv_{\text{cm}}^2$, where M is the total mass of the system; and (2) the kinetic energy associated with the motion of the particles of the system relative to the center of mass, $\Sigma\frac{1}{2}m_iu_i^2$, where $\vec{u}_i$ is the velocity of the ith particle relative to the center of mass.

THEOREM FOR THE KINETIC ENERGY OF A SYSTEM

So

$$K = \sum_i \tfrac{1}{2}m_iv_{\text{cm}}^2 + \sum_i \tfrac{1}{2}m_iu_i^2 = \tfrac{1}{2}Mv_{\text{cm}}^2 + K_{\text{rel}} \tag{8-7}$$

KINETIC ENERGY OF A SYSTEM OF PARTICLES

See **Math Tutorial** *for more information on* **Factoring**

where M is the total mass and K_{rel} is the kinetic energy of the particles *relative to the center of mass*.

To prove this theorem, recall that the kinetic energy K of a system of particles is the sum of the kinetic energies of the individual particles:

$$K = \sum_i K_i = \sum_i \tfrac{1}{2}m_iv_i^2 = \sum_i \tfrac{1}{2}m_i(\vec{v}_i \cdot \vec{v}_i)$$

where we have used the result that $v_i^2 = \vec{v}_i \cdot \vec{v}_i$. The velocity of the i^{th} particle can be written as the sum of the velocity of the center of mass $\vec{v}_{\text{cm}}$ and the velocity of the i^{th} particle relative to the center of mass $\vec{u}_{\text{i}}$:

$$\vec{v}_i = \vec{v}_{\text{cm}} + \vec{u}_i \tag{8-8}$$

Substituting, we obtain

$$\begin{aligned} K &= \sum_i \tfrac{1}{2}m_i(\vec{v}_i \cdot \vec{v}_i) = \sum_i \tfrac{1}{2}m_i(\vec{v}_{\text{cm}} + \vec{u}_i)\cdot(\vec{v}_{\text{cm}} + \vec{u}_i) \\ &= \sum_i \tfrac{1}{2}m_i(v_{\text{cm}}^2 + u_i^2 + 2\vec{v}_{\text{cm}} \cdot \vec{u}_i) \end{aligned}$$

We can write this as the sum of three terms:

$$K = \sum_i \tfrac{1}{2}m_iv_{\text{cm}}^2 + \sum_i \tfrac{1}{2}m_iu_i^2 + \vec{v}_{\text{cm}} \cdot \sum_i m_i\vec{u}_i$$

where in the term on the right we have factored $\vec{v}_{\text{cm}}$ from the sum ($\vec{v}_{\text{cm}}$ is a system parameter and does not change from particle to particle). The quantity $\Sigma m_i\vec{u}_i$ is equal to $M\vec{u}_{\text{cm}}$, where $\vec{u}_{\text{cm}}$ is the velocity of the center of mass relative to the center of mass. It follows that $\vec{u}_{\text{cm}}$ and thus $\Sigma m_i\vec{u}_i$ are equal to zero. (The velocity of anything relative to itself is always equal to zero.) It follows that $\Sigma m_i\vec{u}_i$ is equal to zero, so

$$K = \sum_i \tfrac{1}{2}m_iv_{\text{cm}}^2 + \sum_i \tfrac{1}{2}m_iu_i^2 = \tfrac{1}{2}Mv_{\text{cm}}^2 + K_{\text{rel}}$$

which completes the proof of Equation 8-7. If the net external force is zero, $\vec{v}_{cm}$ remains constant and the kinetic energy associated with bulk motion of the system $\frac{1}{2}Mv_{cm}^2$ does not change. Only the relative kinetic energy K_{rel} can change in an isolated system.

PRACTICE PROBLEM 8-4

Air-track glider A is moving at 1.0 m/s in the $+x$ direction along a frictionless horizontal air track. An identical glider, glider B, is parked on the track ahead of glider A. The mass of each glider is 1.0 kg, and the system consists of the two gliders. (*a*) What is the velocity of the center of mass, and what is the velocity of each glider, relative to the center of mass? (*b*) What is the kinetic energy of each glider relative to the center of mass? (*c*) What is the total kinetic energy relative to the center of mass? (*d*) The gliders collide and stick together. What then is the total kinetic energy relative to the center of mass?

8-3 COLLISIONS

A car crashes head-on into another car. A bat smashes into a baseball. A dart lands with a resounding "thunk" in the bull's-eye of a dartboard. Each of these is an example of a collision in which two objects approach and interact strongly for a very short time.

During the brief time of collision, any external forces on the two objects are usually much much weaker than the forces of interaction between the two objects. Thus, the colliding objects can usually be treated as an isolated system for the duration of the collision. During the collision the only significant forces are the internal interaction forces, which are equal and opposite. As a result, momentum is conserved. That is, the total momentum of the system the instant before the collision is equal to the total momentum the instant following the collision. In addition, the collision time is usually so short that the displacements of the colliding objects *during the collision* can be neglected.

When the total kinetic energy of the two-object system is the same after the collision as before, the collision is called an **elastic collision.** Otherwise, it is called an **inelastic collision.** An extreme case is the **perfectly inelastic collision,** during which all of the kinetic energy relative to the center of mass is converted to thermal or internal energy of the system, and the two objects share a common velocity (often because they stick together) at the end of the collision. We examine these different types of collisions in more detail later in this section.

IMPULSE AND AVERAGE FORCE

When two objects collide, they usually exert very large forces on each other for a very brief time. The force exerted by a baseball bat on a ball, for example, may be several thousand times the weight of the ball, but this enormous force is exerted for only a millisecond or so. Such forces are sometimes called *impulsive forces*. Figure 8-7 shows the time variation of the magnitude of a typical force exerted by one object on another during a collision. The force is large during much of the collision time interval $\Delta t = t_f - t_i$. For other times the force is negligibly small. The **impulse** $\vec{I}$ of a force $\vec{F}$ during time interval $\Delta t = t_f - t_i$ is a vector defined as

$$\vec{I} = \int_{t_i}^{t_f} \vec{F}\,dt \qquad 8\text{-}9$$

DEFINITION—IMPULSE

The impulse is a measure of both the strength and the duration of the collision force. The x component of the impulse of the force is the area under its F_x-versus-t curve, and the S.I. units of impulse are newton seconds (N·s).

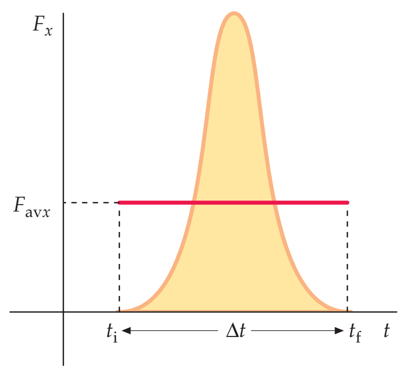

FIGURE 8-7 Typical time variation of force during a collision. The area under the F_x-versus-t curve is the x component of the impulse, I_x. $F_{av\,x}$ is the average force for time interval Δt. The rectangular area $F_{av\,x}\,\Delta t$ is the same as the area under the F_x-versus-t curve.

The net force $\vec{F}_{\text{net}}$ acting on a particle is related to the rate of change of momentum of the particle by Newton's second law: $\vec{F}_{\text{net}} = d\vec{p}/dt$. Taking the time integral of both sides of this equation gives

$$\int_{t_i}^{t_f} \vec{F}_{\text{net}}\, dt = \int_{t_i}^{t_f} \frac{d\vec{p}}{dt}\, dt = \vec{p}_f - \vec{p}_i$$

Recognizing the left side of this equation as the impulse of the net force, we have

$$\vec{I}_{\text{net}} = \Delta\vec{p} \qquad \text{8-10}$$

IMPULSE–MOMENTUM THEOREM FOR A PARTICLE

where $\vec{I}_{\text{net}} = \int_{t_i}^{t_f} \vec{F}_{\text{net}}\, dt$ and $\Delta\vec{p} = \vec{p}_f - \vec{p}_i$. Equation 8-10 is called the impulse–momentum theorem *for a particle*. Also, the net impulse on *a system* due to the external forces acting on the system equals the change in the total momentum of the system:

$$\vec{I}_{\text{net ext}} = \int_{t_i}^{t_f} \vec{F}_{\text{net ext}}\, dt = \Delta\vec{P}_{\text{sys}} \qquad \text{8-11}$$

IMPULSE–MOMENTUM THEOREM FOR A SYSTEM

By definition, the average of a force $\vec{F}$ for the interval $\Delta t = t_f - t_i$ is given by

$$\vec{F}_{\text{av}} = \frac{1}{\Delta t}\int_{t_i}^{t_f} \vec{F}\, dt = \frac{1}{\Delta t}\vec{I} \qquad \text{8-12}$$

AVERAGE FORCE

Rearranging gives

$$\vec{I} = \vec{F}_{\text{av}}\, \Delta t \qquad \text{8-13}$$

IMPULSE AND AVERAGE FORCE

The average force is the constant force that gives the same impulse as the actual force in the time interval Δt, as shown by the rectangle in Figure 8-7. The average net force can be calculated from the change in momentum if a collision time is known. This time can often be estimated using the displacement of one of the bodies during the collision.

PROBLEM-SOLVING STRATEGY

Estimating the Average Force

PICTURE To estimate the average force $\vec{F}_{\text{av}}$ we first estimate the impulse of the force $\vec{I}$. The impulse of the force equals the net impulse (assuming any other forces are negligible). The net impulse is equal to the change in momentum, and the change in momentum equals the product of the mass m and the change of velocity $\vec{v}_f - \vec{v}_i$. An estimate of the change in velocity can be gotten from estimates of both the collision time Δt and the displacement $\Delta\vec{r}$.

SOLVE

1. Calculate (or estimate) the impulse $\vec{I}$ and the time Δt. This estimate assumes that during the collision, the collision force on the object is very

large compared to all other forces on the object. This procedure works *only* if the displacement during the collision can be determined.

2. Draw a sketch showing the before and after position of the object. Add coordinate axes and label the pre- and postcollision velocities $\vec{v}_i$ and $\vec{v}_f$. In addition, label the displacement $\Delta\vec{r}$ during the collision.
3. Calculate the change in momentum of the object during a collision. The impulse on the object equals its change in momentum ($\vec{I} = \Delta\vec{p} = m\,\Delta\vec{v}$).
4. Use kinematics to estimate the collision time. This means using both $\vec{v}_{av} \approx \frac{1}{2}(\vec{v}_i + \vec{v}_f)$ and $\Delta\vec{r} = \vec{v}_{av}\,\Delta t$ to obtain $\Delta\vec{r} \approx \frac{1}{2}(\vec{v}_i + \vec{v}_f)\,\Delta t$, and then solving for Δt.
5. Use $\vec{F}_{av} = \vec{I}/\Delta t = m\,\Delta\vec{v}/\Delta t$ to calculate the average force (Equation 8-13).

CHECK Average force is a vector. Your result for average force should have the same direction as the change in velocity vector.

Example 8-5 A Karate Collision

(Robert R. Edwards/ BOB-E.)

With an expert karate blow, you shatter a concrete block. Consider your hand to have a mass 0.70 kg, to be moving 5.0 m/s as it strikes the block, and to stop 6.0 mm beyond the point of contact. (*a*) What impulse does the block exert on your hand? (*b*) What is the approximate collision time and the average force the block exerts on your hand?

PICTURE The net impulse equals the change in momentum $\Delta\vec{p}$. We find $\Delta\vec{p}$ from the mass and velocity of your hand. The time of collision for Part (*b*) comes from the given displacement during the collision and by *estimating* the average velocity during the collision using a constant-acceleration kinematic formula.

SOLVE

(*a*) 1. Make a before and after sketch of your hand and the block. In the before picture, the edge of you hand is just reaching the block. Include a vertical coordinate axis on the sketch (Figure 8-8).

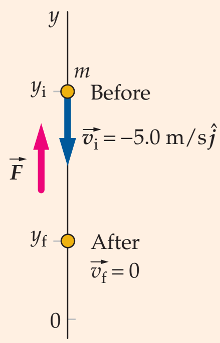

FIGURE 8-8

2. Set the impulse equal to the change in momentum: $\vec{I} = \Delta\vec{p} = m\,\Delta\vec{v}$

3. The initial velocity $\vec{v}_i$ is that of the hand just before it hits the block. The final velocity is zero:
$$\vec{v}_i = -5.0\text{ m/s}\,\hat{j}$$
$$\vec{v}_f = 0$$

4. Substitute the values from step 3 into the equation from step 2 to find the impulse exerted by the block on your hand:
$$\vec{I} = m\,\Delta\vec{v} = (0.70\text{ kg})[0 - (-5.0\text{ m/s}\,\hat{j})]$$
$$= 3.5\text{ kg}\cdot\text{m/s}\,\hat{j} = \boxed{3.5\text{ N}\cdot\text{s}\,\hat{j}}$$

(*b*) 1. The displacement equals the average velocity multiplied by the time. We estimate the average velocity by assuming constant acceleration. For constant a_y, $v_{av\,y} \approx \frac{1}{2}(v_{iy} + v_{fy})$:
$$\Delta y = v_{av}\,\Delta t \approx \tfrac{1}{2}(v_{iy} + v_{fy})\,\Delta t$$

2. Because we have chosen up as the $+y$ direction, both Δy and $v_{av\,y}$ are negative. Calculate Δt:
$$\Delta t \approx \frac{\Delta y}{\frac{1}{2}(v_{iy} + v_{fy})} = \frac{-0.006\text{ m}}{-2.5\text{ m/s}} = 0.0024\text{ s} = 2.4\text{ ms}$$

3. From Equation 8-12, the average force is the impulse divided by the collision time:
$$\vec{F}_{av} = \frac{\vec{I}}{\Delta t} = \frac{3.5\text{ N}\cdot\text{s}\,\hat{j}}{2.4\text{ ms}} = \boxed{1.5\text{ kN}\,\hat{j}}$$

CHECK The average force on your hand is in the $+y$ direction (upward). This is the same direction as the change in velocity vector, as expected. (The average force by the edge of your hand on the block is equal and opposite to the average force by the block on the hand.)

TAKING IT FURTHER Note that the average force relatively is large. Assuming the mass of a hand is about one kilogram, the average force is about 150 times the weight of a hand. The average collision force is much larger than the gravitational force on the hand during the collision.

Example 8-6 A Crumpled Car

A car equipped with an 80-kg crash-test dummy (Figure 8-9) drives into a massive concrete wall at 25 m/s (about 56 mi/h.) Estimate the displacement of the dummy during the crash.

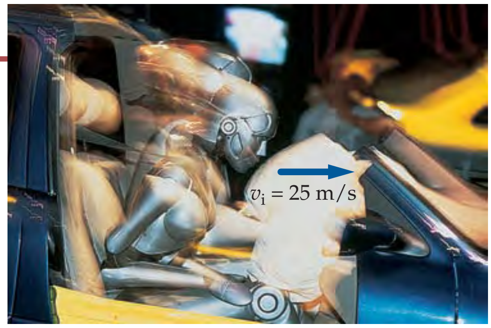

FIGURE 8-9 *(Romilly Lockyer/ The Image Bank.)*

PICTURE The passenger compartment of a modern car is designed to remain rigid, whereas the front and rear ends of the car are designed to collapse upon impact. Assume the dummy is halfway between the front and rear bumpers and that the front end of the car completely collapses.

SOLVE

1. The front end of the car is the engine compartment, the radiator, the grill and the bumper. Estimate the fraction of the entire length of the car that the front end occupies.

   The front end is approximately 25% of the length of the car.

2. Estimate the displacement of the passenger compartment if the front end completely crumples.

   As the front end completely crumples, the displacement of the rest of the car, including the dummy, might be equal to 25 percent of the length of the car.

3. Estimate the length of a typical car.

   The length of a car is about 4.0 m (about 13 ft).

4. The length of the displacement is equal to the length of the front end.

   The length of the displacement is 25% of the length of the car, or about $\boxed{1.0\text{ m}}$.

CHECK The dummy was 2.0 m from the wall at impact. Our result is half of that distance, which is plausible.

Example 8-7 A Crash Test

Try It Yourself

For the car crash described in Example 8-6, estimate the average force that the seat belt exerts on the dummy during the crash.

PICTURE To estimate the average force, calculate the impulse $\vec{I}$, and then divide it by an estimate of the collision time, Δt.

SOLVE

Cover the column on the right and try these on your own before looking at the answers.

Steps / **Answers**

1. Relate the average force to the impulse, and thus to the change in momentum.

   $\vec{I} = \vec{F}_{av}\,\Delta t = \Delta\vec{p}$

2. Sketch and label a figure showing a representation of the dummy both before and after the crash (Figure 8-10).

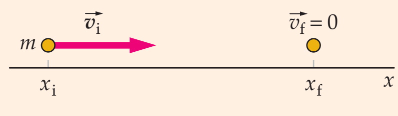

FIGURE 8-10

3. Find the change in the dummy's momentum. Let the forward direction of the car be the $+x$ direction.

   $\Delta\vec{p} = m\vec{v}_f - m\vec{v}_i = -2000\text{ N}\cdot\text{s}\,\hat{i}$

4. Relate the time to the displacement, assuming constant acceleration.

   $\Delta x = v_{av}\,\Delta t$

5. Get the displacement of the dummy during the crash from step 4 of Example 8-6:

   $\Delta x = 1.0\text{ m}$

6. Estimate the average velocity and use it and the steps-4 and -5 results to find the time.

   $\vec{v}_{av} \approx \frac{1}{2}(\vec{v}_f + \vec{v}_i) = 12.5\text{ m/s}\,\hat{i}$, so
   $\Delta t = 0.080\text{ s} = 80\text{ ms}$

7. Substitute the step-3 and step-6 results into the step-1 result and solve for the force.

   $\vec{F}_{av} = \boxed{-25\text{ kN}\,\hat{i}}$

CHECK The average force is in the $-x$ direction, which is opposite to the forward direction of the car. This result is what is expected because the force must oppose the forward motion of the dummy.

TAKING IT FURTHER The magnitude of the average acceleration is $a_{av} = \Delta v/\Delta t \approx 300\ \mathrm{m/s^2}$, or roughly $30g$. Such an acceleration means a net force about 30 times the weight of the dummy, clearly enough to cause serious injuries. An air bag increases the stopping time somewhat, which helps to reduce the force. In addition, the air bag allows the force to be distributed over a much larger area. In Figure 8-11, plot (*a*) shows the average force on the dummy as a function of the stopping distance. With no seat belt or air bag, you either fly though the windshield, or are stopped in a small fraction of a meter by the dashboard or steering wheel. Plot (*b*) shows the force as a function of the initial velocity for three stopping distances: 2.0 m, 1.5 m, and 1.0 m.

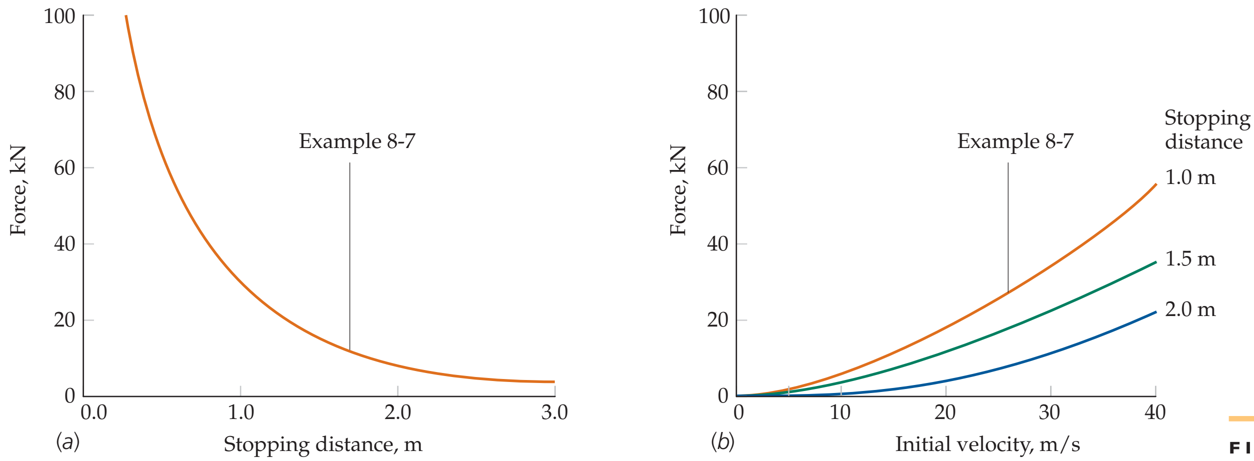

FIGURE 8-11

Example 8-8 Hitting a Golf Ball

You strike a golf ball with a driving iron. What are reasonable estimates for the magnitudes of the (*a*) impulse $\vec{I}$, (*b*) collision time Δt, and (*c*) average force $\vec{F}_{av}$? A typical golf ball has a mass $m = 45$ g and a radius $r = 2.0$ cm. For a typical drive, the range R is roughly 190 m (about 210 yd). Assume the ball leaves the ground at an angle $\theta_0 = 13°$ above the horizontal (Figure 8-12).

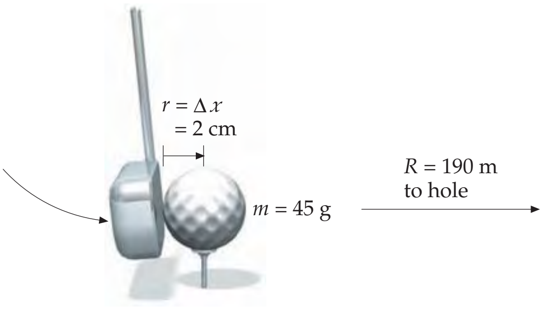

FIGURE 8-12

PICTURE Let v_0 denote the speed of the ball as it leaves the clubface. The impulse on the ball equals its change in momentum (mv_0) during the collision. We estimate v_0 from the range. We estimate the collision time from the displacement Δx and the average velocity $\frac{1}{2}(v_{ix} + v_{fx})$ during the collision, assuming constant acceleration. Taking $\Delta x = 2.0$ cm (half the diameter of the ball), the average force is then obtained from the impulse $\vec{I}$ and collision time Δt.

SOLVE

(*a*) 1. Set the impulse equal to the change in momentum of the ball:

$$I_x = F_{av\,x}\,\Delta t = \Delta p_x$$

2. Make a sketch showing the ball in both the pre- and postcollision positions (Figure 8-13):

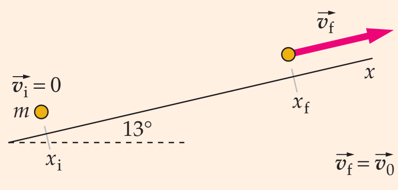

FIGURE 8-13

3. The speed v_f immediately after the collision is related to the range R, which is given by $R = (v_0^2/g)\sin 2\theta_0$ (Equation 2-23) with v_0 equal to the post-collision speed v_f:

$$R = \frac{v_f^2}{g}\sin 2\theta_0$$

4. Take $\theta_0 = 13°$ and calculate the initial speed for the projectile motion:

$$v_0 = \sqrt{\frac{Rg}{\sin 2\theta_0}} = \sqrt{\frac{(190\ \mathrm{m})(9.81\ \mathrm{m/s^2})}{\sin 26°}} = 65.2\ \mathrm{m/s}$$

5. Use this value of v_0 to calculate the impulse:

$$I_x = \Delta p_x = m(v_{0x} - 0) = (0.045\,\text{kg})(65.2\,\text{m/s}) = 2.93\,\text{kg}\cdot\text{m/s} = \boxed{2.90\,\text{N}\cdot\text{s}}$$

(*b*) Calculate the collision time Δt using $\Delta x = 2.0$ cm and $v_{\text{av}x} = \frac{1}{2}(v_{\text{i}x} + v_{\text{f}x})$:

$$\Delta t = \frac{\Delta x}{v_{\text{av}x}} = \frac{\Delta x}{\frac{1}{2}(0 + v_0)} = \frac{0.020\,\text{m}}{\frac{1}{2}(65.2\,\text{m/s})} = 6.13 \times 10^{-4}\,\text{s} = \boxed{6.1 \times 10^{-4}\,\text{s}}$$

(*c*) Use the calculated values of I_x and Δt to find the magnitude of the average force:

$$F_{\text{av}} = F_{\text{av}x} = \frac{I_x}{\Delta t} = \frac{2.93\,\text{N}\cdot\text{s}}{6.13 \times 10^{-4}\,\text{s}} = 4.78\,\text{kN} = \boxed{4.8\,\text{kN}}$$

CHECK The weight of the ball is mg, which is $(0.045\,\text{kg})(9.81\,\text{N/kg}) \approx 0.50\,\text{N}$. We found the force of the golf club on the ball to be many times the weight of the ball, as expected.

TAKING IT FURTHER In this example, the force of the air on the ball has been left out of our analysis. However, for an actual golf shot the effects of the air are definitely *not* negligible, as any player with a slice can verify.

COLLISIONS IN ONE DIMENSION

Collisions in which the colliding objects move along the same straight line, say along the x axis, both before, during, and after the collision are called one-dimensional collisions (Figure 8-14).

FIGURE 8-14 In stock car racing, a driver sometimes bumps his car into the car ahead to "send a message"—an example of an inelastic collision. *(Sam Sharpe/The Sharpe Image/Corbis.)*

For motion along the x axis, v represents a speed and v_x represents velocity (a signed quantity). We are now departing this convention and adopting a less specific but more concise notation. In the discussion that follows and in the remainder of this book, the symbol "v" may represent either a speed or a velocity in one dimension. In each appearance of v, it will be up to the reader to determine from context whether v represents a speed or a velocity.

> ! The symbol "v" can represent either a speed or a velocity in one dimension. (In one dimension, velocity is a signed quantity.)

Consider an object of mass m_1 with initial velocity $v_{1\text{i}}$ approaching a second object of mass m_2 that is moving in the same direction with initial velocity $v_{2\text{i}}$. If $v_{2\text{i}} < v_{1\text{i}}$, the objects collide. Let $v_{1\text{f}}$ and $v_{2\text{f}}$ be their velocities after the collision. The two objects can be considered an isolated system. Conservation of momentum gives one equation between the two unknown velocities $v_{1\text{f}}$ and $v_{2\text{f}}$:

$$m_1 v_{1\text{f}} + m_2 v_{2\text{f}} = m_1 v_{1\text{i}} + m_2 v_{2\text{i}} \qquad \text{8-14}$$

To determine $v_{1\text{f}}$ and $v_{2\text{f}}$, a second equation is needed. That second equation depends on the type of collision.

Perfectly inelastic collisions In *perfectly* inelastic collisions, the objects *have the same velocity after the collision*, often because they are stuck together. A low-speed collision between a moving railroad car and an initially stationary railroad car in which the two cars couple (Figure 8-15) is a perfectly inelastic collision. For perfectly inelastic collisions, the final velocities are equal to each other and to the velocity of the center of mass:

$$v_{1\text{f}} = v_{2\text{f}} = v_{\text{cm}}$$

Substituting this result into Equation 8-14 gives

$$(m_1 + m_2)v_{\text{cm}} = m_1 v_{1\text{i}} + m_2 v_{2\text{i}} \qquad \text{8-15}$$

It is sometimes useful to express the kinetic energy, K, of a particle in terms of its momentum, p. For a mass, m, moving along the x axis with velocity, v, we have

$$K = \tfrac{1}{2}mv^2 = \frac{(mv)^2}{2m}$$

Because $p = mv$,

$$K = \frac{p^2}{2m} \qquad \text{8-16}$$

FIGURE 8-15 The engine bumps into the car causing the two to couple together—an example of a perfectly inelastic collision. *(Courtesy of Dick Tinder.)*

We can apply this to a perfectly inelastic collision where one object is initially at rest. The momentum of the system is that of the incoming object:

$$P_{sys} = p_{1i} = m_1 v_{1i}$$

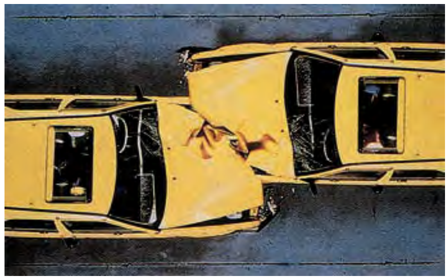
The initial kinetic energy is

$$K_i = \frac{P_{sys}^2}{2m_1} \qquad \text{8-17}$$

After colliding, the objects move together as a single mass $m_1 + m_2$ with velocity v_{cm}. Momentum is conserved, so the final momentum equals P_{sys}. The final kinetic energy is then

$$K_f = \frac{P_{sys}^2}{2(m_1 + m_2)} \quad \text{(perfectly inelastic collisions)} \qquad \text{8-18}$$

Comparing Equations 8-17 and 8-18, we see that the final kinetic energy is less than the initial kinetic energy.



(Romilly Lockyer/The Image Bank.)

Example 8-9 A Catch in Space

An astronaut of mass 60 kg is on a space walk to repair a communications satellite when he realizes he needs to consult the repair manual. You happen to have it with you, so you throw it to him with speed 4.0 m/s relative to the spacecraft. He is at rest relative to the spacecraft before catching the 3.0-kg book (Figure 8-16). Find (*a*) his velocity just after he catches the book, (*b*) the initial and final kinetic energies of the book–astronaut system, and (*c*) the impulse exerted by the book on the astronaut.

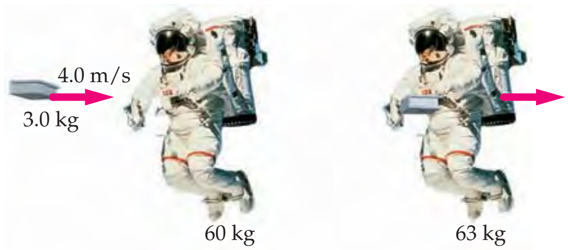


FIGURE 8-16

PICTURE This collision is a perfectly inelastic collision. So, following the catch, the book and astronaut move with the same final velocity. (*a*) We find the final velocity using conservation of momentum, as expressed in Equation 8-15. (*b*) The kinetic energies of the book and astronaut can be calculated directly from their masses and their initial and final velocities. (*c*) The impulse exerted by the book on the astronaut equals the change in momentum of the astronaut.

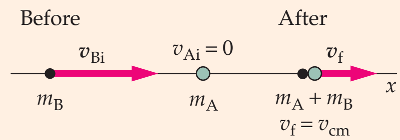

FIGURE 8-17

SOLVE

(*a*) 1. Make a drawing (Figure 8-17) showing the objects just before and just after the catch. Let the direction you throw the book be the $+x$ direction:

2. Use conservation of momentum to relate the final velocity of the system v_f to the initial velocities:

$$m_B v_{Bi} + m_A v_{Ai} = (m_A + m_B)v_f$$

3. Solve for v_f:

$$v_f = \frac{m_B v_B + m_A v_A}{m_B + m_A} = \frac{(3.0\text{ kg})(4.0\text{ m/s}) + (60\text{ kg})(0\text{ m/s})}{3.0\text{ kg} + 60\text{ kg}}$$
$$= 0.190\text{ m/s} = \boxed{0.19\text{ m/s}}$$

(*b*) 1. Because the astronaut is initially at rest, the initial kinetic energy of the book–astronaut system is the initial kinetic energy of the book:

$$K_{sys\,i} = K_{Bi} = \tfrac{1}{2}m_B v_{Bi}^2 = \tfrac{1}{2}(3.0\text{ kg})(4.0\text{ m/s})^2 = \boxed{24\text{ J}}$$

2. The final kinetic energy is the kinetic energy of the book and astronaut moving together at v_f:

$$K_{sys\,f} = \tfrac{1}{2}(m_B + m_A)v_f^2 = 2(63\text{ kg})(0.190\text{ m/s})^2 = 1.14\text{ J} = \boxed{1.1\text{ J}}$$

(*c*) Set the impulse exerted on the astronaut equal to the change in momentum of the astronaut:

$$I_{\text{by B on A}} = \Delta p_A = m_A \Delta v_A = (60\text{ kg})(0.190\text{ m/s} - 0)$$
$$= 11.4\text{ kg}\cdot\text{m/s} = \boxed{11\text{ N}\cdot\text{s}}$$

CHECK The final velocity, the Part (*a*) step-3 result, is equal to the velocity of the center of mass ($v_f = v_{cm}$). Before the collision, the book–astronaut system had both kinetic energy associated with the motion of the center of mass and kinetic energy relative to the center of mass. After the collision, the kinetic energy relative to the center of mass is equal to zero. As expected, the total kinetic energy of the system decreased.

TAKING IT FURTHER Most of the initial kinetic energy in this collision is lost by conversion to thermal energy. In addition, the impulse exerted by the book on the astronaut is equal and opposite to that exerted by the astronaut on the book, so the total change in momentum of the book–astronaut system is zero.

Example 8-10 A Ballistic Pendulum

In a feat of public marksmanship, you fire a bullet into a hanging wood block (Figure 8-18), which is a device known as a *ballistic pendulum*. The block, with bullet embedded, swings upward. Noting the height reached at the top of the swing, you immediately inform the crowd of the bullet's speed. How fast was the bullet traveling?

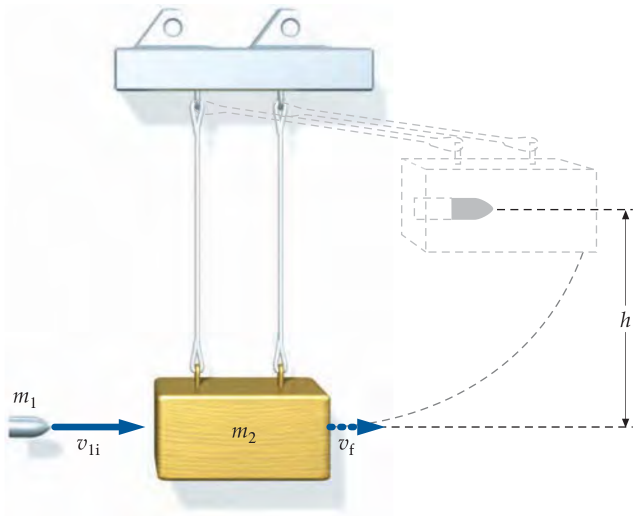

FIGURE 8-18

PICTURE Although the block moves upward after the collision, we can still consider this a one-dimensional collision, because the direction of the bullet and the block just after the collision is in the bullet's original direction of motion. The precollision velocity of the bullet v_{1i} is related to the postcollision velocity of the bullet–block system v_f by conservation of momentum. The speed v_f is related to the height, h, by conservation of mechanical energy. Let m_1 be the mass of the bullet and m_2 be the mass of the block.

SOLVE

1. Using conservation of mechanical energy *after* the collision, we relate the postcollision speed v_f to the maximum height h:

$$\tfrac{1}{2}(m_1 + m_2)v_f^2 = (m_1 + m_2)gh$$
$$v_f = \sqrt{2gh}$$

2. Using conservation of momentum *during* the collision we relate velocities v_{1i} and v_f:

$$m_1 v_{1i} = (m_1 + m_2)v_f$$
$$v_{1i} = \frac{m_1 + m_2}{m_1} v_f$$

3. Substituting for v_f in the step-2 result, we can solve for v_{1i}:

$$v_{1i} = \frac{m_1 + m_2}{m_1} v_f = \boxed{\frac{m_1 + m_2}{m_1}\sqrt{2gh}}$$

CHECK The mass of the block is much greater than the mass of the bullet. Thus, we expect the speed of the bullet to be much greater than the speed of the block after impact. Our step-2 result meets this expectation.

TAKING IT FURTHER We assumed that the time of the collision is so short that the displacement of the block during the collision is negligible. This assumption means the block had the postcollision speed v_f while still at the lowest point in the arc.

CONCEPT CHECK 8-1

Can this example be solved by equating the initial kinetic energy of the bullet with the potential energy of the block–bullet composite at maximum height? That is, is mechanical energy conserved both during the perfectly inelastic collision and during the rise of the pendulum?

Example 8-11 Collision with an Empty Box

Try It Yourself

You repeat your feat of Example 8-10, this time with an empty box as the target. The bullet strikes the box and passes through it completely. A laser ranging device indicates that the bullet emerged with half its initial velocity. Hearing this, you correctly report how high the target must have swung. How high did it swing?

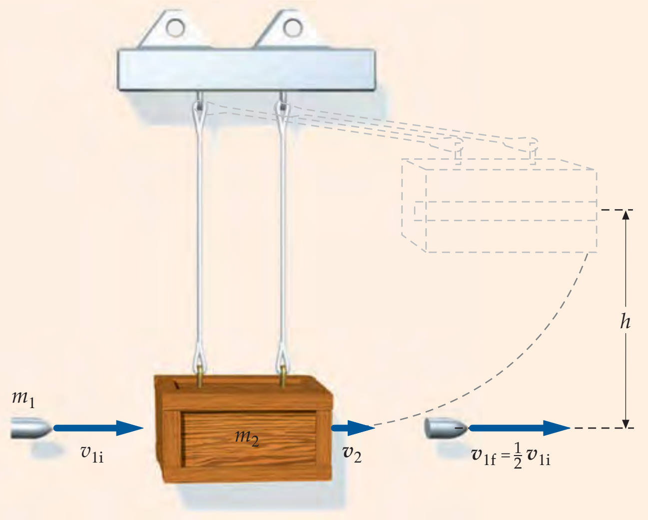

FIGURE 8-19

PICTURE The height h is related to the box's speed v_2 just after colliding by the conservation of mechanical energy (Figure 8-19). This speed can be determined using conservation of momentum.

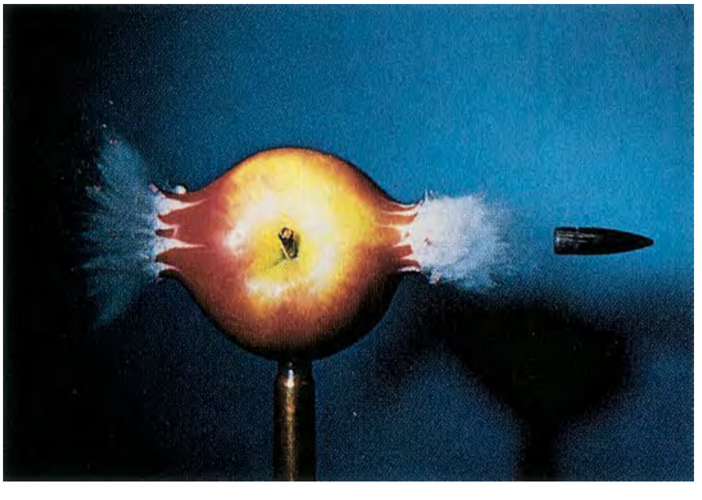
SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. Use conservation of mechanical energy to relate the final height h to the speed v_2 of the box just after the collision.	$m_2gh = \frac{1}{2}m_2v_2^2$
2. Use conservation of momentum to write an equation relating v_{1i} to the postcollision speed of the box, v_2.	$m_1v_{1i} = m_2v_2 + m_1(\frac{1}{2}v_{1i})$
3. Eliminate v_2 from the two equations and solve for h.	$h = \boxed{\dfrac{m_1^2v_{1i}^2}{8m_2^2g}}$

CHECK The quotient v^2/g has units of m^2/s^2 divided by m/s^2, which reduce to just m (meters). Thus, the step-3 result has appropriate units for height.

TAKING IT FURTHER The collision of the bullet and the box is an inelastic collision, but it is not a perfectly inelastic collision, because the two objects do not have the same velocity after the collision. Inelastic collisions also occur in microscopic systems. For example, when an electron collides with an atom, the atom is sometimes excited to a higher internal energy state. As a result, the total kinetic energy of the atom and the electron is less after the collision than before the collision.



A bullet traveling 850 m/s collides inelastically with an apple, which disintegrates completely moments later. Exposure time is less than a millionth of a second. (*Estate of Harold E. Edgerton/ Palm Press Inc.*)

Example 8-12 Collisions with Putty *Conceptual*

Mary has two small balls of equal mass, a ball of plumber's putty and a one of Silly Putty. She throws the ball of plumber's putty at a block suspended by strings shown in Figure 8-20. The ball strikes the block with a "thonk" and falls to the floor. The block subsequently swings to a maximum height h. If she had thrown the ball of Silly Putty (instead of the plumber's putty) at the same speed, would the block subsequently have risen to a height greater than h? Silly Putty, unlike plumber's putty, is elastic and would bounce back from the block.

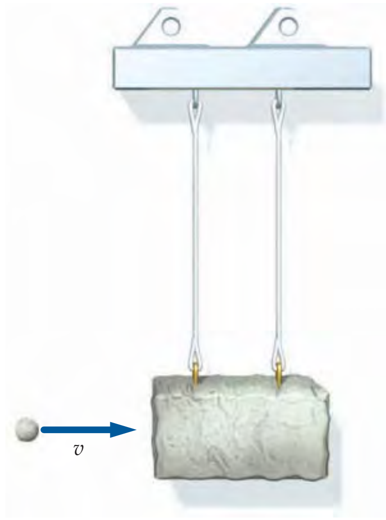


FIGURE 8-20

PICTURE During impact the change in momentum of the ball–block system is zero. The greater the magnitude of the change in momentum of the ball is, the greater the magnitude of the change in momentum of the block is. Does magnitude of the change in momentum of the ball increase more if the ball bounces back than if it does not?

SOLVE

The ball of plumber's putty loses a large fraction of its forward momentum. The ball of Silly Putty would lose all of its forward momentum and then gain momentum in the opposite direction. It would undergo a larger change in momentum than did the ball of plumber's putty.

The block would swing to a greater height after being struck with the ball of Silly Putty than it did after being struck with the ball of plumbers putty.

CHECK The block exerts a backward impulse on the ball of plumber's putty to slow the ball to a stop. The same backward impulse on the ball of Silly Putty would also bring it to a stop, and an additional backward impulse on the ball would give it momentum in the backward direction. Thus, the block exerts the larger backward impulse on the Silly-Putty ball. In accord with Newton's third law, the impulse of a ball on the block is equal and opposite to the impulse of the block on the ball. Thus, the Silly-Putty ball exerts the larger forward impulse on the block, giving the block a larger forward change in momentum.

Elastic collisions In elastic collisions, the kinetic energy of the system is the same before and after the collision. Elastic collisions are an ideal that is sometimes approached but never realized in the macroscopic world. If a ball dropped onto a concrete platform bounces back to its original height, then the collision between the ball and the concrete would be elastic. That situation has never been observed. At the microscopic level, elastic collisions are common. For example, the collisions between air molecules at the temperatures found on the surface of Earth are almost always elastic.

Figure 8-21 shows two objects before and after they have a one-dimensional head-on collision. Momentum is conserved during this collision so

$$m_1v_{1f} + m_2v_{2f} = m_1v_{1i} + m_2v_{2i} \tag{8-19}$$

The collision is elastic. Only for elastic collisions is the kinetic energy the same after the collision as before the collision. Therefore,

$$\tfrac{1}{2}m_1v_{1f}^2 + \tfrac{1}{2}m_2v_{2f}^2 = \tfrac{1}{2}m_1v_{1i}^2 + \tfrac{1}{2}m_2v_{2i}^2 \tag{8-20}$$

These two equations are sufficient to determine the final velocities of the two objects if given the initial velocities and the masses. However, the quadratic nature of Equation 8-20 often complicates the solution of simultaneous Equations 8-19 and 8-20. Such problems can be treated more easily if we express the velocity of the two

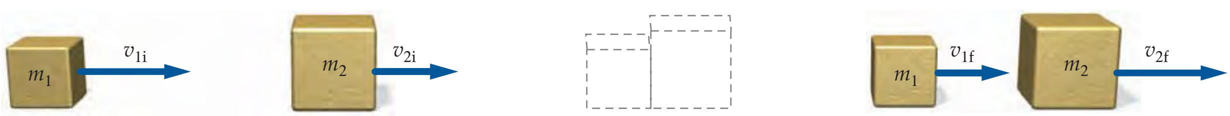

FIGURE 8-21 Closing (approaching) and separating (receding) in a head-on elastic collision.

objects relative to each other after the collision in terms of their relative velocity before the collision. Rearranging Equation 8-20 gives

$$m_2(v_{2f}^2 - v_{2i}^2) = m_1(v_{1i}^2 - v_{1f}^2)$$

Because $(v_{2f}^2 - v_{2i}^2) = (v_{2f} - v_{2i})(v_{2f} + v_{2i})$ and $(v_{1i}^2 - v_{1f}^2) = (v_{1i} - v_{1f})(v_{1i} + v_{1f})$, we have

$$m_2(v_{2f} - v_{2i})(v_{2f} + v_{2i}) = m_1(v_{1i} - v_{1f})(v_{1i} + v_{1f}) \qquad \text{8-21}$$

From conservation of momentum, we have that

$$m_1v_{1f} + m_2v_{2f} = m_1v_{1i} + m_2v_{2i}$$

Rearranging the equation for conservation of momentum (Equation 8-19) gives

$$m_2(v_{2f} - v_{2i}) = m_1(v_{1i} - v_{1f}) \qquad \text{8-22}$$

Dividing Equation 8-21 by Equation 8-22, we get

$$v_{2f} + v_{2i} = v_{1i} + v_{1f}$$

Rearranging yet again, we obtain

$$v_{1i} - v_{2i} = v_{2f} - v_{1f} \qquad \text{8-23}$$

RELATIVE VELOCITIES IN AN ELASTIC COLLISION

where $v_{1i} - v_{2i}$ is the *speed of approach* (closing speed) of the two particles before the collision and $v_{2f} - v_{1f}$ is the *speed of separation* following the collision (Figure 8-22). Equation 8-23 states:

In elastic collisions, the speed of separation equals the speed of approach.

Solving head-on elastic-collision problems is *always* easier using Equations 8-19 and 8-23 rather than Equations 8-19 and 8-20.

! Equation 8-23 is valid only if the initial and final kinetic energies are equal, so it applies *only* to elastic collisions.

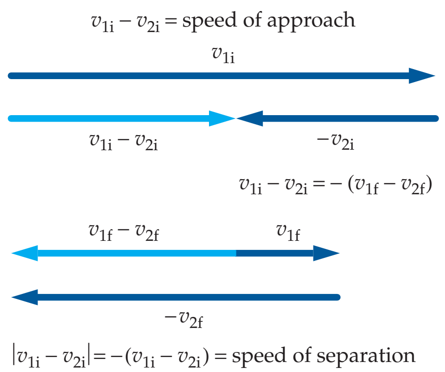

FIGURE 8-22

Example 8-13 Elastic Collision of Two Blocks

A 4.0-kg block moving to the right at 6.0 m/s undergoes an elastic head-on collision with a 2.0-kg block moving to the right at 3.0 m/s (Figure 8-23). Find their final velocities.

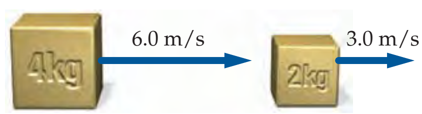

FIGURE 8-23

PICTURE Conservation of momentum and the equality of the initial and final kinetic energies (expressed as a reversal of relative velocities) give two equations for the two unknown final velocities. Let subscript 1 denote the 4.0-kg block, subscript 2 the 2.0-kg block.

SOLVE

1. Apply conservation of momentum and simplify to obtain an equation relating the two final velocities:

$$m_1v_{1i} + m_2v_{2i} = m_1v_{1f} + m_2v_{2f}$$
$$(4.0\,\text{kg})(6.0\,\text{m/s}) + (2.0\,\text{kg})(3.0\,\text{m/s}) = (4.0\,\text{kg})v_{1f} + (2.0\,\text{kg})v_{2f}$$
$$\text{so} \quad 2v_{1f} + v_{2f} = 15\,\text{m/s}$$

2. Because this is a head-on elastic collision, we can use Equation 8-23 to obtain a second equation:

$$v_{2f} - v_{1f} = v_{1i} - v_{2i}$$
$$= 6.0\,\text{m/s} - 3.0\,\text{m/s} = 3.0\,\text{m/s}$$

3. Subtract the step-2 result from the step-1 result and solve for v_{1f}:

$$2v_{1f} + v_{1f} = 12\,\text{m/s} \quad \text{so} \quad v_{1f} = \boxed{4.0\,\text{m/s}}$$

4. Substitute into the step-2 result and solve for v_{2f}:

$$v_{2f} - 4.0\,\text{m/s} = 3.0\,\text{m/s} \quad \text{so} \quad v_{2f} = \boxed{7.0\,\text{m/s}}$$

CHECK As a check, we calculate the initial and final kinetic energies.

$$K_i = \tfrac{1}{2}(4.0\,\text{kg})(6.0\,\text{m/s})^2 + \tfrac{1}{2}(2.0\,\text{kg})(3.0\,\text{m/s})^2 = 72\,\text{J} + 9.0\,\text{J} = 81\,\text{J}.$$
$$K_f = \tfrac{1}{2}(4.0\,\text{kg})(4.0\,\text{m/s})^2 + \tfrac{1}{2}(2.0\,\text{kg})(7.0\,\text{m/s})^2 = 32\,\text{J} + 49\,\text{J} = 81\,\text{J}.$$

The pre- and postcollision kinetic energies are equal, as expected.

Example 8-14 Elastic Collision of a Neutron and a Nucleus

A neutron of mass m_n and speed v_{ni} undergoes a head-on elastic collision with a carbon nucleus of mass m_C initially at rest (Figure 8-24). (*a*) What are the final velocities of both particles? (*b*) What fraction f of its initial kinetic energy does the neutron lose?

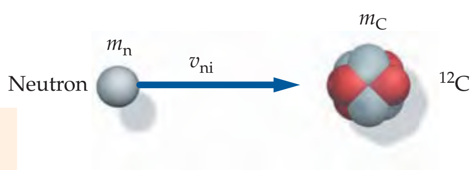

FIGURE 8-24

PICTURE Conservation of momentum and conservation of kinetic energy allow us to find the final velocities. Because the kinetic energy of the carbon nucleus is initially zero, its final kinetic energy equals the kinetic energy lost by the neutron.

SOLVE

(*a*) 1. Use conservation of momentum to obtain one relation for the final velocities:

$$m_n v_{ni} = m_n v_{nf} + m_C v_{Cf}$$

2. Use Equation 8-23 to equate the speeds of recession and approach:

$$v_{Cf} - v_{nf} = v_{ni} - v_{Ci}$$
$$= v_{ni} - 0$$
$$\text{so} \quad v_{Cf} = v_{ni} + v_{nf}$$

3. To eliminate v_{Cf}, substitute the expression for v_{Cf} from step 2 into the step-1 result:

$$m_n v_{ni} = m_n v_{nf} + m_C(v_{ni} + v_{nf})$$

4. Solve for v_{nf}:

$$v_{nf} = \boxed{-\frac{m_C - m_n}{m_n + m_C} v_{ni}}$$

5. Substitute the step-4 result into the step-2 result and solve for v_{Cf}:

$$v_{Cf} = v_{ni} - \frac{m_C - m_n}{m_n + m_C} v_{ni} = \boxed{\frac{2m_n}{m_n + m_C} v_{ni}}$$

(*b*) 1. The collision is elastic, so the kinetic energy lost by the neutron is the final kinetic energy of the carbon nucleus:

$$f = \frac{-\Delta K_n}{K_{ni}} = \frac{K_{Cf}}{K_{ni}} = \frac{\frac{1}{2}m_C v_{Cf}^2}{\frac{1}{2}m_n v_{ni}^2} = \frac{m_C}{m_n}\left(\frac{v_{Cf}}{v_{ni}}\right)^2$$

2. Solve the Part-(*a*) step-5 result for the ratio of the velocities; substitute into the Part-(*b*) step-1 result, and solve for the fractional energy loss of the neutron:

$$f = \frac{m_C}{m_n}\left(\frac{2m_n}{m_n + m_C}\right)^2 = \boxed{\frac{4m_n m_C}{(m_n + m_C)^2}}$$

CHECK Note that our calculated value for v_{nf} is negative. The neutron m_n bounces back from the more massive carbon nucleus m_C. This result is expected when a light particle undergoes a head-on elastic collision with a more massive particle that is initially at rest.

TAKING IT FURTHER The fractional energy loss for head-on collisions depends on the ratio of the masses (see Figure 8-25).

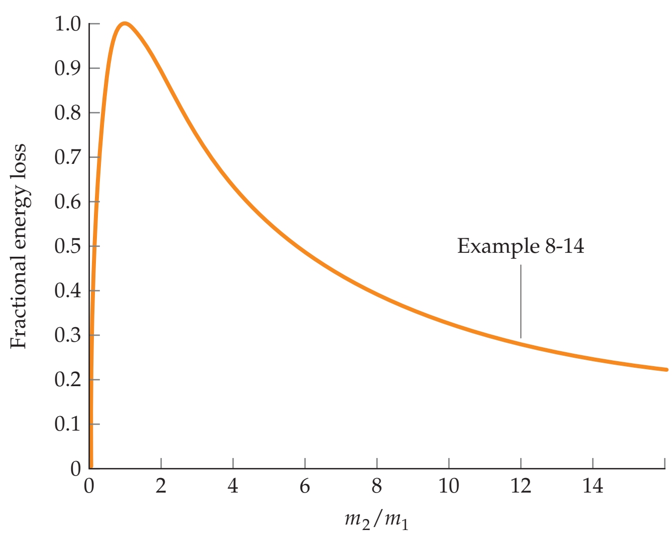

FIGURE 8-25 Fractional energy loss as a function of the ratio of the two masses. The maximum energy loss occurs when $m_1 = m_2$.

PRACTICE PROBLEM 8-5 Consider an elastic head-on collision between a moving object (object 1) and a second moving object of equal mass (object 2). Use Equations 8-19 and 8-23 to show that the two objects exchange velocities. That is, show that the final velocity of object 2 equals the initial velocity of object 1, and vice versa.

The final velocity of the incoming particle v_{1f} and that of the originally stationary particle v_{2f} are related to the initial velocity of the incoming particle by

$$v_{1f} = \frac{m_1 - m_2}{m_1 + m_2} v_{1i} \qquad \text{8-24}a$$

and

$$v_{2f} = \frac{2m_1}{m_1 + m_2} v_{1i} \qquad \text{8-24}b$$

These equations were derived in Example 8-14. Here we show they give plausible results for limiting values of the masses. When a very massive object (say a bowling ball) collides with a light stationary object (say a Ping-Pong ball), the massive object is essentially unaffected. Before the collision, the relative speed of approach is v_{1i}. If the massive object continues with a velocity that is essentially v_{1i} after the collision, the velocity of the smaller object must be $2v_{1i}$, so that the speed of recession is equal to the speed of approach. This result also follows from Equations 8-24*a* and 8-24*b* if we take m_2 to be much smaller than m_1, in which case $v_{1f} \approx v_{1i}$ and $v_{2f} \approx 2v_{1i}$, as expected.

The coefficient of restitution Most collisions lie somewhere between the extreme cases of elastic, in which the relative velocities are reversed, and perfectly inelastic, in which there is no relative velocity after the collision. The **coefficient of restitution** *e* is a measure of the elasticity of a collision. It is defined as the ratio of the speed of recession to the speed of approach.

$$e = \frac{v_{rec}}{v_{app}} = \frac{v_{1f} - v_{2f}}{v_{2i} - v_{1i}} \qquad \text{8-25}$$

DEFINITION—COEFFICIENT OF RESTITUTION

For an elastic collision, $e = 1$. For a perfectly inelastic collision, $e = 0$.

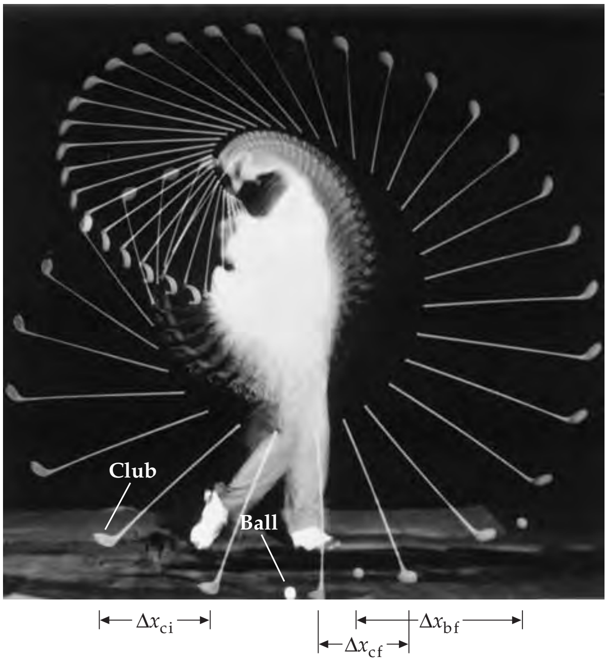

FIGURE 8-26
(Estate of Harold E. Edgerton/Palm Press Inc.)

PRACTICE PROBLEM 8-6
From the picture (Figure 8-26) of the golf club hitting the golf ball, estimate the coefficient of restitution of the golf ball–golf club interaction.

COLLISIONS IN TWO AND THREE DIMENSIONS

For one-dimensional collisions, the directions of the initial and final velocity vectors can be specified by a + or a −. For two- or three-dimensional collisions, this is not the case. During such a collision, momentum is conserved in each of the *x*, *y*, and *z* directions.

Inelastic collisions For collisions in two or three dimensions, the total initial momentum is the sum of the initial momentum vectors of each object involved in the collision. Because following a perfectly inelastic collision the two objects have the same final velocity and because momentum is conserved, we have $m_{1i}\vec{v}_{1i} + m_2\vec{v}_{2i} = (m_1 + m_2)\vec{v}_f$. Due to this relation we know that the velocity vectors, and thus the collision, takes place in a single plane. In addition, from the definition of the center of mass we know that $\vec{v}_f = \vec{v}_{cm}$.

Example 8-15 A Car–Truck Collision

You are at the wheel of a 1200-kg car traveling east through an intersection when a 3000-kg truck traveling north through the intersection crashes into your car, as shown in Figure 8-27. Your car and the truck remain stuck together after impact. The driver of the truck claims you were at fault because you were speeding. You look for evidence to disprove this claim. First, there are no skid marks, indicating that neither you nor the truck driver saw the accident coming and braked hard; second, the posted speed limit for the road on which you were driving is 80 km/h; third, the speedometer of the truck was smashed on impact, leaving the needle stuck at 50 km/h; and fourth, the wreck initially skidded from the impact zone at an angle of 59° north of east. Does this evidence support or undermine the claim that you were speeding?

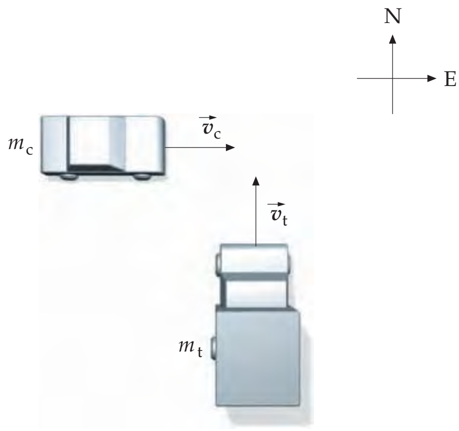

FIGURE 8-27

PICTURE We are given the masses of the vehicles and the velocity of the truck at impact. We know this is a perfectly inelastic collision because the car and truck stick together. Use conservation of momentum to determine your car's initial velocity.

SOLVE

1. Make a drawing (Figure 8-28) showing the two objects just before and just after the collision. Choose a coordinate system so that initially the car is traveling in the $+x$ direction and the truck is traveling in the $+y$ direction:

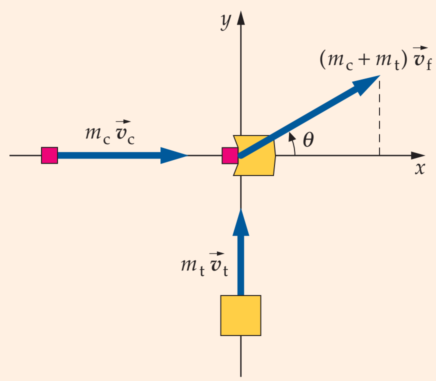

FIGURE 8-28

2. Write out the conservation of momentum equation in terms of masses and velocities:
$$m_c\vec{v}_c + m_t\vec{v}_t = (m_c + m_t)\vec{v}_f$$

3. Equate the x component of the initial momentum to the x component of the final momentum:
$$m_cv_c + 0 = (m_c + m_t)v_f\cos\theta$$

4. Equate the y component of the initial momentum to the y component of the final momentum:
$$0 + m_tv_t = (m_c + m_t)v_f\sin\theta$$

5. Eliminate v_f by dividing the y component equation by the x component equation:
$$\frac{m_tv_t}{m_cv_c} = \frac{\sin\theta}{\cos\theta} = \tan\theta$$
$$\text{so}\quad v_c = \frac{m_tv_t}{m_c\tan\theta} = \frac{(3000\text{ kg})(50\text{ km/h})}{(1200\text{ kg})\tan 59°} = \boxed{75\text{ km/h}}$$

6. Does this undermine the truck driver's claim that you were speeding?

> Because 75 km/h is less than the 80 km/h speed limit, the truck driver's claim is undermined by the careful application of physics.

CHECK The mass of the truck is 2.5 times the mass of the car. If the car were going 80 km/h, the truck's speed would be 5/8 that of the car, and the ratio of the magnitude of the momentum of the truck to that of the car would be $2.5 \times 5/8 = 1.56$. Because $\tan^{-1} 1.56 = 57°$ and 57° is slightly less than 59°, the step-6 result seems about right.

Next, we consider a three-dimensional inelastic collision in which the colliding objects do not share the same final velocity.

Example 8-16 A Glancing Collision

An object with mass m_1 and with an initial speed of 20 m/s undergoes an off-center collision with a second object of mass m_2. The second object is initially at rest. After the collision the first object is moving at 15 m/s at an angle of 25° with the direction of the initial velocity of the first object. In what direction is the second object moving?

PICTURE Momentum is conserved during this collision. It is a two-dimensional collision, so we equate the sum of the initial momentum vectors to the sum of the final momentum vectors and solve for the desired direction. (The problem does not indicate whether or not the collision is elastic, so we do not assume that it is.)

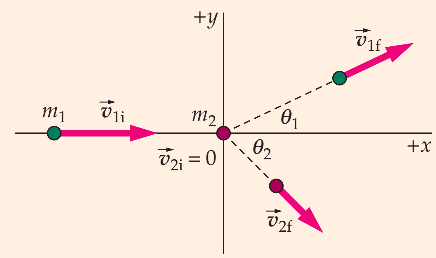

FIGURE 8-29

SOLVE

1. Sketch the two particles both before and after the collision (Figure 8-29). Choose the $+x$ direction to be the direction of the initial velocity of object 1. Include velocity vectors and labels in the sketch:

2. Write down the conservation of momentum relation, both in vector and in component form:

$$m_1\vec{v}_{1i} + 0 = m_1\vec{v}_{1f} + m_2\vec{v}_{2f}$$

or
$$m_1v_{1ix} = m_1v_{1fx} + m_2v_{2fx}$$
$$m_1v_{1iy} = m_1v_{1fy} + m_2v_{2fy}$$

3. Express the component equations in terms of magnitudes and angles:

$$m_1v_{1i} = m_1v_{1f}\cos\theta_1 + m_2v_{2f}\cos\theta_2$$
$$0 = m_1v_{1f}\sin\theta_1 + m_2v_{2f}\sin\theta_2$$

4. In order to solve for θ_2 we exploit the relation $\tan\theta = \sin\theta/\cos\theta$. First we solve the step-3 results for the ratio $\sin\theta_2/\cos\theta_2$:

$$m_2v_{2f}\sin\theta_2 = -m_1v_{1f}\sin\theta_1$$
$$m_2v_{2f}\cos\theta_2 = m_1v_{1i} - m_1v_{1f}\cos\theta_1$$

so
$$\frac{m_2v_{2f}\sin\theta_2}{m_2v_{2f}\cos\theta_2} = \frac{-m_1v_{1f}\sin\theta_1}{m_iv_{1i} - m_1v_{1f}\cos\theta_1}$$

and
$$\tan\theta_2 = \frac{-\sin\theta_1}{\dfrac{v_{1i}}{v_{1f}} - \cos\theta_1}$$

5. Substitute in numbers and solve for θ_2:

$$\tan\theta_2 = \frac{-\sin 25°}{\dfrac{20}{15} - \cos 25°} = -0.990$$

$$\therefore\ \theta_2 = \boxed{-45°}$$

CHECK In step 1 we chose a coordinate system such that $\theta_1 = +25°$. We expected that θ_2 would be between zero and $-90°$. Our result that $\theta_2 = -45°$ meets this expectation.

TAKING IT FURTHER The problem did not specify either m_2 or v_{2f}, so you may have been surprised that solving for θ_2 was possible. It was possible because both initial and one final momentum vectors were fully specified in the problem statement, so the conservation of momentum relation (step 2) completely specifies the other final momentum vector. Once all four momentum vectors were fully specified, solving for the direction of the final momentum of particle 2 became possible.

Elastic collisions Elastic collisions in two and three dimensions are more complicated than those we have already covered. Figure 8-30 shows an off-center collision between an object of mass m_1 moving with velocity $\vec{v}_{1i}$ parallel to the x axis toward an object of mass m_2 that is initially at rest at the origin. This type of collision is often referred to as a *glancing* collision (as opposed to a head-on collision). The distance b between the centers measured perpendicular to the direction of $\vec{v}_{1i}$ is called the *impact parameter*. After the collision, object 1 moves off with velocity $\vec{v}_{1f}$, making an angle θ_1 with the direction of its initial velocity, and object 2 moves with velocity $\vec{v}_{2f}$, making an angle θ_2 with $\vec{v}_{1i}$. The final velocities depend on the impact parameter and on the type of force exerted by one object on the other.

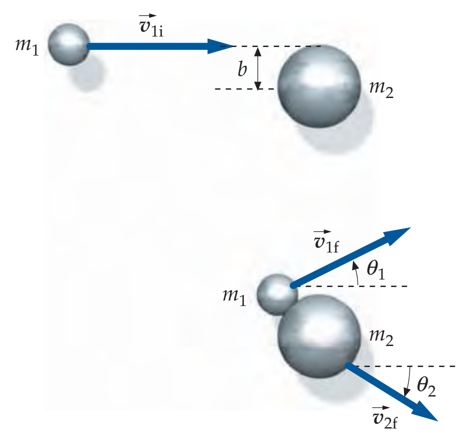

FIGURE 8-30 Off-center collision. The final velocities depend on the impact parameter b and on the type of force exerted by one object on the other.

Linear momentum is conserved, so we know that

$$\vec{P}_{\mathrm{sys}} = m_1\vec{v}_{1\mathrm{i}} = m_1\vec{v}_{1\mathrm{f}} + m_2\vec{v}_{2\mathrm{f}} \tag{8-26}$$

We can see from this equation that the vector $\vec{v}_{2\mathrm{f}}$ must lie in the plane formed by $\vec{v}_{1\mathrm{i}}$ and $\vec{v}_{1\mathrm{f}}$, which we will take to be the xy plane. Assuming that we know the initial velocity $\vec{v}_{1\mathrm{i}}$, we have four unknowns: the x and y components of both final velocities; or alternatively, the two final speeds and the two angles of deflection. We can apply the law of conservation of momentum in component form to give us two of the needed relations among these quantities:

$$m_1v_{1\mathrm{i}} = m_1v_{1\mathrm{f}}\cos\theta_1 + m_2v_{2\mathrm{f}}\cos\theta_2 \tag{8-27}$$

$$0 = m_1v_{1\mathrm{f}}\sin\theta_1 - m_2v_{2\mathrm{f}}\sin\theta_2 \tag{8-28}$$

Because the collision is elastic, we can use the conservation of kinetic energy to find a third relation:

$$\tfrac{1}{2}m_1v_{1\mathrm{i}}^2 = \tfrac{1}{2}m_1v_{1\mathrm{f}}^2 + m_2v_{2\mathrm{f}}^2 \tag{8-29}$$

We need an additional equation to be able to solve for the unknowns. The fourth relation depends on the impact parameter b and on the type of interacting force exerted by the colliding objects on each other. In practice, the fourth relation is often found experimentally, by measuring the angle of deflection or the angle of recoil. Such a measurement can then give us information about the type of interacting force between the bodies.

Now let us consider the interesting special case of the glancing elastic collision of two objects *of equal mass* when one is initially at rest (Figure 8-31*a*). If $\vec{v}_{1\mathrm{i}}$ and $\vec{v}_{1\mathrm{f}}$ are the initial and final velocities of object 1, and if $\vec{v}_{2\mathrm{f}}$ is the final velocity of object 2, conservation of momentum gives

$$m\vec{v}_{1\mathrm{i}} = m\vec{v}_{1\mathrm{f}} + m\vec{v}_{2\mathrm{f}}$$

or

$$\vec{v}_{1\mathrm{i}} = \vec{v}_{1\mathrm{f}} + \vec{v}_{2\mathrm{f}}$$

These vectors form the triangle shown in Figure 8-31*b*. Because the collision is elastic,

$$\tfrac{1}{2}mv_{1\mathrm{i}}^2 = \tfrac{1}{2}mv_{1\mathrm{f}}^2 + \tfrac{1}{2}mv_{2\mathrm{f}}^2$$

or

$$v_{1\mathrm{i}}^2 = v_{1\mathrm{f}}^2 + v_{2\mathrm{f}}^2 \tag{8-30}$$

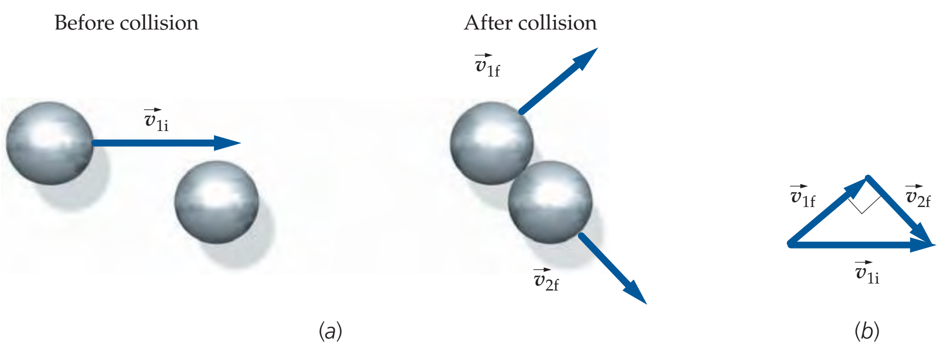

FIGURE 8-31 (*a*) Off-center elastic collision of two spheres of equal mass when one sphere is initially at rest. After the collision, the spheres move off at right angles to each other. (*b*) The velocity vectors for this collision form a right triangle.

(Joe Strunk/Visuals Unlimited.)

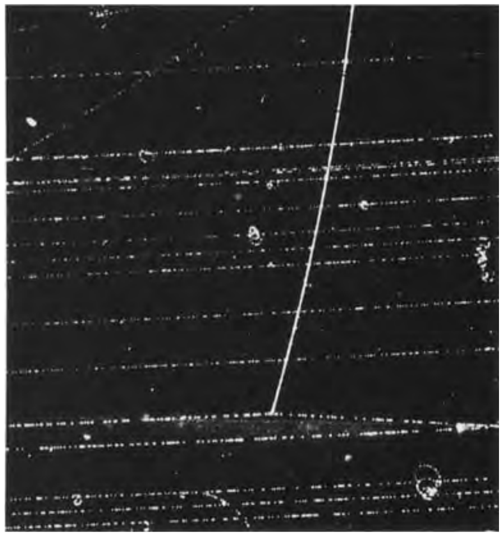
! The relation $v_{1\mathrm{i}} - v_{2\mathrm{i}} = v_{2\mathrm{f}} - v_{1\mathrm{f}}$ (Equation 8-23) is very useful for solving 1-dimensional elastic-collision problems. Do not think you can use this equation, or a vector form of the equation, to solve 2- or 3-dimensional elastic-collision problems. You cannot.

Multiflash photograph of an off-center elastic collision of two balls of equal mass. The dotted ball, entering from the left, strikes the striped ball, which is initially at rest. The final velocities of the two balls are perpendicular to each other. *(Berenice Abbot/Photo Researchers.)*

Equation 8-30 is the Pythagorean theorem for a right triangle formed by the vectors $\vec{v}_{1f}$, $\vec{v}_{2f}$, and $\vec{v}_{1i}$, with the hypotenuse of the triangle being $\vec{v}_{1i}$. So for this special case, the final velocity vectors $\vec{v}_{1f}$ and $\vec{v}_{2f}$ are perpendicular to each other, as shown in Figure 8-31*b*.

PRACTICE PROBLEM 8-7

In a friendly game of pool, the cue ball moving at speed v_0 glances off the initially stationary 2 ball. The collision is elastic, the 2 ball is at rest prior to the collision, and the cue ball is deflected 30° from its pre-collision path. What is the speed of the 2 ball following the collision? (The 2 ball and the cue ball have the same mass.)



Proton–proton collision in a liquid-hydrogen bubble chamber. A proton entering from the left interacts with a stationary proton. The two then move off at right angles. The slight curvature of the tracks is due to a magnetic field. *(Brookhaven National Laboratory.)*

* 8-4 COLLISIONS IN THE CENTER-OF-MASS REFERENCE FRAME

If the net external force on a system remains zero, the velocity of the center of mass remains constant in any inertial reference frame. It is often convenient to do calculations in an alternate reference frame that moves with the center of mass. Relative to the original reference frame, called the laboratory reference frame, this reference frame moves with a constant velocity $\vec{v}_{cm}$ relative to the laboratory frame. A reference frame that moves at the same velocity as the center of mass is called the **center-of-mass reference frame.** If a particle has velocity $\vec{v}$ relative to the laboratory reference frame, then its velocity relative to the center-of-mass reference frame is $\vec{u} = \vec{v} - \vec{v}_{cm}$. Because the total momentum of a system equals the total mass times the velocity of the center of mass, the total momentum is also zero in the center-of-mass frame. Thus, the center-of-mass reference frame is also a **zero-momentum reference frame.**

The mathematics of collisions is greatly simplified when considered from the center-of-mass reference frame. The velocities of the particles in the center-of-mass frame are $\vec{u}_1$ and $\vec{u}_2$. The momenta, $m_1\vec{u}_1$ and $m_2\vec{u}_2$, of the two incoming objects are equal and opposite:

$$m_1\vec{u}_1 + m_2\vec{u}_2 = 0$$

After a perfectly inelastic collision, the objects remain at rest. However, for an elastic head-on collision the direction of each velocity vector is reversed without changing its magnitude. That is,

$$\vec{u}_{1i} = -\vec{u}_{1f} \quad \text{and} \quad \vec{u}_{2i} = -\vec{u}_{2f} \quad \text{(one dimensional collision)}$$

Consider a simple two-particle system in a reference frame in which one particle of mass m_1 is moving with a velocity $\vec{v}_1$ and a second particle of mass m_2 is moving with a velocity $\vec{v}_2$ (Figure 8-32). In this frame, the velocity of the center of mass is

$$\vec{v}_{cm} = \frac{m_1\vec{v}_1 + m_2\vec{v}_2}{m_1 + m_2}$$

We can transform the velocities of each particle to its velocity in the center-of-mass reference frame by subtracting $\vec{v}_{cm}$ from it. Thus, the velocities of the particles in the center-of-mass frame are $\vec{u}_1$ and $\vec{u}_2$, given by

$$\vec{u}_1 = \vec{v}_1 - \vec{v}_{cm} \qquad \text{8-31}a$$

and

$$\vec{u}_2 = \vec{v}_2 - \vec{v}_{cm} \qquad \text{8-31}b$$

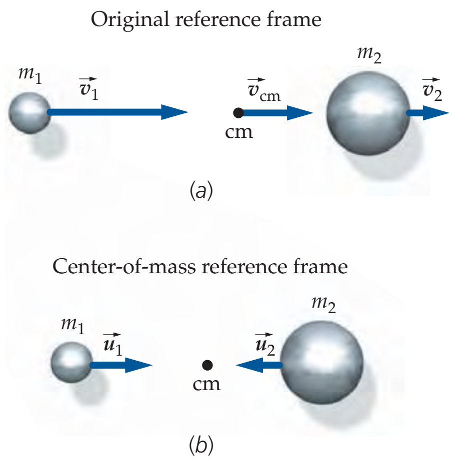


FIGURE 8-32 (*a*) Two particles viewed from a frame in which the center of mass has a velocity $\vec{v}_{cm}$. (*b*) The same two particles viewed from a reference frame for which the center of mass is at rest.

Example 8-17 The Elastic Collision of Two Blocks

Find the final velocities for the elastic head-on collision in Example 8-13 (in which a 4.0-kg block moving right at 6.0 m/s collides elastically with a 2.0-kg block moving right at 3.0 m/s) by transforming their velocities to the center-of-mass reference frame.

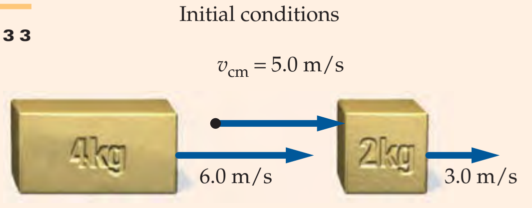
PICTURE We transform to the center-of-mass reference frame by first finding v_{cm} and subtracting it from each velocity. We then solve the collision by reversing the velocities and transforming back to the original frame.

SOLVE

1. Calculate the velocity of the center of mass v_{cm} (Figure 8-33):

$$v_{cm} = \frac{m_1 v_{1i} + m_2 v_{2i}}{m_1 + m_2} = \frac{(4.0\text{ kg})(6.0\text{ m/s}) + (2.0\text{ kg})(3.0\text{ m/s})}{4.0\text{ kg} + 2.0\text{ kg}} = 5.0\text{ m/s}$$

FIGURE 8-33

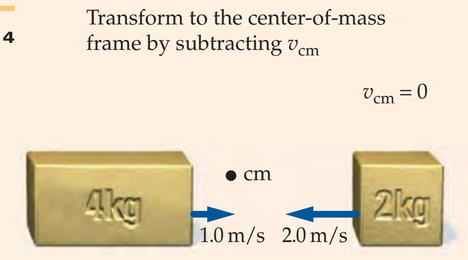


2. Transform the initial velocities to the center-of-mass reference frame by subtracting v_{cm} from the initial velocities (Figure 8-34):

$$u_{1i} = v_{1i} - v_{cm} = 6.0\text{ m/s} - 5.0\text{ m/s} = 1.0\text{ m/s}$$

$$u_{2i} = v_{2i} - v_{cm} = 3.0\text{ m/s} - 5.0\text{ m/s} = -2.0\text{ m/s}$$

FIGURE 8-34

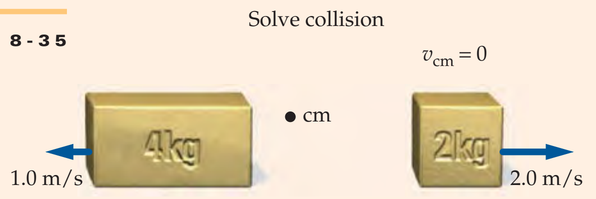


3. Solve the collision in the center-of-mass reference frame by reversing the velocity of each object (Figure 8-35):

$$u_{1f} = -u_{1i} = -1.0\text{ m/s}$$

$$u_{2f} = -u_{2i} = +2.0\text{ m/s}$$

FIGURE 8-35

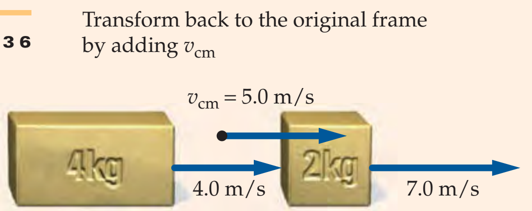


4. To find the final velocities in the original frame, add v_{cm} to each final velocity (Figure 8-36).

$$v_{1f} = u_{1f} + v_{cm} = -1.0\text{ m/s} + 5.0\text{ m/s} = \boxed{4.0\text{ m/s}}$$

$$v_{2f} = u_{2f} + v_{cm} = 2.0\text{ m/s} + 5.0\text{ m/s} = \boxed{7.0\text{ m/s}}$$

FIGURE 8-36



CHECK This result is the same result found in Example 8-13.

PRACTICE PROBLEM 8-8 Verify that the total momentum of the system both before the collision and after the collision is zero in the center-of-mass reference frame.

8-5 CONTINUOUSLY VARYING MASS AND ROCKET PROPULSION

A creative and important step in solving physics problems is specifying the system. In this section, we explore situations in which the system has a continuously changing mass. One example of such a system is a rocket. For a rocket, we specify the system to be the rocket plus any unspent fuel in it. As the spent fuel (the exhaust) spews out the back, the mass of the system decreases. Another example is the sand falling onto base of an hourglass (Figure 8-37). We specify the system as the sand currently resting on the base. The mass of the system continues to increase as the sand on the base continues to accumulate.

On the Jovian moon Io there is a large volcano. When the volcano erupts the speed of the effluence exceeds the escape speed of Io. Consequently, a stream of the effluence is projected into space. The material in the stream collides with and sticks to the surface of an asteroid passing through the stream. We now consider the effect of the impact of this material on the motion of the asteroid. Doing so involves developing an equation, that is, a version of Newton's second law for systems with continuously varying mass.

Suppose a continuous stream of matter moving at velocity $\vec{u}$ is impacting an object of mass M that is moving with velocity $\vec{v}$ (Figure 8-38). These impacting particles stick to the object, increasing its mass by ΔM during time Δt. In addition, during time Δt the velocity $\vec{v}$ changes by $\Delta\vec{v}$, as shown. Applying the impulse–momentum theorem to this system gives

$$\vec{F}_{\text{net ext}}\,\Delta t = \Delta\vec{P} = \vec{P}_{\text{f}} - \vec{P}_{\text{i}} = [(M + \Delta M)(\vec{v} + \Delta\vec{v})] - [M\vec{v} + \Delta M\vec{u}]$$

where the first term in square brackets is the momentum at time $t + \Delta t$ and the second term in square brackets is the momentum at time t. Rearranging terms gives

$$\vec{F}_{\text{net ext}}\,\Delta t = M\,\Delta\vec{v} + \Delta M\,(\vec{v} - \vec{u}) + \Delta M\,\Delta\vec{v} \qquad \text{8-32}$$

Dividing through Equation 8-32 by Δt gives

$$\vec{F}_{\text{net ext}} = M\frac{\Delta\vec{v}}{\Delta t} + \frac{\Delta M}{\Delta t}(\vec{v} - \vec{u}) + \frac{\Delta M}{\Delta t}\Delta\vec{v}$$

Taking the limit as $\Delta t \to 0$ (which also means as $\Delta M \to 0$ and as $\Delta\vec{v} \to 0$) gives

$$\vec{F}_{\text{net ext}} = M\frac{d\vec{v}}{dt} - \frac{dM}{dt}(\vec{v} - \vec{u}) + \frac{dM}{dt}(0)$$

Rearranging once again, we obtain

$$\vec{F}_{\text{net ext}} + \frac{dM}{dt}\vec{v}_{\text{rel}} = M\frac{d\vec{v}}{dt} \qquad \text{8-33}$$

NEWTON'S SECOND LAW—CONTINUOUSLY VARIABLE MASS

where $\vec{v}_{\text{rel}} = \vec{u} - \vec{v}$ is the velocity of the impacting material relative to the object. Note that except for the term $(dM/dt)\vec{v}_{\text{rel}}$, Equation 8-33 is the identical to the equation for Newton's second law for a system with constant mass.

FIGURE 8-37 *(Brand-X Pictures/PunchStock.)*

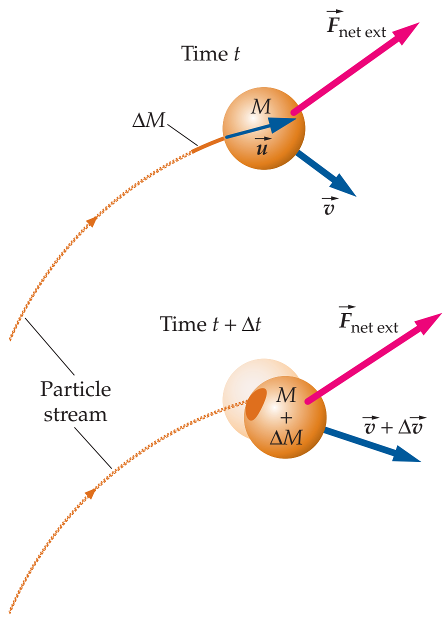


FIGURE 8-38 Particles in a continuous stream and moving at velocity $\vec{u}$ undergo perfectly inelastic collisions with an object of mass M moving at velocity $\vec{v}$. In addition, there is a net external force $\vec{F}_{\text{net ext}}$ acting on the object. The system is shown at time t and again at time $t + \Delta t$.

Example 8-18 A Falling Rope

A uniform rope of mass M and length L is held by one end, with the other end just touching the surface of a scale pan. The rope is released and begins to fall. Find the force of the rope on the scale pan just as the midpoint of the rope reaches the scale pan.

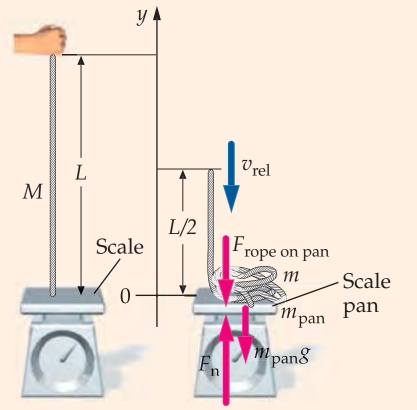

FIGURE 8-39 A very flexible rope of length L and mass M is released from rest and falls on the pan of a scale.

PICTURE Apply Equation 8-33 to the system consisting of the scale pan and that portion of the rope on the scale at time t. There are two external forces on that system, the force of gravity and the normal force exerted by the scale on the scale pan. The impact velocities of the different points along the falling rope depend upon their initial heights above the scale pan. The normal force exerted by the scale must both change the momentum of the rope impacting the scale, support the weight of both the pan and that portion of the rope already on the pan.

SOLVE

1. Draw a sketch of the situation (Figure 8-39). Include the initial configuration and the configuration at an arbitrary time later. Include a coordinate axis:

2. Express Equation 8-33 in component form. Let m denote the mass of the system (the pan plus that portion of the rope on the scale). The velocity of the system remains zero, so the dv_y/dt is zero:
$$F_{\text{net ext}\,y} + \frac{dm}{dt}v_{\text{rel}\,y} = m\frac{dv_y}{dt}$$
$$F_n - mg + \frac{dm}{dt}v_{\text{rel}\,y} = 0$$

3. Let dm denote the mass of the rope segment of length $d\ell$ that falls on the scale during time dt. Because the rope is uniform, the relation between dm and $d\ell$ is:
$$\frac{dm}{d\ell} = \frac{M}{L}$$

4. Solve for dm/dt by multiplying both sides of the step-3 result by $d\ell/dt$:
$$\frac{dm}{dt} = \frac{M}{L}\frac{d\ell}{dt}$$

5. $d\ell/dt$ is the impact speed of the segment, so $v_{\text{rel}\,y} = -d\ell/dt$. ($v_{\text{rel}\,y}$ is negative because up is the $+y$ direction and the rope is descending). Substituting this into the step-4 result gives:
$$\frac{dm}{dt} = -\frac{M}{L}v_{\text{rel}\,y}$$

6. Substituting the step-5 result into the step-2 result and solving for F_n gives:
$$F_n = mg + \frac{M}{L}v^2_{\text{rel}\,y}$$

7. Until it touches the scale, each point along the rope falls with the free-fall acceleration $\vec{g}$. Using $v_y^2 = v_{0y}^2 + 2a_y\,\Delta y$ (Equation 2-23) with $\Delta y = -L/2$ gives:
$$v^2_{\text{rel}\,y} = v^2_{\text{rel}\,y0} + 2a_y\,\Delta y = 0 + 2(-g)(-L/2) = gL$$

8. Substituting the step-7 result into the step-6 result, with $m = m_{pan} + \frac{1}{2}M$, gives:
$$F_n = \left(m_{pan} + \frac{M}{2}\right)g + \frac{M}{L}gL = m_{pan}g + \frac{3}{2}Mg$$

9. The normal force of the scale on the scale pan equals the weight of the pan plus the force by the rope on the pan:
$$F_n = m_{pan}g + F_{\text{by rope on pan}}$$
so $F_{\text{by rope on pan}} = F_n - m_{pan}g$

10. Subtract $m_{pan}g$ from both sides of the step-8 result and substitute into the step-9 result:
$$F_{\text{by rope on pan}} = \boxed{\frac{3}{2}Mg}$$

CHECK When the midpoint of the rope strikes the scale pan, the force of the rope currently on the scale pan is greater than $\frac{1}{2}Mg$ (the weight of the rope on the pan at that instant), as expected. We expect the force of the rope on the pan to be greater than $\frac{1}{2}Mg$ because the scale pan must both support the weight of the rope on it, and stop the momentum of the impacting rope.

PRACTICE PROBLEM 8-9 Find the force exerted by the scale pan on the rope (*a*) just before the upper end of the rope reaches the pan, and (*b*) just after the upper end of the rope comes to rest on the pan.

Rocket propulsion is a striking example of the conservation of momentum in action. We now derive the rocket equation (a special case of Equation 8-33). The mass of the rocket changes continuously as it burns fuel and expels exhaust gas. Consider a rocket moving straight up with velocity $\vec{v}$ relative to Earth, as shown in Figure 8-40. Assuming that the fuel is burned at a constant rate R, the rocket's mass at time t is

$$M = M_0 - Rt \qquad \text{8-34}$$

where M_0 is the initial mass of the rocket. The exhaust gases leave the rocket engine with velocity $\vec{u}_{\text{ex}}$ relative to the rocket, and the rate at which the fuel is burned is the rate at which the mass M decreases. We choose the rocket, including unspent fuel in it, as the system. Neglecting air drag, the only external force on the system is that of gravity. With $\vec{F}_{\text{net ext}} = M\vec{g}$ and $dM/dt = -R$, equation 8-33 becomes the **rocket equation:**

$$M\vec{g} - R\vec{u}_{\text{ex}} = M\frac{d\vec{v}}{dt} \qquad \text{8-35}$$

ROCKET EQUATION

FIGURE 8-40 *(NASA/ Superstock.)*

The quantity $-R\vec{u}_{\text{ex}}$ is the force exerted on the rocket by the exhaust gases. This force is called the **thrust** $\vec{F}_{\text{th}}$:

$$\vec{F}_{\text{th}} = -R\vec{u}_{\text{ex}} = -\left|\frac{dM}{dt}\right|\vec{u}_{\text{ex}} \qquad \text{8-36}$$

DEFINITION—ROCKET THRUST

The rocket is moving straight up, so we choose upward as the positive y direction and express Equation 8-35 in component form

$$-Mg - Ru_{\text{ex}\,y} = M\frac{dv_y}{dt}$$

The direction of $\vec{u}_{\text{ex}}$ is downward, so $u_{\text{ex}\,y} = -u_{\text{ex}}$. Substituting gives

$$-Mg + Ru_{\text{ex}} = M\frac{dv_y}{dt} \qquad \text{8-37}$$

Solving for dv_y/dt (the acceleration) gives

$$\frac{dv_y}{dt} = \frac{Ru_{\text{ex}}}{M} - g$$

where Ru_{ex}/M is the contribution of the thrust to the acceleration and $-g$ is the contribution of the gravitational force to the acceleration. Substituting for M from Equation 8-34 gives

$$\frac{dv_y}{dt} = \frac{Ru_{\text{ex}}}{M_0 - Rt} - g \qquad \text{8-38}$$

Equation 8-38 is solved by integrating both sides with respect to time. For a rocket starting at rest at $t = 0$, this gives

$$v_y = \int_0^{t_f}\left(\frac{Ru_{\text{ex}}}{M_0 - Rt} - g\right)dt = u_{\text{ex}}\int_0^{t_f}\frac{dt}{b - t} - \int_0^{t_f} g\,dt = -u_{\text{ex}}\ln\frac{b - t_f}{b} - gt_f$$

where $b = M_0/R$. Rearranging, after substituting t for t_f and M_0/R for b, gives

$$v_y = u_{\text{ex}}\ln\left(\frac{M_0}{M_0 - Rt}\right) - gt \qquad \text{8-39}$$

Example 8-19 Liftoff

The Saturn V rocket used in the Apollo moon-landing program had an initial mass M_0 of 2.85×10^6 kg, 73.0 percent of which was fuel, a burn rate R of 13.84×10^3 kg/s, and a thrust F_{th} of 34.0×10^6 N. Find (*a*) the exhaust speed relative to the rocket, (*b*) the burn time t_b, (*c*) the acceleration at liftoff, (*d*) the acceleration at just before burnout t_b, and (*e*) the final speed of the rocket.

PICTURE (*a*) The exhaust speed relative to the rocket can be found from the thrust and burn rate. (*b*) The mass of the rocket without any fuel is 73.0% of the initial mass. To find the burn time, you need to find the total mass of fuel burned, which is the initial mass minus the mass at burnout. (*c*) and (*d*) The acceleration is found from Equation 8-38. (*e*) The final speed is given by Equation 8-39.

SOLVE

(*a*) 1. Calculate u_{ex} from the given thrust and burn rate.

$$F_{th} = \left|\frac{dM}{dt}\right| u_{ex}$$

$$\text{so} \quad u_{ex} = \frac{F_{th}}{|dM/dt|} = \frac{34.0 \times 10^6\ \text{N}}{13.84 \times 10^3\ \text{kg/s}} = \boxed{2.46\ \text{km/s}}$$

(*b*) 1. Calculate the mass M_b of the rocket at burnout (when it runs out of fuel).

$$M_b = 0.270 M_0 = 7.70 \times 10^5\ \text{kg}$$

2. The mass of the fuel equals the burn rate multiplied by the burn time t_b.

$$M_{fuel} = Rt_b$$

$$\text{so} \quad t_b = \frac{M_{fuel}}{R} = \frac{M_0 - M_b}{R} = \boxed{150\ \text{s}}$$

(*c*) Calculate dv_y/dt at $t = 0$ using Equation 8-38.

Initially,

$$\frac{dv_y}{dt} = \frac{u_{ex}}{M_0}\left|\frac{dM}{dt}\right| - g = \frac{2.46\ \text{km/s}}{2.85 \times 10^6\ \text{kg}}(13.84 \times 10^3\ \text{kg/s}) - 9.81\ \text{m/s}^2$$

$$= \boxed{2.14\ \text{m/s}^2}$$

(*d*) Calculate dv_y/dt at $t = t_b$ using Equation 8-38.

At burnout,

$$\frac{dv_y}{dt} = \frac{u_{ex}}{M_b}\left|\frac{dM}{dt}\right| - g = \frac{2.46\ \text{km/s}}{7.70 \times 10^5\ \text{kg}}(13.84 \times 10^3\ \text{kg/s}) - 9.81\ \text{m/s}^2$$

$$= \boxed{34.3\ \text{m/s}^2}$$

(*e*) Calculate the speed at $t = t_b$ using Equation 8-39.

$$v_y = u_{ex} \ln\left(\frac{M_0}{M_0 - Rt}\right) - gt = \boxed{1.75\ \text{km/s}}$$

CHECK At burnout, the mass being accelerated is 73 percent less than the mass being accelerated at liftoff. Therefore, we would expect the acceleration at burnout to be much larger than the initial acceleration. This is shown by our results in Parts (*c*) and (*d*).

TAKING IT FURTHER (1) The initial acceleration is small—only $0.21g$. At burnout (also called flameout), the rocket's acceleration has increased to $3.5g$. Immediately following burnout, the acceleration is $-g$. The speed of the rocket at burnout is 1.75 km/s = 6300 km/h ≈ 3900 mi/h. (2) The calculations for Parts (*d*) and (*e*) assume the rocket moved vertically upward and that g did not vary with altitude. In practice the actual rocket initially moved vertically upward, but it then gradually turned eastward.

Physics Spotlight

Pulse Detonation Engines: Faster (and Louder)

Liquid-fueled rocket engines need expensive, delicate pumps to compress the fuel to very high pressures in the combustion chamber. Most jet engines are gas-turbine engines, which have many moving parts with tight tolerances and high maintenance needs. Rocket and aeronautical engineers want an engine with higher fuel efficiency, few moving parts, and an ability to operate at a wide range of speeds.

The *pulse detonation engine* (PDE) may fulfill these requirements. The PDE is powered by *detonation* rather than *deflagration*.

Both detonation and deflagration are types of combustion. Deflagration propagates slower than the speed of sound by heating up the air around it. Fireworks, properly tuned automobile engines, and charcoal barbecues with too much starter fluid on them are deflagrations. Detonation propagates faster than the speed of sound—sometimes much faster, by a shock wave that compresses and ignites the air. Confined high explosives used in mining and demolition detonate; improperly tuned car engines can also have internal detonations.

In a PDE, a detonation tube is closed at one end, and open at the other for exhaust. Air and fuel are admitted into the closed end, and are ignited by a spark. This starts a deflagration. As the deflagration moves down the complex interior surface* of the detonation tube, it is compressed quickly and begins to detonate. Once the detonation begins, it propagates much faster than the speed of sound. Detonation wavefronts as fast as Mach 5 have been measured in various laboratories.† The exhaust leaves the open end of the tube very rapidly. Because the exhaust has such a high velocity, it has higher momentum than the same exhaust would have from a deflagration. This gives a greater thrust to the rocket for the same amount of fuel. Detonation has given double the impulse of deflagration, using the same fuel and apparatus.‡

The only moving parts in the PDE are the valves to admit the fuel/air mixture. The ignition can be supplied by an automobile spark plug, and the rest of the engine is just the detonation tube. It seems very simple at first glance. But combustion is a complex process, and the combustion in a PDE is over very quickly. To power a jet or rocket, the PDE needs many detonations per second, just as an automobile needs many combustion incidents per second to move. PDEs have been tested at 80 detonations per second for several minutes and hours, but ideally, PDEs would reach speeds of a few hundred detonations per second.§

But detonation is a violent process. It is extremely loud, and causes the engine to vibrate even more than existing jet and rocket engines do.° Excess vibration can be harmful to rockets and jets. The noise produced by existing PDEs is not practical for a vehicle with a human pilot or passenger. Finally, heavy tubes have been used to contain the detonation. The tubes need to be made of a material strong enough to withstand the detonations, but lightweight enough to fly.

By early 2006, no planes have flown with a PDE, but the idea of engines for jets and rockets that cost less, generate a wide range of thrusts, and have higher fuel efficiency is well worth pursuing.

Summary

The conservation of momentum for an isolated system is a fundamental law of nature that has applications in all areas of physics.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Momentum		
Definition for a particle	$\vec{p} = m\vec{v}$	8-1
Kinetic energy of a particle	$K = \dfrac{p^2}{2m}$	8-16
Momentum of a system	$\vec{P}_{\text{sys}} = \sum_i m_i \vec{v}_i = M\vec{v}_{\text{cm}}$	8-3
Newton's second law for a system	$\vec{F}_{\text{net ext}} = \dfrac{d\vec{P}_{\text{sys}}}{dt}$	8-4
Law of conservation of momentum	If the net external force acting on a system remains zero, the total momentum of the system is conserved.	
2. Energy of a System		
Kinetic energy	The kinetic energy associated with the motion of the particles of a system relative to its center of mass is $K_{\text{rel}} = \Sigma \frac{1}{2} m_i u_i^2$, where u_i is the speed of the ith particle relative to the center of mass. $K = \frac{1}{2} M v_{\text{cm}}^2 + K_{\text{rel}}$	8-7
3. Collisions		
Impulse	The impulse of a force is defined as the integral of the force over the time interval during which the force acts. $\vec{I} = \int_{t_i}^{t_f} \vec{F}\, dt$	8-9
Impulse–momentum theorem	$\vec{I}_{\text{net}} = \int_{t_i}^{t_f} \vec{F}_{\text{net}} dt = \Delta \vec{p}$	8-10
Average force	$\vec{F}_{\text{av}} = \dfrac{1}{\Delta t}\int_{t_i}^{t_f} \vec{F}\, dt = \dfrac{\vec{I}}{\Delta t}$ (so $\vec{I} = \vec{F}_{\text{av}}\, \Delta t$)	8-13
Elastic collisions	An elastic collision between two objects is one in which the sum of their kinetic energies is the same before and after the collision.	
Relative speeds of approach and separation	For an elastic collision, the speed of separation equals the speed of approach. For a *head-on* elastic collision, $v_{2\text{f}} - v_{1\text{f}} = v_{1\text{i}} - v_{2\text{i}}$	8-23
Perfectly inelastic collisions	Following a perfectly inelastic collision, the two objects stick together and move with the velocity of the center of mass.	
*Coefficient of restitution	The coefficient of restitution e is a measure of the elasticity. It is the ratio of the separation speed to the closing speed: $e = \dfrac{v_{2\text{f}} - v_{1\text{f}}}{v_{1\text{i}} - v_{2\text{i}}}$ For an elastic collision, $e = 1$; for a perfectly inelastic collision $e = 0$.	8-25
***4. Continuously Variable Mass**		
Newton's second law	$\vec{F}_{\text{net ext}} + \dfrac{dM}{dt}\vec{v}_{\text{rel}} = M\dfrac{d\vec{v}}{dt}$ where $R = \lvert dM/dt \rvert$ is the burn rate.	8-33
Rocket equation	$M\vec{g} - R\vec{u}_{\text{ex}} = M\dfrac{d\vec{v}}{dt}$	8-35
Thrust	$\vec{F}_{\text{th}} = -R\vec{u}_{\text{ex}} = -\left\lvert \dfrac{dM}{dt} \right\rvert \vec{u}_{\text{ex}}$	8-36

Answer to Concept Check

8-1 No

Answers to Practice Problems

8-1 8.4 J

8-2 140 s. The grain leaking out does not impart any momentum to the rest of the system. If the ground were frictionless and flat, all of the grain initially in the car would arrive at the switchyard along with the car.

8-3 1.32 m/s. She gains more speed by throwing them sequentially rather than simultaneously.

8-4 (*a*) $v_{cm} = 0.50$ m/s, $v_A = +0.50$ m/s, and $v_B = -0.50$ m/s, (*b*) $K_{A\,rel} = K_{B\,rel} = 0.125$ J, (*c*) $K_{rel} = 0.25$ J, (*d*) $K_{rel} = 0$

8-5 Momentum conservation implies $v_{1i} + v_{2i} = v_{1f} + v_{2f}$, elastic collision implies $v_{1i} - v_{2i} = v_{2f} - v_{1f}$. Together, these imply $v_{2f} = v_{1i}$ and $v_{1f} = v_{2i}$.

8-6 0.73

8-7 $\frac{1}{2}v_0$

8-8 Before: $P_{sys\,i} = (4.0\text{ kg})(1.0\text{ m/s}) + (2.0\text{ kg})(-2.0\text{ m/s}) = 0.0\text{ kg}\cdot\text{m/s}$;
After: $P_{sys\,f} = (4.0\text{ kg})(-1.0\text{ m/s}) + (2.0\text{ kg})(2.0\text{ m/s}) = 0.0\text{ kg}\cdot\text{m/s}$

8-9 (*a*) $3Mg$, (*b*) Mg

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimates.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

For all problems, use 9.81 m/s² for the free-fall acceleration and neglect friction and air resistance unless instructed to do otherwise.

• Single-concept, single-step, relatively easy

•• Intermediate-level, may require synthesis of concepts

••• Challenging

SSM Solution is in the *Student Solutions Manual*

Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • Show that if two particles have equal kinetic energies, the magnitudes of their momenta are equal only if they have the same mass. SSM

2 • Particle A has twice the momentum and four times the kinetic energy of particle B. What is the ratio of the mass of particle A to that of particle B? Explain your reasoning.

3 • Using SI units, show that the units of momentum squared divided by those of mass is equivalent to the joule.

4 • True or false:

(*a*) The total linear momentum of a system may be conserved even when the mechanical energy of the system is not.
(*b*) For the total linear momentum of a system to be conserved, there must be no external forces acting on the system.
(*c*) The velocity of the center of mass of a system changes only when there is a net external force on the system.

5 • If a bullet is fired due west, explain how conservation of linear momentum enables you to predict that the recoil of the rifle will be exactly due east. Is kinetic energy conserved here?

6 • A child jumps from a small boat to a dock. Why does she have to jump with more effort than she would need if she were jumping through an identical displacement, but from a boulder to a tree stump?

7 •• Much of the early research in rocket motion was done by Robert Goddard, physics professor at Clark College in Worcester, Massachusetts. A quotation from a 1920 editorial in the *New York Times* illustrates the public's opinion of his work: "That Professor Goddard with his 'chair' at Clark College and the countenance of the Smithsonian Institution does not know the relation between action and reaction, and the need to have something better than a vacuum against which to react—to say that would be absurd. Of course, he only seems to lack the knowledge ladled out daily in high schools."* The belief that a rocket needs something to push against was a prevalent misconception before rockets in space were commonplace. Explain why that belief is wrong. SSM

* On page 43 of the July 17, 1969, edition of the *New York Times* "A Correction" to their editorial of 1920 was printed. This commentary, which was published three days before man's first walk on the moon, stated that "it is now definitely established that a rocket can function in a vacuum as well as in an atmosphere. *The Times* regrets the error.

8 • Two identical bowling balls are moving with the same center-of-mass velocity, but one just slides down the alley without rotating, whereas the other rolls down the alley. Which ball has more kinetic energy?

9 • A philosopher tells you, "Changing motion of objects is impossible. Forces always come in equal but opposite pairs. Therefore, all forces cancel out. Because forces cancel, the momenta of objects can never be changed." Answer his argument.

10 • A moving object collides with a stationary object. Is it possible for both objects to be at rest immediately after the collision? (Assume any external forces acting on this two-object system are negligibly small.) Is it possible for one object to be at rest immediately after the collision? Explain.

11 • Several researchers in physics education claim that part of the cause of physical misconceptions among students comes from special effects they observe in cartoons and movies. Using the conservation of linear momentum, how would you explain to a class of high school physics students what is conceptually wrong with a superhero hovering at rest in midair while tossing massive objects such as cars at villains? Does this action violate the conservation of energy as well? Explain.

12 •• A struggling physics student asks, "If only external forces can cause the center of mass of a system of particles to accelerate, how can a car move? Doesn't the car's engine supply the force needed to accelerate the car?" Explain what external agent produces the force that accelerates the car, and explain how the engine makes that agent do so.

13 •• When we push on the brake pedal to slow down a car, a brake pad is pressed against the rotor so that the friction of the pad slows the rotation of the rotor and thus the rotation of the wheel. However, the friction of the pad against the rotor cannot be the force that slows the car down because it is an internal force—both the rotor and the wheel are parts of the car, so any forces between them are internal, not external forces. What external agent exerts the force that slows down the car? Give a detailed explanation of how this force operates.

14 •• Explain why a circus performer falling into a safety net can survive unharmed, while a circus performer falling from the same height onto the hard concrete floor suffers serious injury or death. Base your explanation on the impulse–momentum theorem.

15 •• In Problem 14, estimate the ratio of the collision time with the safety net to the collision time with the concrete for the performer falling from a height of 25 m. *Hint: Use the procedure outlined in step 4 of the Problem-Solving Strategy located in Section 8-3.* SSM

16 •• (*a*) Why does a drinking glass survive a fall onto a carpet but not a fall onto a concrete floor? (*b*) On many automobile race tracks, dangerous curves are surrounded by massive bails of hay. Explain how this setup reduces the chances of car damage and driver injury.

17 • True or false:

(*a*) Following any perfectly inelastic collision, the kinetic energy of the system is zero in all inertial reference frames.
(*b*) For a head-on elastic collision, the relative speed of recession equals the relative speed of approach.
(*c*) In a perfectly inelastic head-on collision with one object initially at rest, only some of the system's kinetic energy is dissipated.
(*d*) After a perfectly inelastic head-on collision along the east–west horizontal axis, the two objects are observed to be moving west. The initial total system momentum was therefore to the west.

18 •• Under what conditions can all the initial kinetic energy of an isolated system consisting of two colliding objects be lost in a collision? Explain how this result can be, and yet the momentum of the system can be conserved.

19 •• Consider a perfectly inelastic collision of two objects of equal mass. (*a*) Is the loss of kinetic energy greater if the two objects are moving in opposite directions, each moving at speed $v/2$, or if one of the two objects is initially at rest and the other has an initial speed of v? (*b*) In which of these situations is the percentage loss in kinetic energy the greatest?

20 •• A double-barreled pea shooter is shown in Figure 8-41. Air is blown into the left end of the pea shooter, and identical peas A and B are positioned inside each straw as shown. If the pea shooter is held horizontally while the peas are shot off, which pea, A or B, will travel farther after leaving the straw? Explain. (Base your explanation on the impulse–momentum theorem.)

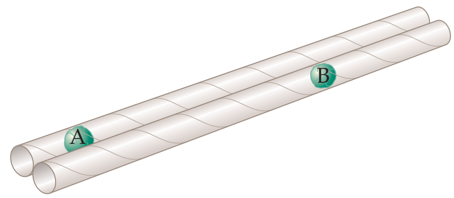

FIGURE 8-41 Problem 20

21 •• A particle of mass m_1 traveling with a speed v makes a head-on elastic collision with a stationary particle of mass m_2. In which scenario will the largest amount of energy be imparted to the particle of mass m_2? (*a*) $m_2 < m_1$, (*b*) $m_2 = m_1$, (*c*) $m_2 > m_1$, (*d*) None of the above

22 •• **ENGINEERING APPLICATION, CONTEXT-RICH** Suppose you are in charge of an accident reconstruction team that has reconstructed an accident in which a car was "rear-ended," causing the two cars to lock bumpers and skid to a halt. During the trial, you are on the stand as an expert witness for the prosecution and the lawyer for the defense claims that you wrongly neglected friction and the force of gravity during the fraction of a second while the cars collided. Defend your report. Why were you correct in ignoring these forces? You did not ignore these two forces in your skid analysis both before and after the collision. Can you explain to the jury why you did not ignore these two forces during the pre- and postcollision skids?

23 •• Nozzles for a garden hose are often made with a right-angle shape, as shown in Figure 8-42. If you open the nozzle to spray water out, you will find that the nozzle presses against your hand with a pretty strong force—much stronger than if you used a nozzle not bent into a right angle. Why is this situation true?

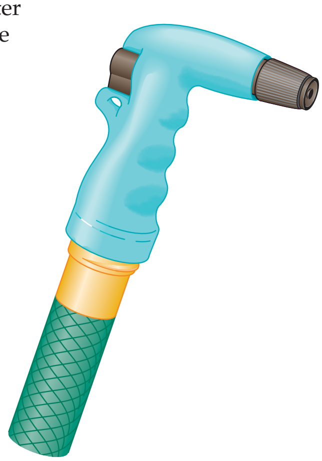

FIGURE 8-42 Problem 23

CONCEPTUAL PROBLEMS FROM OPTIONAL SECTIONS

24 • Describe a perfectly inelastic head-on collision between two stunt cars as viewed in the center-of-mass reference frame.

25 •• One air-hockey puck is initially at rest. An identical air-hockey puck collides with it, striking it with a glancing blow. Assume the collision is elastic and neglect any rotational motion of the pucks. Describe the collision in the center-of-mass frame of the pucks.

26 •• A baton with one end more massive than the other is tossed at an angle into the air. (*a*) Describe the trajectory of the center of mass of the baton in the reference frame of the ground. (*b*) Describe the motion of the two ends of the baton in the center-of-mass frame of the baton.

27 •• Describe the forces acting on a descending Lunar lander as it fires its retrorockets to slow down for a safe landing. (Assume the lander's mass loss during the rocket firing is not negligible.)

28 •• A railroad car rolling along by itself is passing by a grain elevator, which is dumping grain into it at a constant rate. (*a*) Does momentum conservation imply that the railroad car should be slowing down as it passes the grain elevator? Assume that the track is frictionless and perfectly level and that the grain is falling vertically. (*b*) If the car is slowing down, this situation implies that there is some external force acting on the car to slow it down. Where does this force come from? (*c*) After passing the elevator, the railroad car springs a leak, and grain starts leaking out of a vertical hole in its floor at a constant rate. Should the car speed up as it loses mass?

29 •• To show that even really intelligent people can make mistakes, consider the following problem, which was asked of a freshman class at Caltech on an exam (paraphrased): *A sailboat is sitting in the water on a windless day. In order to make the boat move, a misguided sailor sets up a fan in the back of the boat to blow into the sails to make the boat move forward. Explain why the boat will not move.* The idea was that the net force of the wind pushing the sail forward would be counteracted by the force pushing the fan back (Newton's third law). However, as one of the students pointed out to his professor, the sailboat *could* in fact move forward. Why is that? SSM

ESTIMATION AND APPROXIMATION

30 •• **ENGINEERING APPLICATION** A 2000-kg car traveling at 90 km/h crashes into an immovable concrete wall. (*a*) Estimate the time of collision, assuming that the center of the car travels halfway to the wall with constant acceleration. (Use any plausible length for the car.) (*b*) Estimate the average force exerted by the wall on the car.

31 •• In hand-pumped railcar races, a speed of 32.0 km/h has been achieved by teams of four people. A car that has a mass equal to 350 kg is moving at that speed toward a river when Carlos, the chief pumper, notices that the bridge ahead is out. All four people (each with a mass of 75.0 kg) simultaneously jump backward off the car with a velocity that has a horizontal component of 4.00 m/s relative to the car. The car proceeds off the bank and falls into the water a horizontal distance of 25.0 m from the bank. (*a*) Estimate the time of the fall of the railcar. (*b*) What is the horizontal component of the velocity of the pumpers when they hit the ground?

32 •• A wooden block and a gun are firmly fixed to opposite ends of a long glider mounted on a frictionless air track (Figure 8-43). The block and gun are a distance L apart. The system is initially at rest. The gun is fired and the bullet leaves the gun with a velocity v_b and impacts the block, becoming imbedded in it. The mass of the bullet is m_b and the mass of the gun–glider–block system is m_p. (*a*) What is the velocity of the glider immediately after the bullet leaves the gun? (*b*) What is the velocity of the glider immediately after the bullet comes to rest in the block? (*c*) How far does the glider move while the bullet is in transit between the gun and the block?

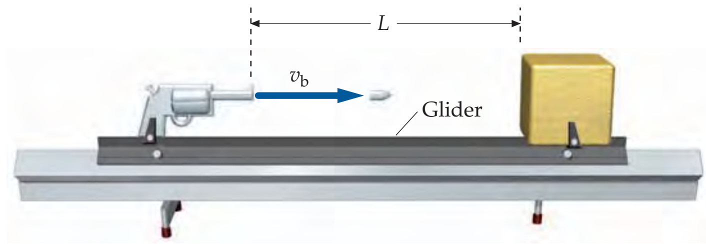

FIGURE 8-43 Problem 32

CONSERVATION OF LINEAR MOMENTUM

33 • Tyrone, a 85-kg teenager, runs off the end of a horizontal pier and lands on a free-floating 150-kg raft that was initially at rest. After he lands on the raft, the raft, with him on it, moves away from the pier at 2.0 m/s. What was Tyrone's speed as he ran off the end of the pier? SSM

34 •• A 55-kg woman contestant on a reality television show is at rest at the south end of a horizontal 150-kg raft that is floating in crocodile-infested waters. She and the raft are initially at rest. She needs to jump from the raft to a platform that is several meters off the north end of the raft. She takes a running start. When she reaches the north end of the raft she is running at 5.0 m/s relative to the raft. At that instant, what is her velocity relative to the water?

35 • A 5.0-kg object and a 10-kg object, both resting on a frictionless table, are connected by a massless compressed spring. The spring is released and the objects fly off in opposite directions. The 5.0-kg object has a velocity of 8.0 m/s to the left. What is the velocity of the 10-kg object?

36 • Figure 8-44 shows the behavior of a projectile just after it has broken up into three pieces. What was the speed of the projectile the instant before it broke up: (*a*) v_3, (*b*) $v_3/3$, (*c*) $v_3/4$, (*d*) $4v_3$, (e) $(v_1 + v_2 + v_3)/4$?

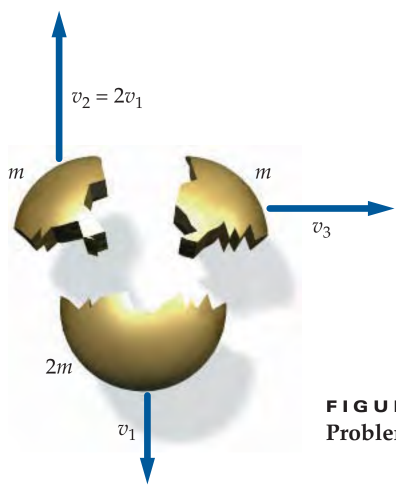

FIGURE 8-44 Problem 36

37 • A shell of mass m and speed v explodes into two identical fragments. If the shell was moving horizontally with respect to Earth, and one of the fragments is subsequently moving vertically with speed v, find the velocity $\vec{v}\,'$ of the other fragment immediately following the explosion.

38 •• For this week's physics lab, the experimental setup consists of two gliders on a horizontal frictionless air track (see Figure 8-45). Each glider supports a strong magnet centered on top of it, and the magnets are oriented so they attract each other. The mass of glider 1 and its magnet is 0.100 kg, and the mass of glider 2 and its magnet is 0.200 kg. You and your lab partners are instructed to take the origin to be at the left end of the track and to center glider 1 at $x_1 = 0.100$ m and glider 2 at $x_2 = 1.600$ m. Glider 1 is 10.0 cm long, and glider 2 is 20.0 cm long, and each glider has its center of mass at its geometric center. When the two gliders are released from rest, they will move toward each other and stick. (*a*) Predict the position of the center of each glider when they first touch. (*b*) Predict the velocity that the two gliders will continue to move with after they stick. Explain the reasoning behind this prediction for your lab partners.

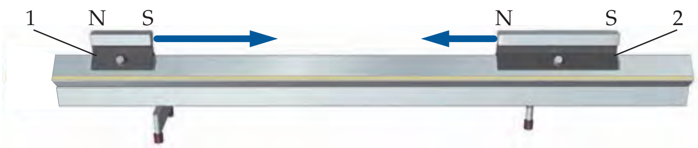

FIGURE 8-45 Problem 38

39 •• Bored, a boy shoots his pellet gun at a piece of cheese that sits on a massive block of ice. On one particular shot, his 1.2-g pellet gets stuck in the cheese, causing it to slide 25 cm before coming to a stop. If the muzzle velocity of the gun is known to be 65 m/s, and the cheese has a mass of 120 g, what is the coefficient of friction between the cheese and the ice?

40 ••• **MULTISTEP** A wedge of mass M is placed on a frictionless, horizontal surface, and a block of mass m is placed on the wedge, which also has a frictiononless surface (Figure 8-46). The block's center of mass moves downward a distance h as the block slides from its initial position to the horizontal floor. (*a*) What are the speeds of the block and of the wedge as they separate from each other and go their own ways? (*b*) Check your calculation plausibility by considering the limiting case when $M \gg m$.

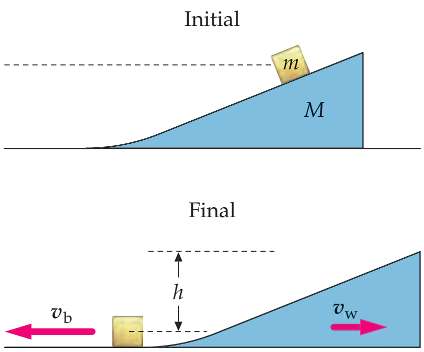

FIGURE 8-46 Problem 40

KINETIC ENERGY OF A SYSTEM OF PARTICLES

41 •• **MULTISTEP** A 3.0-kg block is traveling to the right (the $+x$ direction) at 5.0 m/s, and a second 3.0-kg block is traveling to the left at 2.0 m/s. (*a*) Find the total kinetic energy of the two blocks. (*b*) Find the velocity of the center of mass of the two-block system. (*c*) Find the velocity of each block relative to the center of mass. (*d*) Find the kinetic energy of the blocks relative to the center of mass. (*e*) Show that your answer for Part (*a*) is greater than your answer for Part (*d*) by an amount equal to the kinetic energy associated with the motion of the center of mass. SSM

42 •• Repeat Problem 41 with the second 3.0-kg block replaced by a 5.0-kg block moving to the right at 3.0 m/s.

IMPULSE AND AVERAGE FORCE

43 • You kick a soccer ball whose mass is 0.43 kg. The ball leaves your foot with an initial speed of 25 m/s. (*a*) What is the magnitude of the impulse associated with the force of your foot on the ball? (*b*) If your foot is in contact with the ball for 8.0 ms, what is the magnitude of the average force exerted by your foot on the ball? SSM

44 • A 0.30-kg brick is dropped from a height of 8.0 m. It hits the ground and comes to rest. (*a*) What is the impulse exerted by the ground on the brick during the collision? (*b*) If it takes 0.0013 s from the time the brick first touches the ground until it comes to rest, what is the average force exerted by the ground on the brick at impact?

45 • A meteorite that has a mass equal to 30.8 tonnes (1 tonne = 1000 kg) is exhibited in the American Museum of Natural History in New York City. Suppose that the kinetic energy of the meteorite as it hit the ground was 617 MJ. Find the magnitude of the impulse experienced by the meteorite up to the time its kinetic energy was halved (which took about $t = 3.0$ s). Also find the average force exerted on the meteorite during this time interval.

46 •• A 0.15-kg baseball traveling horizontally is hit by a bat and its direction is exactly reversed. Its velocity changes from $+20$ m/s to -20 m/s. (*a*) What is the magnitude of the impulse delivered by the bat to the ball? (*b*) If the baseball is in contact with the bat for 1.3 ms, what is the average force exerted by the bat on the ball?

47 •• A 60-g handball moving with a speed of 5.0 m/s strikes the wall at a 40° angle with the normal, and then bounces off with the same speed at the same angle with the normal. It is in contact with the wall for 2.0 ms. What is the average force exerted by the ball on the wall?

48 •• **ESTIMATION** You throw a 150-g ball straight up to a height of 40.0 m. (*a*) Use a reasonable value for the displacement of the ball while it is in your hand to estimate the time the ball is in your hand while you are throwing it. (*b*) Calculate the average force exerted by your hand while you are throwing it. (Is it okay to neglect the gravitational force on the ball while it is being thrown?)

49 •• A 0.060-g handball is thrown straight toward a wall with a speed of 10 m/s. It rebounds straight backward at a speed of 8.0 m/s. (*a*) What impulse is exerted on the wall? (*b*) If the ball is in contact with the wall for 3.0 ms, what average force is exerted on the wall by the ball? (*c*) The rebounding ball is caught by a player who brings it to rest. In the process, her hand moves back 0.50 m. What is the impulse received by the player? (*d*) What average force was exerted on the player by the ball?

50 •• A spherical 0.34-kg orange, 2.0 cm in radius, is dropped from the top of a 35-m-tall building. After the orange strikes the pavement, its shape is that of a 0.50-cm-thick pancake. Neglect air resistance and assume that the collision is completely inelastic. (*a*) How much time did the orange take to completely "squish" to a stop? (*b*) What average force did the pavement exert on the orange during the collision?

51 •• The pole vault landing pad at an Olympic competition contains what is essentially a bag of air that compresses from its "resting" height of 1.2 m down to 0.20 m as the vaulter is slowed to a stop. (*a*) What is the time interval during which a vaulter who has just cleared a height of 6.40 m slows to a stop? (*b*) What is the time interval if instead the vaulter is brought to rest by a 20-cm layer of sawdust that compresses to 5.0 cm when he lands? (*c*) Qualitatively discuss the difference in average force the vaulter experiences from the two different landing pads. That is, which landing pad would exert the least force on the vaulter and why?

52 ••• Large limestone caverns have been formed by dripping water. (*a*) If water droplets of 0.030 mL fall from a height of 5.0 m at a rate of 10 droplets per minute, what is the average force exerted on the limestone floor by the droplets of water during a 1.0-min period? (Assume the water does not accumulate on the floor.) (*b*) Compare this force to the weight of one water droplet.

COLLISIONS IN ONE DIMENSION

53 • A 2000-kg car traveling to the right at 30 m/s is chasing a second car of the same mass that is traveling in the same direction at 10 m/s. (*a*) If the two cars collide and stick together, what is their speed just after the collision? (*b*) What fraction of the initial kinetic energy of the cars is lost during this collision? Where does it go? SSM

54 • An 85-kg running back moving at 7.0 m/s makes a perfectly inelastic head-on collision with a 105-kg linebacker who is initially at rest. What is the speed of the players just after their collision?

55 • A 5.0-kg object with a speed of 4.0 m/s collides head-on with a 10-kg object moving toward it with a speed of 3.0 m/s. The 10-kg object stops dead after the collision. (*a*) What is the postcollision speed of the 5.0-kg object? (*b*) Is the collision elastic?

56 • A small superball of mass m moves with speed v to the right toward a much more massive bat that is moving to the left with speed v. Find the speed of the ball after it makes an elastic head-on collision with the bat.

57 •• A proton that has a mass m and is moving at 300 m/s undergoes a head-on elastic collision with a stationary carbon nucleus of mass $12m$. Find the velocities of the proton and the carbon nucleus after the collision.

58 •• A 3.0-kg block moving at 4.0 m/s has a head-on elastic collision with a stationary block of mass 2.0 kg. Use conservation of momentum and the fact that the relative speed of recession equals the relative speed of approach to find the velocity of each block after the collision. Check your answer by calculating the initial and final kinetic energies of each block.

59 •• A block of mass $m_1 = 2.0$ kg slides along a frictionless table with a speed of 10 m/s. Directly in front of it, and moving in the same direction with a speed of 3.0 m/s, is a block of mass $m_2 = 5.0$ kg. A massless spring that has a force constant $k = 1120$ N/m is attached to the second block, as in Figure 8-47. (*a*) What is the velocity of the center of mass of the system? (*b*) During the collision, the spring is compressed by a maximum amount Δx.

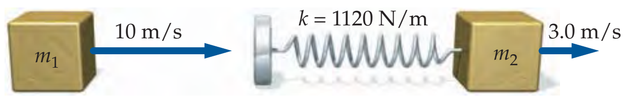

FIGURE 8-47 Problem 59

What is the value of Δx? (*c*) The blocks will eventually separate again. What are the velocities of the two blocks measured in the reference frame of the table, after they separate?

60 •• A bullet of mass m is fired vertically from below into a thin horizontal sheet of plywood of mass M that is initially at rest, supported by a thin sheet of paper (Figure 8-48). The bullet punches through the plywood, which rises to a height, H, above the paper before falling back down. The bullet continues rising to a height, h, above the paper. (*a*) Express the upward velocity of the bullet and the plywood immediately after the bullet exits the plywood in terms of h and H. (*b*) What is the speed of the bullet? (*c*) What is the mechanical energy of the system before and after the inelastic collision? (*d*) How much mechanical energy is dissipated during the collision?

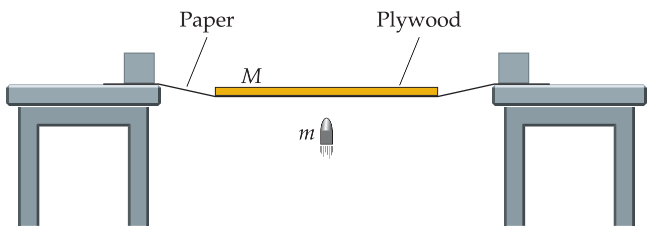

FIGURE 8-48 Problem 60

61 •• A proton of mass m is moving with initial speed v_0 directly toward the center of an α particle of mass $4m$, which is initially at rest. Both particles carry positive charge, so they repel each other. (The repulsive forces are sufficient to prevent the two particles from coming into direct contact.) Find the speed v_α of the α particle (*a*) when the distance between the two particles is a minimum, and (*b*) later when the two particles are far apart.

62 •• An electron collides elastically with a hydrogen atom that is initially at rest. Assume all the motion occurs along a straight line. What fraction of the electron's initial kinetic energy is transferred to the atom? (Take the mass of the hydrogen atom to be 1840 times the mass of an electron.)

63 •• A 16-g bullet is fired into the bob of a 1.5-kg ballistic pendulum (Figure 8-18). When the bob is at its maximum height, the strings make an angle of 60° with the vertical. The pendulum strings are 2.3 m long. Find the speed of the bullet prior to impact. SSM

64 •• Show that in a one-dimensional elastic collision, if the mass and velocity of object 1 are m_1 and v_{1i}, and if the mass and velocity of object 2 are m_2 and v_{2i}, then their final velocities v_{1f} and v_{2f} are given by

$$v_{1f} = \frac{m_1 - m_2}{m_1 + m_2} v_{1i} + \frac{2m_2}{m_1 + m_2} v_{2i}$$

and

$$v_{2f} = \frac{2m_1}{m_1 + m_2} v_{1i} + \frac{m_2 - m_1}{m_1 + m_2} v_{2i}$$

65 •• Investigate the plausibility of the results of Problem 64 by calculating the final velocities in the following limits: (*a*) When the two masses are equal, show that the particles "swap" velocities: $v_{1f} = v_{2i}$ and $v_{2f} = v_{1i}$. (*b*) If $m_2 \gg m_1$, and $v_{2i} = 0$, show that $v_{1f} \approx -v_{1i}$ and $v_{2f} \approx 0$. (*c*) If $m_1 \gg m_2$, and $v_{2i} = 0$, show that $v_{1f} \approx v_{1i}$ and $v_{2f} \approx 2v_{1i}$.

66 •• A bullet of mass m_1 is fired horizontally with a speed v_0 into the bob of a ballistic pendulum of mass m_2. The pendulum consists of a bob attached to one end of a very light rod of length L. The rod is free to rotate about a horizontal axis through its other end. The bullet is stopped in the bob. Find the minimum v_0 such that the bob will swing through a complete circle.

67 •• A bullet of mass m_1 is fired horizontally with a speed v into the bob of a ballistic pendulum of mass m_2 (Figure 18-19). Find the maximum height h attained by the bob if the bullet passes through the bob and emerges with a speed $v/3$.

68 •• A heavy wooden block rests on a flat table and a high-speed bullet is fired horizontally into the block, the bullet stopping in it. How far will the block slide before coming to a stop? The mass of the bullet is 10.5 g, the mass of the block is 10.5 kg, the bullet's impact speed is 750 m/s, and the coefficient of kinetic friction between the block and the table is 0.220. (Assume that the bullet does not cause the block to spin.)

69 •• A 0.425-kg ball with a speed of 1.30 m/s rolls across a level surface toward an open 0.327-kg box that is resting on its side. The ball enters the box, and the box (with the ball inside it) then slides across the surface a distance of 0.520 m. What is the coefficient of kinetic friction between the box and the table? SSM

70 •• Tarzan is in the path of a pack of stampeding elephants when Jane swings in to the rescue on a rope vine, hauling him off to safety. The length of the vine is 25 m, and Jane starts her swing with the rope horizontal. If Jane's mass is 54 kg, and Tarzan's mass is 82 kg, to what height above the ground will the pair swing after she rescues him? (Assume the rope is vertical when she grabs him.)

71 •• Scientists estimate that the meteorite responsible for the creation of Barringer Meteorite Crater in Arizona weighed roughly 2.72×10^5 tonnes (1 tonne = 1000 kg) and was traveling at a speed of 17.9 km/s. Take Earth's orbital speed to be about 30.0 km/s. (*a*) What should the direction of impact be if Earth's orbital speed is to be changed by the maximum possible amount? (*b*) Assuming the condition of collision in Part (*a*), estimate the maximum percentage change in Earth's orbital speed as a result of this collision. (*c*) What mass of an asteroid, having a speed equal to Earth's orbital speed, would be necessary to change Earth's orbital speed by 1.00%? SSM

72 ••• William Tell shoots an apple from his son's head. The speed of the 125-g arrow just before it strikes the apple is 25.0 m/s, and at the time of impact it is traveling horizontally. If the arrow sticks in the apple and the arrow/apple combination strikes the ground 8.50 m behind the son's feet, how massive was the apple? Assume the son is 1.85 m tall.

EXPLOSIONS AND RADIOACTIVE DECAY

73 •• The beryllium isotope ^{8}Be is unstable, decays into two α particles ($m_\alpha = 6.64 \times 10^{-27}$ kg), and releases 1.5×10^{-14} J of energy. Determine the velocities of the two α particles that arise from the decay of a ^{8}Be nucleus at rest, assuming that all the energy appears as kinetic energy of the particles. SSM

74 •• The light isotope, ^{5}Li, of lithium is unstable and breaks up spontaneously into a proton and an α particle. In this process, 3.15×10^{-13} J of energy are released, appearing as the kinetic energy of the two decay products. Determine the velocities of the proton and the α particle that arise from the decay of a ^{5}Li nucleus at rest. (*Note*: The masses of the proton and alpha particle are $m_p = 1.67 \times 10^{-27}$ kg and $m_\alpha = 4\,m_p = 6.64 \times 10^{-27}$ kg.)

75 ••• A 3.00-kg projectile is fired with an initial speed of 120 m/s at an angle of 30.0° with the horizontal. At the top of its trajectory, the projectile explodes into two fragments of masses 1.00 kg and 2.00 kg. At 3.60 s after the explosion, the 2.00-kg fragment lands on the ground directly below the point of explosion. (*a*) Determine the velocity of the 1.00-kg fragment immediately after the explosion. (*b*) Find the distance between the point of firing and the point at which the 1.00-kg fragment strikes the ground. (*c*) Determine the energy released in the explosion.

76 ••• The boron isotope ^{9}B is unstable and disintegrates into a proton and two α particles. The total energy released as kinetic energy of the decay products is 4.4×10^{-14} J. In one such event, with the ^{9}B nucleus at rest prior to decay, the velocity of the proton is measured as 6.0×10^6 m/s. If the two α particles have equal energies, find the magnitude and the direction of their velocities with respect to the direction of the proton.

COEFFICIENT OF RESTITUTION

77 • **ENGINEERING APPLICATION, CONTEXT-RICH** You are in charge of measuring the coefficient of restitution for a new alloy of steel. You convince your engineering team to accomplish this task by simply dropping a small ball onto a plate, both ball and plate made from the experimental alloy. If the ball is dropped from a height of 3.0 m and rebounds to a height of 2.5 m, what is the coefficient of restitution? SSM

78 • According to official racquetball rules, to be acceptable for tournament play, a ball must bounce to a height of between 173 and 183 cm when dropped from a height of 254 cm at room temperature. What is the acceptable range of values for the coefficient of restitution for the racquetball–floor system?

79 • A ball bounces to 80 percent of its original height. (*a*) What fraction of its mechanical energy is lost each time it bounces? (*b*) What is the coefficient of restitution of the ball–floor system?

80 •• A 2.0-kg object moving to the right at 6.0 m/s collides head-on with a 4.0-kg object that is initially at rest. After the collision, the 2.0-kg object is moving to the left at 1.0 m/s. (*a*) Find the velocity of the 4.0-kg object after the collision. (*b*) Find the energy lost in the collision. (*c*) What is the coefficient of restitution for these objects?

81 •• A 2.0-kg block moving to the right with a speed of 5.0 m/s collides with a 3.0-kg block that is moving in the same direction at 2.0 m/s, as in Figure 8-49. After the collision, the 3.0-kg block moves to the right at 4.2 m/s. Find (*a*) the velocity of the 2.0-kg block after the collision, and (*b*) the coefficient of restitution between the two blocks.

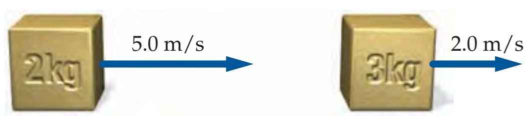

FIGURE 8-49 Problem 81

82 ••• **CONTEXT-RICH** To keep homerun records and distances consistent from year to year, organized baseball randomly checks the coefficient of restitution between new baseballs and wooden surfaces similar to that of an average bat. Suppose you are in charge of making sure that no "juiced" baseballs are produced. (*a*) In a random test, you find one that when dropped from 2.0 m rebounds 0.25 m. What is the coefficient of restitution for this ball? (*b*) What is the maximum distance home run shot you would expect from this ball, neglecting any effects due to air resistance and making reasonable assumptions for bat speeds and incoming pitch speeds? Is this a "juiced" ball, a "normal" ball, or a "dead" ball?

83 •• **CONCEPTUAL** To make puck handling easy, hockey pucks are kept frozen until they are used in the game. (*a*) Explain why room-temperature pucks would be more difficult to handle on the end of a stick than a frozen puck. (*Hint: Hockey pucks are made of rubber.*) (b) A room-temperature puck rebounds 15 cm when dropped onto a wooden surface from 100 cm. If a frozen puck has only half the coefficient of restitution of a room-temperature one, predict how high the frozen puck would rebound under the same conditions. SSM

COLLISIONS IN MORE THAN ONE DIMENSION

84 •• In Section 8-3, it was proved by using geometry that when a particle elastically collides with another particle of equal mass that is initially at rest, the two postcollision velocities are perpendicular. Here we examine another way of proving this result that illustrates the power of vector notation. (*a*) Given that $\vec{A} = \vec{B} + \vec{C}$, square both sides of this equation (obtain the scalar product of each side with itself) to show that $A^2 = B^2 + C^2 + 2\vec{B}\cdot\vec{C}$. (*b*) Let the momentum of the initially moving particle be $\vec{P}$ and the momenta of the particles after the collision be $\vec{p}_1$ and $\vec{p}_2$. Write the vector equation for the conservation of linear momentum and square both sides (obtain the dot product of each side with itself). Compare it to the equation gotten from the elastic collision condition (kinetic energy is conserved) and finally show that these two equations imply that $\vec{p}_1 \cdot \vec{p}_2 = 0$.

85 •• In a pool game, the cue ball, which has an initial speed of 5.0 m/s, makes an elastic collision with the eight ball, which is initially at rest. After the collision, the eight ball moves at an angle of 30° to the right of the original direction of the cue ball. Assume that the balls have equal mass. (*a*) Find the direction of motion of the cue ball immediately after the collision. (*b*) Find the speed of each ball immediately after the collision.

86 •• Object A, which has a mass m and a velocity $v_0\hat{i}$, collides with object B, which has a mass $2m$ and a velocity $\frac{1}{2}v_0\hat{j}$. Following the collision, object B has a velocity of $\frac{1}{4}v_0\hat{i}$. (*a*) Determine the velocity of object A after the collision. (*b*) Is the collision elastic? If not, express the change in the kinetic energy in terms of m and v_0.

87 •• A puck of mass 5.0 kg moving at 2.0 m/s approaches an identical puck that is stationary on frictionless ice. After the collision, the first puck leaves with a speed v_1 at 30° to the original line of motion; the second puck leaves with speed v_2 at 60°, as in Figure 8-50. (*a*) Calculate the speeds v_1 and v_2. (*b*) Was the collision elastic? SSM

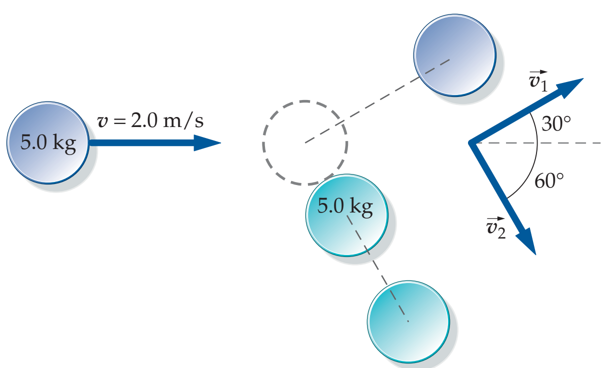

FIGURE 8-50 Problem 87

88 •• Figure 8-51 shows the result of a collision between two objects of unequal mass. (*a*) Find the speed v_2 of the larger mass after the collision; also find the angle θ_2. (*b*) Show that the collision is elastic.

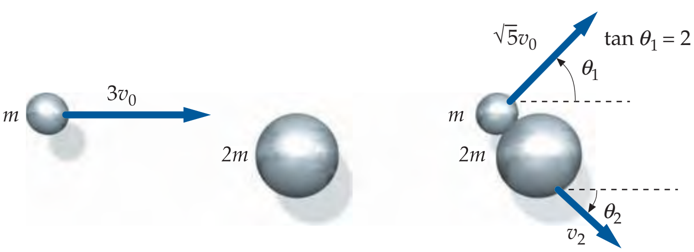

FIGURE 8-51 Problem 88

89 •• A 2.0-kg ball moving at 10 m/s makes an off-center collision with a 3.0-kg ball that is initially at rest. After the collision, the 2.0-kg ball is deflected at an angle of 30° from its original direction of motion and the 3.0-kg ball is moving at 4.0 m/s. Find the speed of the 2.0-kg ball and the direction of the 3.0-kg ball after the collision. *Hint:* $\sin^2\theta + \cos^2\theta = 1$.

90 •• A particle has initial speed v_0. It collides with a second particle with the same mass that is initially at rest. The first particle is deflected through an angle ϕ. Its speed after the collision is v. The second particle recoils, and its velocity makes an angle θ with the initial direction of the first particle. (*a*) Show that $\tan\theta = (v\sin\phi)/[(v_0 - v\cos\phi)]$. (*b*) Show that if the collision is elastic, then $v = v_0\cos\phi$.

* CENTER-OF-MASS REFERENCE FRAME

91 •• In the center-of-mass reference frame, a particle with mass m_1 and momentum p_1 makes an elastic head-on collision with a second particle of mass m_2 and momentum $p_2 = -p_1$. After the collision the first particle's momentum is p_1'. Write the total kinetic initial energy in terms of m_1, m_2, and p_1 and the total final energy in terms of m_1, m_2, and p_1', and show that $p_1' = \pm p_1$. If $p_1' = -p_1$, the particle is merely turned around by the collision and leaves with the speed it had initially. What is the situation for the $p_1' = +p_1$ solution?

92 •• **MULTISTEP** A 3.0-kg block is traveling in the $-x$ direction at 5.0 m/s, and a 1.0-kg block is traveling in the $+x$ direction at 3.0 m/s. (*a*) Find the velocity v_{cm} of the center of mass. (*b*) Subtract v_{cm} from the velocity of each block to find the velocity of each block in the center-of-mass reference frame. (*c*) After they make a head-on elastic collision, the velocity of each block is reversed (in the center-of-mass frame). Find the velocity of each block in the center-of-mass frame after the collision. (*d*) Transform back into the original frame by adding v_{cm} to the velocity of each block. (*e*) Check your result by finding the initial and final kinetic energies of the blocks in the original frame and comparing them.

93 •• Repeat Problem 92 with the second block having a mass of 5.0 kg and moving to the right at 3.0 m/s. SSM

* SYSTEMS WITH CONTINUOUSLY VARYING MASS: ROCKET PROPULSION

94 • **ENGINEERING APPLICATION** A rocket burns fuel at a rate of 200 kg/s and exhausts the gas at a speed of 6.00 km/s relative to the rocket. Find the magnitude of the thrust of the rocket.

95 •• **ENGINEERING APPLICATION** A rocket has an initial mass of 30,000 kg, 80 percent of which is the fuel. It burns fuel at a rate of 200 kg/s and exhausts its gas at a relative speed of 1.80 km/s. Find (*a*) the thrust of the rocket, (*b*) the time until burnout, and (*c*) the rocket's speed at burnout, assuming it moves straight upward near the surface of Earth. Assume g is constant and neglect any effects of air resistence.

96 •• **ENGINEERING APPLICATION** The *specific impulse* of a rocket propellant is defined as $I_{sp} = F_{th}/(Rg)$, where F_{th} is the thrust of the propellant, g is the magnitude of free-fall acceleration, and R is the rate at which the propellant is burned. The rate depends predominantly on the type and exact mixture of the propellant. (*a*) Show that the specific impulse has the dimension of time. (*b*) Show that $u_{ex} = gI_{sp}$, where u_{ex} is the relative speed of the exhaust. (*c*) What is the specific impulse (in seconds) of the propellant used in the Saturn V rocket of Example 8-19.

97 ••• **SPREADSHEET, ENGINEERING APPLICATION** The initial *thrust-to-weight ratio* τ_0 of a rocket is $\tau_0 = F_{th}/(m_0 g)$, where F_{th} is the rocket's thrust and m_0 the initial mass of the rocket, including the propellant. (*a*) For a rocket launched straight up from Earth's surface, show that $\tau_0 = 1 + (a_0/g)$, where a_0 is the initial acceleration of the rocket. For manned rocket flight, τ_0 cannot be made much larger than 4 for the comfort and safety of the astronauts. (As the rocket lifts off, the astronauts will feel that their weight is equal to τ_0 times their normal weight.) (*b*) Show that the final velocity of a rocket launched from Earth's surface can, in terms of τ_0 and I_{sp} (see Problem 96), be written as

$$v_f = gI_{sp}\left[1n\left(\frac{m_0}{m_f}\right) - \frac{1}{\tau_0}\left(1 - \frac{m_f}{m_0}\right)\right]$$

where m_f is the mass of the rocket (not including the spent propellant). (*c*) Using a **spreadsheet** program or **graphing calculator,** graph v_f as a function of the mass ratio m_0/m_f for $I_{sp} = 250$ s and $\tau_0 = 2$ for values of the mass ratio from 2 to 10. (Note that the mass ratio cannot be less than 1.) (*d*) To lift a rocket into orbit, a final velocity after burnout of $v_f = 7.0$ km/s is needed. Calculate the mass ratio required of a single-stage rocket to do this, using the values of specific impulse and thrust ratio given in Part (*b*). For engineering reasons, it is difficult to make a rocket with a mass ratio much greater than 10. Can you see why multistage rockets are usually used to put payloads into orbit around Earth? SSM

98 •• **ENGINEERING APPLICATION** The height that a model rocket launched from Earth's surface can reach can be estimated by assuming that the burn time is short compared to the total flight time; the rocket is therefore in free-fall for most of the flight. (This estimate neglects the burn time in calculations of both time and displacement.) For a model rocket with specific impulse $I_{sp} = 100$ s, mass ratio $m_0/m_f = 1.20$, and initial thrust-to-weight ratio $\tau_0 = 5.00$ (these parameters are defined in Problems 96 and 97), estimate (*a*) the height the rocket can reach, and (*b*) the total flight time. (*c*) Justify the assumption used in the estimates by comparing the flight time from Part (*b*) to the time it takes to consume the fuel.

GENERAL PROBLEMS

99 • A 250-g model-train car traveling at 0.50 m/s links up with a 400-g car that is initially at rest. What is the speed of the cars immediately after they link up? Find the pre- and postcollision kinetic energies of the two-car system. SSM

100 • **MULTISTEP** A 250-g model-train car traveling at 0.50 m/s heads toward a 400-g car that is initially at rest. (*a*) Find the total kinetic energy of the two-car system. (*b*) Find the velocity of each car in the center-of-mass reference frame, and use these velocities to calculate the kinetic energy of the two-car system in the center-of-mass reference frame. (*c*) Find the kinetic energy associated with the motion of the center of mass of the system. (*d*) Compare your answer for Part (*a*) with the sum of your answers for Parts (*b*) and (*c*).

101 •• A 1500-kg car traveling north at 70 km/h collides at an intersection with a 2000-kg car traveling west at 55 km/h. The two cars stick together. (*a*) What is the total momentum of the system before the collision? (*b*) What are the magnitude and direction of the velocity of the wreckage just after the collision.

102 •• A 60-kg woman stands on the back of a 6.0-m-long, 120-kg raft that is floating at rest in still water. The raft is 0.50 m from a fixed pier, as shown in Figure 8-52. (*a*) The woman walks to the front of the raft and stops. How far is the raft from the pier now? (*b*) While the woman walks, she maintains a constant speed of 3.0 m/s relative to the raft. Find the total kinetic energy of the system (woman plus raft), and compare your answer with the kinetic energy if the woman walked at 3.0 m/s on a raft tied to the pier. (*c*) Where do these kinetic energies come from, and where do they go when the woman stops at the front of the raft? (*d*) On land, the woman puts a lead shot 6.0 m. Then, standing at the back of the raft, she aims forward, and puts the shot so that just after it leaves her hand, it has the same velocity relative to her as it did when she threw it from the ground. Approximately, where does her shot land?

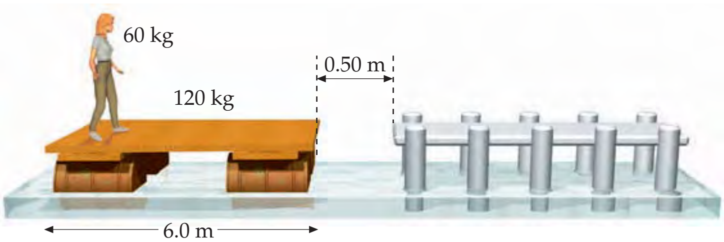

FIGURE 8-52 Problem 102

103 •• A 1.0-kg steel ball and a 2.0-m cord of negligible mass make up a simple pendulum that can pivot without friction about the point O, as in Figure 8-53. This pendulum is released from rest in a horizontal position, and when the ball is at its lowest point it strikes a 1.0-kg block sitting at rest on a shelf. Assume that the collision is perfectly elastic and that the coefficient of kinetic friction between the block and shelf is 0.10. (*a*) What is the velocity of the block just after impact? (*b*) How far does the block slide before coming to rest (assuming that the shelf is long enough)?

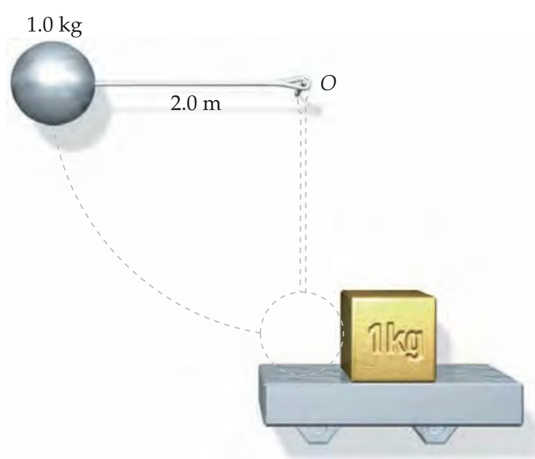

FIGURE 8-53 Problem 103

104 •• Figure 8-54 shows a World War I cannon mounted on a railcar and set so that it will project a shell at an angle of 30° above the horizontal. With the car initially at rest on a horizontal frictionless track, the cannon fires a 200-kg projectile at 125 m/s. (All values are for the frame of reference of the track.). (*a*) Will the vector momentum of the car–cannon–shell system be the same just before and just after the shell is fired? Explain your answer. (*b*) If the mass of the railcar plus cannon is 5000 kg, what will be the recoil velocity of the car along the track after the firing? (*c*) The shell is observed to rise to a maximum height of 180 m as it moves through its trajectory. At this point, its speed is 80.0 m/s. On the basis of this information, calculate the amount of thermal energy produced by air friction on the shell from the cannon's mouth to this maximum height.

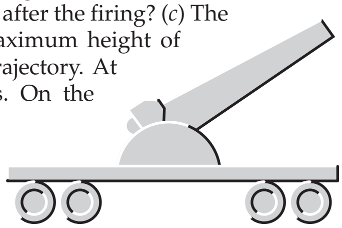

FIGURE 8-54 Problem 104

105 ••• **MULTISTEP** One popular, if dangerous, classroom demonstration involves holding a baseball an inch or so directly above a basketball that you are holding a few feet above a hard floor, and dropping the two balls simultaneously. The two balls will collide just after the basketball bounces from the floor; the baseball will then rocket off into the ceiling tiles, while the basketball will stop in midair. (*a*) Assuming that the collision of the basketball with the floor is elastic, what is the relation between the velocities of the balls just before they collide? (*b*) Assuming the collision between the two balls is elastic, use the result of Part (*a*) and the conservation of momentum and the conservation of energy to show that, if the basketball is three times as heavy as the baseball, the final velocity of the basketball will be zero. (This is approximately the true mass ratio, which is why the demonstration is so dramatic.) (*c*) If the speed of the baseball is v just before the collision, what is its speed just after the collision? SSM

106 ••• (*a*) In Problem 105, if we held a third ball above the baseball and basketball and wanted both the baseball and basketball to stop in midair, what should the ratio of the mass of the top ball to the mass of the baseball be? (*b*) If the speed of the top ball is v just before the collision, what is its speed just after the collision?

107 ••• In the "slingshot effect," the transfer of energy in an elastic collision is used to boost the energy of a space probe so that it can escape from the solar system. All speeds are relative to an inertial frame in which the center of the Sun remains at rest. Figure 8-55 shows a space probe moving at 10.4 km/s toward Saturn, which is moving at 9.6 km/s toward the probe. Because of the gravitational attraction between Saturn and the probe, the probe swings around Saturn and heads back in the opposite direction with speed v_f. (*a*) Assuming this collision to be a one-dimensional elastic collision with the mass of Saturn much much greater than that of the probe, find v_f. (*b*) By what factor is the kinetic energy of the probe increased? Where does this energy come from? SSM

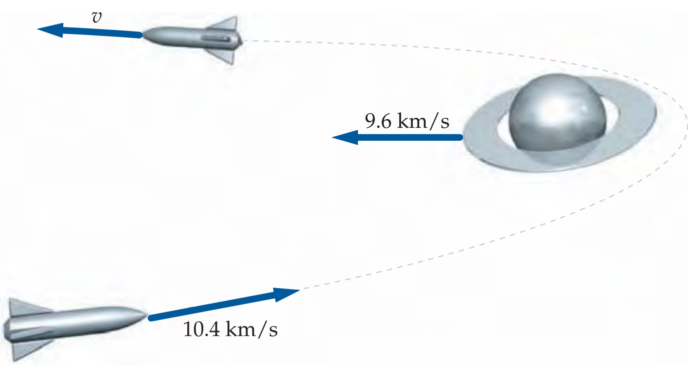

FIGURE 8-55 Problem 107

108 •• A 13-kg block is at rest on a level floor. A 400-g glob of putty is thrown at the block so that the putty travels horizontally, hits the block, and sticks to it. The block and putty slide 15 cm along the floor. If the coefficient of kinetic friction is 0.40, what is the initial speed of the putty?

109 ••• **CONTEXT-RICH** Your accident-reconstruction team has been hired by the local police to analyze the following accident. A careless driver rear-ended a car that was halted at a stop sign. Just before impact, the driver slammed on his brakes, locking the wheels. The driver of the struck car had his foot solidly on the brake pedal, locking his brakes. The mass of the struck car was 900 kg, and that of the initially moving vehicle was 1200 kg. On collision, the bumpers of the two cars meshed. Police determine from the skid marks that after the collision the two cars moved 0.76 m together. Tests revealed that the coefficient of kinetic friction between the tires and pavement was 0.92. The driver of the moving car claims that he was traveling at less than 15 km/h as he approached the intersection. Is he telling the truth? SSM

110 •• A pendulum consists of a compact 0.40-kg bob attached to a string of length 1.6 m. A block of mass m rests on a horizontal frictionless surface. The pendulum is released from rest at an angle of 53° with the vertical. The bob collides elastically with the block at the lowest point in its arc. Following the collision, the maximum angle of the pendulum with the vertical is 5.73°. Determine the mass m.

111 ••• A 1.00-kg block (mass m) and a second block (mass M) are both initially at rest on a frictionless inclined plane (Figure 8-56). Mass M rests against a spring that has a force constant of 11.0 kN/m. The distance along the plane between the two blocks is 4.00 m. The 1.00-kg block is released, making an elastic collision with the larger block. The 1.00-kg block then rebounds a distance of 2.56 m back up the inclined plane. The block of mass M momentarily comes to rest 4.00 cm from its initial position. Find M. SSM

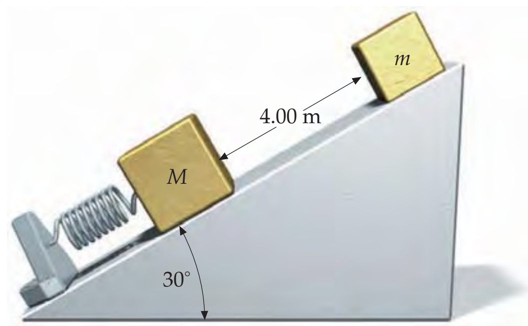

FIGURE 8-56 Problem 111

112 ••• A neutron of mass m makes an elastic head-on collision with a stationary nucleus of mass M. (*a*) Show that the kinetic energy of the nucleus after the collision is given by $K_{\text{nucleus}} = [4mM/(m + M)^2]K_n$, where K_n is the initial kinetic energy of the neutron. (*b*) Show that the *fractional* change in the kinetic energy of the neutron is given by

$$\frac{\Delta K_n}{K_n} = -\frac{4(m/M)}{(1 + [m/M])^2}$$

(*c*) Show that this expression gives plausible results both if $m \ll M$ and if $m = M$. What is the best stationary nucleus for the neutron to collide head-on with if the objective is to produce a maximum loss in the kinetic energy of the neutron?

113 ••• **ENGINEERING APPLICATION** The mass of a carbon nucleus is approximately 12 times the mass of a neutron. (*a*) Use the results of Problem 112 to show that after N head-on collisions of a neutron with carbon nuclei at rest, the kinetic energy of the neutron is approximately $0.716^N K_0$, where K_0 is its initial kinetic energy. (*b*) Neutrons emitted in the fission of a uranium nucleus have kinetic energies of about 2.0 MeV. For such a neutron to cause the fission of another uranium nucleus in a reactor, its kinetic energy must be reduced to about 0.020 eV. How many head-on collisions are needed to reduce the kinetic energy of a neutron from 2.0 MeV to 0.020 eV, assuming elastic head-on collisions with stationary carbon nuclei?

114 ••• **ENGINEERING APPLICATION** On average, a neutron actually loses only 63 percent of its energy in an elastic collision with a hydrogen atom (not 100 percent) and 11 percent of its energy in an elastic collision with a carbon atom (not 28 percent). (These numbers are an average over all types of collisions, not just head-on ones. Thus, the results are lower than the ones determined from analyses like that in Problem 112, because most collisions are not head-on.) Calculate the actual number of collisions, on average, needed to reduce the energy of a neutron from 2.0 MeV to 0.020 eV if the neutron collides with (*a*) stationary hydrogen atoms and (*b*) stationary carbon atoms.

115 ••• Two astronauts at rest face each other in space. One, who has mass m_1, throws a ball of mass m_b to the other, whose mass is m_2. The second astronuat catches the ball and throws it back to the first astronaut. Following each throw, the ball has a speed of v relative to the thrower. After each has made one throw and one catch, (*a*) how fast are the astronauts moving? (*b*) How much has the two-astronaut system's kinetic energy changed and where did this energy come from? SSM

116 ••• A stream of elastic glass beads, each with a mass of 0.50 g, comes out of a horizontal tube at a rate of 100 per second (see Figure 8-57). The beads fall a distance of 0.50 m to a balance pan and bounce back to their original height. How much mass must be placed in the other pan of the balance to keep the pointer at zero?

FIGURE 8-57 Problem 116

117 ••• A dumbbell consisting of two balls of mass m connected by a massless 1.00-m-long rod rests on a frictionless floor against a frictionless wall with one ball directly above the other. The center-to-center distance between the balls is equal to 1.00 m. The dumbbell then begins to slide down the wall, as in Figure 8-58. Find the speed of the bottom ball at the moment when it equals the speed of the top ball.

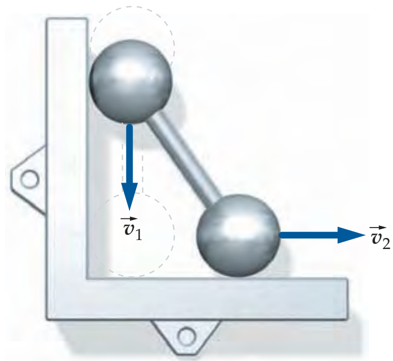

FIGURE 8-58 Problem 117

CHAPTER 9

THE LONDON EYE IS A 135-METER-HIGH OBSERVATION WHEEL THAT CARRIES A MAXIMUM OF 800 PASSENGERS.
(Ian Britton/FreeFoto.com.)

Rotation

? What is the torque required to stop the wheel so that the passengers travel a distance of 10 m as the wheel slows to a stop? (See Example 9-15.)

In Chapters 4 and 5, we explored Newton's laws. In Chapters 6 and 7, we examined the conservation of energy, and we studied the conservation of momentum in Chapter 8. We discovered tools (laws, theorems, and problem-solving techniques) that are useful in analyzing new situations and solving new problems in those chapters. We now continue to use those tools as we explore rotational motion.

Rotational motion is all around us. Earth rotates about its axis. Wheels, gears, propellers, motors, the drive shaft in a car, a CD in its player, a pirouetting ice skater, all rotate.

In this chapter, we consider rotation about an axis that is fixed in space, as in a merry-go-round, or about an axis that is moving without changing its direction in space, as in a rolling wheel on a car that is traveling in a straight line. The study of rotational motion is continued in Chapter 10 where more general examples of rotational motion are considered.

9-1 ROTATIONAL KINEMATICS: ANGULAR VELOCITY AND ANGULAR ACCELERATION

Every point of a rigid object rotating about a fixed axis moves in a circle whose center is on the axis and whose radius is the radial distance from the axis of rotation to that point. A radius drawn from the rotation axis to any point on the body sweeps out the same angle in the same time. Imagine a disk spinning about a fixed axis perpendicular to the disk and through its center (Figure 9-1). Let r_i be the distance from the center of the disk to the ith particle (Figure 9-2), and let θ_i be the angle measured counterclockwise from a fixed reference line in space to a radial line from the axis to the particle. As the disk rotates through an angle $d\theta$, the particle moves through a circular arc of directed length ds_i, such that

$$ds_i = r_i\,d\theta \qquad \text{9-1}$$

where $d\theta$ is measured in radians. If counterclockwise is designated as the positive direction, then $d\theta$, θ_i, and ds_i, shown in Figure 9-2, are all positive. (If clockwise is designated the positive direction, they are all negative.) The angle θ_i, the directed length ds_i, and the distance r_i vary from particle to particle, but the ratio ds_i/r_i, called the **angular displacement** $d\theta$, is the same for all particles of the disk. For one complete revolution, the arc length s_i is $2\pi r_i$ and the angular displacement $\Delta\theta$ is

$$\Delta\theta = \frac{s_i}{r_i} = \frac{2\pi r_i}{r_i} = 2\pi\text{ rad} = 360° = 1\text{ rev}$$

The time rate of change of the angle is the same for all particles of the disk, and is called the angular velocity ω of the disk. The instantaneous **angular velocity** ω is an angular displacement of short duration divided by the time. That is,

$$\omega = \frac{d\theta}{dt} \qquad \text{9-2}$$

DEFINITION—ANGULAR VELOCITY

so ω is positive if $d\theta$ is positive and negative if $d\theta$ is negative. All points on the disk undergo the same angular displacement during the same time, so they all have the same angular velocity. The SI units of ω are rad/s. Because radians are dimensionless, the dimension of angular velocity is that of reciprocal time, T^{-1}. The magnitude of the angular velocity is called the **angular speed.** We often use revolutions per minute (rev/min or RPM) to specify the angular speed. To convert between revolutions, radians, and degrees, we use

$$1\text{ rev} = 2\pi\text{ rad} = 360°$$

PRACTICE PROBLEM 9-1

A compact disk is rotating at 3000 rev/min. What is its angular speed in radians per second?

Angular acceleration is the rate of change of angular velocity. If the rotation rate of a rotating object increases, the angular speed $|\omega|$ increases. (If $|\omega|$ is increasing, and if the angular velocity ω is clockwise, then the change in the angular velocity $\Delta\omega$ is also clockwise.) The average angular acceleration vector

$$\alpha_{av} = \frac{\Delta\omega}{\Delta t} \qquad \text{9-3}$$

DEFINITION—AVERAGE ANGULAR ACCELERATION

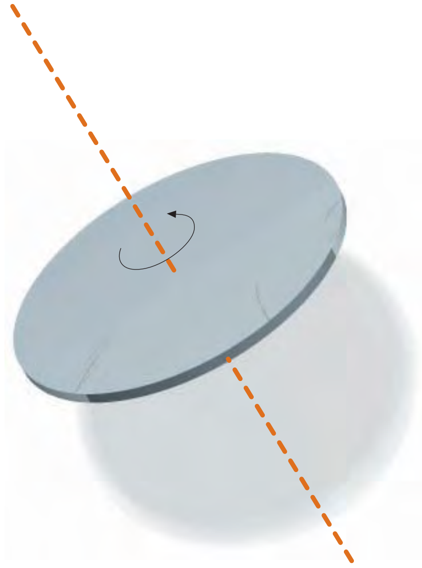

FIGURE 9-1

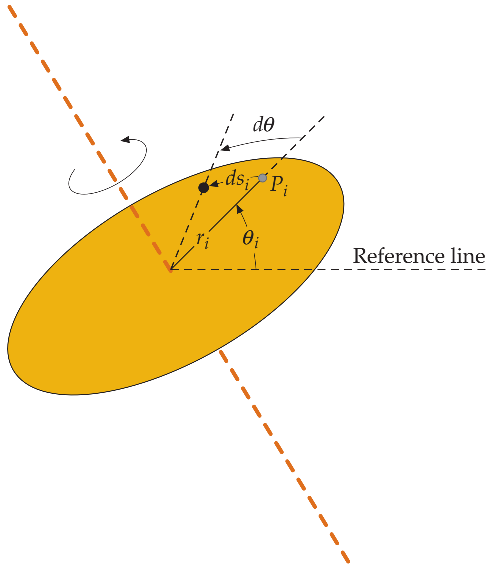

FIGURE 9-2

(Fred Habegger/Grant Heilman Photography, Inc.)

is always in the same direction as $\Delta\omega$. If the rotation rate decreases, then both $\Delta\omega$ and α_{av} are in the opposite direction to ω.

The instantaneous rate of change of angular velocity is called the **angular acceleration** α. That is,

$$\alpha = \frac{d\omega}{dt} = \frac{d^2\theta}{dt^2} \qquad 9\text{-}4$$

DEFINITION—ANGULAR ACCELERATION

The SI units of α are rad/s^2. α is positive if ω is increasing, and α is negative if ω is decreasing.

The angular displacement θ, the angular velocity ω, and angular acceleration α are analogous to the linear displacement x, linear velocity v_x, and linear acceleration a_x in one-dimensional motion. If the angular acceleration α is constant, we can integrate both sides of $d\omega = \alpha\, dt$ (Equation 9-4) to obtain:

$$\omega = \omega_0 + \alpha t \qquad 9\text{-}5$$

CONSTANT ANGULAR ACCELERATION

where the constant of integration ω_0 is the initial angular velocity. (Equation 9-5 is the rotational analog of the equation $v_x = v_{0x} + a_x t$.) Substituting $d\theta/dt$ in Equation 9-5, we obtain $d\theta = (\omega_0 + \alpha t)dt$. Integrating both sides of this equation gives

$$\theta = \theta_0 + \omega_0 t + \tfrac{1}{2}\alpha t^2 \qquad 9\text{-}6$$

CONSTANT ANGULAR ACCELERATION

(which is the rotational analog of $x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$). By eliminating t from Equations 9-5 and 9-6, we get

$$\omega^2 = \omega_0^2 + 2\alpha(\theta - \theta_0) \qquad 9\text{-}7$$

CONSTANT ANGULAR ACCELERATION

These constant-angular-acceleration kinematic equations have exactly the same form as the equations for constant linear acceleration developed in Chapter 2.

Star tracks in a time exposure of the night sky. *(David Malin/Anglo-Australian Telescope Board.)*

Example 9-1 A CD Player

A compact disk rotates from rest to 500 rev/min in 5.5 s. (*a*) What is its angular acceleration, assuming that it is constant? (*b*) How many revolutions does the disk make in 5.5 s? (*c*) How far does a point on the rim 6.0 cm from the center of the disk travel during the 5.5 s it takes to get to 500 rev/min?

PICTURE Part (*a*) is analogous to the one-dimensional linear problem of finding the acceleration, given the time and the final velocity. Part (*b*) is analogous to the one-dimensional linear problem of finding the displacement, given the time and the final velocity. Part (*c*), unlike Parts (*a*) and (*b*), involves both a linear quantity (distance traveled) and an angular quantity (angular displacement). Thus, Part (*c*) is not analogous to a one-dimensional angular problem.

SOLVE

(*a*) 1. The angular acceleration is related to the initial and final angular velocities:

$$\omega = \omega_0 + \alpha t = 0 + \alpha t$$

2. Solve for α:

$$\alpha = \frac{\omega}{t} = \frac{500\text{ rev/min}}{5.5\text{ s}} \times \frac{2\pi\text{ rad}}{1\text{ rev}} \times \frac{1\text{ min}}{60\text{ s}}$$
$$= 9.52\text{ rad/s}^2 = \boxed{9.5\text{ rad/s}^2}$$

(*b*) 1. The angular displacement is related to the time by Equation 9-6:

$$\theta - \theta_0 = \omega_0 t + \tfrac{1}{2}\alpha t^2 = 0 + \tfrac{1}{2}(9.52\text{ rad/s}^2)(5.5\text{ s})^2$$
$$= 144\text{ rad}$$

2. Convert radians to revolutions:

$$144\text{ rad} \times \frac{1\text{ rev}}{2\pi\text{ rad}} = 22.9\text{ rev} = \boxed{23\text{ rev}}$$

(*c*) The distance traveled Δs is r times the angular displacement in radians:

$$\Delta s = r\Delta\theta = (6.0\text{ cm})(144\text{ rad}) = 8.65\text{ m} = \boxed{8.7\text{ m}}$$

CHECK The average angular velocity is 250 rev/min. In 5.5 s, the compact disk rotates (250 rev/60 s)(5.5 s) = 23 rev.

TAKING IT FURTHER A compact disk is scanned by a laser that begins at the inner radius of 2.4 cm and moves to the outer radius of 6.0 cm. As the laser moves outward, the angular velocity of the disk decreases from 500 rev/min to 200 rev/min so that the linear (tangential) velocity of the disk at the point where the laser beam strikes remains constant.

PRACTICE PROBLEM 9-2 (*a*) Convert 500 rev/min to rad/s. (*b*) Check the result of Part (*b*) in the example using $\omega^2 = \omega_0^2 + 2\alpha(0 - \theta_0)$.

The linear velocity v_t of a particle on the disk is tangent to the circular path of the particle and has magnitude ds_i/dt. We can relate this tangential velocity to the angular velocity of the disk using Equations 9-1 and 9-2:

$$v_t = \frac{ds_i}{dt} = \frac{r_i d\theta}{dt} = r_i \frac{d\theta}{dt}$$

so

$$v_t = r_i\omega \qquad 9\text{-}8$$

Similarly, the tangential acceleration of a particle on the disk is dv_t/dt:

$$a_t = \frac{dv_t}{dt} = r_i \frac{d\omega}{dt}$$

so

$$a_t = r\alpha \qquad 9\text{-}9$$

Each particle of the disk also has a centripetal acceleration, which points inward along the radial line and has the magnitude

$$a_c = \frac{v_t^2}{r_i} = \frac{(r_i\omega)^2}{r_i}$$

so

$$a_c = r_i\omega^2 \qquad 9\text{-}10$$

! Equations that contain both linear and angular parameters, such as Equations 9-1, 9-8, 9-9, and 9-10, are valid only if the angle values are expressed in radians.

PRACTICE PROBLEM 9-3

A point on the rim of a compact disk is 6.00 cm from the axis of rotation. Find the tangential speed v_t, tangential acceleration a_t, and centripetal acceleration a_c of the point when the disk is rotating at a constant angular speed of 300 rev/min.

PRACTICE PROBLEM 9-4

Find the linear speed of a point on the CD in Example 9-1 at (*a*) $r = 2.40$ cm, when the disk rotates at 500 rev/min, and (*b*) $r = 6.00$ cm, when the disk rotates at 200 rev/min.

9-2 ROTATIONAL KINETIC ENERGY

The kinetic energy of a rigid object rotating about a fixed axis is the sum of the kinetic energies of the individual particles that collectively constitute the object. The kinetic energy of the ith particle, with mass m_i, is

$$K = \tfrac{1}{2}m_i v_i^2$$

Summing over all the particles and using $v_i = r_i\omega$ gives

$$K = \sum_i \left(\tfrac{1}{2}m_i v_i^2\right) = \tfrac{1}{2}\sum (m_i r_i^2 \omega^2) = \tfrac{1}{2}\Big(\sum_i m_i r_i^2\Big)\omega^2$$

The sum in the expression farthest to the right is the object's **moment of inertia** I for the axis of rotation.

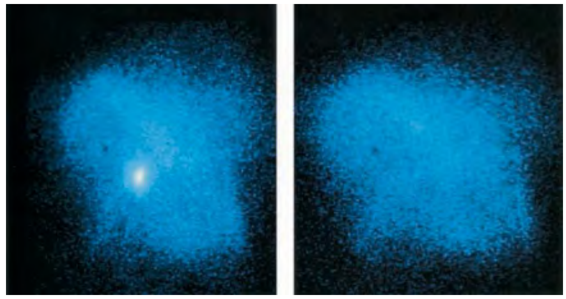
$$I = \sum_i m_i r_i^2 \qquad \text{9-11}$$

MOMENT OF INERTIA DEFINED

The kinetic energy is thus

$$K = \tfrac{1}{2} I\omega^2 \qquad \text{9-12}$$

KINETIC ENERGY OF ROTATING OBJECT



The Crab Pulsar is one of the fastest-rotating neutron stars known, but it is slowing down. It appears to blink on (left) and off (right) like the rotating lamp in a lighthouse, at the fast rate of about 30 times per second, but the period is increasing by about 10^{-5} s/y. This rate of loss in rotational energy is equivalent to the power output of 100,000 suns. The lost kinetic energy appears as light emitted by electrons accelerated in the magnetic field of the pulsar. *(David Malin/ Anglo-Australian Telescope Board.)*

Example 9-2 A Rotating System of Particles

An object consists of four point particles, each of mass m, connected by rigid massless rods to form a rectangle of edge lengths $2a$ and $2b$, as shown in Figure 9-3. The system rotates with angular speed ω about an axis in the plane of the figure through the center, as shown. (*a*) Find the kinetic energy of this object using Equations 9-11 and 9-12. (*b*) Check your result by individually calculating the kinetic energy of each particle and then taking their sum.

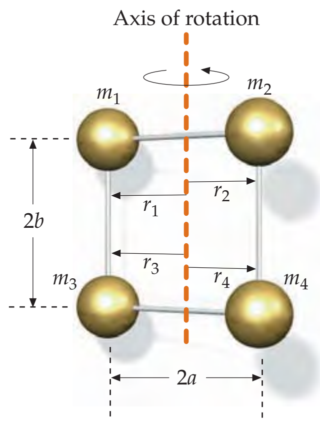


FIGURE 9-3

PICTURE Because we are given that the objects are point particles, we use Equation 9-11 to calculate I and then use Equation 9-12 to calculate K.

SOLVE

(*a*) 1. Apply the definition of moment of inertia $I = \Sigma m_i r_i^2$ (Equation 9-11), where r_i is the radial distance from the rotation axis to the particle of mass m_i:
$$I = \sum_i m_i r_i^2 = m_1 r_1^2 + m_2 r_2^2 + m_3 r_3^2 + m_4 r_4^2$$

2. The masses m_i and the distances r_i are given:
$$m_1 = m_2 = m_3 = m_4 = m$$
$$r_1 = r_2 = r_3 = r_4 = a$$

3. Substitution gives the moment of inertia:
$$I = ma^2 + ma^2 + ma^2 + ma^2 = 4ma^2$$

4. Using Equation 9-12, solve for the kinetic energy:
$$K = \tfrac{1}{2}I\omega^2 = \tfrac{1}{2}4ma^2\omega^2 = \boxed{2ma^2\omega^2}$$

(*b*) 1. To find the kinetic energy of the ith particle, we must first find its speed:
$$K_i = \tfrac{1}{2}m_i v_i^2$$

2. The particles are all moving in circles of radius a. Find the speed of each particle:
$$v_i = r_i\omega = a\omega \quad (i = 1, \ldots, 4)$$

3. Substitute into the Part-(*b*) step-1 result:
$$K_i = \tfrac{1}{2}m_i v_i^2 = \tfrac{1}{2}ma^2\omega^2$$

4. Each particle has the same kinetic energy. Sum the kinetic energies to get the total:
$$K = \sum_{i=1}^{4} K_i = \tfrac{1}{2}m_1 v_1^2 + \tfrac{1}{2}m_2 v_2^2 + \tfrac{1}{2}m_3 v_3^2 + \tfrac{1}{2}m_4 v_4^2$$
$$= 4\left(\tfrac{1}{2}ma^2\omega^2\right) = 2ma^2\omega^2$$

5. Compare with the Part-(*a*) result:
$\boxed{\text{The two calculations give the same result.}}$

CHECK The fact that the two calculations give the same result is a plausibility check.

TAKING IT FURTHER Notice that I is independent of the length b. The moment of inertia depends only upon how far from the axis the masses are, and not where along the axis they are.

PRACTICE PROBLEM 9-5 Find the moment of inertia of this system for rotation about an axis parallel to the first axis but passing through two of the particles, as shown in Figure 9-4.

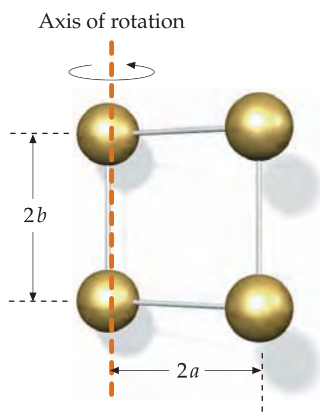

FIGURE 9-4

9-3 CALCULATING THE MOMENT OF INERTIA

The moment of inertia about an axis is a measure of the inertial resistance of the object to changes in its rotational motion about the axis. It is the rotational analog of mass. The farther an element of mass is from the axis, the greater its contribution to the moment of inertia about that axis. Thus, unlike the mass of an object, which is a property of the object itself, the moment of inertia depends on the location of the axis as well as the mass distribution of the object.

! The moment of inertia of an object about an axis depends both on the mass and on the distribution of the mass relative to the axis.

SYSTEMS OF DISCRETE PARTICLES

For systems consisting of discrete particles, we can compute the moment of inertia about a given axis directly from Equation 9-11. We can also use Equation 9-10 to obtain approximate values for the moment of inertia, as is done in the following example.

Example 9-3 Estimating the Moment of Inertia

Estimate the moment of inertia of a thin uniform rod of length L and mass M about an axis perpendicular to the rod and through one end. Execute this estimation by modeling the rod as three point masses, each point mass representing one-third of the rod.

PICTURE Divide the rod into three identical segments, each of mass $\frac{1}{3}M$ and length $\frac{1}{3}L$, and approximate each segment as a point mass located at its center of mass. Apply $I = \Sigma m_i r_i^2$ (Equation 9-11) to obtain an approximate value for I.

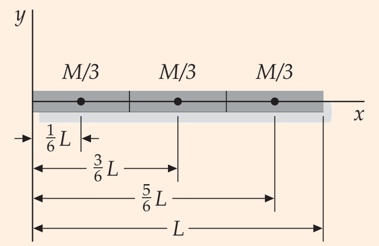

FIGURE 9-5

SOLVE

1. Sketch the rod divided into three segments and superpose the point-particle constructs at the center of each segment (Figure 9-5):
2. Apply the equation $I = \Sigma m_i r_i^2$ to the approximate system (the point-particle constructs):
$$I = \Sigma m_i r_i^2 \approx m_1 r_1^2 + m_2 r_2^2 + m_3 r_3^2$$
3. The mass of each particle is $\frac{1}{3}M$, and the distances of the particles from the axis are $\frac{1}{6}L$, $\frac{3}{6}L$, and $\frac{5}{6}L$:
$$I \approx (\tfrac{1}{3}M)(\tfrac{1}{6}L)^2 + (\tfrac{1}{3}M)(\tfrac{3}{6}L)^2 + (\tfrac{1}{3}M)(\tfrac{5}{6}L)^2$$
$$= \frac{1}{3}M\left(\frac{1 + 3^2 + 5^2}{6^2}\right)L^2 = \boxed{\frac{35}{108}ML^2}$$

CHECK The exact value for the moment of inertia of the rod about this axis is $\frac{1}{3}ML^2$. (The exact value is calculated in Example 9-4.) One-third is equal to 36/108, so our result is within 1% of the exact value.

PRACTICE PROBLEM 9-6 The contribution to the moment of inertia of the third of the rod farthest from the axis is many times greater than is the contribution of the third closest to the axis. About how many times greater is it?

CONTINUOUS OBJECTS

To calculate the moment of inertia for continuous objects, we imagine the object to consist of a continuum of very small mass elements. Thus, the finite sum $\Sigma m_i r_i^2$ in Equation 9-11 becomes the integral

$$I = \int r^2\,dm \qquad 9\text{-}13$$

where r is the radial distance from the axis to mass element dm. To evaluate this integral, we first express dm as a density times an element of length, area, or volume, as is done in the following examples.

Example 9-4 Moment of Inertia of a Thin Uniform Rod

Find the moment of inertia of a thin uniform rod of length L and mass M about an axis perpendicular to the rod and through one end.

PICTURE Use $I = \int r^2\,dm$ (Equation 9-13) to calculate the moment of inertia about the specified axis. The rod is uniform, which means that for any segment of the rod, the mass per unit length λ is equal to M/L.

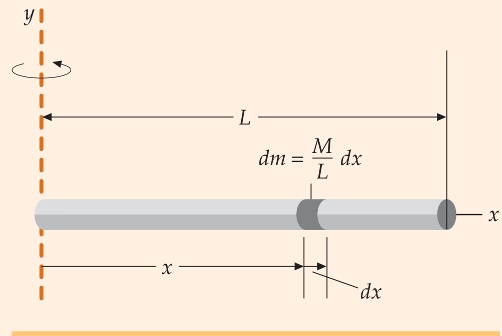

FIGURE 9-6

SOLVE

1. Draw a sketch (Figure 9-6) showing the rod along the $+x$ axis with its end at the origin. To calculate I about the y axis, we choose a mass element dm at a distance x from the axis:
2. The moment of inertia about the y axis is given by the integral: $$I = \int x^2\,dm$$
3. To compute the integral, we first relate dm to dx. Express dm in terms of the linear mass density λ and dx: $$dm = \lambda\,dx = \frac{M}{L}dx$$
4. Substitute and perform the integration. We choose integration limits so that we integrate through the mass distribution in the direction of increasing x: $$I = \int x^2\,dm = \int_0^L x^2\frac{M}{L}dx = \frac{M}{L}\int_0^L x^2\,dx$$ $$= \frac{M}{L}\frac{1}{3}x^3\Big|_0^L = \frac{M}{L}\frac{L^3}{3} = \boxed{\frac{1}{3}ML^2}$$

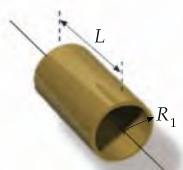
CHECK This result is in good agreement with the approximate result obtained in Example 9-3.

TAKING IT FURTHER The moment of inertia about the z axis is also $\frac{1}{3}ML^2$, and that about the x axis is zero (assuming that all of the mass is a negligible distance from the x axis).

We can calculate I for continuous objects of various shapes, again using Equation 9-13 (Table 9-1). Some of these calculations are done here.

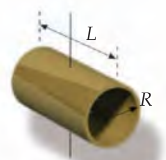
Table 9-1 Moments of Inertia of Uniform Bodies of Various Shapes

Thin cylindrical shell about axis



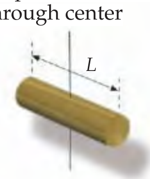
$I = MR^2$

Thin cylindrical shell about diameter through center



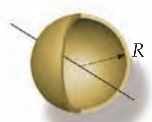
$I = \frac{1}{2}MR^2 + \frac{1}{12}ML^2$

Thin rod about perpendicular line through center



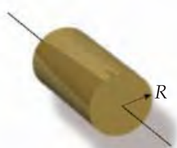
$I = \frac{1}{12}ML^2$

Thin spherical shell about diameter



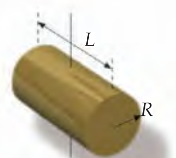
$I = \frac{2}{3}MR^2$

Solid cylinder about axis



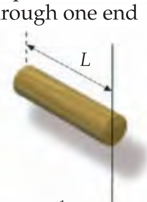
$I = \frac{1}{2}MR^2$

Solid cylinder about diameter through center



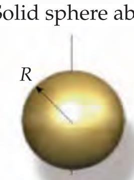
$I = \frac{1}{4}MR^2 + \frac{1}{12}ML^2$

Thin rod about perpendicular line through one end



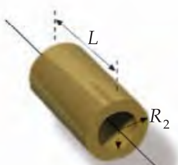
$I = \frac{1}{3}ML^2$

Solid sphere about diameter



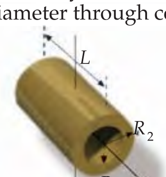
$I = \frac{2}{5}MR^2$

Hollow cylinder about axis



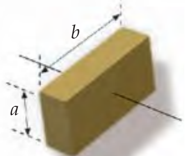
$I = \frac{1}{2}M(R_1^2 + R_2^2)$

Hollow cylinder about diameter through center



$I = \frac{1}{4}M(R_1^2 + R_2^2) + \frac{1}{12}ML^2$

Solid rectangular parallelepiped about axis through center perpendicular to face



$I = \frac{1}{12}M(a^2 + b^2)$

*A disk is a cylinder whose length L is negligible. By setting $L = 0$, the above formulas for cylinders hold for disks.

Hoop about a perpendicular axis through its center Assume that a hoop has mass M and radius R (Figure 9-7). The axis of rotation is the symmetry axis of the hoop, which is perpendicular to the plane of the hoop and through its center. All the mass is at a distance $r = R$, and the moment of inertia is

$$I = \int r^2\,dm = \int R^2\,dm = R^2\int dm = MR^2$$

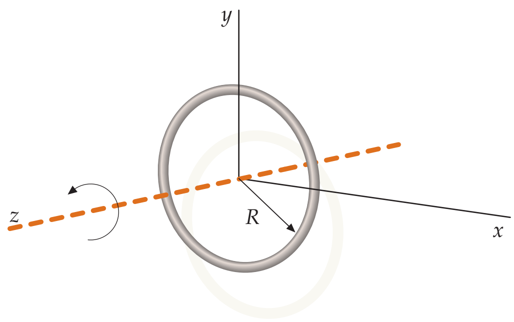


FIGURE 9-7

Uniform disk about a perpendicular axis through its center For the case of a uniform disk that has mass M and radius R, we expect that I will be smaller than MR^2 because, unlike the hoop, virtually all of the mass is closer to the axis than R. In Figure 9-8, each mass element is a hoop (or ring) of radius r and thickness dr. The moment of inertia of any given mass element is $r^2\,dm$. Because the disk is uniform, the mass per unit area σ is the same for any piece of it, so $\sigma = M/A$, where $A = \pi R^2$ is the area of the disk. Because the area of each hoop-shaped mass element is $dA = 2\pi r\,dr$, the mass of each element is

$$dm = \sigma dA = \frac{M}{A}2\pi r\,dr$$

We thus have

$$I = \int r^2\,dm = \int_0^R r^2\sigma\,2\pi r\,dr = 2\pi\sigma\int_0^R r^3\,dr = 2\pi\frac{M}{A}\frac{r^4}{4}\bigg|_0^R$$

$$= \frac{2\pi M}{A}\frac{R^4}{4} = \frac{\pi M}{2\pi R^2}R^4 = \frac{1}{2}MR^2$$

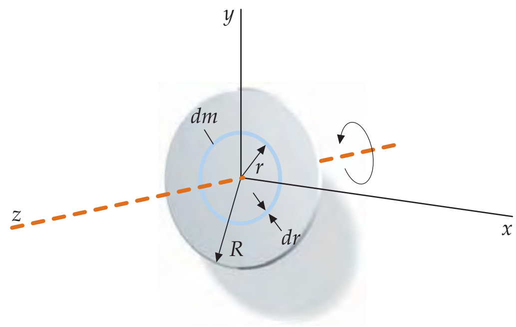

FIGURE 9-8

Uniform solid cylinder about its axis We consider a cylinder to be a set of disks, each with mass dm and moment of inertia $dI = \frac{1}{2}(dm)R^2$ (Figure 9-9). The moment of inertia of the complete cylinder is then

$$I = \int \frac{1}{2}dm\,R^2 = \frac{1}{2}R^2\int dm = \frac{1}{2}MR^2$$

where M is the total mass of the cylinder.

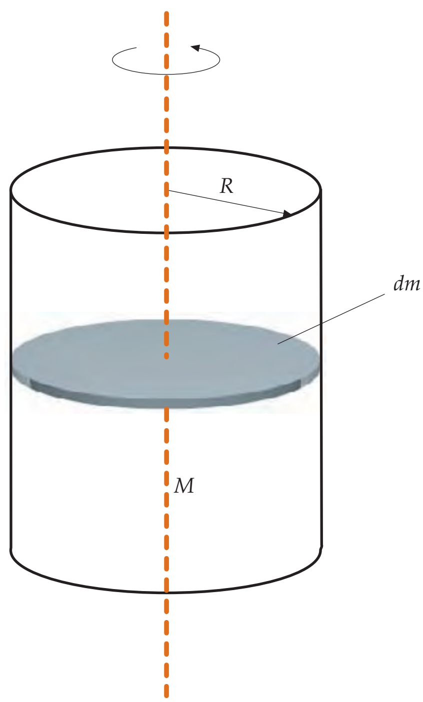

FIGURE 9-9

CONCEPT CHECK 9-1

Consider two identical uniform one-inch-diameter disks A and B. You drill a quarter-inch-diameter hole through the center of disk B. Which disk, A or B, then has the greater moment of inertia? (For each disk, consider only the moment of inertia about the axis through the center of, and perpendicular to, the disk.)

CONCEPT CHECK 9-2

Consider two uniform one-inch-radius disks A and B. The disks are identical, except that the density of B is slightly greater than that of A. You drill a quarter-inch-diameter hole through the center of disk B and find that the disks now have identical masses. Which disk, A or B, then has the greater moment of inertia? (For each disk, consider only the moment of inertia about the axis through the center of, and perpendicular to, the disk.)

THE PARALLEL-AXIS THEOREM

We can often simplify the calculation of moments of inertia for various objects by using the **parallel-axis theorem,** which relates the moment of inertia about an axis through the center of mass to the moment of inertia about a second, parallel axis (Figure 9-10). Let I be the moment of inertia, and let I_{cm} be the moment of inertia about a parallel axis through the center of mass. In addition, let M be the total mass of the object and let h be the distance between the two axes. The parallel-axis theorem states that

$$I = I_{cm} + Mh^2 \tag{9-14}$$

PARALLEL-AXIS THEOREM

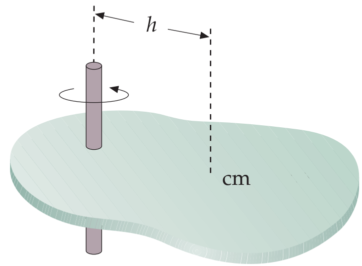

FIGURE 9-10 An object rotating about an axis parallel to an axis through the center of mass and a distance h from it.

Example 9-2 and the Practice Problem following it illustrate a special case of this theorem with $h = a, M = 4m$, and $I_{cm} = 4ma^2$.

Example 9-5 Applying the Parallel-Axis Theorem *Try It Yourself*

A thin uniform rod of mass M and length L on the x axis (Figure 9-11) has one end at the origin. Using the parallel-axis theorem, find the moment of inertia about the y' axis, which is parallel to the y axis, and through the center of the rod.

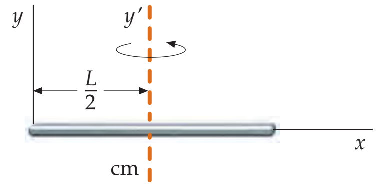

FIGURE 9-11

PICTURE Here you know that $I = \frac{1}{3}ML^2$ about one end (see Example 9-4) and want to find I_{cm}. Use the parallel-axis theorem with $h = \frac{1}{2}L$.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. Apply the parallel-axis theorem to write I about the end in terms of I_{cm}.	$I = I_{cm} + Mh^2$ $I_y = I_{y'} + M(\frac{1}{2}L)^2$
2. Substitute, using $\frac{1}{3}ML^2$ for I_y, I_{cm} for $I_{y'}$, and solve for I_{cm}.	$I_{cm} = I_y - Mh^2 = \frac{1}{3}ML^2 - M(\frac{1}{2}L)^2 = \boxed{\frac{1}{12}ML^2}$

CHECK Calculate the moment of inertia by direct integration. This calculation is the same as the calculation in Example 9-4 except that the integration limits are from $-\frac{1}{2}L$ to $+\frac{1}{2}L$. The result is

$$I = \int x^2\,dm = \frac{M}{L}\int_{-L/2}^{+L/2} x^2\,dx = \frac{M}{L}\frac{1}{3}x^3\Big|_{-L/2}^{+L/2} = \frac{M}{3L}\left(\frac{L^3}{8} + \frac{L^3}{8}\right) = \frac{1}{12}ML^2$$

which is the same as the step-2 result.

TAKING IT FURTHER The step-2 result is only 25% of the result gotten in Example 9-4, where the uniform rod is rotated about an axis through one end.

* PROOF OF THE PARALLEL-AXIS THEOREM

To prove the parallel-axis theorem, we start with an object (Figure 9-12) that is rotating about a fixed axis, one that does not pass through the center of mass. The kinetic energy K of such an object is given by $\frac{1}{2}I\omega^2$ (Equation 9-12), where I is the moment of inertia about the fixed axis. We saw in Chapter 8 (Equation 8-7) that the kinetic energy of a system can be written as the sum of its translational kinetic energy $(\frac{1}{2}Mv_{cm}^2)$ and the kinetic energy relative to the center of mass. For an object that is rotating, the kinetic energy relative to its center of mass is $\frac{1}{2}I_{cm}\omega^2$, where I_{cm}

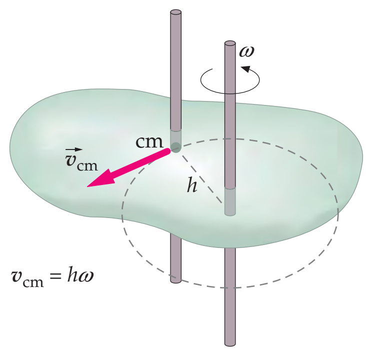

FIGURE 9-12

is the moment of inertia about the axis through the center of mass.* Thus, the total kinetic energy of the object is

$$K = \tfrac{1}{2}Mv_{\rm cm}^2 + \tfrac{1}{2}I_{\rm cm}\omega^2$$

The center of mass moves along a circular path of radius h, so $v_{\rm cm} = h\omega$ Substituting $\tfrac{1}{2}I_{\rm cm}\omega^2$ for K and $h\omega$ for $v_{\rm cm}$ gives

$$\tfrac{1}{2}I\omega^2 = \tfrac{1}{2}Mh^2\omega^2 + \tfrac{1}{2}I_{\rm cm}\omega^2$$

Multiplying through this equation by $2/\omega^2$ gives

$$I = Mh^2 + I_{\rm cm}$$

which completes the proof of the parallel-axis theorem.

PRACTICE PROBLEM 9-7

Using the parallel-axis theorem, show that when comparing the moments of inertia of an object about two parallel axes, the moment of inertia is less about the axis that is nearer to the center of mass.

Example 9-6 A Flywheel-Powered Car *Context-Rich*

You are driving an experimental hybrid vehicle that is designed for use in stop-and-go traffic. In a car with conventional brakes, each time you brake to a stop the kinetic energy is dissipated as heat. In this hybrid vehicle, the braking mechanism transforms the translational kinetic energy of the vehicle's motion into the rotational kinetic energy of a massive flywheel. As the car returns to cruising speed, this energy is transferred back into the translational kinetic energy of the car. The 100-kg flywheel is a hollow cylinder with an inner radius R_1 of 25.0 cm, an outer radius R_2 of 40.0 cm, and a maximum angular speed of 30,000 rev/min. On a dark and dreary night, the car runs out of gas 15.0 mi from home with the flywheel spinning at maximum speed. Is there sufficient energy stored in the flywheel for you and your nervous grandmother to make it home? (When driving at the minimum highway speed of 40.0 mi/h, air drag and rolling friction dissipate energy at 10.0 kW.)

PICTURE The kinetic energy is calculated directly from $K = \tfrac{1}{2}I\omega^2$.

SOLVE

1. The kinetic energy of rotation is	$K = \tfrac{1}{2}I\omega^2$
2. Calculate the moment of inertia of the hollow cylinder using an expression from Table 9-1:	$I = \tfrac{1}{2}m(R_1^2 + R_2^2) = 11.1\ \text{kg}\cdot\text{m}^2$
3. Convert ω to rad/s:	$\omega = 30{,}000\ \text{rev/min} = 3142\ \text{rad/s}$
4. Substitute these values to find the kinetic energy:	$K = \tfrac{1}{2}I\omega^2 = 54.9\ \text{MJ}$
5. Energy is dissipated at 10 kW at a speed of 40 mi/h. To find the energy dissipated during the 15-mi trip, we first need to find the time required for the trip:	$\Delta x = v\,\Delta t,$ so $\Delta t = 1350\ \text{s}$
6. The energy is dissipated at 10 kW for 1350 s. The total energy dissipated is	13.5 MJ
7. Is there enough energy stored in the flywheel?	54.9 MJ are available and 13.5 MJ are dissipated. $\boxed{\text{Yes, there is more than enough energy stored in the flywheel.}}$

CHECK There are 130 MJ of energy in a gallon of gasoline. If the engine is 10% efficient, only 13 MJ/gal are available to move the car. The initial energy in the flywheel is more than the energy available to move the car in three gallons of gasoline. This energy should be more than enough to get you the 15 mi needed to get home.

* *Relative to its center of mass* means "relative to an inertial reference frame in which the center of mass is at least momentarily at rest."

Example 9-7 The Pivoted Rod

A uniform thin rod of length L and mass M, pivoted at one end as shown in Figure 9-13, is held horizontal and then released from rest. Assuming that effects due to friction and air resistance are negligible, find (*a*) the angular speed of the rod as it sweeps through the vertical position, and (*b*) the force exerted on the rod by the pivot at this instant. (*c*) What initial angular speed would be needed for the rod to just reach a vertical position at the top of its swing?

PICTURE We choose everything shown in Figure 9-13 plus Earth as the system. (*a*) As the rod swings down, the potential energy decreases and the kinetic energy increases. Because the pivot is frictionless, mechanical energy remains constant. The angular speed of the rod is then found from its rotational kinetic energy. (*b*) To find the force of the pivot we apply Newton's second law for a system to the rod. (*c*) As in Part (*a*), mechanical energy remains constant.

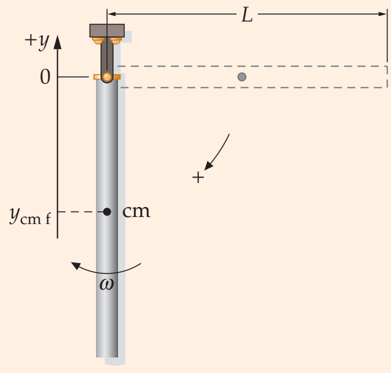

FIGURE 9-13

SOLVE

(*a*) 1. The diagram of the rod (Figure 9-13) shows both the initial and final configurations of the rod-Earth system. The origin of the y axis is at the same height as the rotation axis.

2. Apply conservation of mechanical energy to relate the initial and final mechanical energies:

$$K_{\text{f}} + U_{\text{f}} = K_{\text{i}} + U_{\text{i}}$$

$$\tfrac{1}{2}I\omega_{\text{f}}^2 + Mgy_{\text{cm f}} = \tfrac{1}{2}I\omega_{\text{i}}^2 + Mgy_{\text{cm i}}$$

$$\frac{1}{2}I\omega_{\text{f}}^2 + Mg\left(-\frac{L}{2}\right) = 0 + 0$$

3. Solve for ω_{f}.

$$\omega_{\text{f}} = \sqrt{\frac{MgL}{I}}$$

4. Obtain I from Table 9-1 and substitute into the step-3 result:

$$I = \tfrac{1}{3}ML^2 \quad \text{so} \quad \omega_{\text{f}} = \sqrt{\frac{MgL}{\frac{1}{3}ML^2}} = \boxed{\sqrt{\frac{3g}{L}}}$$

(*b*) 1. Draw a free-body diagram of the rod as it sweeps through the vertical position at the bottom of its swing (Figure 9-14).

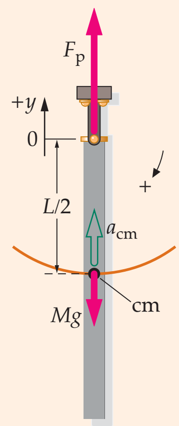

FIGURE 9-14

2. Apply Newton's second law for a system to the rod. At the bottom of the swing the acceleration of the center of mass is in the centripetal (upward) direction:

$$\Sigma F_{\text{ext}\,y} = Ma_{\text{cm}}$$

$$F_{\text{p}} - Mg = Ma_{\text{cm}}$$

3. Relate the acceleration of the center of mass to the angular speed using $a_{\text{c}} = r\omega^2$. Substitute the Part-(*a*) step-4 result for ω and solve for a_{cm}:

$$a_{\text{cm}} = r\omega^2$$

$$a_{\text{cm}} = \frac{L}{2}\frac{3g}{L} = \frac{3}{2}g$$

4. Substitute into the Part-(*b*) step-2 result and calculate F_{p}:

$$F_{\text{p}} = Mg + Ma_{\text{cm}} = Mg + M\tfrac{3}{2}g = \boxed{\tfrac{5}{2}Mg}$$

(*c*) 1. The initial angular velocity ω_i is related to the initial kinetic energy:

$$K_{\text{i}} = \tfrac{1}{2}I\omega_{\text{i}}^2$$

2. Make a diagram of the rod showing both the initial and final configuration (Figure 9-15). Include the same coordinate axis as in Part (*a*):

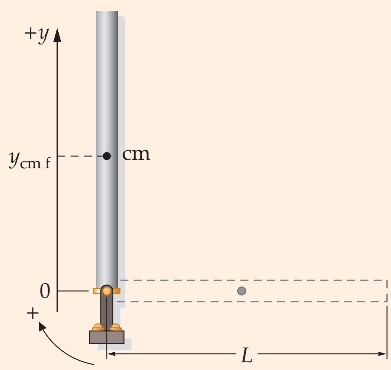

FIGURE 9-15

3. Apply conservation of mechanical energy to relate the initial kinetic energy to the final position:

$$K_{\text{f}} + U_{\text{f}} = K_{\text{i}} + U_{\text{i}}$$

$$\tfrac{1}{2}I\omega_{\text{f}}^2 + Mgy_{\text{cm f}} = \tfrac{1}{2}I\omega_{\text{i}}^2 + Mgy_{\text{cm i}}$$

$$0 + Mg\frac{L}{2} = \frac{1}{2}I\omega_{\text{i}}^2 + 0$$

4. Solve for the initial angular velocity:

$$\omega_{\text{i}} = \sqrt{\frac{MgL}{I}} = \sqrt{\frac{MgL}{\frac{1}{3}ML^2}} = \boxed{\sqrt{\frac{3g}{L}}}$$

CHECK It is no coincidence that the answers to Part (*a*) and Part (*c*) are identical. The decrease in both height and potential energy in Part (*a*) is equal to the increase in height and potential energy in Part (*c*). Thus, the increase in kinetic energy in Part (*a*) is equal to the decrease in kinetic energy in Part (*c*).

Example 9-8 A Winch and a Bucket

A winch is at the top of a deep well. The drum of the winch has mass m_w and radius R. Virtually all its mass is concentrated a distance R from the axis. A cable wound around the drum suspends a bucket of water of mass m_b. The entire cable has mass m_c and length L. Just when you have the bucket at the highest point, your hand slips and the bucket falls back down the well, unwinding the winch cable as it goes. How fast is the bucket moving after it has fallen a distance d, where d is less than L? Assume that effects due to friction and air resistance are negligible.

(D. S. Kerr/ Visuals Unlimited.)

PICTURE As the load falls, mechanical energy of the drum-cable-bucket of water-Earth system remain constant. Choose the initial potential energy to be zero. When the load has fallen a distance d, the center of mass of the hanging part of the cable has dropped a distance $d/2$. Because the hanging part of the cable moves with speed v and the cable does not stretch or become slack, the entire cable must move at speed v. We find v from the conservation of mechanical energy.

SOLVE

1. Make a diagram of the system in both its initial and its final configuration (Figure 9-16). Include a y axis with the origin at the height of the rotation axis of the drum.

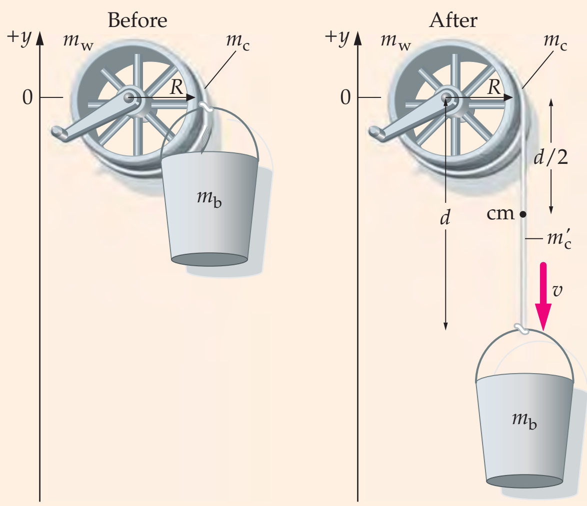

FIGURE 9-16

2. Apply conservation of mechanical energy. Choose the potential energy to be zero when the bucket of water is at the highest point:

$$U_f + K_f = U_i + K_i$$
$$= 0 + 0 = 0$$

3. Write an expression for the total potential energy when the bucket has fallen a distance d. Let m'_c denote the mass of the hanging part of the cable:

$$U_f = U_{bf} + U_{cf} + U_{wf}$$
$$= m_b g(-d) + m'_c g\left(-\frac{d}{2}\right) + 0$$
$$= -(m_b + \tfrac{1}{2}m'_c)gd$$

4. Express the total kinetic energy when the bucket is falling with speed v. All the cable and the entire mass of the drum move with the same speed v as the bucket:

$$K_f = K_{fc} + K_{fb} + K_{fw}$$
$$= \tfrac{1}{2}m_c v^2 + \tfrac{1}{2}m_b v^2 + \tfrac{1}{2}m_w v^2$$
$$= \tfrac{1}{2}(m_c + m_b + m_w)v^2$$

5. Substitute into the conservation of mechanical energy equation (step 2) and solve for v:

$$-(m_b + \tfrac{1}{2}m'_c)gd + \tfrac{1}{2}(m_c + m_b + m_w)v^2 = 0$$
$$\text{so} \quad v = \sqrt{\frac{(2m_b + m'_c)gd}{(m_c + m_b + m_w)}}$$

6. Assume that the cable is uniform and express m'_c in terms of m_c, d, and L:

$$\frac{m'_c}{d} = \frac{m_c}{L} \Rightarrow m'_c = \frac{d}{L}m_c$$

7. Substitute the step-6 result into the step-5 result:

$$v = \boxed{\sqrt{\frac{(2m_b L + m_c d)gd}{(m_c + m_b + m_w)L}}}$$

CHECK The step-7 result has the correct dimensions for speed because acceleration times length has dimensions of length squared divided by time squared.

TAKING IT FURTHER Because the entire mass of the drum is moving at the same speed v, we can express its kinetic energy as $\frac{1}{2}m_w v^2$. However, we can also express it as $\frac{1}{2}I_w\omega^2$, where $I_w = m_w R^2$ and $\omega = v/R$. With these substitutions, $K_w = \frac{1}{2}I_w\omega^2 = \frac{1}{2}m_w R^2(v^2/R^2) = \frac{1}{2}m_w v^2$.

9-4 NEWTON'S SECOND LAW FOR ROTATION

To set a top spinning, you twist it. In Figure 9-17, a disk is set spinning by the forces $\vec{F}_1$ and $\vec{F}_2$ exerted at the edges of the disk in the tangential direction. The directions of these forces and their points of application are important. If the same forces are applied at the same points but in the radial direction (Figure 9-18*a*), the disk will not start to spin. In addition, if the same forces are applied in the tangential direction, but at points closer to the center of the disk (Figure 9-18*b*), the disk will not gain angular speed as quickly.

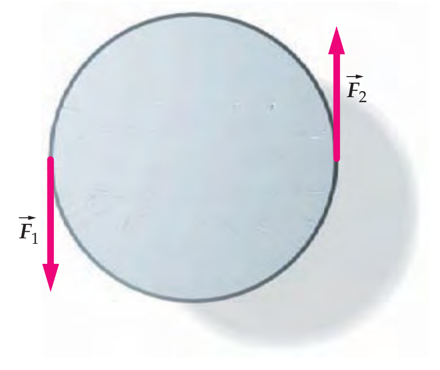

FIGURE 9-17

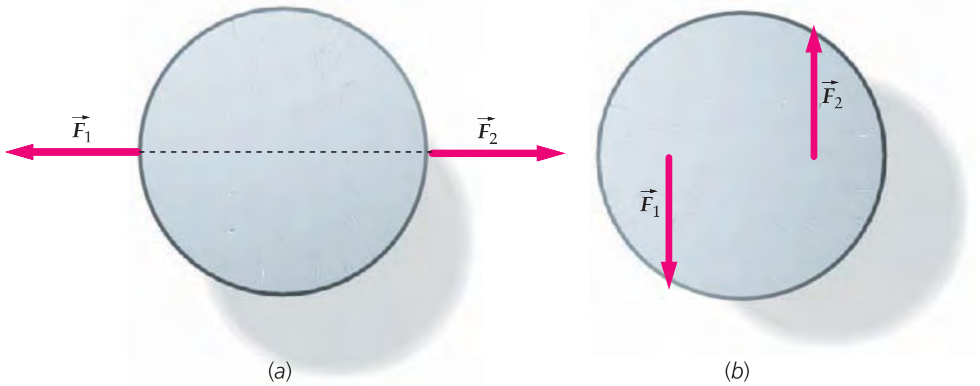

FIGURE 9-18

Figure 9-19 shows a particle of mass m attached to one end of a massless rigid rod of length r. The rod is free to rotate about a fixed axis perpendicular to the rod and passing through the end of the rod at A. Consequently, the particle is constrained to move in a circle of radius r. A single force $\vec{F}$ is applied to the particle as shown. Applying Newton's second law to the particle and taking components in the tangential direction gives

$$F_t = ma_t$$

where $F_t = F\sin\phi$ is the tangential component of $\vec{F}$ and a_t is the tangential component of the acceleration. We wish to obtain an equation involving angular quantities. Substituting $r\alpha$ for a_t (Equation 9-9) and multiplying both sides by r gives

$$rF_t = mr^2\alpha \qquad 9\text{-}15$$

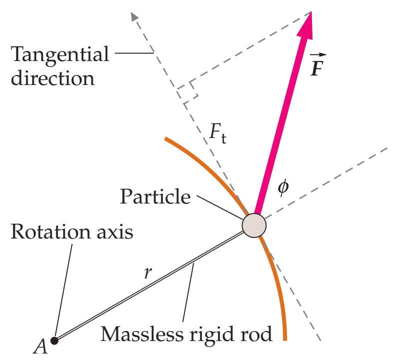

FIGURE 9-19

The product rF_t is the **torque τ** about the rotation axis associated with the force. That is,

$$\tau = F_t r \qquad 9\text{-}16$$

TORQUE ABOUT AN AXIS

(Torque about a point is defined as a vector quantity in Chapter 10. What we refer to as "torque about an axis" is the component of the torque vector parallel with the axis.)

Substituting τ for rF_t in Equation 9-15 gives

$$\tau = mr^2\alpha \qquad 9\text{-}17$$

A rigid object that rotates about a fixed axis is just a collection of individual particles, each of which is constrained to move in a circular path with the same angular velocity ω and acceleration α. Applying Equation 9-17 to the ith of these particles gives

$$\tau_{i\,\text{net}} = m_i r_i^2\alpha$$

where $\tau_{i\text{net}}$ is the torque due to the net force on the ith particle. Summing both sides over all particles gives

$$\sum \tau_{i\,\text{net}} = \sum m_i r_i^2 \alpha = \left(\sum m_i r_i^2\right)\alpha = I\alpha \qquad 9\text{-}18$$

See **Math Tutorial** *for more information on* **Trigonometry**

In Chapter 8, we saw that the net force acting on a system of particles is equal to the net *external* force acting on the system because the internal forces (those exerted by the particles within the system on one another) cancel in pairs. The treatment of internal torques exerted by the particles within a system on one another leads to a similar result, that is, the net torque acting on a system equals the net *external* torque acting on the system. We can thus write Equation 9-18 as

$$\tau_{\text{net ext}} = \sum \tau_{\text{ext}} = I\alpha \qquad 9\text{-}19$$

NEWTON'S SECOND LAW FOR ROTATION

This equation is the rotational analog of Newton's second law for linear motion ($\Sigma\vec{F} = m\vec{a}$).

(Richard Menga/ Fundamental Photographs.)

CALCULATING TORQUES

Figure 9-20 shows a force $\vec{F}$ acting on an object constrained to rotate about a fixed axis A, not shown, which passes through O and is perpendicular to the page. The positive tangential direction is shown at the point of application of the force, and r is the radial distance of this point of application from axis A. The torque τ due to this force about axis A is $\tau = F_{\text{t}}r$ (Equation 9-16). In principle, the expression $F_{\text{t}}r$ is all that is needed to calculate torques. However, in practice, calculations are often simpler if alternative expressions for torque are used. From the figure, we can see that

$$F_{\text{t}} = F\sin\phi$$

where ϕ is the angle between the radial direction and the direction of the force. Thus, we can express the torque as $\tau = F_{\text{t}}r = (F\sin\phi)r$. The *line of action* of a force is the line through the point of application of the force that is parallel to the force. From Figure 9-21 we can see that $r\sin\phi = \ell$, where the **moment arm** ℓ is the perpendicular distance between A and the line of action. (The moment arm is also called the *lever arm*.) Consequently, the torque is also given by $\tau = F\ell$. Putting all three equivalent expressions for the torque in one place, we have

$$\tau = F_{\text{t}}r = F\sin\phi\, r = F\ell \qquad 9\text{-}20$$

EQUIVALENT EXPRESSIONS FOR TORQUE

The torque of a force about an axis is also called the *moment of the force* about the axis.

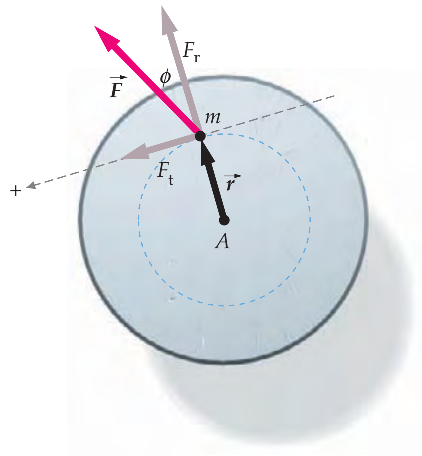

FIGURE 9-20 The force $\vec{F}$ produces a torque $F_{\text{t}}R$ about the center.

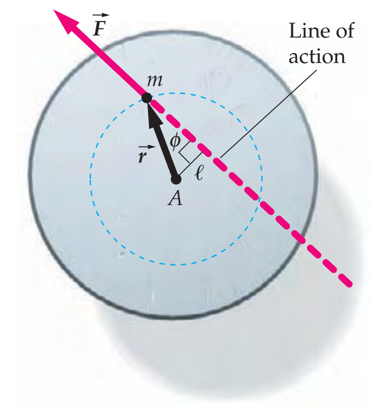

FIGURE 9-21 The force $\vec{F}$ produces a torque $F\ell$ about the center.

TORQUE DUE TO GRAVITY

We can model an extended object as an assembly of microscopic point particles, and there is a microscopic gravitational force on each particle. Each of these microscopic gravitational forces exerts a microscopic torque about a given axis, and the net gravitational torque on the object is the sum of these microscopic torques. The net gravitational torque can be calculated by considering the total gravitational force (the sum of the microscopic gravitational forces) to act at a single point-the **center of gravity.** Consider an object (Figure 9-22) constrained to rotate about a horizontal axis A coming out of the page. We choose the z axis of our coordinate system to coincide with axis A, and choose the x axis direction to be horizontal and the y axis vertical as shown. The torque on a particle of mass m_i due to gravity is $m_i g x_i$, where x_i is the moment arm of the force $m_i\vec{g}$. The net gravitational torque on

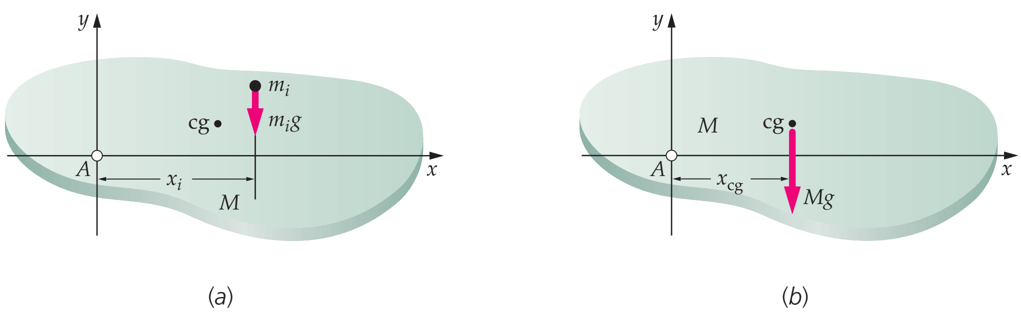

FIGURE 9-22 In a uniform gravitational field, the center of gravity coincides with the center of mass.

the object is the sum of the gravitational torques for all the particles that make up the object. That is, $\tau_{\text{grav net}} = \Sigma m_i g x_i$. If $\vec{g}$ is uniform (has the same magnitude and direction) throughout the region of space occupied by object, then g can be factored out of the sum. Factoring g out of the sum gives $\tau_{\text{grav net}} = (\Sigma m_i x_i)g$. You should recognize the sum in the parentheses as Mx_{cg} (see Equation 5-13). Substituting this for the sum gives

$$\tau_{\text{grav net}} = Mgx_{\text{cg}} \tag{9-21}$$

TORQUE DUE TO GRAVITY

! For any object in a uniform gravitational field, the center of gravity and the center of mass coincide.

The torque due to a uniform gravitational field is calculated as if the entire gravitational force is applied at the center of gravity.

9-5 APPLICATIONS OF NEWTON'S SECOND LAW FOR ROTATION

In this section, we give several applications of Newton's second law for rotation as expressed in Equation 9-19.

PROBLEM-SOLVING STRATEGY

Applying Newton's Second Law for Rotation

PICTURE Angular accelerations for rigid objects can be found by using free-body diagrams and Newton's second law for rotation, which is $\tau_{\text{net ext}} = \Sigma\tau_{\text{ext}} = I\alpha$. If $\tau_{\text{net ext}}$ is constant, then the constant angular acceleration equations apply. Time intervals and angular positions, velocities, and angular accelerations can then be determined using these equations.

SOLVE

1. Draw a free-body diagram with the object shown as a likeness of the object (not just as a dot).
2. Draw each force vector along the line of action of that force.
3. On the diagram indicate the positive direction (clockwise or counterclockwise) for rotations.

CHECK Make sure that the signs of your results are consistent with your choice for the positive directions of rotation.

Example 9-9 A Stationary Bike

To get some exercise without going anywhere, you set your bike on a stand so that the rear wheel is free to turn. As you pedal, the chain applies a force of 18 N to the rear sprocket wheel at a distance of $r_s = 7.0$ cm from the rotation axis of the wheel. Consider the wheel to be a hoop ($I = MR^2$) of radius $R = 35$ cm and mass $M = 2.4$ kg. What is the angular velocity of the wheel after 5.0 s?

PICTURE The angular velocity is found from the angular acceleration, which is found from Newton's second law for rotation. Because the forces are constant, the torques are also constant. Thus, the constant angular acceleration equations apply. Note that $\vec{F}$ acts in the direction of the chain, so the line of action of $\vec{F}$ is tangent to the sprocket wheel, and the moment arm is the radius r_s of the sprocket wheel (Figure 9-23).

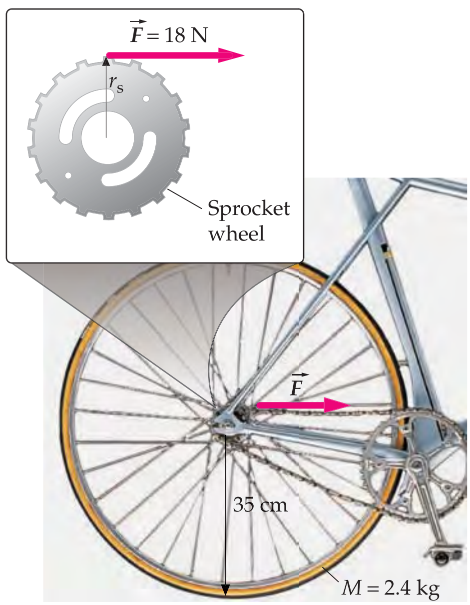

FIGURE 9-23

SOLVE

1. The angular velocity is related to the angular acceleration and the time: $\omega = \omega_0 + \alpha t = 0 + \alpha t$
2. Apply Newton's second law for rotational motion to relate α to the net torque and the moment of inertia: $\tau_{\text{net}} = I\alpha$
3. The only torque acting on the system is that due to the applied force F with moment arm r_s: $\tau_{\text{net}} = Fr_s$
4. Substitute this value for the torque and $I = MR^2$ for the moment of inertia: $$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{Fr_s}{MR^2}$$
5. Substitute into the step-1 result and solve for the angular velocity after 5.0 s: $$\omega = \alpha t = \frac{Fr_s}{MR^2}t = \frac{(18\text{ N})(0.070\text{ m})}{(2.4\text{ kg})(0.35\text{ m})^2}5.0\text{ s} = 21.4\text{ rad/s} = \boxed{21\text{ rad/s}}$$

CHECK The tangential speed of the rim is given by $R\omega = (0.36\text{ m})(21\text{ rad/s}) = 7.6\text{ m/s}$, which is a plausible speed. (A world-class runner can sprint at speeds in excess of 10 m/s.)

Example 9-10 A Uniform Rod, Pivoted at One End

A uniform thin rod of length L and mass M is pivoted at one end. It is held horizontal and released. Effects due to friction and air resistance are negligible. Find (*a*) the angular acceleration of the rod immediately following its release, and (*b*) the magnitude of the force F_A exerted on the rod by the pivot at this instant.

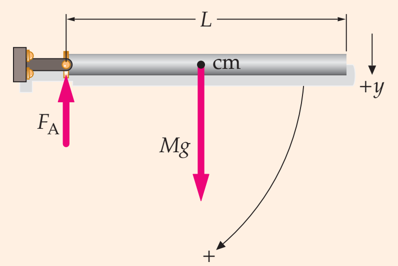

FIGURE 9-24

PICTURE The angular acceleration is found from Newton's second law for rotation (Equation 9-19). The force F_A is found from Newton's second law for a system (Equation 5-23). The tangential acceleration of the center of mass is related to the angular acceleration (Equation 9-6), and the centripetal acceleration of the center of mass is related to the angular speed (Equation 9-7).

SOLVE

(*a*) 1. Sketch a free-body diagram of the rod (Figure 9-24).

2. Write Newton's second law for rotation: $\Sigma\tau_{\text{ext}} = I\alpha$

3. Compute the torque due to gravity about the given axis. The rod is uniform so its center of gravity is at its center, a distance $L/2$ from the axis: $$\tau_{\text{grav}} = Mg\frac{L}{2}$$

4. Find the moment of inertia about the end of the rod from Table 9-1: $I = \frac{1}{3}ML^2$

5. Substitute these values into the step-2 equation to compute α: $$\alpha = \frac{\tau_{\text{grav}}}{I} = \frac{Mg(L/2)}{(1/3)ML^2} = \boxed{\frac{3g}{2L}}$$

(*b*) 1. Write Newton's second law for a system for the rod: $$\Sigma F_{\text{ext}\,y} = Ma_{\text{cm}\,y}$$ $$Mg - F_A = Ma_{\text{cm}\,y}$$

2. Use the relation $a_c = r\omega^2$ to find $a_{\text{cm c}}$. Immediately following release, $\omega = 0$: $$a_{\text{cm c}} = r_{\text{cm}}\omega^2 = \frac{L}{2}\omega^2 = 0$$

3. We now have two equations and three unknowns, $\alpha, \alpha_{\text{cm}\,y}$, and F_A. Use the relation $a_t = r\alpha$ to obtain a third equation, one relating $a_{\text{cm}\,y}$ to α. Then substitute the Part-(*a*) step- 5 result for α. $$a_t = r\alpha$$ $$a_{\text{cm}\,y} = a_{\text{cm t}} = r_{\text{cm}}\alpha = \frac{L}{2}\frac{3g}{2L} = \frac{3}{4}g$$

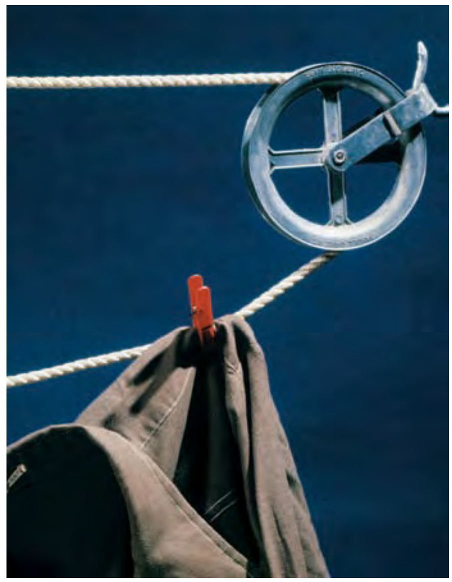
4. Substitute the Part-(*b*) step-3 result into the Part-(*b*) step-1 result and solve for F_A: $$Mg - F_A = M\tfrac{3}{4}g$$ so $F_A = \boxed{\tfrac{1}{4}Mg}$

CHECK The axis exerts an upward force on the rod. Consequently, we expect that following release, the acceleration of the center of mass will be somewhat less than the free-fall acceleration g. Our Part-(*b*) step-3 result confirms this expectation.

TAKING IT FURTHER Just after the rod is released, the acceleration of the center of mass is directed straight down. Because the net external force and the acceleration of the center of mass are in the same direction, it follows that $\vec{F}_A$ does not have a horizontal component at this instant.

PRACTICE PROBLEM 9-8 A small pebble of mass $m \ll M$ is placed on top of the rod at its center. Just after the rod is released find (*a*) the acceleration of the pebble, and (*b*) the force it exerts on the rod.

NONSLIP CONDITIONS



(*Fundamental Photographs.*)

In physics courses, there are many situations in which a taut string is in contact with a rotating pulley wheel. For the string not to slip on the pulley wheel, the parts of the string and the wheel that are in direct contact with each other must share the same tangential velocity. As a result,

$$v_t = R\omega \qquad 9\text{-}22$$

NONSLIP CONDITION FOR v_t AND ω

where v_t is the tangential velocity of the string and $R\omega$ is the tangential velocity of the perimeter of the pulley wheel. The wheel has radius R and is rotating with angular velocity ω. Differentiating both sides of the nonslip condition (Equation 9-22) with respect to time gives

$$a_t = R\alpha \qquad 9\text{-}23$$

a_t AND α UNDER NONSLIP CONDITIONS

where a_t is the tangential acceleration of the string and α is the angular acceleration of the wheel.

Example 9-11 Tension in a String

An object of mass m is suspended from a light string that is wound around the rim of a pulley wheel that has moment of inertia I and radius R. The wheel bearing is frictionless and the string does not slip on the rim. The wheel is released from rest. It starts to rotate as the object descends and the string unwinds. Find the tension in the string and the acceleration of the object.

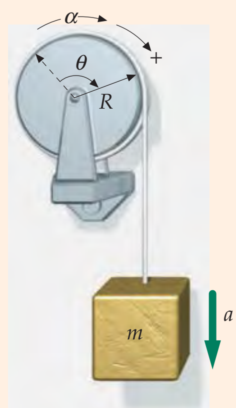


FIGURE 9-25

PICTURE The object descends with a downward acceleration a, while the wheel rotates with an angular acceleration α (Figure 9-25). We apply Newton's second law for rotation to the wheel to determine α, and Newton's second law to the object to obtain a. Relate a_t and α using the nonslip condition.

SOLVE

1. Draw a free-body diagram of the pulley wheel, drawing each force vector with its tail at the point of application of the force. Put labels on the diagram and indicate the positive rotational direction as shown in Figure 9-26:

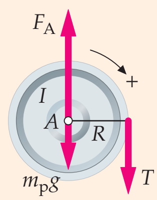

FIGURE 9-26

2. The only force that exerts a torque on the wheel is the tension T, which has moment arm R. Apply Newton's second law for rotational motion to relate T to the angular acceleration α:

$$\Sigma\tau_{\text{ext}} = I\alpha$$
$$TR = I\alpha$$

3. Draw a free-body diagram for the suspended object, and apply Newton's second law to relate T to the tangential acceleration a_t (Figure 9-27):

$$\Sigma F_{\text{ext}\,y} = ma_y$$
$$mg - T = ma_t$$

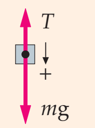

FIGURE 9-27

4. We have two equations for three unknowns, T, a_t, and α. A third equation is the relation between a_t and α, called the nonslip condition. (The tangential accelerations of the object, the string, and the perimeter of the wheel are all equal.):

$$a_t = R\alpha$$

5. We now have three equations enabling us to determine T, a_t, and α. To solve for T, substitute into the step-4 equation. Substitute for α using the step-2 result and for a_t using the step-3 result. Then solve for T.

$$\frac{mg - T}{m} = R\frac{TR}{I}$$

so $T = \boxed{\dfrac{mg}{1 + (mR^2/I)}}$

6. Substitute this result for T into the step-3 result and solve for a_t. The object and the wheel perimeter gain speed at the same rate. Thus, a_t is the acceleration of the wheel perimeter:

$$mg - \frac{mg}{1 + (mR^2/I)} = ma_t$$

so $a_t = \boxed{\dfrac{1}{1 + (I/mR^2)}g}$

CHECK Let us evaluate our results for a couple of limiting cases. If $I = 0$, the object should fall freely and the string should be slack; our results give $T = 0, a_t = g$, as expected. For very large values of I we expect the wheel to remain at rest. If $I \to \infty$, our equations give $T \to mg$ and $a_t \to 0$, as expected.

Example 9-12 Two Blocks and a Pulley I — *Conceptual*

The system shown in Figure 9-28 is released from rest. The mass of the pulley wheel is not negligible, but the friction in the bearing is negligible. The string does not slip on the pulley wheel. Given that $m_1 > m_2$, what can be determined about the tensions T_1 and T_2?

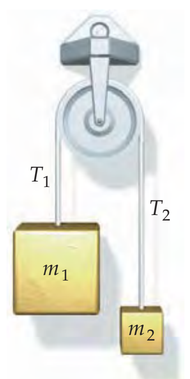

FIGURE 9-28

PICTURE Following release m_1 will accelerate downward, m_2 will accelerate upward, and the pulley wheel will angularly accelerate counterclockwise. Apply Newton's second law to each mass and apply Newton's second law for rotations to the pulley wheel.

SOLVE

1. Because m_1 accelerates downward, the net force on it must be downward: $\quad m_1g > T_1$

2. Because m_2 accelerates upward, the net force on it must be upward: $\quad T_2 > m_2g$

3. Because the angular acceleration of the pulley wheel is counterclockwise, the net torque on it must be counterclockwise. Because the two moment arms are equal, larger torque means larger tension: $\quad \tau_1 > \tau_2 \quad \text{so} \quad T_1 > T_2$

4. Combining the three results gives: $\quad \boxed{m_1g > T_1 > T_2 > m_2g}$

CHECK If T_1 were not greater than T_2, the angular acceleration of the pulley wheel would not be counterclockwise.

Example 9-13 Two Blocks and a Pulley II

Try It Yourself

Two blocks are connected by a string that passes over a pulley of radius R and moment of inertia I. The block of mass m_1 slides on a frictionless, horizontal surface; the block of mass m_2 is suspended from the string (Figure 9-29). Find the acceleration a of the blocks and the tensions T_1 and T_2. The string does not slip on the pulley.

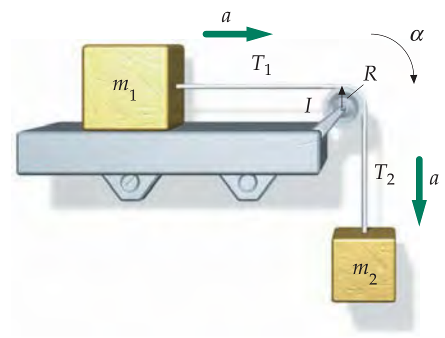

FIGURE 9-29

PICTURE The tensions T_1 and T_2 are not equal because the pulley has mass and because there is static friction between the string and the pulley (Figure 9-29). (If the two tensions were equal, the torque on the pulley by the string would be zero.) Note that T_2 exerts a clockwise torque and T_1 exerts a counterclockwise torque on the pulley. Use Newton's second law for each block, and Newton's second law for rotational motion for the pulley. Relate α and a using the nonslip condition.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. Draw a free-body diagram for each block and for the pulley, as shown in Figure 9-30. Note that the center of mass of the pulley wheel does not accelerate, so the support must exert a force on the axle F_s that balances the resultant of the gravitational force on the wheel and the forces exerted on it by the string.	
2. Apply Newton's second law to each block.	$T_1 = m_1 a; \quad m_2 g - T_2 = m_2 a;$
3. Apply Newton's second law for rotation to the pulley wheel.	$T_2 R - T_1 R = I\alpha$
4. We have three equations and four unknowns. To get a fourth equation, use the nonslip condition. The acceleration a of the blocks is equal to the tangential acceleration a_t of the string and pulley-wheel perimeter.	$a_t = R\alpha$ $a = a_t = R\alpha$
5. We have four equations and four unknowns, so the rest is algebra. Do the algebra and obtain expressions for a, T_1, and T_2. *Hint: To find a, obtain expressions for T_1 and T_2 from the step-2 results. Substitute these results into the step-3 result to obtain an equation with unknowns a and α. Use the step-4 result to eliminate α and solve for a.*	$a = \boxed{\dfrac{m_2}{m_1 + m_2 + (I/R)^2} g}$ $T_1 = m_1 a = \boxed{\dfrac{m_2}{m_1 + m_2 + (I/R)^2} m_1 g}$ $T_2 = m_2(g - a) = \boxed{\dfrac{m_1 + (I/R)^2}{m_1 + m_2 + (I/R)^2} m_2 g}$

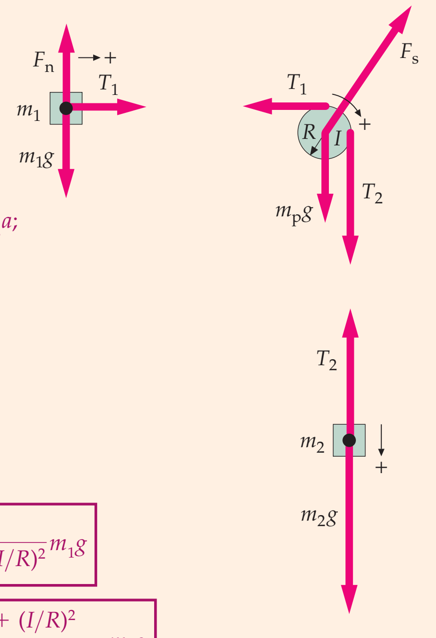

FIGURE 9-30

CHECK If $I = 0, T_1 = T_2$, and $a = m_2 g/(m_1 + m_2)$, as expected. If $I \to \infty$, then $a \to 0, T_1 \to 0$, and $T_2 \to m_2 g$, again as expected.

! Do not assume that the tension in a string passing over a pulley is the same on either side of the pulley. If it were, the string would not exert a torque on the pulley wheel and the wheel would not change its rotation rate. Use two distinct labels, such as T_1 and T_2, for the tensions in the string on opposite sides of the wheel.

POWER

When you spin up an object, you do work on it, increasing its kinetic energy. Consider the force $\vec{F}$ acting on a rotating object. As the object rotates through an angle $d\theta$, the point of application of the force moves a distance $ds = r\,d\theta$, and the force does work

$$dW = F_t\,ds = F_t r\,d\theta = \tau\,d\theta$$

where τ is the torque exerted by the force $\vec{F}$, and F_t is the tangential component of $\vec{F}$. The work dW done by a torque τ on an object when the object rotates through a small angle $d\theta$ is thus

$$dW = \tau\,d\theta \qquad 9\text{-}24$$

WORK

The rate at which the torque does work—the power input of the torque—is

$$P = \frac{dW}{dt} = \tau\frac{d\theta}{dt}$$

or

$$P = \tau\omega \qquad 9\text{-}25$$

POWER

Equations 9-24 and 9-25 are the rotational analogs of the linear equations $dW = F_{\|}\, d\ell$ and $P = F_{\|} v$.

Example 9-14 Torque Exerted by an Automobile Engine

The maximum torque produced by the 5.4-L V8 engine of a 2005 Ford GT is 678 N · m of torque at 4500 rev/min. Find the power output of the engine operating at these maximum torque conditions.

PICTURE The power equals the product of the torque and angular velocity (in radians per second).

SOLVE

1. Write the power in terms of τ and ω: $P = \tau\omega$
2. Convert rev/min to rad/s: $\omega = 4500\text{ rev/min} = 471\text{ rad/s}$
3. Calculate the power: $P = (678\text{ N}\cdot\text{m})\cdot(471\text{ rad/s}) = \boxed{320\text{ kW}}$

CHECK One horsepower equals 746 watts, so $320\text{ kW} \times 1\text{ hp}/0.746\text{ kW} = 429\text{ hp}$. This value is plausible for a high-performance automobile engine.

PRACTICE PROBLEM 9-9 The maximum power produced by the Ford GT engine is 500 hp at 6000 rev/min. What is the torque when the engine is operating at maximum horsepower?

There are many parallels between one-dimensional linear motion and rotational motion about a fixed axis. The similarities of the formulas can be seen in Table 9-2. The relations are the same, but the symbols are different.

Example 9-15 Stopping the Wheel

The specifications for the London Eye include that it be able to brake to a stop so that the passenger compartments move no more than 10 m during braking. The operating speed of the 135-m-diameter 1600-tonne wheel is 2.0 rev/h. (One tonne equals 1000 kg.) A picture of the wheel can be found at the beginning of this chapter. (*a*) Estimate the torque that is required to stop the wheel so the rim travels 10 m during the braking. (*b*) Assuming that the braking force is applied at the rim, what is the magnitude of the breaking force?

PICTURE The work done on the wheel is equal to its change in kinetic energy. Use $dW = \tau\, d\theta$ (Equation 9-24) to calculate the work in terms of the torque. Almost all of the mass is near the perimeter of the wheel (see the picture on the first page of this chapter). This suggests a way to estimate the moment of inertia. The braking force can be found from the torque.

SOLVE

(*a*) 1. Set the work done equal to the change in kinetic energy: $W = \Delta K$

2. Using $dW = \tau\, d\theta$ (Equation 9-24), relate the work to the torque and the angular displacement:

$$W = \tau\, \Delta\theta$$

3. Using $ds = r\, d\theta$ (Equation 9-2), relate the angular displacement to the stopping distance s:

$$s = r\,\Delta\theta \Rightarrow \Delta\theta = \frac{s}{r} = \frac{10\text{ m}}{67.5\text{ m}} = 0.148\text{ rad}$$

4. The mass is concentrated near the rim of the wheel, so $I \approx mr^2$:

$$I = mr^2 = (1.6 \times 10^6\text{ kg})(67.5\text{ m})^2$$
$$= 7.29 \times 10^9\text{ kg}\cdot\text{m}^2$$

5. Substitute into the step-1 result and solve for the torque. The initial angular velocity is $2.0\text{ rev/h} = 3.49 \times 10^{-3}\text{ rad/s}$:

$$\tau\,\Delta\theta = 0 - \tfrac{1}{2}I\omega_0^2$$

so $$\tau = -\frac{I\omega_0^2}{2\,\Delta\theta} = -\frac{(7.29 \times 10^9\text{ kg}\cdot\text{m}^2)(3.49 \times 10^{-3}\text{ rad/s})^2}{2\,(0.148\text{ rad})}$$
$$= \boxed{-3.0 \times 10^5\text{ N}\cdot\text{m}}$$

(*b*) 1. The line of action of the braking force is tangent to the rim, so the moment arm is equal to the radius of the wheel.

$$|\tau| = FR$$
$$F = \frac{|\tau|}{R} = \frac{3.0 \times 10^5\text{ N}\cdot\text{m}}{67.5\text{ m}} = \boxed{4.4 \times 10^3\text{ N}}$$

CHECK From the expression for the torque in step 5 of Part (*a*) we can see that τ is negative if $\Delta\theta$ is positive, and vice versa. This result is expected because the torque opposes the motion during braking.

TAKING IT FURTHER The braking force of 1.3×10^5 N is approximately equal to one-half ton.

Table 9-2 Analogs in Fixed-Axis Rotational and One-Dimensional Linear Motion

Rotational Motion		Linear Motion	
Angular displacement	$\Delta\theta$	Displacement	Δx
Angular velocity	$\omega = \frac{d\theta}{dt}$	Velocity	$v_x = \frac{dx}{dt}$
Angular acceleration	$\alpha = \frac{d\omega}{dt} = \frac{d^2\theta}{dt^2}$	Acceleration	$a_x = \frac{dv_x}{dt} = \frac{d^2x}{dt^2}$
Constant-angular-acceleration equations	$\omega = \omega_0 + \alpha t$	Constant-acceleration equations	$v_x = v_{0x} + a_x t$
	$\Delta\theta = \omega_{av}\,\Delta t$		$\Delta x = v_{av\,x}\,\Delta t$
	$\omega_{av} = \frac{1}{2}(\omega_0 + \omega)$		$v_{av\,x} = \frac{1}{2}(v_{0x} + v_x)$
	$\theta = \theta_0 + \omega_0 t + \frac{1}{2}\alpha t^2$		$x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$
	$\omega^2 = \omega_0^2 + 2\alpha\,\Delta\theta$		$v_x^2 = v_{0x}^2 + 2a_x\,\Delta x$
Torque	τ	Force	F_x
Moment of inertia	I	Mass	m
Work	$dW = \tau\, d\theta$	Work	$dW = F_x\, dx$
Kinetic energy	$K = \frac{1}{2}I\omega^2$	Kinetic energy	$K = \frac{1}{2}mv^2$
Power	$P = \tau\omega$	Power	$P = F_x v_x$
Angular momentum*	$L = I\omega$	Momentum	$p_x = mv_x$
Newton's second law	$\tau_{net} = I\alpha = \frac{dL}{dt}$	Newton's second law	$F_{net\,x} = ma_x = \frac{dp_x}{dt}$

*Angular momentum is introduced in Chapter 10.

9-6 ROLLING OBJECTS

ROLLING WITHOUT SLIPPING

When a spool rolls without slipping down an incline (Figure 9-31), the points of the spool in contact with the incline are instantaneously at rest and the spool rotates about a rotation axis through the contact points. This can be observed because rapid motion causes blurring, which means the part of the spool that is moving slowest is blurred the least. In Figure 9-32 a wheel of radius R is rolling without slipping along a flat surface. Point P on the wheel moves as shown with speed

FIGURE 9-31 A spool that has dots on it is rolling without slipping down an inclined meter stick. The shaft of the spool is in contact with the stick. The exposure time for this photo was long enough that the dots appear as streaks, with the length of the streaks increasing with distance from the rotation axis. *(Loren Winters/Visuals Unlimited.)*

$$v = r\omega \qquad \text{9-26}$$

NONSLIP CONDITION FOR SPEED

where r is the radial distance from the rotation axis to point P. The center of mass of the wheel moves with speed

$$v_{cm} = R\omega \qquad \text{9-27}$$

NONSLIP CONDITION FOR v_{cm}

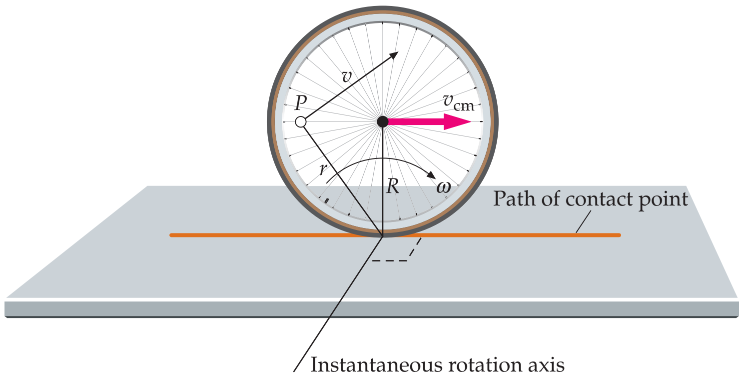

FIGURE 9-32 As the disk rolls to the right, point P moves upward and to the right. Point P reaches its greatest height when is passes over the center of the disk.

For a point on the very top of the wheel, $r = 2R$, so the top of the wheel is moving at twice the speed of the center of the wheel.

Differentiating both sides of Equation 9-27 gives

$$a_{cm} = R\alpha \qquad \text{9-28}$$

NONSLIP CONDITION FOR ACCELERATION

A falling yo-yo that is unwinding from a string—the top end of which is held fixed—follows the same nonslip conditions as the wheel.

A wheel of radius R is rolling without slipping along a straight path. As the wheel rotates through angle ϕ (Figure 9-33), the point of contact between the wheel and the surface moves a distance s that is related to ϕ by

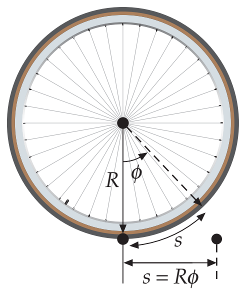

FIGURE 9-33

$$s = R\phi \qquad \text{9-29}$$

NONSLIP CONDITION FOR DISTANCE

If the wheel is rolling on a flat surface, the wheel's center of mass remains directly over the point of contact, so it also moves through distance $R\phi$.

In Chapter 8 we saw (Equation 8-7) that the kinetic energy of a system can be written as the sum of its translational kinetic energy ($\frac{1}{2}Mv_{cm}^2$) and the kinetic energy relative to the center of mass K_{rel}. For an object that is rotating, the kinetic energy relative to an inertial frame moving with center of mass $\frac{1}{2}I_{cm}\omega^2$. Thus, the total kinetic energy of the object is

$$K = \tfrac{1}{2}Mv_{cm}^2 + \tfrac{1}{2}I_{cm}\omega^2 \qquad \text{9-30}$$

TOTAL KINETIC ENERGY OF A ROTATING OBJECT

! Remember, a rolling object has both translational and rotational kinetic energy.

Example 9-16 A Bowling Ball

A bowling ball that has an 11-cm radius and a 7.2-kg mass is rolling without slipping at 2.0 m/s on a horizontal ball return. It continues to roll without slipping up a hill to a height h before momentarily coming to rest and then rolling back down the hill. Model the bowling ball as a uniform sphere and find h.

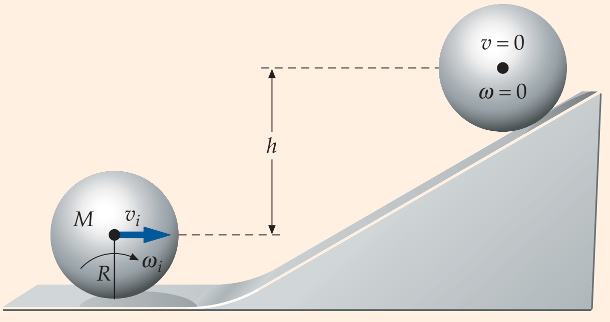

FIGURE 9-34

PICTURE No slipping occurs, so no energy is dissipated by kinetic friction. No external forces act on the ball–hill–Earth system, so no external forces do work on the system. The initial kinetic energy, which is the translational kinetic energy, $\frac{1}{2}Mv_{\text{cm}}^2$, plus the kinetic energy of rotation about the center of mass, $\frac{1}{2}I_{\text{cm}}\omega^2$, is converted to potential energy Mgh. Because the sphere rolls without slipping, the initial linear and angular speeds are related by $v_{\text{cm}} = R\omega$

SOLVE

1. Make a labeled sketch showing the ball in both its initial and final positions (Figure 9-34).
2. No external forces act on the system, so the work done by external forces is zero, and no slipping occurs, so no energy is dissipated by kinetic friction. Thus, mechanical energy is constant:

$$W_{\text{ext}} = \Delta E_{\text{mech}} + \Delta E_{\text{therm}}$$
$$0 = \Delta E_{\text{mech}} + 0$$

3. Apply conservation of mechanical energy with $U_{\text{i}} = 0$ and $K_{\text{f}} = 0$. Write the total initial kinetic energy K_{i} in terms of the speed v_{cm} and the angular speed ω_1:

$$U_{\text{f}} + K_{\text{f}} = U_{\text{i}} + K_{\text{i}}$$
$$Mgh + 0 = 0 + \tfrac{1}{2}Mv_{\text{cm i}}^2 + \tfrac{1}{2}I_{\text{cm}}\omega_{\text{i}}^2$$

4. Substitute from $\omega_{\text{i}} = v_{\text{cm i}}/R$ and $I_{\text{cm}} = \frac{2}{5}MR^2$ and solve for h:

$$Mgh = \frac{1}{2}Mv_{\text{cm i}}^2 + \frac{1}{2}\left(\frac{2}{5}MR^2\right)\frac{v_{\text{cm i}}^2}{R^2} = \frac{7}{10}Mv_{\text{cm i}}^2$$

$$\text{so} \quad h = \frac{7v_{\text{cm i}}^2}{10g} = 0.2854\text{ m} = \boxed{29\text{ cm}}$$

CHECK The height h is independent of the mass. This result is expected because both the kinetic energy and the potential energy are proportional to the mass.

TAKING IT FURTHER The height h is also independent of the radius R of the ball. This result is because $I_{\text{cm}} = \frac{2}{5}MR^2$ and $\omega_{\text{i}} = v_{\text{cm i}}/R$, so in the product $I_{\text{cm}}\omega_{\text{i}}^2$, the Rs cancel.

PRACTICE PROBLEM 9-10 Find the initial kinetic energy of the ball.

Example 9-17 Playing Pool

A cue stick strikes a cue ball horizontally at a point a distance d above the center of the ball (Figure 9-35). Find the value of d for which the cue ball will roll without slipping from the beginning. Express your answer in terms of the radius R of the ball.

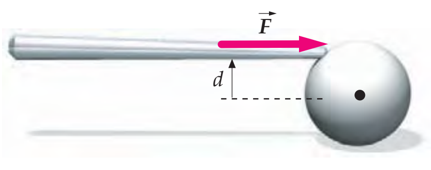

FIGURE 9-35

PICTURE The lines of action of the gravitational and normal forces both pass through the center of mass of the ball, and thus exert no torque about the center of mass. The frictional force exerted by the table is much smaller than the collision force of the cue stick, so its effects during the collision can be ignored. If the stick strikes the ball at the level of the ball's center, the ball initially translates with no rotation. If the stick strikes below the level of the center, the ball initially has backspin. However, if the stick strikes a certain distance d above the level of the center, the ball acquires just the right forward spin and forward translational motion to satisfy the nonslip condition. The value of d determines the torque-to-force ratio applied to the ball and hence the ball's angular acceleration to linear acceleration ratio. The linear acceleration a_{cm} is F/m, independent of d. For the ball to roll without slipping from the start, we find α and a_{cm}, then set $a_{\text{cm}} = R\alpha$ (the nonslip condition) to find d.

SOLVE

1. Sketch a free-body diagram of the ball (Figure 9-36). We are assuming that friction between the ball and the table is negligible, so do not include this frictional force:

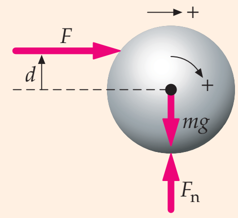

FIGURE 9-36

2. The torque about the horizontal axis through the center of the ball (and out of the page) equals F times d: $\tau = Fd$

3. Apply Newton's second law for a system and Newton's second law for rotational motion about the center of the ball: $F = ma_{cm}$ and $\tau = I_{cm}\alpha$

4. The nonslip condition relates a_{cm} and α: $a_{cm} = R\alpha$

5. Substitute from steps 2 and 3 into step 4: $\dfrac{F}{m} = R\dfrac{Fd}{I_{cm}}$

6. Find the moment of inertia from Table 9-1 and solve for d: $d = \dfrac{I_{cm}}{mR} = \dfrac{\frac{2}{5}mR^2}{mR} = \boxed{\dfrac{2}{5}R}$

CHECK The step-6 result is plausible because the value obtained for d is greater than zero and less than R, as expected.

TAKING IT FURTHER Striking the ball at a point either higher or lower than $2R/5$ from the center will result in the ball rolling *and* slipping (skidding). Skidding is often desirable in the game of pool. Rolling and slipping is discussed in the next subsection.

(Scott Goldsmith/ Stone/Getty.)

When an object rolls down an incline, its center of mass accelerates. The analysis of such a problem is simplified by an important theorem concerning the center of mass:

> Newton's second law for rotation ($\tau = I\alpha$) holds in any inertial reference frame. It also holds in reference frames moving with the center of mass—even when the center of mass is accelerating—as long as the moment of inertia and all torques are computed about an axis through the center of mass. That is,
>
> $$\tau_{\text{net cm}} = I_{cm}\alpha \qquad 9\text{-}31$$

Equation 9-31 is the same as Equation 9-19, except that in Equation 9-31 the torques and the moment of inertia are computed from a reference frame moving with the center of mass. When the center of mass is accelerating (a ball rolling down an incline, for example), the center-of-mass reference frame is a noninertial one, where we would not expect our equations for Newton's second law for rotation to be valid. Nevertheless, they are valid for this special case.

Example 9-18 Acceleration of a Ball That Is Rolling Without Slipping

A uniform solid ball of mass m and radius R rolls without slipping down a plane inclined at an angle ϕ above the horizontal. Find the frictional force and the acceleration of the center of mass.

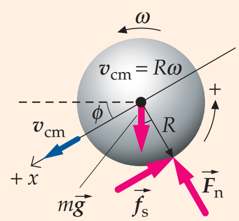

FIGURE 9-37

PICTURE From Newton's second law, the acceleration of the center of mass equals the net force divided by the mass. The forces acting are the gravitational force $m\vec{g}$ downward, the normal force $\vec{F}_n$, and the static frictional force $\vec{f}_s$ acting up the incline (Figure 9-37). As the object accelerates down the incline, its angular velocity must increase to maintain the nonslip condition. This angular acceleration requires a net external torque about the axis through the center of mass. We apply Newton's second law for rotation to find α. The nonslip condition relates α and a_{cm}.

SOLVE

1. Apply Newton's second law for a system in component form for the x axis:
$$\Sigma F_x = ma_{cm\,x}$$
$$mg\sin\phi - f_s = ma_{cm}$$

2. Apply Newton's second law for rotational motion about a horizontal axis passing through the center of mass and perpendicular to $\vec{v}_{cm}$. The moment arms for the normal and gravitational forces each equal zero, so they do not exert torques on the ball:
$$\Sigma\tau_i = I_{cm}\alpha$$
$$f_s R + 0 + 0 = I_{cm}\alpha$$

3. Relate a_{cm} and α using the nonslip condition:
$$a_{cm} = R\alpha$$

4. We now have three equations and three unknowns. Solve the step-1 result for f_s and the step-3 result for α, substitute for these quantities in the step-2 result, and solve for a_{cm}:
$$(mg\sin\phi - ma_{cm})R = I_{cm}\frac{a_{cm}}{R}$$
$$\text{so}\quad a_{cm} = \frac{g\sin\phi}{1 + \dfrac{I_{cm}}{mR^2}}$$

5. Substitute the step-4 result into the step-1 result and solve for f_s:
$$f_s = mg\sin\phi - ma_{cm} = mg\sin\phi - \frac{mg\sin\phi}{1 + \dfrac{I_{cm}}{mR^2}} = \frac{mg\sin\phi}{1 + \dfrac{mR^2}{I_{cm}}}$$

6. For a solid sphere, $I_{cm} = \frac{2}{5}mR^2$ (see Table 9-1). Substitute for I_{cm} in the step-4 and step-5 results:
$$a_{cm} = \frac{g\sin\phi}{1 + \frac{2}{5}} = \boxed{\frac{5}{7}g\sin\phi}$$
$$f_s = \frac{mg\sin\phi}{1 + \frac{5}{2}} = \boxed{\frac{2}{7}mg\sin\phi}$$

CHECK If the incline was frictionless the ball would not rotate and the acceleration would be $g\sin\phi$. With friction, we expect the acceleration to be less than $g\sin\phi$, which is evidenced by our first step-6 result.

TAKING IT FURTHER Because the ball rolls without slipping, the friction is static friction. Note that the result seems independent of the coefficient of static friction. However, we have assumed that the coefficient of static friction was large enough to prevent slipping.

The results of steps 5 and 6 in Example 9-18 apply to any round object with the center of mass at the geometric center that is rolling without slipping. For such objects, $I_{cm} = \beta mR^2$, where $\beta = \frac{2}{5}$ for a solid sphere, $\frac{1}{2}$ for a rolling solid cylinder, 1 for a thin hollow cylinder, and so forth. (These values of β are obtained from the expressions for I found in Table 9-1.) For such objects the step-5 and step-6 results can be expressed as

$$f_s = \frac{mg\sin\phi}{1 + \beta^{-1}} \qquad \text{9-32}$$

$$a_{cm} = \frac{g\sin\phi}{1 + \beta} \qquad \text{9-33}$$

The linear acceleration of any object rolling without slipping down an incline is less than $g\sin\phi$ because of the frictional force directed up the incline. Note that these accelerations are independent of the mass and the radius of the objects. That is, all uniform solid spheres will roll without slipping down an incline with the same acceleration. However, if we release a sphere, a cylinder, and a hoop at the top of an incline, and if they all roll without slipping, the sphere will reach the bottom first because it has the greatest acceleration. The cylinder will be second and the hoop last (Figure 9-38). A block that slides without friction down the incline will arrive at the bottom ahead of all three rolling objects. Perhaps surprisingly, a full can of soda pop that rolls without slipping will reach the bottom almost as fast

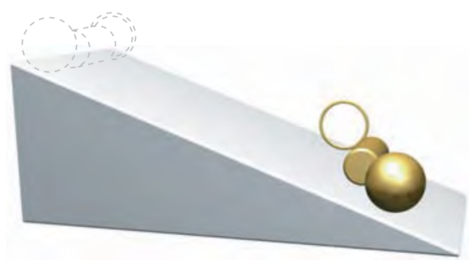

FIGURE 9-38

as the friction-free block. That is because the liquid in the can does not rotate with the can, so the effective moment of inertia of the can full of pop is just the moment of inertia of the metal can.

Static frictional forces do no work on the rolling objects, and if there is no slipping there is no dissipation of energy. Therefore, we use the conservation of mechanical energy to find the final speed of an object released from rest that is rolling without slipping down an incline. At the top of the incline, the total energy is the potential energy mgh. At the bottom, the total energy is kinetic energy. Conservation of mechanical energy therefore gives

$$\tfrac{1}{2}mv_{\mathrm{cm}}^2 + \tfrac{1}{2}I_{\mathrm{cm}}\omega^2 = mgh$$

We can use the nonslip condition to eliminate either v_{cm} or ω. Substituting $I_{\mathrm{cm}} = \beta mR^2$ and $\omega = v_{\mathrm{cm}}/R$, we obtain $\frac{1}{2}mv_{\mathrm{cm}}^2 + \frac{1}{2}\beta mR^2(v_{\mathrm{cm}}^2/R^2) = mgh$. Solving for v_{cm}^2 gives

$$v_{\mathrm{cm}}^2 = \frac{2gh}{1 + \beta} \qquad \text{9-34}$$

For a cylinder, with $\beta = \frac{1}{2}$, we obtain $v_{\mathrm{cm}} = \sqrt{\frac{4}{3}gh}$. Note that this speed is independent of both the mass and the radius of the cylinder, and is less than $\sqrt{2gh}$ (the final speed if there were no friction so that the object just slides down the incline).

For an object rolling without slipping down an incline, the frictional force f_{s} is less than or equal to its maximum value; that is, $f_{\mathrm{s}} \le \mu_{\mathrm{s}}F_{\mathrm{n}}$, where $F_{\mathrm{n}} = mg\cos\phi$. Substituting the expression from Equation 9-32 for the frictional force, we have

$$\frac{mg\sin\phi}{1 + \beta^{-1}} \le \mu_{\mathrm{s}}mg\cos\phi$$

or

$$\tan\phi \le (1 + \beta^{-1})\mu_{\mathrm{s}} \qquad \text{9-35}$$

For a uniform cylinder, $\beta = \frac{1}{2}$, and Equation 9-35 becomes $\tan\phi = 3\mu_{\mathrm{s}}$. If the tangent of the angle of incline is greater than $(1 + \beta^{-1})\mu_{\mathrm{s}}$, the object will slip as it rolls down the incline.

PRACTICE PROBLEM 9-11 A uniform cylinder rolls down a plane inclined at $\phi = 50°$. What is the minimum value of the coefficient of static friction for which the cylinder will roll without slipping?

PRACTICE PROBLEM 9-12 For a uniform hoop of mass m that is rolling without slipping down an incline, (*a*) what is the force of friction, and (*b*) what is the maximum value of $\tan\phi$ for which the hoop will roll without slipping?

* ROLLING WITH SLIPPING

When an object slips (skids) as it rolls, the nonslip condition $v_{\mathrm{cm}} = R\omega$ does not hold. Suppose a bowler releases the ball with no initial rotation ($\omega_0 = 0$). As the ball skids along the bowling lane, $v_{\mathrm{cm}} > R\omega$. However, the kinetic frictional force will both reduce its linear speed v_{cm} (Figure 9-39) and increase its angular speed ω until the nonslip condition $v_{\mathrm{cm}} = R\omega$ is reached, after which the ball rolls without slipping.

Another example of rolling with slipping is a ball with topspin, such as a cue ball struck at a point higher than $\frac{2}{5}R$ above the center (see Example 9-17) so that $v_{\mathrm{cm}} < R\omega$. Then the kinetic frictional force both increases v_{cm} and decreases ω until the nonslip condition $v_{\mathrm{cm}} = R\omega$ is reached (Figure 9-40).

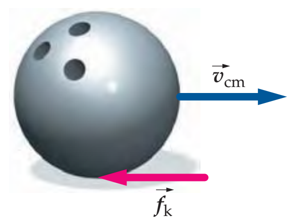

FIGURE 9-39 A bowling ball moving with no initial angular speed. The frictional force $\vec{f}_{\mathrm{k}}$ exerted by the floor reduces the linear speed v_{cm} and increases the angular speed ω until $v_{\mathrm{cm}} = R\omega$.

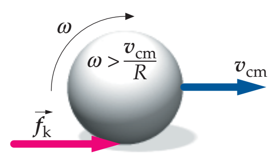

FIGURE 9-40 Ball with excess topspin. The frictional force accelerates the ball in the direction of motion.

Example 9-19 A Skidding Bowling Ball

A bowling ball of mass M and radius R is released at floor level so that at release it is moving horizontally with speed $v_0 = 5.0\,\text{m/s}$ and is not rotating. The coefficient of kinetic friction between the ball and the floor is $\mu_k = 0.080$. Find (*a*) the time the ball skids along the floor (after which it begins rolling without slipping), and (*b*) the distance the ball skids.

PICTURE During the skidding, $v_{cm} > R\omega$. We calculate v_{cm} and ω as functions of time, set v_{cm} equal to $R\omega$, and solve for the time. The linear and angular accelerations are found from $\Sigma F = ma$ and $\Sigma\tau_{cm} = I_{cm}\alpha$. Let the direction of motion be positive. There is slipping so the friction is kinetic (not static). This means that energy is dissipated by friction, so conservation of mechanical energy cannot be used to solve this problem.

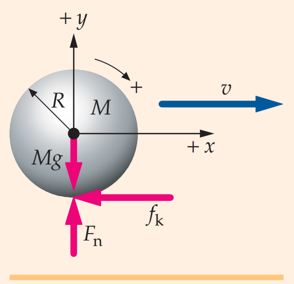

FIGURE 9-41

SOLVE

(*a*) 1. Sketch a free-body diagram of the ball (Figure 9-41).

2. The net force on the ball is the force of kinetic friction f_k, which acts in the negative x direction. Apply Newton's second law:

$$\Sigma F_x = Ma_{cm\,x}$$
$$-f_k = Ma_{cm\,x}$$

3. The acceleration is in the negative x direction and $a_{cm\,y} = 0$. Find f_k by first finding F_n:

$$\Sigma F_y = Ma_{cm\,y} = 0 \Rightarrow F_n = Mg$$
$$\text{so}\quad f_k = \mu_k F_n = \mu_k Mg$$

4. Find the acceleration using the step-2 and step-3 results:

$$-\mu_k Mg = Ma_{cm\,x} \Rightarrow a_{cm\,x} = -\mu_k g$$

5. Relate the linear velocity to the constant acceleration and the time using a kinematic equation:

$$v_{cm\,x} = v_0 + a_{cm\,x}t = v_0 - \mu_k g t$$

6. Find α by applying Newton's second law for rotational motion to the ball. Compute the torques about the axis through the center of mass. Note that the free-body diagram has clockwise as positive:

$$\Sigma\tau = I_{cm}\alpha$$
$$\mu_k MgR + 0 + 0 = \tfrac{2}{5}MR^2\alpha$$
$$\text{so}\quad \alpha = \frac{5}{2}\frac{\mu_k g}{R}$$

7. Relate the angular velocity to the constant angular acceleration and the time using a kinematic equation:

$$\omega = \omega_0 + \alpha t = 0 + \alpha t = \frac{5}{2}\frac{\mu_k g}{R}t$$

8. Solve for the time t at which $v_{cm} = R\omega$:

$$v_{cm} = R\omega$$
$$(v_0 - \mu_k g t) = R\left(\frac{5}{2}\frac{\mu_k g}{R}t\right)$$
$$\text{so}\quad t = \frac{2v_0}{7\mu_k g} = \frac{2(5.0\,\text{m/s})}{7(0.080)(9.81\,\text{m/s}^2)} = \boxed{1.8\,\text{s}}$$

(*b*) The distance traveled while skidding is

$$\Delta x = v_0 t + \tfrac{1}{2}a_{cm}t^2 = v_0\left(\frac{2v_0}{7\mu_k g}\right) + \frac{1}{2}(-\mu_k g)\left(\frac{2v_0}{7\mu_k g}\right)^2 = \frac{12}{49}\frac{v_0^2}{\mu_k g}$$
$$= \frac{12}{49}\frac{(5.0\,\text{m/s})^2}{(0.080)(9.81\,\text{m/s}^2)} = \boxed{7.8\,\text{m}}$$

CHECK A bowling alley is about 60 feet, or 18 m, long. That the ball skids for 7.8 m, almost half way down the alley, is plausible.

TAKING IT FURTHER At a bowling alley, or on television, you can observe bowling balls skidding a considerable distance down the alley. The lanes at a well-maintained bowling alley are lightly oiled and very slick, so the balls skid for considerable distances.

PRACTICE PROBLEM 9-13 Find the speed of the bowling ball when it begins to roll without slipping. Does this speed depend on the value of μ_k?

PRACTICE PROBLEM 9-14 Find the total kinetic energy of the ball as it initiates rolling without slipping.

Physics Spotlight

Spindizzy—Ultracentrifuges

Sample tubes being loaded into an ultracentrifuge. *(Atherotech.)*

One research team studies changes in blood lipids as people change their diets.[*] Another team investigates the stability of viral proteins.[†] All the researchers are using the tool that won Theodor (The) Svedberg the 1926 Nobel Prize in chemistry—the analytical ultracentrifuge.[‡]

As a centrifuge spins, each particle suspended in the sample experiences a force exerted on it by its surroundings in the radially inward direction. In accord with Newton's third law, each particle exerts an equal force in the radially outward direction on its surroundings. Consequently, the particles *sediment*, or settle, to the outer region of the sample tube as the centrifuge spins. Larger, more-dense particles move most quickly to the end of the sample tube farthest from the rotation axis. This movement depends on several variables—the mass, density, and friction coefficients of the particles in the solution. The final result, *sedimentation equilibrium*, has layers, or strata, of particles arranged according to these variables. An ultracentrifuge is powerful enough to analyze complex molecules, and an ultracentrifuge that has windows into the sample chambers to measure changes in the absorption of ultraviolet light is called an analytical ultracentrifuge. These changes in absorption show the *sedimentation velocity*, or the speed at which different particles stratify. From the sedimentation velocities and sedimentation equilibrium, the purity, mass, shape, and composition of complex molecules can be calculated.

To analyze complex molecules, analytical ultracentrifuges must rotate extremely fast. Svedberg's first ultracentrifuge, built with an oil turbine rotor in 1924, spun at 12 000 rev/min, and generated an acceleration of 7000g. In 1935, an ultracentrifuge was created that spun in a vacuum. This prevented delicate samples from being heated by the friction between air and the centrifuge.[§] This centrifuge was able to generate an acceleration of 150 000g at the outer edge of the sample tubes. Today, analytical ultracentrifuges spin at 60 000 rev/min, with accelerations of 250 000g. Other types of ultracentrifuges can generate accelerations as large as 810 000g.[°]

The enormous accelerations and associated forces in these centrifuges cause high mechanical stresses on the rotors. At full speed, a single gram of material in an analytical ultracentrifuge sample tube has an apparent weight equal to 550 lb. In fact, the speed of the rotors is limited mostly by the tensile strength of the materials from which the rotors are made.[#] Over time, the stresses cause material fatigue in the ultracentrifuge. Caustic solutions can also make stress corrosion more likely in aluminum rotors. Rotor failures are catastrophic events[**] and have cracked cement block walls, shattered windows, and sent parts through the laboratory at high speeds.

Fortunately, ultracentrifuge rotor failures are very rare. The rotors in analytic ultracentrifuges are cast from strong materials—titanium, aluminum, or even carbon fiber compounds. The windows of analytic ultracentrifuges are made of optical-grade quartz or sapphire. Samples are carefully balanced in the rotors. Rotors are matched to particular ultracentrifuges and particular purposes. Finally, time logs are kept for each ultracentrifuge rotor. After a set number of hours, the rotors are replaced.

An early user of centrifuges was happy that "by means of the centrifuge, forces can be obtained many times greater than gravity, which otherwise exist only on the very largest planets."[††] Today, ultracentrifuges give researchers the effects of forces nearly 1000 times greater than the force of gravity at the surface of our Sun.

SUMMARY

1. Angular displacement, angular velocity, and angular acceleration are fundamental defined quantities in rotational kinematics.
2. Torque and moment of inertia are important derived dynamic concepts. Torque is a measure of the effect of a force in changing an object's rate of rotation. Moment of inertia is the measure of an object's inertial resistance to angular accelerations. The moment of inertia depends on the distribution of the mass relative to the rotation axis.
3. The parallel-axis theorem, which follows from the definition of the moment of inertia, often simplifies the calculation of I.
4. Newton's second law for rotation, $\Sigma\tau_{\text{ext}} = I\alpha$, is derived from Newton's second law and the definitions of τ, I, and α. It is an important relation for problems involving the rotation of a rigid object about an axis of fixed direction.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Angular Velocity and Angular Acceleration		
Angular velocity	$\omega = \frac{d\theta}{dt}$ (Definition)	9-2
Angular acceleration	$\alpha = \frac{d\omega}{dt}$ (Definition)	9-4
Tangential velocity	$v_{\text{t}} = r\omega$	9-8
Tangential acceleration	$a_{\text{t}} = r\alpha$	9-9
Centripetal acceleration	$a_{\text{c}} = \frac{v^2}{r} = r\omega^2$	9-10
2. Equations for Rotation with Constant Angular Acceleration	$\omega = \omega_0 + \alpha t$	9-5
	$\theta = \theta_0 + \omega_0 t + \frac{1}{2}\alpha t^2$	9-6
	$\omega^2 = \omega_0^2 + 2\alpha(\theta - \theta_0)$	9-7
3. Moment of Inertia		
System of particles	$I = \Sigma m_i r_i^2$ (Definition)	9-11
Continuous object	$I = \int r^2 dm$	9-13
Parallel-axis theorem	The moment of inertia about an axis a distance h from a parallel axis through the center of mass is $I = I_{\text{cm}} + Mh^2$ where I_{cm} is the moment of inertia about the axis through the center of mass and M is the total mass of the object.	9-14
4. Energy		
Kinetic energy for rotation about a fixed axis	$K = \frac{1}{2}I\omega^2$	9-12
Kinetic energy for a rotating object	$K = \frac{1}{2}Mv_{\text{cm}}^2 + \frac{1}{2}I_{\text{cm}}\omega^2$	9-30
Power	$P = \tau\omega$	9-25

TOPIC	RELEVANT EQUATIONS AND REMARKS
5. Torque About an Axis	The torque due to a force equals the product of the tangential component of the force and the radial distance from the axis to the point of application of the force: $$\tau = F_t r = Fr\sin\phi = F\ell \qquad \text{9-20}$$
6. Newton's Second Law for Rotation	$$\tau_{\text{net ext}} = \sum_i \tau_{i\,\text{ext}} = I\alpha \qquad \text{9-19}$$ Newton's second law for rotation holds, even if the reference frame is noninertial, if the moment of inertia and the torques are calculated about an axis through the center of mass.
7. Nonslip Conditions	If a string that is wrapped around a pulley wheel does not slip, the linear and angular quantities are related by $$v_t = R\omega \qquad \text{9-22}$$ $$a_t = R\alpha \qquad \text{9-23}$$
8. Rolling Objects	
Rolling without slipping	$$v_{cm} = R\omega \qquad \text{9-27}$$
*Rolling with slipping	When an object slips while rolling, $v_{cm} \neq R\omega$. Kinetic friction then tends to change both v_{cm} and ω (increasing one while decreasing the other) until $v_{cm} = R\omega$, at which point rolling without slipping occurs.

Answer to Concept Checks

9-1 Disk A has the greater moment of inertia. Mentally divide disk A into two parts, the part closer to the axis than one-eighth inch (Part 1), and the part farther from the axis than one-eighth inch (Part 2). Part 2 alone has the same mass and moment of inertia as does disk B, so the additional moment of inertial of Part 1 gives disk A the greater moment of inertia.

9-2 Disk B has the greater moment of inertia. The two disks have the same mass, but the mass of disk B is distributed farther from its axis than the mass of disk A is from its axis.

Answers to Practice Problems

9-1	314 rad/s
9-2	(a) 500 rev/min = 52.4 rad/s
9-3	$v_t = 1.88$ m/s, $a_t = 0$, $a_c = 59.2$ m/s^2
9-4	(a) 1.26 m/s, (b) 1.26 m/s
9-5	$I = 8ma^2$
9-6	Approximately 25 times greater
9-8	$a = 3g/4$ downward, (b) $F = mg/4$ downward
9-9	594 N · m
9-10	20 J
9-11	0.40
9-12	(a) $f = \frac{1}{2}mg\sin\phi$, ($b$) $\tan\phi \leq 2\mu_s$
9-13	$v_{cm} = \frac{5}{7}v_0$. No.
9-14	$K = \frac{5}{14}mv_0^2$

PROBLEMS

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

For all problems, use 9.81 m/s² for the free-fall acceleration and neglect friction and air resistance unless instructed to do otherwise.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • Two points are on a disk that is turning about a fixed axis perpendicular to the disk and through its center at increasing angular velocity. One point is on the rim and the other point is halfway between the rim and the center. (*a*) Which point moves the greater distance in a given time? (*b*) Which point turns through the greater angle? (*c*) Which point has the greater speed? (*d*) Which point has the greater angular speed? (*e*) Which point has the greater tangential acceleration? (*f*) Which point has the greater angular acceleration? (*g*) Which point has the greater centripetal acceleration?

2 • True or false: (*a*) Angular speed and linear speed have the same dimensions. (*b*) All parts of a wheel rotating about a fixed axis must have the same angular speed. (*c*) All parts of a wheel rotating about a fixed axis must have the same angular acceleration. (*d*) All parts of a wheel rotating about a fixed axis must have the same centripetal acceleration.

3 • Starting from rest and rotating at constant angular acceleration, a disk takes 10 revolutions to reach an angular speed ω. How many additional revolutions at the same angular acceleration are required for it to reach an angular speed of 2ω? (*a*) 10 rev, (*b*) 20 rev, (*c*) 30 rev, (*d*) 40 rev, (*e*) 50 rev?

4 • You are looking down from above at a merry-go-round and observe that it is rotating counterclockwise and that its rotation rate is slowing. If we designate counterclockwise as positive, what is the sign of the angular acceleration?

5 • Chad and Tara go for a ride on a merry-go-round. Chad sits on a pony that is 2.0 m from the rotation axis, and Tara sits on a pony 4.0 m from the axis. The merry-go-round is traveling counterclockwise and is speeding up. Does Chad or Tara have (*a*) the larger linear speed? (*b*) the larger centripetal acceleration? (*c*) the larger tangential acceleration?

6 • Disk B was identical to disk A before a hole was drilled though the center of disk B. Which disk has the largest moment of inertia about its symmetry axis center? Explain your answer.

7 • **CONTEXT-RICH** The pitcher in a baseball game has a blazing fastball. You have not been able to swing the bat in time to hit the ball. You are now just trying to make the bat connect with the ball, hit the ball foul, and avoid a strikeout. So you decide to take your coach's advice and grip the bat high rather than at the very end. This change should increase bat speed; thus, you will be able to swing the bat quicker and increase your chances of hitting the ball. Explain how this theory works in terms of the moment of inertia, angular acceleration, and torque of the bat. SSM

8 • (*a*) Is the direction of an object's angular velocity necessarily the same as the direction net torque on it? Explain. (*b*) If net torque and angular velocity are in opposite directions, what does that tell you about the angular speed? (*c*) Can the angular velocity be zero even if the net torque is not zero? If your answer is yes, give an example.

9 • A disk is free to rotate about a fixed axis. A tangential force applied a distance d from the axis causes an angular acceleration α. What angular acceleration is produced if the same force is applied a distance $2d$ from the axis? (*a*) α, (*b*) 2α, (*c*) $\alpha/2$, (*d*) 4α, (*e*) $\alpha/4$?

10 • The moment of inertia of an object about an axis that does not pass through its center of mass is ______ the moment of inertia about a parallel axis through its center of mass: (*a*) always less than, (*b*) sometimes less than, (*c*) sometimes equal to, (*d*) always greater than.

11 • The motor of a merry-go-round exerts a constant torque on it. As it speeds up from rest, the power output of the motor (*a*) is constant, (*b*) increases linearly with the angular speed of the merry-go-round, (*c*) is zero, (*d*) none of the above. SSM

12 • A constant net torque acts on a merry-go-round from startup until it reaches its operating speed. During this time, the merry-go-round's kinetic energy (*a*) is constant, (*b*) increases linearly with angular speed, (*c*) increases quadratically as the square of the angular speed, (*d*) none of the above.

13 • **ENGINEERING APPLICATION** Most doors knobs are designed so the knob is located on the side opposite the hinges (rather than in the center of the door, for example). Explain why this practice makes doors easier to open.

14 • A wheel of radius R and angular speed ω is rolling without slipping toward the north on a flat, stationary surface. The velocity of the point on the rim that is (momentarily) in contact with the surface is (*a*) equal in magnitude to $R\omega$ and directed toward the north, (*b*) equal to in magnitude $R\omega$ and directed toward the south, (*c*) zero, (*d*) equal to the speed of the center of mass and directed toward the north, (*e*) equal to the speed of the center of mass and directed toward the south.

15 • A uniform solid cylinder and a uniform solid sphere have equal masses. Both roll on a horizontal surface without slipping. If their total kinetic energies are the same, then (*a*) the translational speed of the cylinder is greater than the translational speed of the sphere, (*b*) the translational speed of the cylinder is less than the translational speed of the sphere, (*c*) the translational speeds of the two objects are the same, (*d*), (*a*), (*b*), or (*c*) could be correct, depending on the radii of the objects.

16 • Two identical-looking 1.0-m-long pipes are each plugged with 10 kg of lead. In the first pipe, the lead is concentrated at the middle of the pipe, while in the second the lead is divided into two 5-kg masses placed at opposite ends of the pipe. The ends of the pipes are then sealed using four identical caps. Without opening either pipe, how could you determine which pipe has the lead at the ends?

17 •• Starting simultaneously from rest, a coin and a hoop roll without slipping down an incline. Which of the following statements is true? (*a*) The hoop reaches the bottom first. (*b*) The coin reaches the bottom first. (*c*) The coin and hoop arrive at the bottom simultaneously. (*d*) The race to the bottom depends on their relative masses. (*e*) The race to the bottom depends on their relative diameters.

18 •• For a hoop of mass M and radius R that is rolling without slipping, which is larger, its translational kinetic energy or its kinetic energy relative to the center of mass? (*a*) Its translational kinetic energy is larger. (*b*) Its kinetic energy relative to the center of mass is larger. (*c*) Both energies have the same magnitude. (*d*) The answer depends on the radius of the hoop. (*e*) The answer depends on the mass of the hoop.

19 •• For a disk of mass M and radius R that is rolling without slipping, which is larger, its translational kinetic energy or its kinetic energy relative to the center of mass? (*a*) Its translational kinetic energy is larger. (*b*) Its kinetic energy relative to the center of mass is larger. (*c*) Both energies have the same magnitude. (*d*) The answer depends on the radius of the disk. (*e*) The answer depends on the mass of the disk.

20 •• A perfectly rigid ball rolls without slipping along a perfectly rigid horizontal plane. Show that the frictional force acting on the ball must be zero. *Hint: Consider a possible direction for the action of the frictional force and what effects such a force would have on the velocity of the center of mass and on the angular velocity.*

21 •• A spool is free to rotate about a fixed axis, and a string wrapped around the axle of the spool causes the spool to rotate in a counterclockwise direction (Figure 9-42*a*). However, if the spool is set on a horizontal tabletop, the spool instead (given sufficient frictional force between the table and the spool) rotates in a clockwise

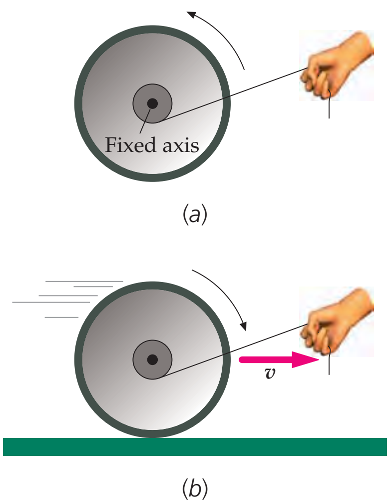

FIGURE 9-42 Problem 21

direction and rolls to the right (Figure 9-42*b*). By considering torque about the appropriate axes, show that these conclusions are both consistent with Newton's second law for rotations. SSM

22 •• You want to locate the center of gravity of an arbitrarily shaped flat object. You are told to suspend the object from a point, and to suspend a plumb line from the same point. Then draw a vertical line on the object to represent the plumb line. Next, you repeat the process using a different suspension point. The center of gravity will be at the intersection of the drawn lines. Explain the principle(s) behind this process.

ESTIMATION AND APPROXIMATION

23 • A baseball is thrown at 88 mi/h and with a spin rate of 1500 rev/min. If the distance between the pitcher's point of release and the catcher's glove is about 61 feet, estimate how many revolutions the ball makes between release and catch. Neglect any effects of gravity or air resistance on the ball's flight.

24 •• Consider the Crab Pulsar, discussed on page 293. Justify the statement that the loss in rotational energy is equivalent to the power output of 100 000 stars. The total power radiated by the Sun is about 4×10^{26} W. Assume that the pulsar has a mass that is 2×10^{30} kg, has a radius that is 20 km, is rotating at about 30 rev/s, and has a rotational period that is increasing at 10^{-5} s/y.

25 •• A 14-kg bicycle has 1.2-m-diameter wheels, each with a mass of 3.0 kg. The mass of the rider is 38 kg. Estimate the fraction of the total kinetic energy of the rider–bicycle system that is associated with rotation of the wheels.

26 •• Why does toast falling off a table always land jelly-side down? The question may sound silly, but it has been a subject of serious scientific enquiry. The analysis is too complicated to reproduce here, but R. D. Edge and Darryl Steinert showed that a piece of toast, pushed gently over the edge of a table until it tilts off, typically falls off the table when it makes an angle of about 30° with the horizontal (Figure 9-43) and at that instant has an angular speed of $\omega = 0.956\sqrt{g/\ell}$, where ℓ is the length of one edge of the piece of toast (assumed to be square).* Assuming that a piece of toast is jelly-side up, what side will it land on if it falls from a 0.500-m-high table? If it falls from a 1.00-m-high table? Assume that $\ell = 10.0$ cm. Ignore any forces due to air resistance.

* For readers interested in this problem and a host of others, we highly recommend Robert Erlich's wonderful book, *Why Toast Lands Jelly-Side Down: Zen and the Art of Physics Demonstrations*.

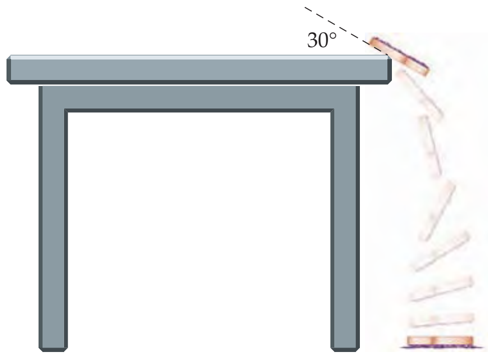

FIGURE 9-43 Problem 26

27 •• Consider your moment of inertia about a vertical axis through the center of your body, both when you are standing straight up with your arms flat against your sides, and when you are standing straight up holding your arms straight out to your sides. Estimate the ratio of the moment of inertia with your arms straight out to the moment of inertia with your arms flat against your sides.

ANGULAR VELOCITY, ANGULAR SPEED, AND ANGULAR ACCELERATION

28 • A particle moves with a constant speed of 25 m/s in a 90-m-radius circle. (*a*) What is its angular speed in radians per second about the center of the circle? (*b*) How many revolutions does it make in 30 s?

29 • A wheel released from rest is rotating with constant angular acceleration of 2.6 rad/s². At 6.0 s after the release: (*a*) What is its angular speed? (*b*) Through what angle has the wheel turned? (*c*) How many revolutions has it completed? (*d*) What is the linear speed and what is the magnitude of the linear acceleration of a point 0.30 m from the axis of rotation? SSM

30 • **MULTISTEP** When a turntable rotating at $33\frac{1}{3}$ rev/min is shut off, it comes to rest in 26 s. Assuming constant angular acceleration, find (*a*) the angular acceleration. During the 26 s, find (*b*) the average angular speed and (*c*) the angular displacement in revolutions.

31 • A 12-cm-radius disk that begins to rotate about its axis at $t = 0$, rotates with a constant angular acceleration of 8.0 rad/s². At $t = 5.0$ s, (*a*) what is the angular speed of the disk, and (*b*) what are the tangential and centripetal components of the acceleration of a point on the edge of the disk?

32 • A 12-m-radius Ferris wheel rotates once each 27 s. (*a*) What is its angular speed (in radians per second)? (*b*) What is the linear speed of a passenger? (*c*) What is the acceleration of a passenger?

33 • A cyclist accelerates uniformly from rest. After 8.0 s, the wheels have rotated 3.0 rev. (*a*) What is the angular acceleration of the wheels? (*b*) What is the angular speed of the wheels at the end of the 8.0 s?

34 • What is the angular speed of Earth in radians per second as it rotates about its axis?

35 • A wheel rotates through 5.0 rad in 2.8 s as it is brought to rest with constant angular acceleration. Determine the wheel's initial angular speed before braking began.

36 • A bicycle has 0.750-m-diameter wheels. The bicyclist accelerates from rest with constant acceleration to 24.0 km/h in 14.0 s. What is the angular acceleration of the wheels?

37 •• **Engineering Application** The tape in a standard VHS videotape cassette has a total length of 246 m, which is enough for the tape to play for 2.0 h (Figure 9-44). As the tape starts, the full reel has a 45-mm outer radius and a 12-mm inner radius. At some point during the play, both reels have the same angular speed. Calculate this angular speed in radians per second and in revolutions per minute. *Hint: Between the two reels the tape moves at constant speed.* SSM

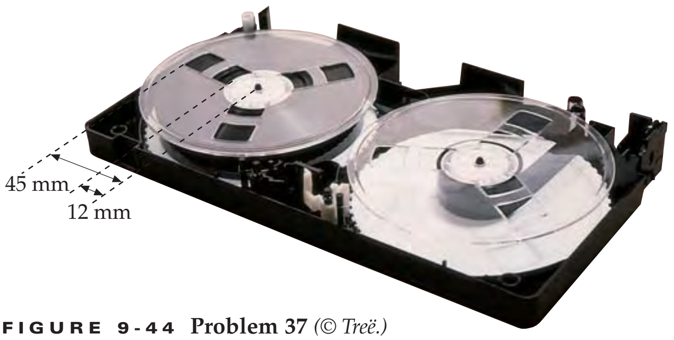

FIGURE 9-44 Problem 37 *(© Treë.)*

38 •• **Context-Rich** To start a lawn mower, you must pull on a rope wound around the perimeter of a flywheel. After you pull the rope for 0.95 s, the flywheel is rotating at 4.5 revolutions per second, at which point the rope disengages. This attempt at starting the mower does not work, however, and the flywheel slows, coming to rest 0.24 s after the disengagement. Assume constant acceleration during both spin-up and spin-down. (*a*) Determine the average angular acceleration during the 4.5-s spin-up and again during the 0.24-s spin-down. (*b*) What is the maximum angular speed reached by the flywheel? (*c*) Determine the ratio of the number of revolutions made during spin-up to the number made during spin-down.

39 ••• Mars orbits the Sun at a mean orbital radius of 228 Gm (1 Gm = 10^9 m) and has an orbital period of 687 d. Earth orbits the Sun at a mean orbital radius of 149.6 Gm. (*a*) The Earth–Sun line sweeps out an angle of 360° during one Earth–year. Approximately what angle is swept out by the Mars-Sun line during one Earth–year? (*b*) How frequently are Mars and the Sun in opposition (on diametrically opposite sides of Earth)?

CALCULATING THE MOMENT OF INERTIA

40 • A tennis ball has a mass of 57 g and a diameter of 7.0 cm. Find the moment of inertia about its diameter. Model the ball as a thin spherical shell.

41 • Four particles, one at each of the four corners of a square with 2.0-m-long edges, are connected by massless rods (Figure 9-45). The masses of the particles are $m_1 = m_3 = 3.0$ kg and $m_2 = m_4 = 4.0$ kg. Find the moment of inertia of the system about the z axis. SSM

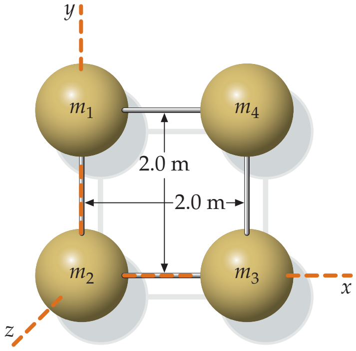

FIGURE 9-45 Problem 41

42 •• Use the parallel-axis theorem and the result for Problem 41 to find the moment of inertia of the four-particle system in Figure 9-45 about an axis that passes through the center of mass and is parallel with the z axis. Check your result by direct computation.

43 • For the four-particle system of Figure 9-45, (*a*) find the moment of inertia I_x about the x axis, which passes through m_2 and m_3, and (*b*) find the moment of inertia I_y about the y axis, which passes through m_1 and m_2.

44 • Determine the moment of inertia of a uniform solid sphere of mass M and radius R about an axis that is tangent to the surface of the sphere (Figure 9-46).

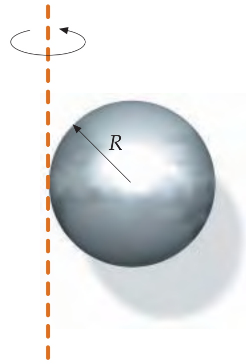

FIGURE 9-46 Problem 44

45 •• A 1.00-m-diameter wagon wheel consists of a thin rim having a mass of 8.00 kg and 6 spokes, each with a mass of 1.20 kg. Determine the moment of inertia of the wagon wheel about its axis.

46 •• **Multistep** Two point masses m_1 and m_2 are separated by a massless rod of length L. (*a*) Write an expression for the moment of inertia I about an axis perpendicular to the rod and passing through it a distance x from mass m_1. (*b*) Calculate dI/dx and show that I is at a minimum when the axis passes through the center of mass of the system.

47 •• A uniform rectangular plate has mass m and edges of lengths a and b. (*a*) Show by integration that the moment of inertia of the plate about an axis that is perpendicular to the plate and passes through one corner is $\frac{1}{3}m(a^2 + b^2)$. (*b*) What is the moment of inertia about an axis that is perpendicular to the plate and passes through its center of mass?

48 •• **Context-Rich** In attempting to ensure a spot on the pep squad, you and your friend Corey research baton-twirling. Each of you is using "The Beast" as a model baton: two uniform spheres, each of mass 500 g and radius 5.00 cm, mounted at the ends of a 30.0-cm uniform rod of mass 60.0 g (Figure 9-47). You want to determine the moment of inertia I of "The Beast" about an axis perpendicular to the rod and passing through its center. Corey uses the approximation that the two spheres can be treated as point particles that are 20.0 cm from the axis of rotation, and that the mass of the rod is negligible. You, however, decide to do an exact calculation. (*a*) Compare the two results. (Give the percentage difference between them). (*b*) Suppose the spheres were replaced by two thin spherical shells, each of the same mass as the original solid spheres. Give a conceptual argument explaining how this replacement would, or would not, change the value of I.

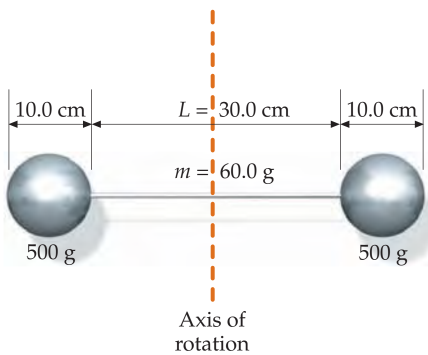

FIGURE 9-47 Problem 48

49 •• The methane molecule (CH_4) has four hydrogen atoms located at the vertices of a regular tetrahedron of edge length 0.18 nm, with the carbon atom at the center of the tetrahedron (Figure 9-48). Find the moment of inertia of this molecule for rotation about an axis that passes through the centers of the carbon atom and one of the hydrogen atoms.

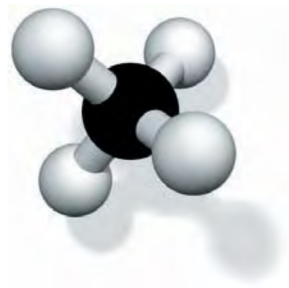

FIGURE 9-48 Problem 49

50 •• A hollow cylinder has mass m, an outside radius R_2, and an inside radius R_1. Use integration to show that the moment of inertia about its axis is given by $I = \frac{1}{2}m(R_2^2 + R_1^2)$. *Hint: Review Section 9-3, where the moment of inertia is calculated for a solid cylinder by direct integration.*

51 •• **BIOLOGICAL APPLICATION** While slapping the water's surface with his tail to communicate danger, a beaver must rotate it about one of its narrow ends. Let us model the tail as a rectangle of uniform thickness and density (Figure 9-49). Estimate its moment of inertia about the line passing through its narrow end (dashed line). Assume that the tail measures 15 by 30 cm with a thickness of 1.0 cm and that the flesh has the density of water.

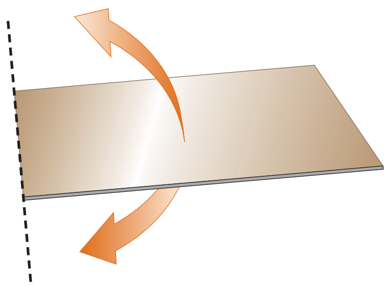

FIGURE 9-49 Problem 51

52 •• **CONTEXT-RICH** To prevent damage to her shoulders, your elderly grandmother wants to purchase the rug beater (Figure 9-50) with the lowest moment of inertia about its grip end. Knowing you are taking physics, she asks your advice. There are two models to choose from. Model A has a 1.0-m-long handle on a 40-cm-edge-length square, where the masses of the handle and square are 1.0 kg and 0.50 kg, respectively. Model B has a 0.75-m-long handle and a 30-cm-edge-length square, where the masses of the handle and square are 1.5 kg and 0.60 kg, respectively. Which model should you recommend? Determine which beater is easier to swing from the very end by computing the moment of inertia for both beaters.

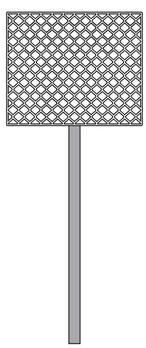

FIGURE 9-50 Problem 52

53 ••• Use integration to show that the moment of inertia of a thin spherical shell of radius R and mass m about an axis through its center is $2mR^2/3$. SSM

54 ••• According to one model, the density of Earth varies with the distance r from the center of Earth as $\rho = C[1.22 - (r/R)]$, where R is the radius of Earth and C is a constant. (*a*) Find C in terms of the total mass M and the radius R. (*b*) According to this model, what is the moment of inertia of Earth about an axis through its center. (See Problem 53.)

55 ••• Use integration to determine the moment of inertia about its axis of a uniform right circular cone of height H, base radius R, and mass M.

56 ••• Use integration to determine the moment of inertia of a thin uniform disk of mass M and radius R about an axis in the plane of the disk and passing through its center. Check your answer by referring to Table 9-1.

57 ••• **ENGINEERING APPLICATION, CONTEXT-RICH** An advertising firm has contacted your engineering firm to create a new advertisement for a local ice-cream stand. The owner of this stand wants to add rotating solid cones (painted to look like ice-cream cones, of course) to catch the eye of travelers. Each cone will rotate about an axis parallel to its base and passing through its apex. The actual size of the cones is to be decided upon, and the owner wonders if it would be more energy-efficient to rotate smaller cones than larger ones. He asks your firm to write a report showing the determination of the moment of inertia of a homogeneous right circular cone of height H, base radius R, and mass M. What is the result of your report?

TORQUE, MOMENT OF INERTIA, AND NEWTON'S SECOND LAW FOR ROTATION

58 • **ENGINEERING APPLICATION, CONTEXT-RICH** A firm wants to determine the amount of frictional torque in their current line of grindstones, so they can redesign them to be more energy efficient. To do this, they ask you to test the best-selling model, which is basically a disk-shaped grindstone of mass 1.70 kg and radius 8.00 cm that operates at 730 rev/min. When the power is shut off, you time the grindstone and find it takes 31.2 s for it to stop rotating. (*a*) What is the angular acceleration of the grindstone? (Assume constant angular acceleration.) (*b*) What is the frictional torque exerted on the grindstone?

59 • A 2.5-kg 11-cm-radius cylinder, initially at rest, is free to rotate about the axis of the cylinder. A rope of negligible mass is wrapped around it and pulled with a force of 17 N. Assuming that the rope does not slip, find (*a*) the torque exerted on the cylinder by the rope, (*b*) the angular acceleration of the cylinder, and (*c*) the angular speed of the cylinder after 0.50 s. SSM

60 •• A grinding wheel is initially at rest. A constant external torque of 50.0 N·m is applied to the wheel for 20.0 s, giving the wheel an angular speed of 600 rev/min. The external torque is then removed, and the wheel comes to rest 120 s later. Find (*a*) the moment of inertia of the wheel, and (*b*) the frictional torque, which is assumed to be constant.

61 •• A pendulum consisting of a string of length L attached to a bob of mass m swings in a vertical plane. When the string is at an angle θ to the vertical, (*a*) calculate the tangential acceleration of the bob using $\Sigma F_t = ma_t$. (*b*) What is the torque exerted about the pivot point? (*c*) Show that $\Sigma\tau = I\alpha$ with $a_t = L\alpha$ gives the same tangential acceleration as found in Part (*a*).

62 ••• A uniform rod of mass M and length L is pivoted at one end and hangs as in Figure 9-51 so that it is free to rotate without friction about its pivot. It is struck a sharp horizontal blow a distance x below the pivot, as shown. (*a*) Show that, just after the rod is struck, the speed of the center of mass of the rod is given by $v_0 = 3xF_0\,\Delta t/(2ML)$, where F_0 and Δt are the average force and duration, respectively, of the blow. (*b*) Find the horizontal component of the force exerted by the pivot on the rod, and show that this force component is zero if $x = \frac{2}{3}L$. This point (the point of impact when the horizontal component of the pivot force is zero) is called the *center of percussion* of the rod-pivot system.

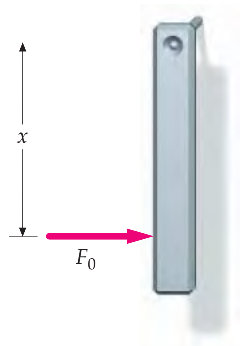

FIGURE 9-51 Problem 62

63 ••• **MULTISTEP** A uniform horizontal disk of mass M and radius R is spinning about the vertical axis through its center with an angular speed ω. When the spinning disk is dropped onto a horizontal tabletop, kinetic-frictional forces on the disk oppose its spinning motion. Let μ_k be the coefficient of kinetic friction between the disk and the tabletop. (*a*) Find the torque $d\tau$ exerted by the force of friction on a circular element of radius r and width dr. (*b*) Find the total torque exerted by friction on the disk. (*c*) Find the time required for the disk to stop rotating.

ENERGY METHODS, INCLUDING KINETIC ENERGY DUE TO ROTATION

64 • The particles in Figure 9-52 are connected by a very light rod. They rotate about the y axis at 2.0 rad/s. (*a*) Find the speed of each particle, and use it to calculate the kinetic energy of this system directly from $\Sigma\frac{1}{2}m_iv_i^2$. (*b*) Find the moment of inertia about the y axis, calculate the kinetic energy from $K = \frac{1}{2}I\omega^2$, and compare your result with your Part-(*a*) result.

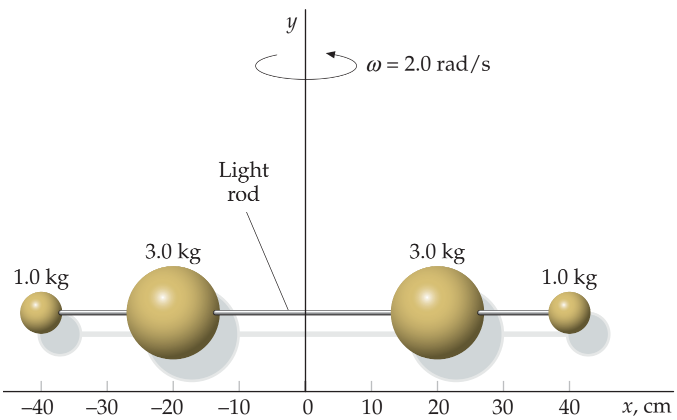

FIGURE 9-52 Problem 64

65 • A 1.4-kg 15-cm-diameter solid sphere is rotating about its diameter at 70 rev/min. (*a*) What is its kinetic energy? (*b*) If an additional 5.0 mJ of energy are added to the kinetic energy, what is the new angular speed of the sphere? SSM

66 •• Calculate the kinetic energy of Earth due to its spinning about its axis, and compare your answer with the kinetic energy of the orbital motion of Earth's center of mass about the Sun. Assume Earth to be a homogeneous sphere of mass 6.0×10^{24} kg and radius 6.4×10^6 m. The radius of Earth's orbit is 1.5×10^{11} m.

67 •• A 2000-kg block is lifted at a constant speed of 8.0 cm/s by a steel cable that passes over a massless pulley to a motor-driven winch (Figure 9-53). The radius of the winch drum is 30 cm. (*a*) What is the tension in the cable? (*b*) What torque does the cable exert on the winch drum? (*c*) What is the angular speed of the winch drum? (*d*) What power must be developed by the motor to drive the winch drum? SSM

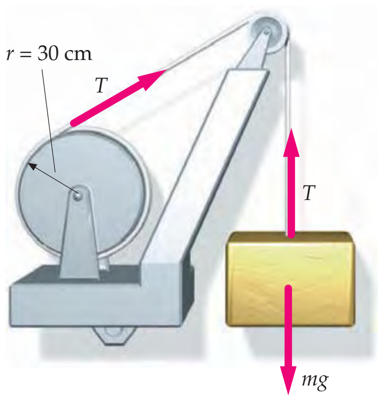

FIGURE 9-53 Problem 67

68 •• A uniform disk that has a mass M and a radius R can rotate freely about a fixed horizontal axis that passes through its center and is perpendicular to the plane of the disk. A small particle that has a mass m is attached to the rim of the disk at the top, directly above the pivot. The system is gently nudged, and the disk begins to rotate. As the particle passes through its lowest point, (*a*) what is the angular speed of the disk, and (*b*) what force is exerted by the disk on the particle?

69 •• A uniform 1.5-m-diameter ring is pivoted at a point on its perimeter so that it is free to rotate about a horizontal axis that is perpendicular to the plane of the ring. The ring is released with the center of the ring at the same height as the axis (Figure 9-54). (*a*) If the ring was released from rest, what was its maximum angular speed? (*b*) What minimum angular speed must it be given at release if it is to rotate a full 360°?

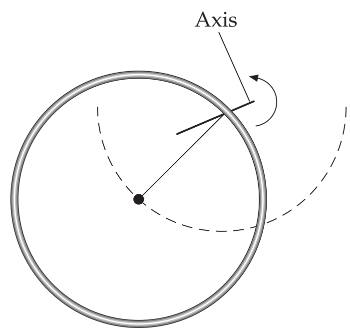

FIGURE 9-54 Problem 69

70 •• **ENGINEERING APPLICATION, CONTEXT-RICH** You set out to design a car that uses the energy stored in a flywheel consisting of a uniform 100-kg cylinder of radius R that has a maximum angular speed of 400 rev/s. The flywheel must deliver an average of 2.00 MJ of energy for each kilometer of distance. Find the smallest value of R for which the car can travel 300 km without the flywheel needing to be reenergized.

PULLEYS, YO-YOS, AND HANGING THINGS

71 •• The system shown in Figure 9-55 consists of a 4.0-kg block resting on a frictionless horizontal ledge. This block is attached to a string that passes over a pulley, and the other end of the string is attached to a hanging 2.0-kg block. The pulley is a uniform disk of radius 8.0 cm and mass 0.60 kg. Find the acceleration of each block and the tension in the string. SSM

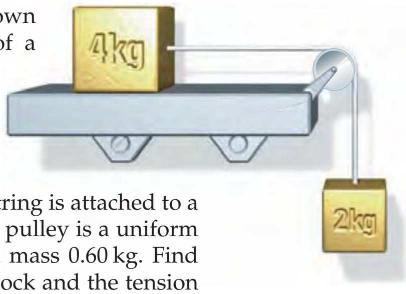

FIGURE 9-55
Problems 71–74

72 •• For the system in Problem 71, the 2.0-kg block is released from rest. (*a*) Find the speed of the block after it falls a distance of 2.5 m. (*b*) What is the angular speed of the pulley at this instant?

73 •• For the system in Problem 71, if the (frictionless) ledge were adjustable in angle, at what angle would it have to be tilted upward so that once the system is set into motion the blocks will continue to move at constant speed?

74 •• In the system shown in Figure 9-55, there is a 4.0-kg block resting on a horizontal ledge. The coefficient of kinetic friction between the ledge and the block is 0.25. The block is attached to a string that passes over a pulley, and the other end of the string is attached to a hanging 2.0-kg block. The pulley is a uniform disk of radius 8.0 cm and mass 0.60 kg. Find the acceleration of each block and the tensions in the segments of string between each block and the pulley.

75 •• A 1200-kg car is being raised over water by a winch. At the moment the car is 5.0 m above the water (Figure 9-56), the gearbox breaks, allowing the winch drum to spin freely as the car falls. During the car's fall, there is no slipping between the (massless) rope, the pulley wheel, and the winch drum. The moment of inertia of the winch drum is $320\,\mathrm{kg \cdot m^2}$, and the moment of inertia of the pulley wheel is $4.00\,\mathrm{kg \cdot m^2}$. The radius of the winch drum is 0.800 m, and the radius of the pulley is 0.300 m. Assume that the car starts to fall from rest. Find the speed of the car as it hits the water.

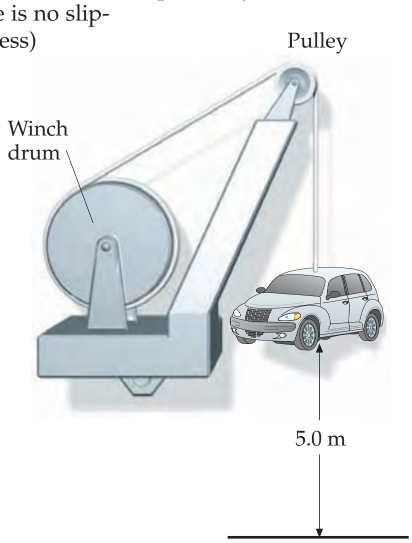

FIGURE 9-56
Problem 75

76 •• The system in Figure 9-57 is released from rest when the 30-kg block is 2.0 m above the ledge. The pulley is a uniform 5.0-kg disk with a radius of 10 cm. Just before the 30-kg block hits the ledge, find (*a*) its speed, (*b*) the angular speed of the pulley, and (*c*) the tensions in the strings. (*d*) Find the time of descent for the 30-kg block. Assume that the string does not slip on the pulley.

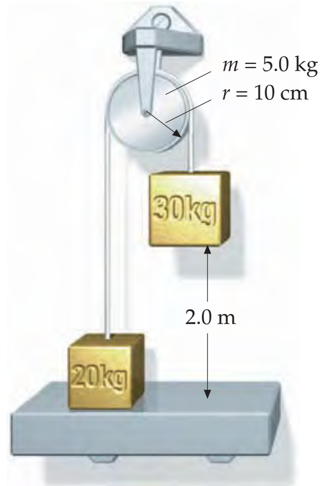

FIGURE 9-57
Problem 76

77 •• A uniform solid sphere of mass M and radius R is free to rotate about a horizontal axis through its center. A string is wrapped around the sphere and is attached to an object of mass m (Figure 9-58). Assume that the string does not slip on the sphere. Find (*a*) the acceleration of the object and (*b*) the tension in the string.

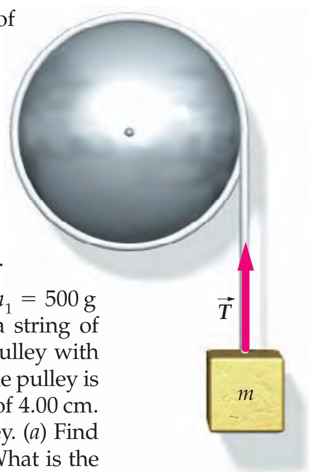

FIGURE 9-58
Problem 77

78 •• Two objects, of masses $m_1 = 500$ g and $m_2 = 510$ g, are connected by a string of negligible mass that passes over a pulley with frictionless bearings (Figure 9-59). The pulley is a uniform 50.0-g disk with a radius of 4.00 cm. The string does not slip on the pulley. (*a*) Find the accelerations of the objects. (*b*) What is the tension in the string between the 500-g block and the pulley? What is the tension in the string between the 510-g block and the pulley? By how much do these tensions differ? (*c*) What would your answers be if you neglected the mass of the pulley?

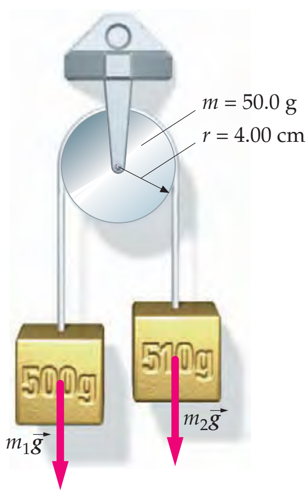

FIGURE 9-59
Problem 78

79 •• Two objects are attached to ropes that are attached to two wheels on a common axle, as shown in Figure 9-60. The two wheels are attached together so that they form a single rigid object. The moment of inertia of the rigid object is $40\ \mathrm{kg \cdot m^2}$. The radii of the wheels are $R_1 = 1.2\ \mathrm{m}$ and $R_2 = 0.40\ \mathrm{m}$. (*a*) If $m_1 = 24\ \mathrm{kg}$, find m_2 such that there is no angular acceleration of the wheels. (*b*) If 12 kg is placed on top of m_1, find the angular acceleration of the wheels and the tensions in the ropes. SSM

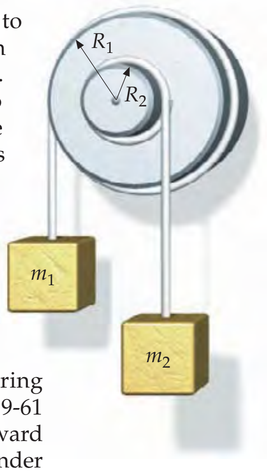

FIGURE 9-60 Problem 79

80 •• The upper end of the string wrapped around the cylinder in Figure 9-61 is held by a hand that is accelerated upward so that the center of mass of the cylinder does not move as the cylinder spins up. Find (*a*) the tension in the string, (*b*) the angular acceleration of the cylinder, and (*c*) the acceleration of the hand.

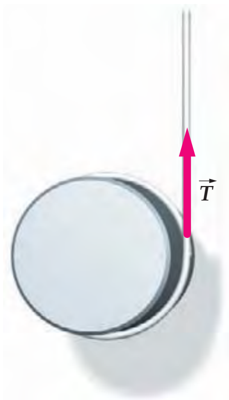

FIGURE 9-61 Problems 80 and 86

81 •• A uniform cylinder of mass m_1 and radius R is pivoted on frictionless bearings. A massless string wrapped around the cylinder is connected to a block of mass m_2 that is on a frictionless incline of angle θ as shown in Figure 9-62. The system is released from rest when the block is at a vertical distance h above the bottom of the incline. (*a*) What is the acceleration of the block? (*b*) What is the tension in the string? (*c*) What is the speed of the block as it reaches the bottom of the incline? (*d*) Evaluate your answers for the special case where $\theta = 90°$ and $m_1 = 0$. Are your answers what you would expect for this special case? Explain. SSM

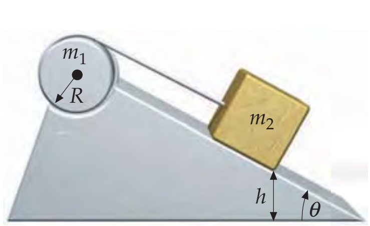

FIGURE 9-62 Problem 81

82 •• A device for measuring the moment of inertia of an object is shown in Figure 9-63. The circular platform is attached to a concentric drum of radius R, and the platform and the drum are free to rotate about a frictionless vertical axis. The string that is wound around the drum passes over a frictionless and massless pulley to a block of mass M. The block is released from rest, and the time t_1 it takes for it to drop a distance D is measured.

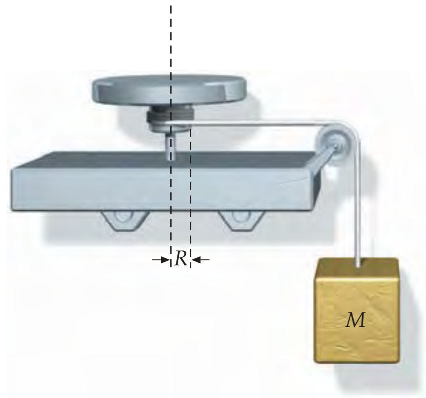

FIGURE 9-63 Problem 82

The system is then rewound, the object whose moment of inertia I we wish to measure is placed on the platform, and the system is again released from rest. The time t_2 required for the block to drop the same distance D then provides the data needed to calculate I. Using $R = 10\ \mathrm{cm}$, $M = 2.5\ \mathrm{kg}$, $D = 1.8\ \mathrm{m}$, $t_1 = 4.2\ \mathrm{s}$, and $t_2 = 6.8\ \mathrm{s}$, (*a*) find the moment of inertia of the platform-drum combination. (*b*) Find the moment of inertia of the platform-drum-object combination. (*c*) Use your results for Parts (*a*) and (*b*) to find the moment of inertia of the object.

OBJECTS ROTATING AND ROLLING WITHOUT SLIPPING

83 • A homogeneous 60-kg cylinder of radius 18 cm is rolling without slipping along a horizontal floor at a speed of 15 m/s. What is the minimum amount of work that was required to give it this motion?

84 • An object is rolling without slipping. What percentage of its total kinetic energy is its translational kinetic energy if the object is (*a*) a uniform sphere, (*b*) a uniform cylinder, or (*c*) a hoop?

85 •• In 1993 a giant 400-kg yo-yo with a radius of 1.5 m was dropped from a crane at height of 57 m. One end of the string was tied to the top of the crane, so the yo-yo unwound as it descended. Assuming that the axle of the yo-yo had a radius of 0.10 m, estimate its linear speed at the end of the fall. SSM

86 •• A uniform cylinder of mass M and radius R has a string wrapped around it. The string is held fixed, and the cylinder falls vertically as shown in Figure 9-61. (*a*) Show that the acceleration of the cylinder is downward with a magnitude $a = 2g/3$. (*b*) Find the tension in the string.

87 •• A 0.10-kg yo-yo consisting of two solid disks, each of radius 10 cm, is joined by a massless rod of radius 1.0 cm. A string is wrapped around the rod. One end of the string is held fixed and is under tension as the yo-yo is released. The yo-yo rotates as it descends vertically. Find (*a*) the acceleration of the yo-yo, and (*b*) the tension T.

88 •• A uniform solid sphere rolls down an incline without slipping. If the linear acceleration of the center of mass of the sphere is $0.20g$, then what is the angle the incline makes with the horizontal?

89 •• A thin spherical shell rolls down an incline without slipping. If the linear acceleration of the center of mass of the shell is $0.20g$, what is the angle the incline makes with the horizontal?

90 •• A basketball rolls without slipping down an incline of angle θ. The coefficient of static friction is μ_s. Model the ball as a thin

spherical shell. Find (*a*) the acceleration of the center of mass of the ball, (*b*) the frictional force acting on the ball, and (*c*) the maximum angle of the incline for which the ball will roll without slipping.

91 •• A uniform solid cylinder of wood rolls without slipping down an incline of angle θ. The coefficient of static friction is μ_s. Find (*a*) the acceleration of the center of mass of the cylinder, (*b*) the frictional force acting on the cylinder, and (*c*) the maximum angle of the incline for which the cylinder will roll without slipping.

92 •• Released from rest at the same height, a thin spherical shell and solid sphere of the same mass m and radius R roll without slipping down an incline through the same vertical drop H (Figure 9-64). Each is moving horizontally as it leaves the ramp. The spherical shell hits the ground a horizontal distance L from the end of the ramp and the solid sphere hits the ground a distance L' from the end of the ramp. Find the ratio L'/L.

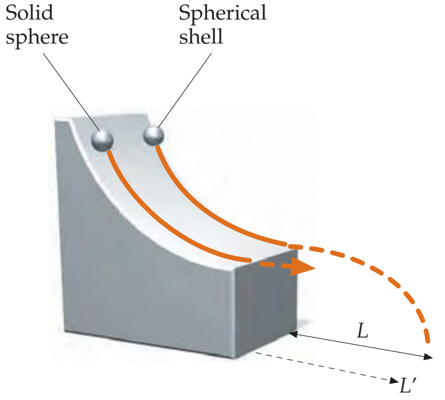

FIGURE 9-64 Problem 92

93 •• A uniform, thin cylindrical shell and a solid cylinder roll horizontally without slipping. The speed of the cylindrical shell is v. The solid cylinder and the hollow cylinder encounter an incline that they climb without slipping. If the maximum height they reach is the same, find the initial speed v' of the solid cylinder. SSM

94 •• A thin cylindrical shell and a solid sphere start from rest and roll without slipping down a 3.0-m-long inclined plane. The cylinder arrives at the bottom of the incline 2.4 s after the sphere. Determine the angle the incline makes with the horizontal.

95 •• A wheel has a thin 3.0-kg rim and four spokes, each of mass 1.2 kg. Find the kinetic energy of the wheel when it is rolling at 6.0 m/s on a horizontal surface.

96 ••• A uniform solid cylinder of mass M and radius R is at rest on a slab of mass m, which in turn rests on a horizontal, frictionless table (Figure 9-65). If a horizontal force $\vec{F}$ is applied to the slab, it accelerates and the cylinder rolls without slipping. Find the acceleration of the slab in terms of M, R, and F.

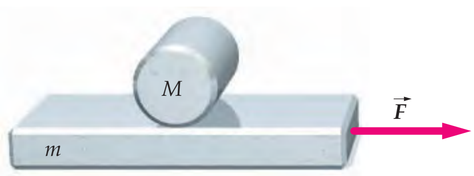

FIGURE 9-65 Problems 96–98

97 ••• (*a*) Find the angular acceleration of the cylinder in Problem 96. Is the cylinder rotating clockwise or counterclockwise? (*b*) What is the cylinder's linear acceleration (magnitude and direction) relative to the table? (*c*) What is the magnitude and direction of the linear acceleration of the center of mass of the cylinder relative to the slab?

98 ••• **MULTISTEP** If the force in Problem 96 acts over a distance d, in terms of the symbols given, find (*a*) the kinetic energy of the slab, and (*b*) the total kinetic energy of the cylinder. (*c*) Show that the total kinetic energy of the slab-cylinder system is equal to the work done by the force.

99 ••• **ENGINEERING APPLICATION** Two large gears that are being designed as part of a large machine are shown in Figure 9-66; each is free to rotate about a fixed axis through its center. The radius and moment of inertia of the smaller gear are 0.50 m and 1.0 kg · m^2, respectively, and the radius and moment of inertia of the larger gear are 1.0 m and 16 kg · m^2, respectively. The lever attached to the smaller gear is 1.0 m long and has a negligible mass. (*a*) If a worker will typically apply a force of 2.0 N to the end of the lever, as shown, what will be the angular accelerations of the two gears? (*b*) Another part of the machine (not shown) will apply a force tangentially to the outer edge of the larger gear to temporarily keep the gear system from rotating. What should the magnitude and direction of this force (clockwise or counterclockwise) be? SSM

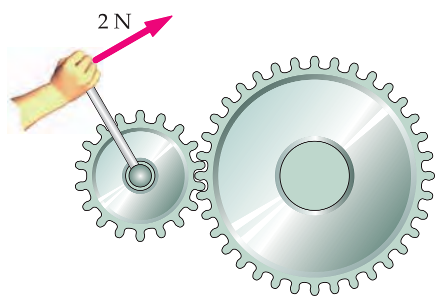

FIGURE 9-66 Problem 99

100 ••• **ENGINEERING APPLICATION, CONTEXT-RICH** As the chief design engineer for a major toy company, you are in charge of designing a "loop-the-loop" toy for youngsters. The idea, as shown in Figure 9-67, is that a ball of mass m and radius r will roll down an inclined track and around the loop without slipping. The ball starts from rest at a height h above the tabletop that supports the whole track. The loop radius is R. Determine the minimum height h, in terms of R and r, for which the ball will remain in contact with the track during the whole of its loop-the-loop journey. (Do not neglect the size of the ball's radius when doing this calculation.)

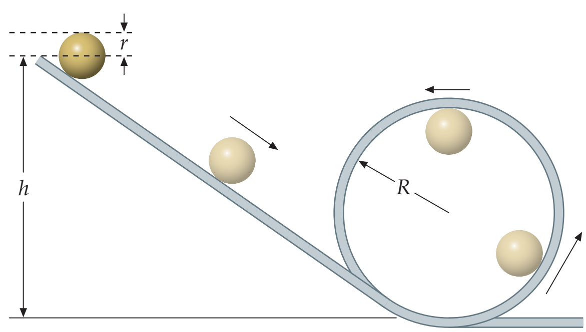

FIGURE 9-67 Problem 100

ROLLING WITH SLIPPING

101 •• A bowling ball of mass M and radius R is released so that at the instant it touches the floor it is moving horizontally with a speed v_0 and is not rotating. It slides for a time t_1 a distance s_1 before it begins to roll without slipping. (*a*) If μ_k is the coefficient of kinetic friction between the ball and the floor, find s_1, t_1, and the final speed v_1 of the ball. (*b*) Find the ratio of the final kinetic energy to the initial kinetic energy of the ball. (*c*) Evaluate s_1, t_1, and v_1 for $v_0 = 8.0$ m/s and $\mu_k = 0.060$.

102 •• **CONTEXT-RICH** During a game of pool, the cue ball (a uniform sphere of radius r) is at rest on the horizontal pool table (Figure 9-68). You strike the ball horizontally with your cue stick, which delivers a large horizontal force of magnitude F_0 for a short time. The stick strikes the ball at a point a vertical height h above the tabletop. Assume that the striking location is above the ball's center. Show that the ball's angular speed ω is related to the initial linear speed of its center of mass v_{cm} by $\omega = (5/2)v_{cm}(h - r)/r^2$. Estimate the ball's rotation rate just after the hit using reasonable estimates for h, r, and v_{cm}.

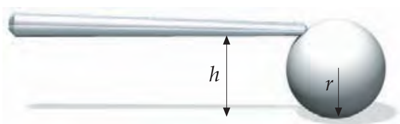

FIGURE 9-68 Problem 102

103 •• A uniform solid sphere is set rotating about a horizontal axis at an angular speed ω_0 and then is placed on the floor with its center of mass at rest. If the coefficient of kinetic friction between the sphere and the floor is μ_k, find the speed of the center of mass of the sphere when the sphere begins to roll without slipping.

104 •• A uniform solid ball that has a mass of 20 g and a radius of 5.0 cm rests on a horizontal surface. A sharp force is applied to the ball in a horizontal direction 9.0 cm above the horizontal surface. During impact the force increases linearly from 0.0 N to 40.0 kN in 1.0×10^{-4} s, and then it decreases linearly to 0.0 N in 1.0×10^{-4} s. (*a*) What is the speed of the ball just after impact? (*b*) What is the angular speed of the ball after impact? (*c*) What is the speed of the ball when it begins to roll without slipping? (*d*) How far does the ball travel along the surface before it begins to roll without slipping? Assume that $\mu_k = 0.50$.

105 •• A 0.16-kg billiard ball whose radius is 3.0 cm is given a sharp blow by a cue stick. The applied force is horizontal and the line of action of the force passes through the center of the ball. The speed of the ball just after the blow is 4.0 m/s, and the coefficient of kinetic friction between the ball and the billiard table is 0.60. (*a*) How long does the ball slide before it begins to roll without slipping? (*b*) How far does it slide? (*c*) What is its speed once it begins rolling without slipping? SSM

106 •• A billiard ball that is initially at rest is given a sharp blow by a cue stick. The force is horizontal and is applied at a distance $2R/3$ below the centerline, as shown in Figure 9-69. The speed of the ball just after the blow is v_0 and the coefficient of kinetic friction between the ball and the billiard table is μ_k. (*a*) What is the angular speed of the ball just after the blow? (*b*) What is the speed of the ball once it begins to roll without slipping? (*c*) What is the kinetic energy of the ball just after the hit?

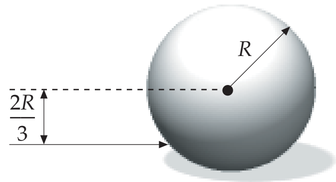

FIGURE 9-69 Problem 106

107 •• A bowling ball of radius R has an initial speed v_0 down the lane and a forward spin $\omega_0 = 3v_0/R$ just after its release. The coefficient of kinetic friction is μ_k. (*a*) What is the speed of the ball just as it begins rolling without slipping? (*b*) For how long a time does the ball slide before it begins rolling without slipping? (*c*) What distance does the ball slide down the lane before it begins rolling without slipping?

GENERAL PROBLEMS

108 •• The radius of a small playground merry-go-round is 2.2 m. To start it rotating, you wrap a rope around its perimeter and pull with a force of 260 N for 12 s. During this time, the merry-go-round makes one complete rotation. Neglect any effects of friction. (*a*) Find the angular acceleration of the merry-go-round. (*b*) What torque is exerted by the rope on the merry-go-round? (*c*) What is the moment of inertia of the merry-go-round?

109 •• A uniform 2.00-m-long stick is raised at an angle of 30° to the horizontal above a sheet of ice. The bottom end of the stick rests on the ice. The stick is released from rest. The bottom end of the stick remains in contact with the ice at all times. How far will the bottom end of the stick have traveled during the time the rest of the stick is falling to the ice? Assume that the ice is frictionless.

110 •• A uniform 5.0-kg disk has a radius of 0.12 m and is pivoted so that it rotates freely about its axis (Figure 9-70). A string wrapped around the disk is pulled with a force equal to 20 N. (*a*) What is the torque being exerted by this force about the rotation axis? (*b*) What is the angular acceleration of the disk? (*c*) If the disk starts from rest, what is its angular speed after 5.0 s? (*d*) What is its kinetic energy after the 5.0 s? (*e*) What is the angular displacement of the disk during the 5.0 s? (*f*) Show that the work done by the torque, $\tau\,\Delta\theta$, equals the kinetic energy.

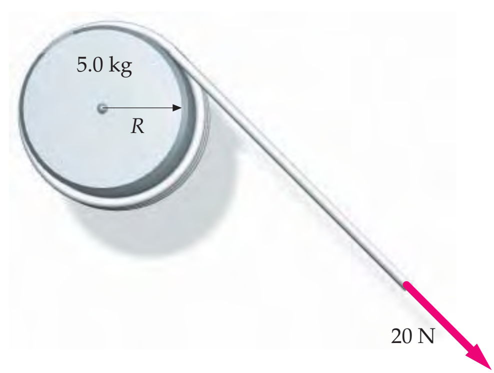

FIGURE 9-70 Problem 110

111 •• A uniform 0.25-kg thin rod that has an 80-cm length is free to rotate about a fixed horizontal axis perpendicular to and through one end of the rod. It is held horizontal and released. Immediately after it is released, what is (*a*) the acceleration of the center of the rod, and (*b*) the initial acceleration of the free end of the rod? (*c*) What is the speed of the center of mass of the rod when the rod is (momentarily) vertical?

112 •• A marble of mass M and radius R rolls without slipping down the track on the left from a height h_1, as shown in Figure 9-71. The marble then goes up the *frictionless* track on the right to a height h_2. Find h_2.

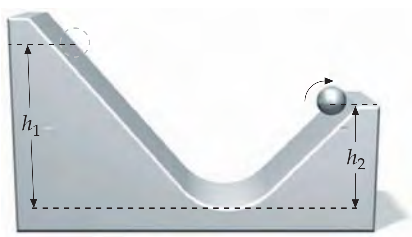

FIGURE 9-71 Problem 112

113 •• A uniform 120-kg disk with a radius equal to 1.4 m initially rotates with an angular speed of 1100 rev/min. A constant tangential force is applied at a radial distance of 0.60 m from the axis. (*a*) How much work must this force do to stop the wheel? (*b*) If the wheel is brought to rest in 2.5 min, what torque does the force produce? What is the magnitude of the force? (*c*) How many revolutions does the wheel make in these 2.5 min? SSM

114 •• A day-care center has a merry-go-round that consists of a uniform 240-kg circular wooden platform 4.00 m in diameter. Four children run alongside the merry-go-round and push tangentially along the platform's circumference until, starting from rest, the merry-go-round is spinning at 2.14 rev/min. During the spin-up: (*a*) If each child exerts a sustained force equal to 26 N, how far does each child run? (*b*) What is the angular acceleration of the merry-go-round? (*c*) How much work does each child do? (*d*) What is the increase in the kinetic energy of the merry-go-round?

115 •• A uniform 1.5-kg hoop with a 65-cm radius has a string wrapped around its circumference and lies flat on a horizontal frictionless table. The free end of the string is pulled with a constant horizontal force equal to 5.0 N and the string does not slip on the hoop. (*a*) How far does the center of the hoop travel in 3.0 s? (*b*) What is the angular speed of the hoop after 3.0 s?

116 •• A hand-driven grinding wheel is a uniform 60-kg disk with a 45-cm radius. It has a handle of negligible mass 65 cm from the rotation axis. A compact 25-kg load is attached to the handle when it is at the same height as the horizontal rotation axis. Ignoring the effects of friction, find (*a*) the initial angular acceleration of the wheel, and (*b*) the maximum angular speed of the wheel.

117 •• A uniform disk of radius R and mass M is pivoted about a horizontal axis parallel to its symmetry axis and passing through a point on its perimeter, so that it can swing freely in a vertical plane (Figure 9-72). It is released from rest with its center of mass at the same height as the pivot. (*a*) What is the angular speed of the disk when its center of mass is directly below the pivot? (*b*) What force is exerted by the pivot on the disk at this moment?

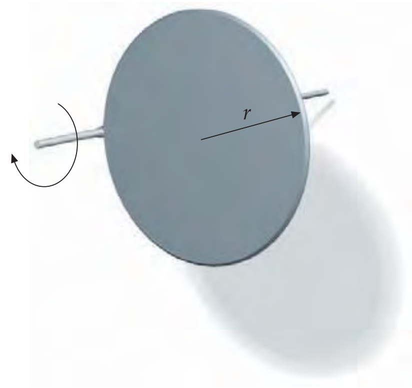

FIGURE 9-72 Problem 117

118 •• **ENGINEERING APPLICATION** The roof of the student dining hall at your college will be supported by high cross-braced wooden beams attached in the shape of an upside-down L (Figure 9-73). Each vertical beam is 10.0 ft high and 2.0 ft wide, and the horizontal cross-member is 8.0 ft long. The mass of the vertical beam is 350 kg, and the mass of the horizontal beam is 280 kg. As the workers were building the hall, one of these structures started to fall over before it was anchored into place. (Luckily they stopped it before it fell.) (*a*) If it started falling from an upright position, what was the initial angular acceleration of the structure? Assume that the bottom did not slide across the floor and that it did not fall out of plane; that is, during the fall, the structure remained in the vertical plane defined by the initial position of the structure. (*b*) What would be the magnitude of the initial linear acceleration of the upper right corner of the horizontal beam? (*c*) What would the horizontal component of the initial linear acceleration be at this same location? (*d*) Estimate the structure's rotational speed at impact.

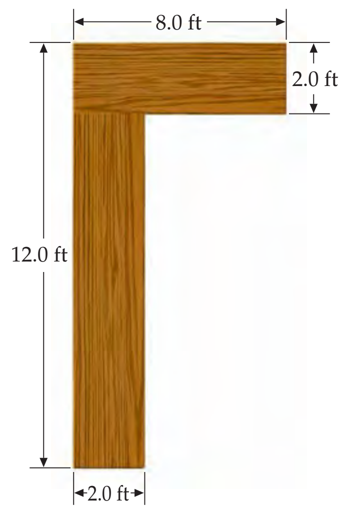

FIGURE 9-73 Problem 118

119 •• **CONTEXT-RICH** You are participating in league bowling with your friends. Time after time, you notice that your bowling ball rolls back to you without slipping on the flat section of track. When the ball encounters the slope that brings it up to the ball return, it is moving at 3.70 m/s. The length of the sloped part of the track is 2.50 m. The radius of the bowling ball is 11.5 cm. (*a*) What is

the angular speed of the ball before it encounters the slope? (*b*) If the speed with which the ball emerges at the top of the incline is 0.40 m/s, what is the angle (assumed constant) that the sloped section of the track makes with the horizontal? (*c*) What is the magnitude of the angular acceleration of the ball while it is on the slope? SSM

120 •• Figure 9-74 shows a hollow cylinder that has a length equal to 1.80 m, a mass equal to 0.80 kg, and radius equal to 0.20 m. The cylinder is free to rotate about a vertical axis that passes through its center and is perpendicular to the cylinder. Two objects are inside the cylinder. Each object has a mass equal to 0.20 kg and is attached to a spring that has a force constant k and an unstressed length equal to 0.40 m. The inside walls of the cylinder are frictionless. (*a*) Determine the value of the force constant if the objects are located 0.80 m from the center of the cylinder when the cylinder rotates at 24 rad/s. (*b*) How much work is required to bring the system from rest to an angular speed of 24 rad/s?

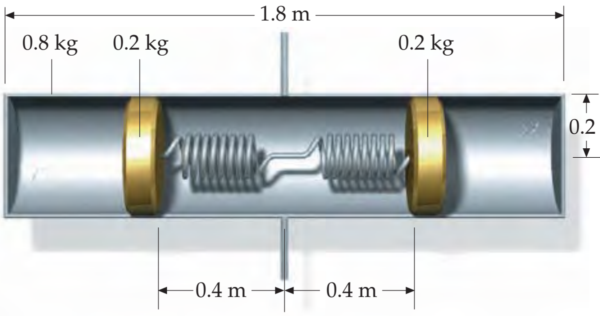

FIGURE 9-74 Problems 120 and 123

121 •• A popular classroom demonstration involves taking a meterstick and holding it horizontally at the 0.0-cm end with a number of pennies spaced evenly along its surface. If the hand is suddenly relaxed so that the meterstick pivots freely about the 0.0-cm mark under the influence of gravity, an interesting thing is seen during the first part of the stick's rotation: the pennies nearest the 0.0-cm mark remain on the meterstick, while those nearest the 100-cm mark are left behind by the falling meterstick. (This demonstration is often called the "faster than gravity" demonstration.) Suppose this demonstration is repeated without any pennies on the meterstick. (*a*) What would the initial acceleration of the 100.0-cm mark then be? (The initial acceleration is the acceleration just after the release.) (*b*) What point on the meterstick would then have an initial acceleration greater than g? SSM

122 •• A solid metal rod 1.5 m long is free to pivot without friction about a fixed horizontal axis perpendicular to the rod and passing through one of its ends. The rod is held in a horizontal position. Small coins, each of mass m, are placed on the rod 25 cm, 50 cm, 75 cm, 1 m, 1.25 m, and 1.5 m from the pivot. If the free end is now released, calculate the initial force exerted on each coin by the rod. Assume that the masses of the coins can be ignored in comparison to the mass of the rod.

123 •• Suppose that for the system described in Problem 120, the force constants are each 60 N/m. The system starts from rest and slowly accelerates until the masses are 0.80 m from the center of the cylinder. How much work was done in the process?

124 ••• A string is wrapped around a uniform solid cylinder of radius R and mass M that rests on a horizontal frictionless surface. (The string does not touch the surface because there is a groove cut in the surface to provide space for the string to clear.) The string is pulled horizontally from the top with force F. (*a*) Show that the magnitude of the angular acceleration of the cylinder is twice the magnitude of the angular acceleration needed for rolling without slipping, so that the bottom point on the cylinder slides backward against the table. (*b*) Find the magnitude and direction of the frictional force between the table and cylinder that would be needed for the cylinder to roll without slipping. What would be the magnitude of acceleration of the cylinder in this case?

125 ••• **SPREADSHEET** Let us calculate the position y of the falling load attached to the winch in Example 9-8 as a function of time by numerical integration. Let the $+y$ direction be straight downward. Then $v(y) = dy/dt$, or

$$t = \int_0^y \frac{1}{v(y')}dy' \approx \sum_{i=0}^{N} \frac{1}{v(y'_i)}\Delta y'$$

where t is the time taken for the bucket to fall a distance y, $\Delta y'$ is a small increment of y', and $y' = N\Delta y'$. Hence, we can calculate t as a function of d by numerical summation. Make a graph of y versus t between 0 s and 2.00 s. Assume that $m_w = 10.0$ kg, $R = 0.50$ m, $m_b = 5.0$ kg, $L = 10.0$ m, and $m_c = 3.50$ kg. Use $\Delta y' = 0.10$ m. Compare this position to the position of the falling load if it were in free-fall. SSM

126 ••• Figure 9-75 shows a solid cylinder that has mass M and radius R to which a second solid cylinder that has mass m and radius r is attached. A string is wound about the smaller cylinder. The larger cylinder rests on a horizontal surface. The coefficient of static friction between the larger cylinder and the surface is μ_s. If a light tension is applied to the string in the vertical direction, the cylinder will roll to the left; if the tension is applied with the string horizontally to the right, the cylinder rolls to the right. Find the angle between the string and the horizontal that will allow the cylinder to remain stationary when a light tension is applied to the string.

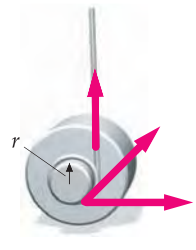

FIGURE 9-75 Problem 126

127 ••• In problems dealing with a pulley with a nonzero moment of inertia, the magnitude of the tensions in the ropes hanging on either side of the pulley are not equal. The difference in the tension is due to the static frictional force between the rope and the pulley; however, the static frictional force cannot be made arbitrarily large. Consider a massless rope wrapped partly around a cylinder through an angle $\Delta\theta$ (measured in radians). It can be shown that if the tension on one side of the pulley is T, while the tension on the other side is T' ($T' > T$), the maximum value of T' that can be maintained without the rope slipping is $T'_{max} = Te^{\mu_s \Delta\theta}$, where μ_s is the coefficient of static friction. Consider the Atwood's machine in Figure 9-76: the pulley has a radius $R = 0.15$ m, the moment of inertia is $I = 0.35\ \mathrm{kg\cdot m^2}$, and the coefficient of static friction between the wheel and the string is $\mu_s = 0.30$. (*a*) If the tension on one side of the pulley is 10 N, what is the maximum tension on the other side that will prevent the rope from slipping on the pulley? (*b*) What is the acceleration of the blocks in this case? (c) If the mass of one of the hanging blocks is 1.0 kg, what is the maximum mass of the other block if, after the blocks are released, the pulley is to rotate without slipping? SSM

FIGURE 9-76 Problem 127

128 ••• A massive, uniform cylinder has a mass m and a radius R (Figure 9-77). It is accelerated by a tension force $\vec{T}$ that is applied through a rope wound around a light drum of radius r that is attached to the cylinder. The coefficient of static friction is sufficient for the cylinder to roll without slipping. (*a*) Find the frictional force. (*b*) Find the acceleration a of the center of the cylinder. (*c*) Show that it is possible to choose r so that a is greater than T/m. (*d*) What is the direction of the frictional force in the circumstances of Part (*c*)?

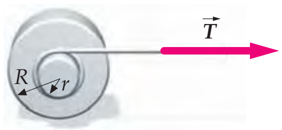

FIGURE 9-77 Problem 128

129 ••• A uniform rod that has a length L and a mass M is free to rotate about a horizontal axis through one end, as shown in Figure 9-78. The rod is released from rest at $\theta = \theta_0$. Show that the parallel and perpendicular components of the force exerted by the axis on the rod are given by $F_{\parallel} = \frac{1}{2}Mg(5\cos\theta - 3\cos\theta_0)$ and $F_{\perp} = \frac{1}{4}Mg\sin\theta$, where $F_{\parallel}$ is the component parallel with the rod and $F_{\perp}$ is the component perpendicular to the rod.

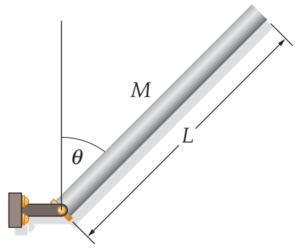

FIGURE 9-78 Problem 129

CHAPTER

10

THE HUBBLE SPACE TELESCOPE WAS PLACED IN ORBIT AND PUT INTO OPERATION IN 1990. ALMOST IMMEDIATELY A MAJOR FLAW IN ITS PRIMARY MIRROR WAS DISCOVERED. HOWEVER, IN 1993 A SERVICE SHIP VISITED THE TELESCOPE AND CORRECTED THE PROBLEM. SINCE THEN, THE HUBBLE HAS PROVIDED SPECTACULAR IMAGES OF THE UNIVERSE. THE IMPACT OF THESE IMAGES HAS BEEN TO ENRICH AND EXTEND OUR KNOWLEDGE ABOUT THE UNIVERSE. THE HUBBLE TELESCOPE IS AN EXTRAORDINARY SCIENTIFIC INSTRUMENT. *(NASA.)*

Angular Momentum

As with conservation of energy and conservation of linear momentum, conservation of angular momentum is one of the basic principles of physics. Experimental evidence shows that angular momentum is never created nor destroyed.

? In order to aim the Hubble telescope in a new direction the telescope must rotate. How is this accomplished? (See Example 10-7.)

In this chapter, we extend our study of rotational motion to situations in which the direction of the axis of rotation may change. Angular velocity, angular acceleration, and torque are presented in Chapter 9. Here we begin by introducing the vector nature of these quantities and of angular momentum, which is the rotational analog of linear momentum. We then show that the net torque acting on a system equals the time rate of change of its angular momentum. Angular momentum is conserved in systems that have zero net external torque. Like conservation of linear momentum, conservation of angular momentum is a fundamental law of nature, relating to even atoms, molecules, subatomic particles, and photons.

10-1 THE VECTOR NATURE OF ROTATION

In Chapter 9, we indicated the direction of rotation about an axis by assigning plus and minus signs to indicate the direction of the angular velocity, just as in Chapter 2 we used plus and minus signs to indicate the direction of the velocity in one-dimensional motion. However, plus and minus signs are *not* adequate to specify the direction of the angular velocity if the direction of the rotation axis is not fixed in space. This inadequacy is overcome by treating the angular velocity as a vector quantity $\vec{\boldsymbol{\omega}}$ directed along the rotation axis. Consider the rotating disk in Figure 10-1. If the rotation is directed as shown, $\vec{\boldsymbol{\omega}}$ is directed as shown; if the rotation direction is reversed, so is the direction of $\vec{\boldsymbol{\omega}}$. The convention relating the direction of $\vec{\boldsymbol{\omega}}$ with the direction of rotation is specified by a convention called the **right-hand rule.** You can obtain the direction of $\vec{\boldsymbol{\omega}}$ by curling the fingers of your right hand in the direction of rotation (Figure 10-2); your thumb then points along the rotation axis in the direction of $\vec{\boldsymbol{\omega}}$.

FIGURE 10-1

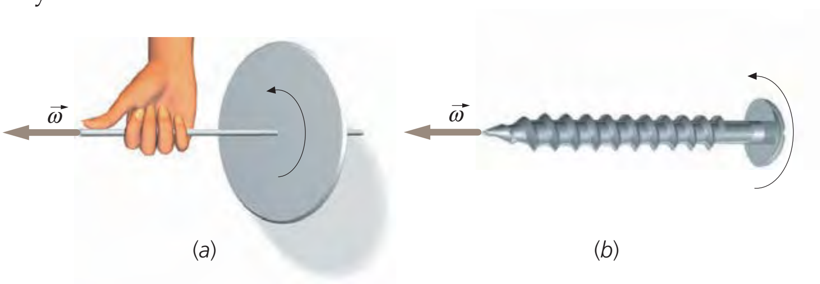

FIGURE 10-2 (*a*) When the fingers of the right hand curl in the direction of rotation, the thumb points in the direction of $\vec{\boldsymbol{\omega}}$, (*b*) Looked at another way, the direction of $\vec{\boldsymbol{\omega}}$ is that of the advance of a rotating right-hand screw.

In Chapter 9, we indicated the direction of torque about an axis by assigning plus and minus signs to indicate the direction of the torque. In this chapter, we define the torque $\vec{\boldsymbol{\tau}}$ about a point as a vector quantity, and, as with $\vec{\boldsymbol{\omega}}$, the direction of $\vec{\boldsymbol{\tau}}$ is specified by a right hand rule. Figure 10-3 shows a force $\vec{\boldsymbol{F}}$ acting on a particle at some position $\vec{\boldsymbol{r}}$ relative to the origin O. The torque $\vec{\boldsymbol{\tau}}$ about O exerted by this force is defined as a vector that is perpendicular to both $\vec{\boldsymbol{F}}$ and $\vec{\boldsymbol{r}}$ and has magnitude $Fr\sin\phi$, where ϕ is the angle between the directions of $\vec{\boldsymbol{F}}$ and $\vec{\boldsymbol{r}}$. If $\vec{\boldsymbol{F}}$ and $\vec{\boldsymbol{r}}$ are both perpendicular to the z axis, as in Figure 10-3, the torque vector $\vec{\boldsymbol{\tau}}$ is parallel to the z axis. If $\vec{\boldsymbol{F}}$ is applied to the rim of a disk of radius r, as shown in Figure 10-4, the torque vector has the magnitude Fr, and is along the axis of rotation in the direction shown.

THE VECTOR PRODUCT

Torque is expressed mathematically as the **vector product** of $\vec{\boldsymbol{r}}$ and $\vec{\boldsymbol{F}}$:

$$\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{r}} \times \vec{\boldsymbol{F}} \qquad \text{10-1}$$

(Because of the $\times$ used to indicate this type of multiplication, the vector product is also called the *cross product.*) The vector product of two vectors $\vec{\boldsymbol{A}}$ and $\vec{\boldsymbol{B}}$ is defined to be a vector $\vec{\boldsymbol{C}} = \vec{\boldsymbol{A}} \times \vec{\boldsymbol{B}}$ whose magnitude equals the area of the parallelogram formed by $\vec{\boldsymbol{A}}$ and $\vec{\boldsymbol{B}}$ (Figure 10-5). The vector $\vec{\boldsymbol{C}}$ is perpendicular to both $\vec{\boldsymbol{A}}$ and $\vec{\boldsymbol{B}}$ in the direction of the thumb of your right hand if you curl your fingers from the direction of $\vec{\boldsymbol{A}}$ toward the direction of $\vec{\boldsymbol{B}}$ (Figure 10-6). If ϕ is the angle between $\vec{\boldsymbol{A}}$ and $\vec{\boldsymbol{B}}$,* and $\hat{n}$ is a unit vector that is perpendicular to both $\vec{\boldsymbol{A}}$ and $\vec{\boldsymbol{B}}$ in the direction of $\vec{\boldsymbol{C}}$, the vector product of $\vec{\boldsymbol{A}}$ and $\vec{\boldsymbol{B}}$ is

$$\vec{\boldsymbol{A}} \times \vec{\boldsymbol{B}} = AB\sin\phi\,\hat{\boldsymbol{n}} \qquad \text{10-2}$$

DEFINITION—VECTOR PRODUCT

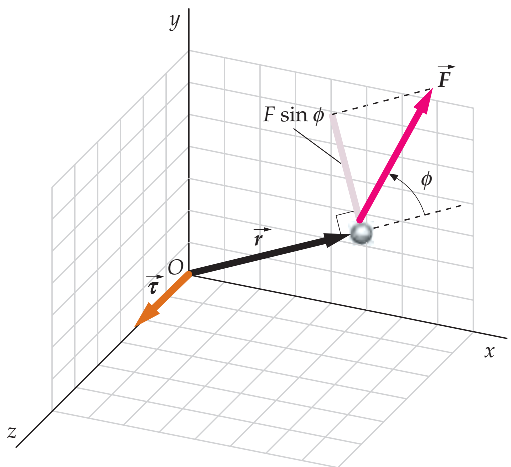

FIGURE 10-3 If $\vec{\boldsymbol{F}}$ and $\vec{\boldsymbol{r}}$ are both perpendicular to the z axis, then $\vec{\boldsymbol{\tau}}$ is parallel with the z axis.

It follows from the definition of the vector product that

$$\vec{\boldsymbol{A}} \times \vec{\boldsymbol{A}} = 0 \qquad \text{10-3}$$

and

$$\vec{\boldsymbol{A}} \times \vec{\boldsymbol{B}} = -\vec{\boldsymbol{B}} \times \vec{\boldsymbol{A}} \qquad \text{10-4}$$

Note that the order in which two vectors are multiplied in a vector product makes a difference. Below is a Problem-Solving Strategy that should help you work with the vector product.

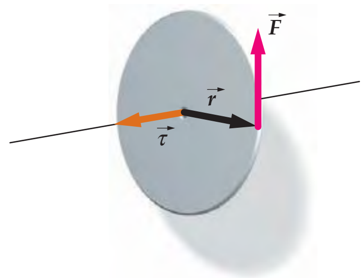

FIGURE 10-4

* The angle between two vectors is the angle between their directions in space.

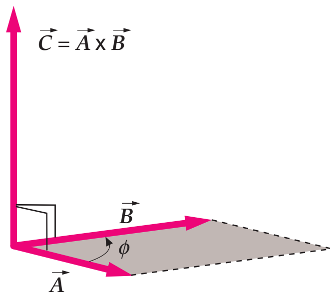

FIGURE 10-5 The vector product $\vec{A} \times \vec{B}$ is a vector $\vec{C}$ that is perpendicular to both $\vec{A}$ and $\vec{B}$, and has a magnitude $AB \sin\phi$, which equals the area of the parallelogram shown.

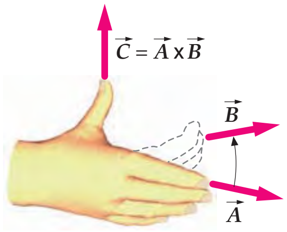

FIGURE 10-6 The direction of $\vec{A} \times \vec{B}$ is given by the right-hand rule when the fingers are rotated from the direction of $\vec{A}$ toward $\vec{B}$ through the angle ϕ.

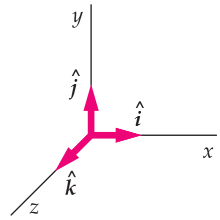

FIGURE 10-7

PROBLEM-SOLVING STRATEGY

Finding the Vector Product of Two Vectors

PICTURE At times it is easier to find a vector product of two vectors by using the equation $\vec{A} \times \vec{B} = AB \sin\phi\, \hat{n}$. At other times it is easier to find the vector product using the Cartesian components of the two vectors.

SOLVE

1. The vector product obeys a distributive law under addition:

$$\vec{A} \times (\vec{B} + \vec{C}) = \vec{A} \times \vec{B} + \vec{A} \times \vec{C} \qquad 10\text{-}5$$

2. If $\vec{A}$ and $\vec{B}$ are functions of some variable such as t, the derivative of $\vec{A} \times \vec{B}$ follows the usual product rule for derivatives:

$$\frac{d}{dt}(\vec{A} \times \vec{B}) = \left(\vec{A} \times \frac{d\vec{B}}{dt}\right) + \left(\frac{d\vec{A}}{dt} \times \vec{B}\right) \qquad 10\text{-}6$$

3. The unit vectors $\hat{i}$, $\hat{j}$, and $\hat{k}$ (Figure 10-7), which are mutually perpendicular, have vector products given by

$$\hat{i} \times \hat{j} = \hat{k},\ \hat{j} \times \hat{k} = \hat{i},\ \text{and}\ \hat{k} \times \hat{i} = \hat{j} \qquad 10\text{-}7a$$

(Reversing the order of multiplication gives $\hat{j} \times \hat{i} = -\hat{k}$, $\hat{k} \times \hat{j} = -\hat{i}$ and $\hat{i} \times \hat{k} = -\hat{j}$, in accord with Equation 10-4. A tool for remembering this is shown in Figure 10-8. Furthermore,

$$\hat{i} \times \hat{i} = \hat{j} \times \hat{j} = \hat{k} \times \hat{k} = 0 \qquad 10\text{-}7b$$

CHECK Make sure that your vector products make sense. For example, the vector product of two vectors is a vector and is perpendicular to each of the two vectors. In addition, check your work to make certain you did not inadvertently reverse the order of the two vectors being multiplied, and thus create a sign error.

TAKING IT FURTHER Any coordinate system for which Equations 10-7*a* and 10-7*b* hold is called a *right-handed coordinate system* (Figure 10-9). Only right-handed coordinate systems are used in this book.

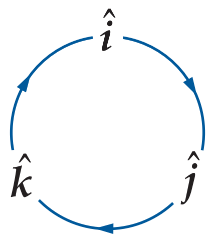

FIGURE 10-8 Taking the vector product by going around this figure in the direction of the arrows (clockwise) and the sign is positive ($\hat{i} \times \hat{j} = \hat{k}$). Going around against the arrows and the sign is negative ($\hat{i} \times \hat{k} = -\hat{j}$).

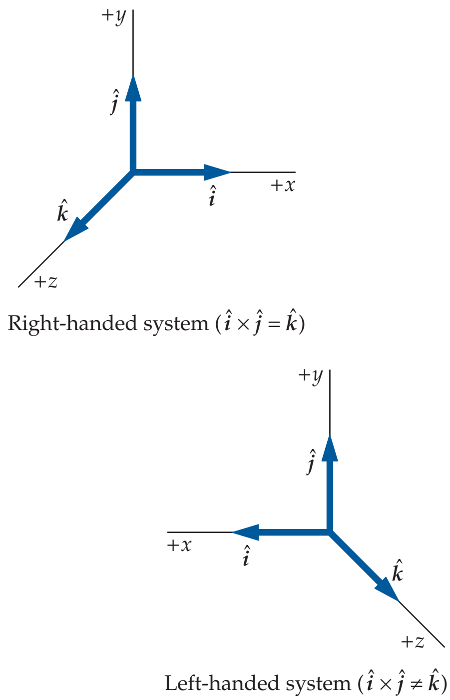

FIGURE 10-9 A right-handed and a left-handed coordinate system. In this book, only right-handed coordinate systems are used.

Example 10-1 Vector Products and Dot Products

If $\vec{A} = 3\hat{j}$, $\vec{A} \times \vec{B} = 9\hat{i}$, and $\vec{A} \cdot \vec{B} = 12$, find $\vec{B}$.

PICTURE Express $\vec{B}$ in terms of its Cartesian components and solve for each Cartesian component of $\vec{B}$ using the given information.

SOLVE

1. Express $\vec{B}$ in terms of its Cartesian components. The task is to solve for each of these components:

$$\vec{B} = B_x\hat{i} + B_y\hat{j} + B_z\hat{k}$$

2. We are given $\vec{A} \cdot \vec{B} = 12$. Evaluate $\vec{A} \cdot \vec{B}$ and simplify using Equation 6-15:

$$\vec{A} \cdot \vec{B} = 3\hat{j} \cdot (B_x\hat{i} + B_y\hat{j} + B_z\hat{k}) = 3B_x\hat{j} \cdot \hat{i} + 3B_y\hat{j} \cdot \hat{j} + 3B_z\hat{j} \cdot \hat{k}$$
$$= 0 + 3B_y + 0 = 3B_y$$

3. Set the step-2 result equal to 12 and solve for B_y:

$$3B_y = 12, \quad \text{so} \quad B_y = 4$$

4. We are given $\vec{A} \times \vec{B} = 9\hat{i}$. Evaluate $\vec{A} \times \vec{B}$ and simplify using Equations 10-7*a* and 10-7*b*:

$$\vec{A} \times \vec{B} = 3\hat{j} \times (B_x\hat{i} + B_y\hat{j} + B_z\hat{k}) = 3B_x\hat{j} \times \hat{i} + 3B_y\hat{j} \times \hat{j} + 3B_z\hat{j} \times \hat{k}$$
$$= 3B_x(-\hat{k}) + 3B_y(0) + 3B_z(\hat{i}) = 3B_z\hat{i} - 3B_x\hat{k}$$

5. Set the step-4 result equal to $9\hat{i}$ and solve for the remaining components of $\vec{B}$:

$$\vec{A} \times \vec{B} = 9\hat{i}$$
$$3B_z\hat{i} - 3B_x\hat{k} = 9\hat{i} \quad \text{so}$$
$$B_z = 3 \text{ and } B_x = 0$$
$$\therefore \vec{B} = 0\hat{i} + 4\hat{j} + 3\hat{k} = \boxed{4\hat{j} + 3\hat{k}}$$

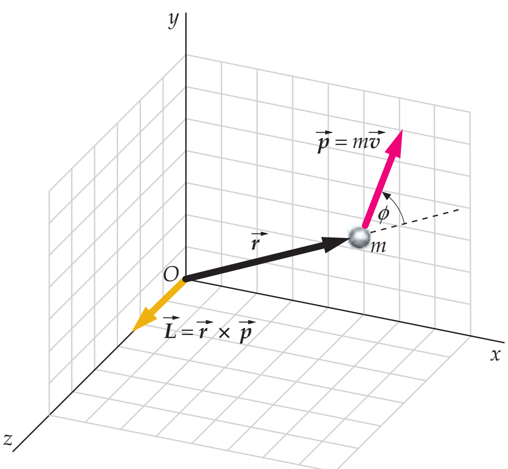
CHECK The vector product of any two vectors is perpendicular to both vectors (except when the vector product is equal to zero). Because $\vec{A} \times \vec{B} = 9\hat{i}$, we expect $\vec{B}$ to be perpendicular to $\hat{i}$, which means we expect the x component of $\vec{B}$ to be zero. Our calculated value of $\vec{B}$ meets this expectation.

10-2 TORQUE AND ANGULAR MOMENTUM

Figure 10-10 shows a particle of mass m moving with a velocity $\vec{v}$ at a position $\vec{r}$ relative to the origin O. The linear momentum of the particle is $\vec{p} = m\vec{v}$. The **angular momentum** $\vec{L}$ of the particle relative to the origin O is defined to be the vector product of $\vec{r}$ and $\vec{p}$:

$$\vec{L} = \vec{r} \times \vec{p} \qquad 10\text{-}8$$

ANGULAR MOMENTUM OF A POINT PARTICLE DEFINED



See **Math Tutorial** for more information on **Trigonometry**

FIGURE 10-10

If $\vec{r}$ and $\vec{p}$ are both perpendicular to the z axis, as in Figure 10-10, $\vec{L}$ is parallel to the z axis and is given by $\vec{L} = \vec{r} \times \vec{p} = mvr \sin\phi\, \hat{k}$. Like torque, angular momentum is defined *relative to a point in space;* in this case the angular momentum is defined about the origin.

Figure 10-11 shows a particle of mass m attached to a circular disk of negligible mass moving in a circle in the xy plane with its center at the origin. The disk is spinning about the z axis with angular speed ω. The speed v of the particle and its angular speed are related by $v = r\omega$. The angular momentum of the particle relative to the center of the disk is

$$\vec{L} = \vec{r} \times \vec{p} = \vec{r} \times m\vec{v} = rmv \sin 90^\circ\, \hat{k} = rmv\hat{k} = mr^2\omega\hat{k} = mr^2\vec{\omega}$$

Note: In this example the angular momentum vector is in the same direction as the angular velocity vector.

Because mr^2 is the moment of inertia for a single particle about the z axis, we have

$$\vec{L} = mr^2\vec{\omega} = I\vec{\omega}$$

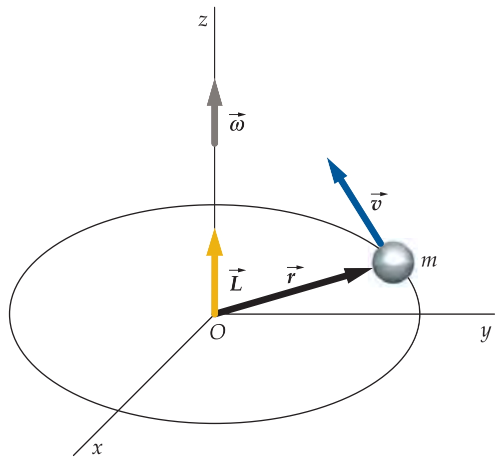


FIGURE 10-11

The angular momentum of this particle about a general point on the z axis is not parallel to the angular velocity vector. Figure 10-12 shows the angular momentum vector $\vec{L}'$ for the same particle attached to the same disk, but with $\vec{L}'$ computed about a point on the z axis that is not at the center of the circle. In this case, the angular momentum is not parallel to the angular velocity vector $\vec{\omega}$, which is parallel to the z axis.

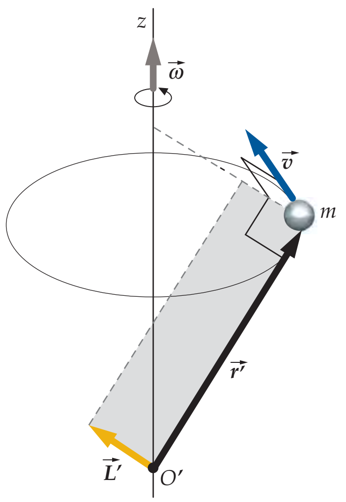

FIGURE 10-12

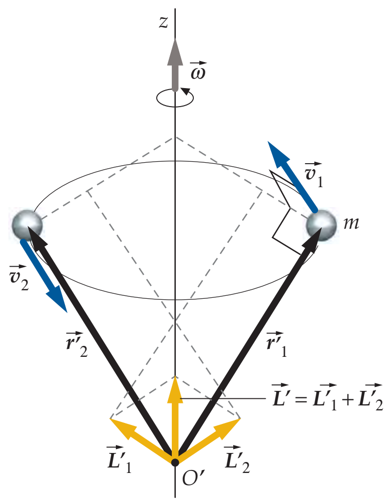

FIGURE 10-13

In Figure 10-13, we attach a second particle of equal mass to the spinning disk at a point diametrically opposite this first particle. The angular-momentum vectors $\vec{L}'_1$ and $\vec{L}'_2$ are shown relative to the same point O'. The total angular momentum $\vec{L}' = \vec{L}'_1 + \vec{L}'_2$ of the two-particle system is again parallel to the angular velocity vector $\vec{\omega}$. In this case, the axis of rotation, the z axis, passes through the center of mass of the two-particle system, and the mass distribution is symmetric about this axis. Such an axis is called a **symmetry axis.** For any system of particles that rotates about a symmetry axis, the total angular momentum (which is the sum of the angular momenta of the individual particles) is parallel to the angular velocity and is given by

$$\vec{L} = I\vec{\omega} \qquad 10\text{-}9$$

ANGULAR MOMENTUM OF A SYSTEM ROTATING ABOUT A SYMMETRY AXIS

where I is a scalar.*

* In more advanced treatments Equation 10-9 is valid about any axis, but I is a tensor of rank 3.

Example 10-2 Angular Momentum About the Origin

Find the angular momentum about the origin for the following situations. (*a*) A car of mass 1200 kg moves in a circle of radius 20 m with a speed of 15 m/s. The circle is in the *xy* plane, centered at the origin. When viewed from a point on the positive *z* axis, the car moves counterclockwise. (*b*) The same car moves in the *xy* plane with velocity $\vec{v} = -(15\text{ m/s})\hat{i}$ along the line $y = y_0 = 20$ m parallel to the *x* axis. (*c*) A uniform disk in the *xy* plane of radius 20 m and mass 1200 kg rotates at 0.75 rad/s about its axis, which is also the *z* axis. When viewed from a point on the positive *z* axis, the disk rotates counterclockwise. Model the car as a point particle and the disk as a uniform disk.

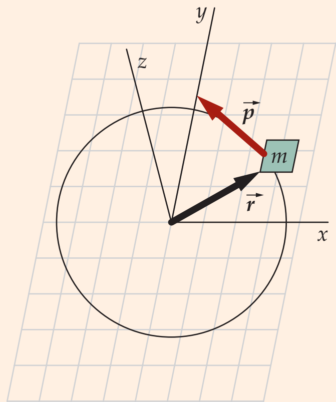

FIGURE 10-14

PICTURE For (*a*) and (*b*) we use $\vec{L} = \vec{r} \times \vec{p}$, because we are modeling the car as a point particle. For (*c*), we use $\vec{L} = I\vec{\omega}$ because we are modeling the disk as a rigid extended body—a disk. Draw a figure and apply the right-hand rule to find the direction of $\vec{L}$.

SOLVE

(*a*) $\vec{r}$ and $\vec{p}$ are perpendicular and $\vec{r} \times \vec{p}$ is in the $+z$ direction (Figure 10-14):

$$\begin{aligned}\vec{L} &= \vec{r} \times \vec{p} = rmv\sin 90°\hat{k}\\ &= (20\text{ m})(1200\text{ kg})(15\text{ m/s})\hat{k}\\ &= \boxed{3.6 \times 10^5\text{ kg}\cdot\text{m}^2/\text{s}\ \hat{k}}\end{aligned}$$

(*b*) 1. For the same car moving in the direction of decreasing *x* along the line $y = 20$ m, we express $\vec{r}$ and $\vec{p}$ in terms of unit vectors:

$$\vec{r} = x\hat{i} + y\hat{j} = x\hat{i} + y_0\hat{j}$$
$$\vec{p} = m\vec{v} = -mv\hat{i}$$

2. Now compute $\vec{r} \times \vec{p}$ (Figure 10-15):

$$\begin{aligned}\vec{L} &= \vec{r} \times \vec{p} = (x\hat{i} + y_0\hat{j}) \times (-mv\hat{i})\\ &= -xmv(\hat{i} \times \hat{i}) - y_0mv(\hat{j} \times \hat{i})\\ &= 0 - y_0mv(-\hat{k}) = y_0mv\hat{k}\\ &= (20\text{ m})(1200\text{ kg})(15\text{ m/s})\hat{k}\\ &= \boxed{3.6 \times 10^5\text{ kg}\cdot\text{m}^2/\text{s}\ \hat{k}}\end{aligned}$$

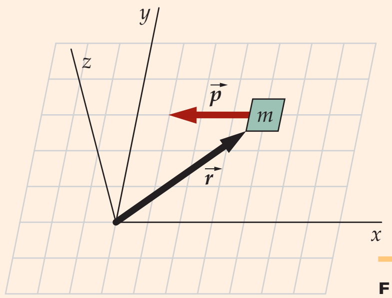

FIGURE 10-15

(*c*) Use $\vec{L} = I\vec{\omega}$ (Figure 10-16):

$$\begin{aligned}\vec{L} &= I\vec{\omega} = I\omega\hat{k} = \tfrac{1}{2}mR^2\omega\hat{k}\\ &= \tfrac{1}{2}(1200\text{ kg})(20\text{ m})^2(0.75\text{ rad/s})\hat{k}\\ &= \boxed{1.8 \times 10^5\text{ kg}\cdot\text{m}^2/\text{s}\ \hat{k}}\end{aligned}$$

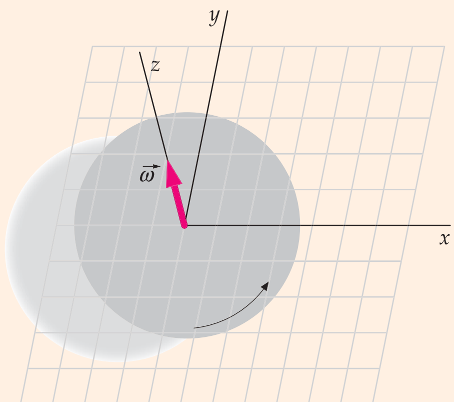

FIGURE 10-16

CHECK In Part (*c*), the velocity of a point on the rim is $v = R\omega = (20\text{ m})(0.75\text{ rad/s}) = 15$ m/s, the same as the velocity of the car in Parts (*a*) and (*b*). The angular momentum of the rotating disk is less than that of the car because virtually all of the mass of the disk is less than 20 m from the axis of rotation.

TAKING IT FURTHER The angular momentum of the car moving in a circle in Part (*a*) is the same as that of the car moving along a straight line in Part (*b*).

There are several additional results concerning torque and angular momentum for a system of particles. The first of these is

$$\vec{\tau}_{\text{net ext}} = \frac{d\vec{L}_{\text{sys}}}{dt} \qquad 10\text{-}10$$

The net external torque about a fixed point acting on a system equals the rate of change of the angular momentum of the system about the same point.

NEWTON'S SECOND LAW FOR ANGULAR MOTION

In Equation 10-10, the net external torque about the point is the vector sum of the external torques about that point acting on the system. Integrating both sides of this equation with respect to time gives

$$\Delta\vec{L}_{\text{sys}} = \int_{t_i}^{t_f} \vec{\tau}_{\text{net ext}}\, dt \qquad 10\text{-}11$$

ANGULAR IMPULSE–ANGULAR-MOMENTUM EQUATION

Equation 10-11 is the rotational analog of $\Delta\vec{P}_{\text{sys}} = \int_{t_i}^{t_f} \vec{F}_{\text{net ext}}\, dt$ (Equation 8-11).

It is often useful to split the total angular momentum of a system about an arbitrary point O into orbital angular momentum and spin angular momentum:

$$\vec{L}_{\text{sys}} = \vec{L}_{\text{orbit}} + \vec{L}_{\text{spin}} \qquad 10\text{-}12$$

SPIN AND ORBITAL ANGULAR MOMENTUM

Earth has spin angular momentum due to its spinning motion about its rotational axis, and it has orbital angular momentum about the center of the Sun due to its orbital motion around the Sun (Figure 10-17). The total angular momentum of Earth relative to the center of the Sun is the vector sum of the spin and orbital angular momenta. $\vec{L}_{\text{spin}}$ is the angular momentum of a system about its center of mass, and $\vec{L}_{\text{orbit}}$ is the angular momentum that a point particle of mass M located at the center of mass and moving at the velocity of the center of mass would have. That is,

$$\vec{L}_{\text{orbit}} = \vec{r}_{\text{cm}} \times M\vec{v}_{\text{cm}} \qquad 10\text{-}13$$

DEFINITION: ORBITAL ANGULAR MOMENTUM

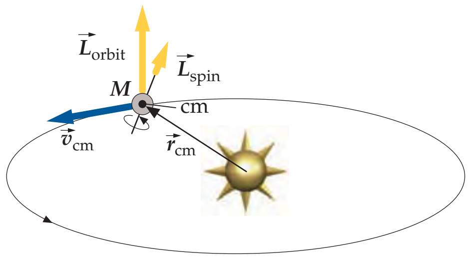

FIGURE 10-17 The total angular momentum of Earth about the center of the Sun is the sum of the orbital and the spin-angular-momentum vectors.

In Chapter 9, torques are computed about axes instead of about points. The relation between the torque about an axis and the torque about a point is straightforward. If point O is the origin and if force $\vec{F}$ exerts torque $\vec{\tau}$ about O, then τ_z (the z component of $\vec{\tau}$) is the torque of $\vec{F}$ about the z axis.

Taking components of vector products requires some care. If $\vec{\tau} = \vec{r} \times \vec{F}$, then

$$\vec{\tau}_z = \vec{r}_{\text{rad}} \times \vec{F}_{xy} \qquad 10\text{-}14$$

TORQUE ABOUT z AXIS

where $\vec{\tau}_z$, $\vec{r}_{\text{rad}}$ and $\vec{F}_{xy}$ (see Figure 10-18) are the vector components of $\vec{\tau}$, $\vec{r}$, and $\vec{F}$. The vector component in a given direction is the scalar component in that direction times the unit vector in that direction. For example, $\vec{\tau}_z = \tau_z\hat{k}$. Here, $\vec{r}_{\text{rad}}$ is the vector component of $\vec{r}$ in the positive radial direction (directly away from the z axis), and $\vec{F}_{xy}$ is the component of $\vec{F}$ perpendicular to the z axis, and thus parallel to the xy plane ($\vec{F}_{xy} = \vec{F} - F_z\hat{k}$). The relation between angular momentum about an axis and angular momentum about a point is also straightforward. If the angular momentum of a point particle about the origin is $\vec{L} = \vec{r} \times \vec{p}$, then the angular momentum of the particle about the z axis is

$$\vec{L}_z = \vec{r}_{\text{rad}} \times \vec{p}_{xy} \qquad 10\text{-}15$$

ANGULAR MOMENTUM ABOUT z AXIS

! Do not confuse torque about a point with torque about an axis. The torque of a force about the z axis is the z component of the torque of the force about any point on the z axis.

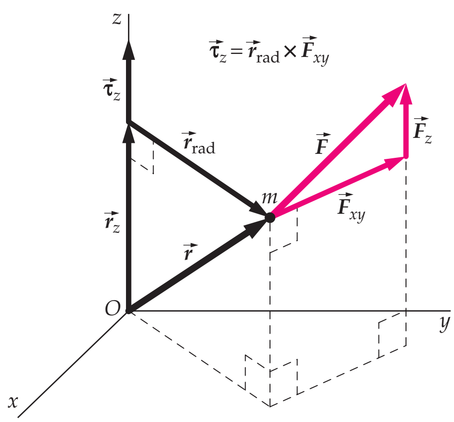

FIGURE 10-18

where $\vec{p}_{xy}$ is the component of the linear momentum $\vec{p}$ perpendicular to the z axis ($\vec{p}_{xy} = \vec{p} - p_z\hat{k}$). Taking the z vector components of both sides of Equation 10-10 gives

$$\vec{\tau}_{\text{net ext } z} = \frac{d\vec{L}_{\text{sys } z}}{dt} \qquad \text{10-16}$$

For a symmetric rigid object rotating about the z axis, $\vec{L}_{\text{sys } z} = I_z\vec{\omega}$, where I_z is the moment of inertia about the z axis. Substituting this into Equation 10-16 gives

$$\vec{\tau}_{\text{net ext } z} = \frac{d\vec{L}_{\text{sys } z}}{dt} = \frac{d}{dt}(I_z\vec{\omega}) = I_z\vec{\alpha} \qquad \text{10-17}$$

where the angular acceleration vector $\vec{\alpha}$ is defined by $\vec{\alpha} = d\vec{\omega}/dt$. (Equation 10-17 is the vector form of Equation 9-18.)

For a system of particles, the total angular momentum about the z axis equals the sum of the angular momenta about the z axis. In addition, the total torque about the z axis is the sum of the external torques about the z axis acting on the system.

(Dick Luria/Science Source/ Photo Researchers.)

Example 10-3 The Atwood's Machine Revisited

An Atwood's machine has two blocks with masses m_1 and m_2 ($m_1 > m_2$) connected by a string of negligible mass that passes over a pulley with frictionless bearings. The pulley is a uniform disk of mass M and radius R. The string does not slip on the pulley. Apply Equation 10-16 to the system consisting of the two blocks, the string, and the pulley, to find the angular acceleration of the pulley and the linear acceleration of the blocks.

PICTURE Let the pulley and blocks be centered in the xy plane with the z axis out of the page and through the center of the pulley at point O, as shown in Figure 10-19. We compute the torques and angular momenta about the z axis and apply Newton's second law for angular motion (Equation 10-10). Because m_1 is greater than m_2, the disk will rotate counterclockwise, which means $\vec{\omega}$ is directed in the $+z$ direction. All the forces are in the xy plane, so all torques are parallel to the z axis. Also, all the velocities are in the xy plane, so all the angular-momentum vectors are also parallel with the z axis. Because the torque, angular velocity, and angular-momentum vectors are all parallel with the z axis, we can treat this as a one-dimensional problem with positive assigned to counterclockwise motion and negative to clockwise motion. The acceleration a of the blocks is related to the angular acceleration α of the pulley by the nonslip condition $a = R\alpha$.

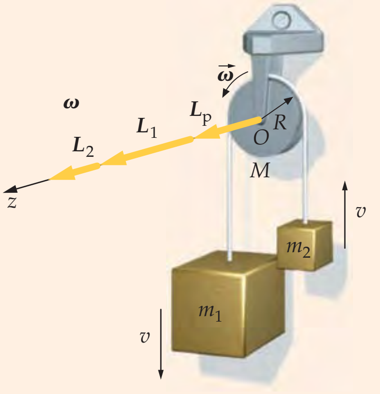

FIGURE 10-19

SOLVE

1. Let the system be everything that moves. Draw a free-body diagram of the system (Figure 10-20). The only thing touching the system is the pulley bearings. The external forces on the system are the normal force of the pulley bearings on the pulley and the gravity forces on the two blocks and the pulley:

2. Express Newton's second law for rotation, z components only (Equation 10-16):
$$\sum \tau_{\text{ext } z} = \frac{dL_z}{dt}$$

3. The total external torque about the z axis is the sum of the torques exerted by the external forces. The moment arms for F_{g1} and F_{g2} each equal R. (The moment arms of F_n and F_{gp} each equal zero.) $F_{g1} = m_1 g$ and $F_{g2} = m_2 g$:
$$\sum \tau_{i\,\text{ext } z} = \tau_n + \tau_{gp} + \tau_{g1} + \tau_{g2}$$
$$= 0 + 0 + m_1 gR - m_2 gR$$

4. The total angular momentum about the z axis equals the angular momentum of the pulley, $\vec{L}_p$, plus the angular momenta of block 1, $\vec{L}_1$, and block 2, $\vec{L}_2$, each in the positive z direction. The pulley has spin angular momentum, but no orbital angular momentum because its center of mass is at rest. Each block has orbital angular momentum, but no spin angular momentum.
$$L_z = L_1 + L_2 + L_p$$
$$= m_1 vR + m_2 vR + I\omega$$

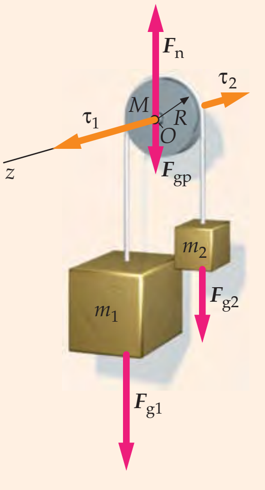

FIGURE 10-20

5. Substitute these results into Newton's second law for rotation in step 2:

$$\sum \tau_{\text{ext}\,z} = \frac{dL_z}{dt}$$

$$m_1gR - m_2gR = \frac{d}{dt}(m_1vR + m_2vR + I\omega)$$

$$m_1gR - m_2gR = (m_1 + m_2)Ra + I\alpha$$

6. Relate I to M and R, and use the nonslip condition to relate α to a and solve for both a and α:

$$m_1gR - m_2gR = (m_1 + m_2)Ra + \tfrac{1}{2}MR^2\frac{a}{R}$$

so $$a = \boxed{\frac{m_1 - m_2}{m_1 + m_2 + \frac{1}{2}M}g}$$

and $$\alpha = \frac{a}{R} = \boxed{\frac{m_1 - m_2}{m_1 + m_2 + \frac{1}{2}M}\frac{g}{R}}$$

CHECK The answers are dimensionally correct. Both the numerators and the denominators contain factors that have the dimensions of mass, so these factors do not contribute to the dimensions of the ratios. For the first answer, a and g have dimension L/T^2, and for the second answer, α and g/R have dimension T^{-2}. Both of these dimensions are what one would expect.

TAKING IT FURTHER (1) This problem could be solved by writing the tensions T_1 on the left and T_2 on the right and using $\tau = I\alpha$ (Equation 10-17) for the pulley and $\Sigma F_y = ma_y$ for each block. However, using angular momentum (Equation 10-16) is easier, and once you have solved for the acceleration, it is straightforward to solve for the two tensions. (2) Because $\vec{L}_2 = \vec{r}_2 \times m_2\vec{v}_2$ (Figure 10-21), the direction of $\vec{L}_2$ is gotten by applying the right-hand rule (Figure 10-6). And because $\vec{\tau}_2 = \vec{r}_2 \times \vec{F}_{g2}$ (Figure 10-21), the direction of $\vec{\tau}_2$ also is gotten by applying the right-hand rule.

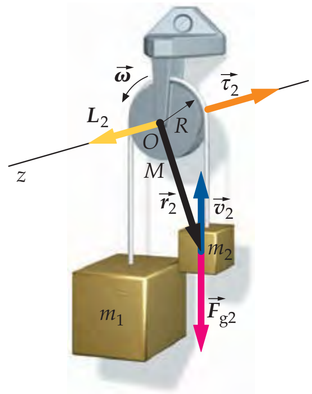

FIGURE 10-21

There are many problems in which the forces, position vectors, and velocities all remain perpendicular to a fixed axis, so the torques, angular velocities, and angular-momentum vectors all remain parallel with an axis of rotation that remains fixed in space. In such cases, we can assign positive and negative values to counterclockwise or clockwise rotations, as we did in Example 10-3, and treat the case like a one-dimensional problem. However, there are other situations, such as the motion of a gyroscope, where torque, angular velocity, and angular momentum must be treated as multidimensional vectors.

THE GYROSCOPE

A *gyroscope* is a common example of an object exhibiting motion in which its axis of rotation changes direction. Figure 10-22 shows a gyroscope consisting of a bicycle wheel that is free to turn on its axle. The axle is pivoted at a point a distance D from the center of the wheel, and the axle is free to rotate about the pivot in any direction. We can give a qualitative understanding of the complex motion of such a system by using Newton's second law for rotation,

$$\vec{\tau}_{\text{net}} = \frac{d\vec{L}}{dt} \qquad (\text{or } \Delta\vec{L} \approx \vec{\tau}_{\text{net}}\,\Delta t) \qquad \text{10-18}$$

along with the relations

$$\vec{\tau}_{\text{net}} = \vec{r}_{\text{cm}} \times M\vec{g}$$

and

$$\vec{L} = I_s\vec{\omega}_s$$

where M is the mass of the wheel-axle system, $\vec{r}_{\text{cm}}$ is the position of the center of mass relative to O, and I_s and ω_s are the moment of inertia and angular velocity of the wheel about its spin axis. (The torque about O on the system that is due to the normal force exerted by the support stand is zero, so the net torque about O is equal to the torque about O that is due to the gravitational force.)

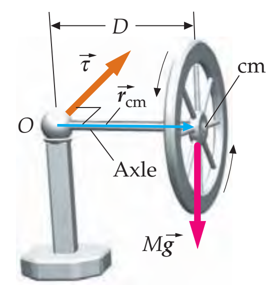

FIGURE 10-22

In accord with Equation 10-18, the *change* in the angular momentum of the system is in the same direction as the net torque acting on the system. We wish to describe the motion of the wheel-axle system after it is released from rest in the horizontal position shown in Figure 10-22, and we will do this first without the wheel spinning, and then with the wheel spinning rapidly. If the wheel *is not* spinning about its axle, Equation 10-18 predicts that upon release the wheel-axle system will simply tip downward, rotating about a horizontal axis that passes through O and is perpendicular to the axle. This prediction is based on the following reasoning. The torque vector is horizontal, perpendicular to the axle, and directed as shown in Figure 10-22. Both the wheel and the axle shaft are initially at rest, so the initial angular momentum $\vec{L}_{\mathrm{i}}$ is zero. Consequently, the change in angular momentum $\Delta\vec{L} = \vec{L}_{\mathrm{f}} - \vec{L}_{\mathrm{i}}$ equals the final angular momentum $\vec{L}_{\mathrm{f}}$, which, according to Equation 10-18, is in the same direction as the torque. The final angular velocity vector $\vec{\omega}_{\mathrm{f}}$ is in the same direction as the final angular-momentum vector $\vec{L}_{\mathrm{f}}$. If you place your right thumb in the direction of $\vec{\omega}_{\mathrm{f}}$, your fingers will curl in the direction of the motion of the wheel-axle system.

If the wheel *is* spinning rapidly about its axle, Equation 10-18 predicts that upon release the wheel-axle system will slowly rotate about a vertical axis through O. This prediction is based on the following reasoning. The torque vector is horizontal, perpendicular to the axle, and directed into the page, just as before. The wheel is spinning clockwise as viewed from O, so the initial angular momentum $\vec{L}_{\mathrm{i}}$ is directed along the axle and away from O. (The direction of $\vec{L}_{\mathrm{i}}$ is obtained from the right-hand rule.) In addition, according to Equation 10-18, $\Delta\vec{L}$ is in the same direction as the net torque, which is initially directed into the page (Figure 10-23*a*). The final angular-momentum vector $\vec{L}_{\mathrm{f}}$ is equal to the initial angular momentum plus the change in angular momentum. That is,

$$\vec{L}_{\mathrm{f}} = \vec{L}_{\mathrm{i}} + \Delta\vec{L}$$

The direction of $\vec{L}_{\mathrm{f}}$ is shown in the vector-addition diagram (Figure 10-23*b*). Because the wheel is spinning rapidly, and because the wheel contains much of the system's mass, the angular momentum of the wheel-axle system is dominated by the spin angular momentum of the wheel, which means that $\vec{L}$ is directed along the axle and away from O. Thus, Equation 10-18 predicts the center of mass of the system will rotate about a vertical axis through O in the direction that keeps the tip of the angular-momentum vector moving horizontally—and in the direction of the torque vector. This motion, which is always surprising when first encountered, is called **precession.** We can calculate the angular speed ω_{p} of precession. In a small time interval dt, the change in the angular momentum has a magnitude dL:

$$dL = \tau\, dt = MgD\, dt$$

where MgD is the magnitude of the torque about the pivot point. From Figure 10-23*b*, the angle $d\phi$ through which the axle moves is

$$d\phi = \frac{dL}{L} = \frac{\tau\, dt}{L} = \frac{MgD\, dt}{L}$$

The angular speed of the precession is thus

$$\omega_{\mathrm{p}} = \frac{d\phi}{dt} = \frac{MgD}{L} = \frac{MgD}{I_{\mathrm{s}}\omega_{\mathrm{s}}} \qquad \text{10-19}$$

If the spin angular speed ω_{s} is very fast, then the precessional angular speed ω_{p} is very slow.

If you release a spinning gyroscope with its spin axis at rest, upon release this axis will initiate precessional motion with an up and down bouncing motion called *nutation.* This initial bouncing motion can be avoided by releasing the gyroscope with the spin axis already rotating with an initial angular velocity exactly equal to ω_{p} (see Equation 10-19).

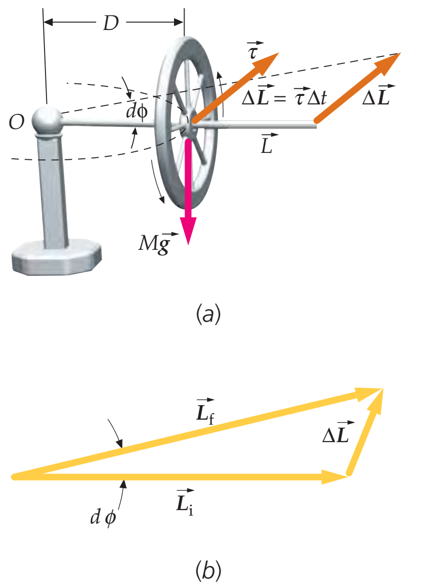

FIGURE 10-23

10-3 CONSERVATION OF ANGULAR MOMENTUM

When the net external torque acting on a system about some point remains zero, we have

$$\vec{\tau}_{\text{net ext}} = \frac{d\vec{L}_{\text{sys}}}{dt} = 0$$

or

$$\vec{L}_{\text{sys}} = \text{constant} \qquad 10\text{-}20$$

Equation 10-20 is a statement of the **law of conservation of angular momentum.**

> If the net external torque acting on a system about some point is zero, the total angular momentum of the system about that point remains constant.
>
> CONSERVATION OF ANGULAR MOMENTUM

This law is the rotational analog of the law of conservation of linear momentum. If a system is isolated from its surroundings, so that there are no external forces or torques acting on it, three quantities are conserved: energy, linear momentum, and angular momentum. The law of conservation of angular momentum is a fundamental law of nature. There are many examples of the conservation of angular momentum in everyday life. Figure 10-24 and Figure 10-25 illustrate angular-momentum conservation in diving and ice skating. Even on the scale of atomic and nuclear physics, where Newtonian mechanics does not hold, the angular momentum of an isolated system is found to be constant over time.

Although conservation of angular momentum is a law, independent of Newton's laws of motion, the fact that the internal torques of a system cancel is suggested by Newton's third law. Consider the two particles shown in Figure 10-26. Let $\vec{F}_{12}$ be the force exerted by particle 1 on particle 2 and $\vec{F}_{21}$ be the force exerted by particle 2 on particle 1. By Newton's third law, $\vec{F}_{21} = -\vec{F}_{12}$. The sum of the torques exerted by these forces about the origin O is

$$\vec{\tau}_1 + \vec{\tau}_2 = \vec{r}_1 \times \vec{F}_{21} + \vec{r}_2 \times \vec{F}_{12} = \vec{r}_1 \times \vec{F}_{21} + \vec{r}_2 \times (-\vec{F}_{21}) = (\vec{r}_1 - \vec{r}_2) \times \vec{F}_{21}$$

The vector $\vec{r}_1 - \vec{r}_2$ is along the line joining the two particles. If $\vec{F}_{21}$ acts parallel to the line joining m_1 and m_2, $\vec{F}_{21}$ and $\vec{r}_1 - \vec{r}_2$ are either parallel or antiparallel and

$$(\vec{r}_1 - \vec{r}_2) \times \vec{F}_{21} = 0$$

If this is true for all the internal forces, the internal torques cancel in pairs.*

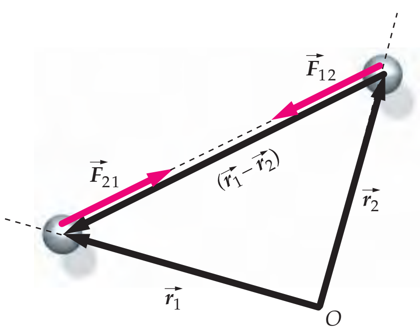

FIGURE 10-26

* Not all forces do come in pairs of equal and opposite forces. For example, the magnetic forces that moving charged particles exert on each other do not.

FIGURE 10-24 Multiflash photograph of a diver. The diver's center of mass moves along a parabolic path after he leaves the board. The angular momentum is provided by the initial external torque due to the force of the board, which does not pass through the diver's center of mass if he leans forward as he jumps. If the diver wanted to undergo one or more somersaults in the air, he would draw in his arms and legs, decreasing his moment of inertia to increase his angular velocity. *(© The Harold E. Edgerton 1992 Trust.)*

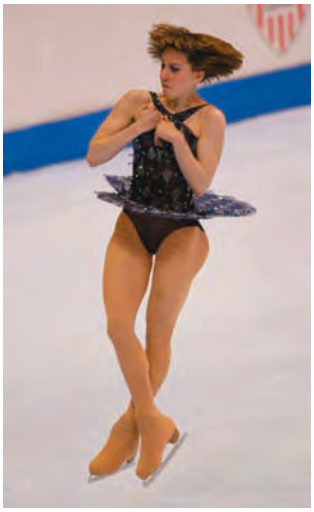

FIGURE 10-25 A spinning skater. Because the torque exerted by the ice is small, the angular momentum of the skater is approximately constant. When she reduces her moment of inertia by drawing in her arms, her angular velocity increases. *(Mike Powell/ Getty.)*

Example 10-4 A Rotating Disk

Disk 1 is rotating freely and has an angular velocity ω_i about a vertical axis that coincides with its symmetry axis, as shown in Figure 10-27. Its moment of inertia about this axis is I_1. It drops onto disk 2, of moment of inertia I_2, that is initially at rest. Disk 2 is centered on the same axis as disk 1 and is free to rotate about that axis. Because of kinetic friction, the two disks eventually attain a common angular velocity ω_f. Find ω_f.

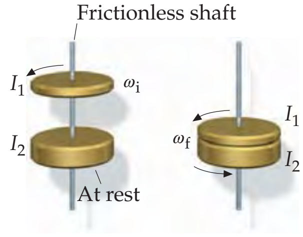

FIGURE 10-27

PICTURE We find the final angular velocity from the final angular momentum, which is equal to the initial angular momentum because there are no external torques acting on the two-disk system. The angular speed of the upper disk is reduced, while that of the lower disk is increased by the forces of kinetic friction. Because the direction of the rotation axis is fixed, the direction of the rotational motion can be specified by a + or − sign. Kinetic friction dissipates mechanical energy, so we expect that the total mechanical energy is decreased.

SOLVE

1. The final angular velocity is related to the initial angular velocity by conservation of angular momentum:

$$L_f = L_i$$
$$(I_1 + I_2)\omega_f = I_1\omega_i$$

2. Solve for the final angular velocity:

$$\omega_f = \boxed{\frac{I_1}{I_1 + I_2}\omega_i = \frac{1}{1 + (I_2/I_1)}\omega_i}$$

CHECK If $I_2 \ll I_1$, the collision should have little effect on the motion of disk 1. Our answer agrees, giving that as $(I_2/I_1) \rightarrow 0$, $\omega_f \rightarrow \omega_i$. (Read "$\rightarrow$" as "approaches".) If $I_2 \gg I_1$, then disk 1 should slow almost to a stop without causing disk 2 to rotate appreciably. Our answer again agrees, giving that as $(I_2/I_1) \rightarrow \infty$, $\omega_f \rightarrow 0$.

TAKING IT FURTHER Plates rotating at differing speeds engage in the drive trains of truck and automobiles. The photo shows such plates in a truck transmission.

The rotating plates in the transmission of a truck make inelastic collisions when engaged. *(Dick Luria/FPG International.)*

In the collision of the two disks in Example 10-4, mechanical energy is dissipated. We can see this by writing the energy in terms of the angular momentum. An object rotating with an angular velocity ω has kinetic energy

$$K = \tfrac{1}{2}I\omega^2 = \frac{(I\omega)^2}{2I}$$

Substituting L for $I\omega$ gives

$$K = \frac{L^2}{2I} \qquad \text{10-21}$$

(This result is analogous with that for linear motion $K = p^2/2m$, Equation 8-25.) The initial kinetic energy in Example 10-4 is

$$K_i = \frac{L_i^2}{2I_1}$$

and the final kinetic energy is

$$K_f = \frac{L_f^2}{2(I_1 + I_2)}$$

Because $L_f = L_i$, the ratio of the final to the initial kinetic energy is

$$\frac{K_f}{K_i} = \frac{I_1}{I_1 + I_2}$$

which is less than one. This interaction of the disks is analogous to a one-dimensional perfectly inelastic collision of two objects.

Example 10-5 Mud in Your Eye *Context-Rich*

You and three of your friends have been bullied for many years by Gene, who has avoided taking physics classes. So you and your three friends who are taking advanced-placement physics decide to teach him a lesson using conservation of angular momentum. Here is your plan. A nearby park has a small merry-go-round (Figure 10-28) with a 3.0-m-diameter turntable that has a 130-kg·m² moment of inertia. You initially get all five of you to stand on the merry-go-round next to the rim while the merry-go-round is rotating at a modest 20 rev/min. When the signal is given, you and your friends will quickly walk to the center of the merry-go-round, leaving Gene near the rim. The merry-go-round will speed up, throwing Gene off and into the mud. (You plan to do this after a heavy rain.) Gene is very quick and very strong, so throwing him off will require that the centripetal acceleration of the rim be at least 4.0 gs. Will this plan work? (Assume that each person has a mass of 60 kg.)

FIGURE 10-28

PICTURE By moving to the center of the merry-go-round, you and your friends are decreasing the moment of inertia of the students–merry-go-round system. No external torques about the axis act on the system (assume effects due to friction and air resistance to be negligible), so the angular momentum about the axis remains constant. The angular momentum is the moment of inertia times the angular velocity, so a decrease in the moment of inertia means an increase in the angular velocity. The angular velocity can be used to find the centripetal acceleration at the rim. Because the direction of the rotation axis is fixed, the direction of the rotational motion can be specified by a + or − sign.

SOLVE

1. The centripetal acceleration depends on the angular speed ω and the radius R:
$$a_c = \omega^2 R$$

2. Angular momentum is conserved. For rotations about a fixed axis, $L = I\omega$:
$$L_f = L_i$$
$$I_f\omega_f = I_i\omega_i$$

3. The moment of inertia of the system is the sum of the moments of inertia of each person plus that of the merry-go-round. Each person has mass $m = 60$ kg:
$$I_i = 5mR^2 + I_{mgr} = 5(60\text{ kg})(1.5\text{ m})^2 + 130\text{ kg}\cdot\text{m}^2 = 805\text{ kg}\cdot\text{m}^2$$

4. To find the final moment of inertia, assume that you and your friends are 30 cm ($\approx$1 ft) from the center:
$$I_f = mR^2 + 4mr^2 + I_{mgr} = (60\text{ kg})(1.5\text{ m})^2 + 4(60\text{ kg})(0.3\text{ m})^2 + 130\text{ kg}\cdot\text{m}^2 = 287\text{ kg}\cdot\text{m}^2$$

5. Using conservation of angular momentum, solve for the final angular velocity:
$$\omega_f = \frac{I_i}{I_f}\omega_i = \frac{805\text{ kg}\cdot\text{m}^2}{287\text{ kg}\cdot\text{m}^2}20\text{ rev/min} = 56.2\text{ rev/min} = 5.88\text{ rad/s}$$

6. Solve for the centripetal acceleration of the rim:
$$a_c = \omega^2 R = (5.88\text{ rad/s})^2(1.5\text{ m}) = 51.9\text{ m/s}^2$$

7. Convert to gs:
$$a_c = 51.9\text{ m/s}^2 \times \frac{1g}{9.81\text{ m/s}^2} = 5.29g = \boxed{5.3g}$$

8. Does Gene end up in the mud?

Success! The acceleration is much greater than 4.0g, so Gene flies off and lands in the mud.

CHECK At the rim of the merry-go-round the four friends are five times farther from the axis than they are after walking to the center. Thus, their contribution to the final moment of inertia of the system is 1/25 of their contribution to the initial moment of inertia. To conserve angular momentum, this large reduction in the moment of inertia will be accompanied by a compensating increase in the angular speed. Our step-5 results show that the angular speed increased from 20 rev/min to 56 rev/min.

TAKING IT FURTHER The linear speed of the rotating merry-go-round is greatest at the rim and decreases to zero at the center. At the rim, everyone is moving in a circle. As the four friends walk toward the center, they are stepping onto a part of the merry-go-round that is moving more slowly than they are, so the frictional force of their feet on the merry-go-round has a component in the tangential direction that speeds up the merry-go-round. Also, the merry-go-round exerts an equal and opposite frictional force on the feet of the four friends, slowing their motion in the tangential direction. The static frictional forces exerted by their feet, result in a net torque on the merry-go-round, increasing its angular momentum about the rotation axis. The equal and opposite static frictional forces on the feet of the friends exert torque in the opposite direction on the friends, so the torques associated with these forces decreases their angular momentum about the axis. The two net torques are equal and opposite, as are the associated angular-momentum changes. Thus, the angular momentum of the students–merry-go-round system remains constant.

The moment of inertia of the students–merry-go-round system decreases as the friends walk toward the center. Thus, the system's moment of inertia decreases while its angular momentum remains constant. As a result, we can see from Equation 10-21 that the kinetic energy of the students–merry-go-round system increases. The energy for this kinetic energy increase comes from the internal energy of the friends. Walking radially inward, like walking up a steep incline, requires the expenditure of internal energy.

Example 10-6 Another Ride on the Merry-go-Round *Try It Yourself*

A 25-kg child in a playground runs with an initial speed of 2.5 m/s along a path *tangent* to the rim of a merry-go-round, whose radius is 2.0 m. The merry-go-round, which is initially at rest, has a moment of inertia of $500\ \mathrm{kg \cdot m^2}$ The child then jumps on (Figure 10-29). Find the final angular velocity of the child and the merry-go-round together.

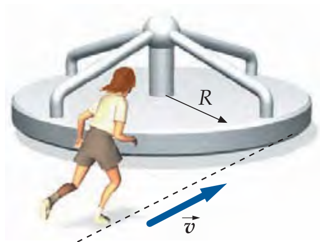

FIGURE 10-29

PICTURE Once the child's feet leave the ground, no external torques about the rotation axis act on the child–merry-go-round system, hence, the total angular momentum of the system about the rotation axis is conserved. The initial angular speed of the merry-go-round is zero. Because the direction of the rotation axis is fixed, the direction of the rotational motion can be specified by a + or − sign.

SOLVE

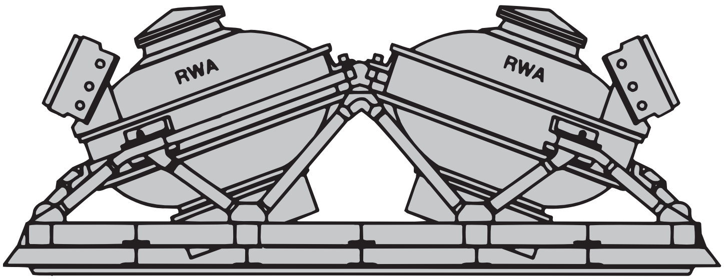
Cover the column at the right and solve it yourself before looking at the answers.

Steps	Answers
1. Write an expression for the initial angular momentum of the child–merry-go-round system. The initial angular momentum of the merry-go-round is zero. The child has mass m and speed v_i in the tangential direction just before making contact with the merry-go-round. Model the child as a point particle.	$L_i = \lvert \vec{r}_{child} \times m\vec{v}_i \rvert = Rmv_i$
2. Write an expression for the total final angular momentum of the child–merry-go-round system in terms of the final angular velocity ω_f.	$L_f = I_{sys}\omega_f = (mR^2 + I_m)\omega_f$
3. Set your expressions in steps 1 and 2 equal and solve for ω_f.	$\omega_f = \dfrac{mvR}{mR^2 + I_m} = \boxed{0.21\ \mathrm{rad/s}}$

CHECK The final speed of the child is $\omega_f R = (0.21\ \mathrm{rad/s})(2.0\ \mathrm{m}) = 0.42\ \mathrm{m/s}$. As expected, this speed is much less then the child's initial speed of 2.5 m/s.

PRACTICE PROBLEM 10-1 Calculate the initial and final kinetic energies of the child–merry-go-round system.

An astronaut examines the reaction wheel of the Hubble Space Telescope. *(NASA/Goddard Space Flight Center.)*



The Hubble Space Telescope is aimed by regulating the spin rates of 45-kg reaction wheels arranged off-axis from each other and spinning at up to 3000 rpm. Software-controlled changes in the spin rates exchange angular momentum between the flywheels and the rest of the satellite. The changes in the angular momentum of the rest of the satellite cause it to slew to different orientations. This aiming mechanism can achieve and hold a target to within 0.005 arcsec, which is equivalent to holding a flashlight beam in Los Angeles on a dime in San Francisco.

Example 10-7 Spinning the Wheel *Conceptual*

You are sitting on a stool on a frictionless turntable holding a bicycle wheel (Figure 10-30). Initially, neither the wheel nor the turntable is spinning. Following instructions from your teacher, you hold the spin axis of the wheel vertical with one hand, and with your other hand you set the wheel spinning counterclockwise (as viewed from above). Surprise! When you start the wheel spinning one way, the turntable, the stool, you, and the axis of the wheel start rotating in the opposite direction. After a few seconds, you use your free hand to brake the spinning motion of the wheel. You are surprised again when you, the stool, and the wheel axis cease rotating as the wheel ceases spinning. Explain.

FIGURE 10-30 As she starts to spin the wheel clockwise, which way does she start to rotate?

PICTURE Because the turntable is frictionless, there are no torques on the student–turntable–stool–wheel system about the axis of the turntable. Thus, the angular momentum of the system about the turntable axis remains constant.

SOLVE

Initially, the entire system is at rest, so its total angular momentum is zero. As it spins up, the wheel acquires an upward-directed spin angular momentum. The total angular momentum of the system must remain zero.

Thus, the orbital angular momentum acquired by the wheel about the turntable axis, plus the angular momentum acquired by you, the stool, and the turntable about the turntable axis, is equal in magnitude to the spin angular momentum of the wheel, but is directed downward. A downward-directed angular momentum means you start rotating clockwise (as viewed from above). As you brake the wheel, its upward-directed spin angular momentum decreases to zero. To keep the total angular momentum of the system equal to zero, the entire system must slow to a stop as the wheel ceases spinning.

CHECK This situation is analogous to that of a person walking on flatbed cart that has frictionless wheel bearings and is on a smooth horizontal track. As the person walks forward, the cart moves backward, but when the person stops walking forward, the cart stops moving backward, as the principle of conservation of linear momentum predicts.

TAKING IT FURTHER The Hubble Space Telescope is aimed at different targets using four wheels mounted on the telescope. The wheels are spun up and spun down by computer-controlled electric motors. As a result the telescope is able to aim at the targets specified in the instructions to the computers.

Example 10-8 Pulling Through a Hole

A particle of mass m moves with speed v_0 in a circle of radius r_0 on a frictionless tabletop. The particle is attached to a string that passes through a hole in the table, as shown in Figure 10-31. The string is slowly pulled downward until the particle is a distance r_f from the hole, after which the particle moves in a circle of radius r_f. (*a*) Find the final velocity in terms of r_0, v_0 and r_f. (*b*) Find the tension when the particle is moving in a circle of radius r in terms of m, r, and the angular momentum $\vec{L}$. (*c*) Calculate the work done on the particle by the tension force $\vec{T}$ by integrating $\vec{T}\cdot d\vec{\ell}$. Express your answer in terms of r and L_0.

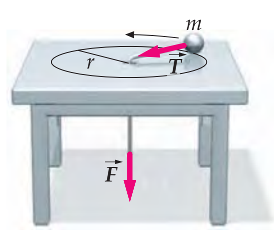


FIGURE 10-31

PICTURE The speed of the particle is related to its angular momentum. The net torque is equal to the rate of change of the angular momentum. Because the net force acting on the particle is the tension force $\vec{T}$ exerted by the string, which is always directed toward the hole, the torque about the vertical axis through the hole is zero. Thus, the angular momentum about this axis remains constant.

SOLVE

(*a*) Conservation of angular momentum relates the final speed to the initial speed and the initial and final radii:

$$L_f = L_0$$
$$mv_f r_f = mv_0 r_0$$
$$\text{so} \quad v_f = \boxed{\frac{r_0}{r_f} v_0}$$

(*b*) 1. Apply Newton's second law to relate T to v and r. Because the particle is being pulled in slowly, the acceleration is virtually the same as if the particle were moving in a circle:

$$T \approx m\frac{v^2}{r}$$

2. Obtain a relation between L, r, and v using the definition of angular momentum. Because the particle is being pulled in slowly, $|\beta| \ll 1$ (Figure 10-32*a*):

$$\vec{L} = \vec{r} \times \vec{p}$$
$$L = rmv\cos\beta \approx rmv \quad (|\beta| \ll 1, \text{so} \cos\beta \approx 1)$$

3. Eliminate v by solving the Part-(*b*) step-2 result for v and then substituting into the Part-(*b*) step-1 result:

$$T = m\frac{v^2}{r} = \frac{m}{r}\left(\frac{L}{mr}\right)^2 = \boxed{\frac{L^2}{mr^3}}$$

(*c*) 1. Make a drawing of the particle as it moves closer to the hole (Figure 10-32*b*). When the particle undergoes displacement $d\vec{\ell}$, its distance r from the axis changes by dr. Because r is decreasing, dr is negative. Thus:

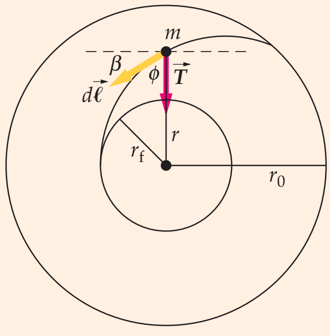
$$dr = -|dr|$$

2. Write $dW = \vec{T}\cdot d\vec{\ell}$ in terms of T and dr:

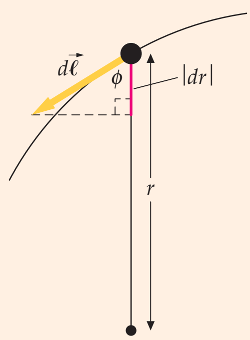
$$dW = \vec{T}\cdot d\vec{\ell} = T\,d\ell\cos\phi$$
$$\text{Because} \quad |dr| = d\ell\cos\phi,$$
$$dW = T|dr| = -T\,dr$$

3. Integrate from r_0 to r_f after substituting for T from the Part-(*b*) step-3 result:

$$W = -\int_{r_0}^{r_f} T\,dr = -\int_{r_0}^{r_f} \frac{L^2}{mr^3}\,dr$$
$$= -\frac{L^2}{m}\int_{r_0}^{r_f} r^{-3}\,dr = -\frac{L^2}{m}\frac{r^{-2}}{-2}\bigg|_{r_0}^{r_f}$$
$$= \boxed{\frac{L^2}{2m}\left(\frac{1}{r_f^2} - \frac{1}{r_0^2}\right)}$$



(*a*)



(*b*)

FIGURE 10-32

CHECK Note that work must be done to pull the string downward. Because r_f is less than r_0, the work is positive. This work is equal to the increase in kinetic energy. We can calculate the change in kinetic energy of the particle directly. Using $K = L^2/2I$, with $L_0 = L_f = L$, and $I = mr^2$, the change in kinetic energy is $K_f - K_i = (L^2/2mr_f^2) - (L^2/2mr_0^2) = (L^2/2m)(r_f^{-2} - r_0^{-2})$, which is the same as the Part-(*c*) step-3 result found by direct integration.

TAKING IT FURTHER The increment of work dW can also be obtained by expressing the increment of displacement $d\vec{\ell}$ as $d\vec{r}$, the change in the position vector $\vec{r}$. The dot product $\vec{T}\cdot d\vec{r}$ is then expanded by using components which give $dW = \vec{T}\cdot d\vec{r} = T_r\,dr = -T\,dr$. In this expansion $T_r = -T$ is the radial component of $\vec{T}$ and dr is the radial component of $d\vec{r}$.

PRACTICE PROBLEM 10-2 At what final radius r_N would the tension be N times the tension at initial radius r_0?

In Figure 10-33 a puck on a frictionless plane is given an initial speed v_0. The puck is attached to a string that wraps around a vertical post. This situation looks similar to Example 10-8, but it is not the same. There is no agent that does work on the puck, nor is there any mechanism for energy dissipation. Thus, mechanical energy must be conserved. Because $K = L^2/(2I)$, where L is the magnitude of the angular momentum about the axis of the post, is constant and I decreases as r_0 decreases, L must also decrease. Note that the tension force does not act toward the axis of the post. The tension force on the puck produces a torque vector $\vec{\tau}$ about the axis of the post in the downward direction, which reduces the puck's angular-momentum vector $\vec{L}$ about the axis, which is in the upward direction.

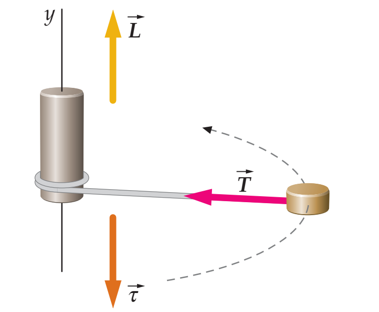


FIGURE 10-33

Example 10-9 The Ballistic Pendulum Revisited

A thin rod of mass M and length d hangs vertically from a pivot attached to one end. A piece of clay of mass m and moving horizontally at speed v hits the rod a distance x from the pivot and sticks to it (Figure 10-34). Find the ratio of the clay–rod system's kinetic energy just after the collision to its kinetic energy just before the collision.

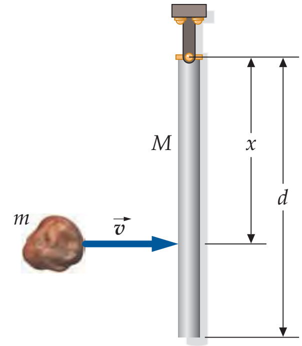

FIGURE 10-34

PICTURE The collision is inelastic, so we do not expect mechanical energy to be constant. During the collision, the pivot exerts a large force on the rod, so the linear momentum of the rod–clay system is not conserved. However, there are no external torques about the horizontal axis perpendicular to the page and through the pivot point, so angular momentum of the system about this axis is conserved. The kinetic energy after the inelastic collision can be written in terms of the angular momentum L_{sys} and the moment of inertia I_f of the combined clay–rod system. Conservation of angular momentum allows you to relate L_{sys} to the mass m and velocity v of the clay. Model the clay as a point particle.

SOLVE

1. Before the collision the kinetic energy of the system is that of the moving clay ball.

$$K_i = \tfrac{1}{2}mv^2$$

2. After the collision it is that of the swinging clay–rod object. Write the kinetic energy after the collision in terms of the angular momentum L_{sys} and the moment of inertia I_f of the clay–rod system.

$$K_f = \frac{L_{sys}^2}{2I_f}$$

3. During the collision, angular momentum is conserved. Write the angular momentum L_{sys} in terms of m, v, and x. Before impact the angular momentum of the rod is zero.

$$L_{sys} = |\vec{r} \times m\vec{v}| = mvx$$

where $\vec{r}$ is the vector from the axis to the clay and $\vec{v}$ is the velocity of the clay before impact.

4. Write I_f in terms of m, x, M, and d.

$$I_f = mx^2 + \tfrac{1}{3}Md^2$$

5. Substitute these expressions for L_{sys} and I_f into your equation for K_f.

$$K_f = \frac{L_{sys}^2}{2I_f} = \frac{(mvx)^2}{2(mx^2 + \frac{1}{3}Md^2)}$$

$$= \frac{3}{2}\frac{m^2x^2v^2}{(3mx^2 + Md^2)}$$

6. Divide the kinetic energy after the collision by the initial kinetic energy.

$$\frac{K_f}{K_i} = \frac{\frac{3}{2}\frac{m^2x^2v^2}{(3mx^2 + Md^2)}}{\frac{1}{2}mv^2} = \boxed{\frac{1}{1 + \dfrac{Md^2}{3mx^2}}}$$

CHECK Md^2 and mx^2 obviously have the same dimensions, so the step-6 result has no dimensions, as is expected for a ratio of two energies. In addition, the ratio K_f/K_i is between zero and one, as expected for an inelastic collision. In the limit that $M/m \to \infty$, $K_f/K_i \to 0$, and in the limit that $M/m \to 0$, $K_f/K_i \to 1$. Both of these limiting values of K_f/K_i meet expectations.

TAKING IT FURTHER This example is the rotational analog of the ballistic pendulum discussed in Example 8-10. In that example, we used conservation of linear momentum to determine the kinetic energy of the pendulum after the collision.

Example 10-10 Tipping the Wheel

Conceptual

A student sitting on a stool that rests on a turntable with frictionless bearings (Figure 10-35*a*) is holding a rapidly spinning bicycle wheel. The rotation axis of the wheel is initially horizontal, and the magnitude of the spin-angular-momentum vector of the spinning wheel is $L_{\text{wheel i}}$. What will happen if the student suddenly tips the axle of the wheel (Figure 10-35*b*) so that after the rotation the spin axis of the wheel is vertical and the wheel is spinning counterclockwise (when viewed from above)?

PICTURE The turntable–stool–student–wheel system is free to rotate about a vertical axis through the center of the turntable. Because the turntable is frictionless, there can be no external torques about this axis. Thus, the angular momentum of the system about this axis remains constant.

SOLVE

Rotating the axle changes the direction, but not the magnitude, of the spin angular momentum of the wheel. The final spin angular momentum of the wheel is directed upward. The initial angular momentum of the turntable–stool–student–wheel system about the vertical axis of the turntable is zero. Thus, the final angular momentum of the system about the same vertical axis is also zero. Following the rotation of the axle, the spin angular momentum of the wheel is counterclockwise (when viewed from above) and equal in magnitude to $L_{\text{wheel i}}$. Conservation of angular momentum dictates that the remaining angular momentum of the system about the vertical axis of the turntable must be clockwise, and equal in magnitude to $L_{\text{wheel i}}$.

The turntable, stool, and student will be rotating clockwise with an angular momentum about the vertical axis of the turntable of magnitude $L_{\text{wheel i}}$.

CHECK The student exerts an upward torque on the spinning wheel when she tips it upward. (Due to the vector product definition of torque, an upward torque requires horizontal forces.) The wheel exerts an equal and opposite torque (also horizontal forces) on the student, causing her to rotate clockwise.

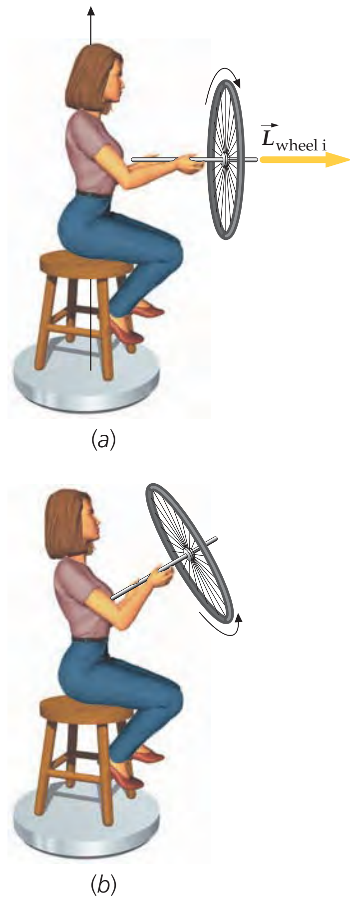

FIGURE 10-35

CONCEPT CHECK 10-1

The bicycle wheel is spinning counterclockwise (if viewed from above) with its spin axis vertical when it is handed to the student who is on the non-rotating turntable. In what direction will the turntable rotate as the student rotates the axis of the wheel toward the horizontal?

PROOFS OF EQUATIONS 10-10, 10-12, 10-13, 10-14, AND 10-15

Proof of Equation 10-10 We now show that Newton's second law implies that the rate of change of the angular momentum of a point particle equals the net torque acting on the particle. If more than one force acts on a particle, then the net torque relative to the origin O is the sum of the torques due to each force:

$$\vec{\tau}_{\text{net}} = \vec{r} \times \vec{F}_1 + \vec{r} \times \vec{F}_2 + \cdots = \vec{r} \times \sum_i \vec{F}_i = \vec{r} \times \vec{F}_{\text{net}}$$

According to Newton's second law, the net force on a particle equals the rate of change of the particle's linear momentum $d\vec{p}/dt$. Thus

$$\vec{\tau}_{\text{net}} = \vec{r} \times \vec{F}_{\text{net}} = \vec{r} \times \frac{d\vec{p}}{dt} \qquad \text{10-22}$$

We now compare this expression with the expression for the time rate of change of the particle's angular momentum. The definition of the angular momentum of a particle (Equation 10-8) is

$$\vec{L} = \vec{r} \times \vec{p}$$

We can compute $d\vec{L}/dt$ using the product rule for derivatives:

$$\frac{d\vec{L}}{dt} = \frac{d}{dt}(\vec{r} \times \vec{p}) = \left(\frac{d\vec{r}}{dt} \times \vec{p}\right) + \left(\vec{r} \times \frac{d\vec{p}}{dt}\right)$$

The second term from the right is zero because $\vec{p} = m\vec{v}$ and $\vec{v} = d\vec{r}/dt$, so

$$\frac{d\vec{r}}{dt} \times \vec{p} = \vec{v} \times m\vec{v} = 0$$

because the vector product of two vectors in the same direction is zero. Thus

$$\frac{d\vec{L}}{dt} = \vec{r} \times \frac{d\vec{p}}{dt}$$

Substituting $\vec{\tau}_{\text{net}}$ for $\vec{r} \times (d\vec{p}/dt)$ (from Equation 10-22) gives

$$\vec{\tau}_{\text{net}} = \frac{d\vec{L}}{dt} \qquad \text{10-23}$$

The net torque acting on a system of particles is the sum of the net torques on the individual particles. The generalization of Equation 10-23 to a system of particles is then

$$\vec{\tau}_{\text{net sys}} = \sum_i \vec{\tau}_{\text{net}\,i} = \sum_i \frac{d\vec{L}_i}{dt} = \frac{d}{dt}\sum_i \vec{L}_i = \frac{d\vec{L}_{\text{sys}}}{dt}$$

In this equation, the sum of the torques may include internal as well as external torques. The sum of the internal torques equals zero, so

$$\vec{\tau}_{\text{net ext}} = \frac{d\vec{L}_{\text{sys}}}{dt} \qquad \text{10-10}$$

NEWTON'S SECOND LAW FOR ANGULAR MOTION

Proofs of Equations 10-12 and 10-13 We now show that the angular momentum of a system of particles can be written as the sum of the orbital angular momentum and the spin angular momentum.

Figure 10-36 shows a system of particles. The angular momentum $\vec{L}_i$ of the ith particle about arbitrary point O is given by

$$\vec{L}_i = \vec{r}_i \times \vec{p}_i = \vec{r}_i \times m_i\vec{v}_i \qquad \text{10-24}$$

and the angular momentum of the system about O is

$$\vec{L} = \Sigma \vec{L}_i = \Sigma(\vec{r}_i \times m_i\vec{v}_i)$$

The angular momentum about the center of mass is given by

$$\vec{L}_{\text{cm}} = \Sigma(\vec{r}_i' \times m_i\vec{u}_i)$$

where $\vec{r}_i'$ and $\vec{u}_i$ are the position and velocity, respectively, of the ith particle relative to the center of mass. It can be seen from the figure that

$$\vec{r}_i = \vec{r}_{\text{cm}} + \vec{r}_i'$$

Differentiating both sides gives

$$\vec{v}_i = \vec{v}_{\text{cm}} + \vec{u}_i$$

Substituting these into Equation 10-24, we have

$$\vec{L}_i = \vec{r}_i \times m_i\vec{v}_i = (\vec{r}_{\text{cm}} \times \vec{r}_i') \times m_i(\vec{v}_{\text{cm}} + \vec{u}_i)$$

Expanding the right side, we obtain

$$\vec{L}_i = (\vec{r}_{\text{cm}} \times m_i\vec{v}_{\text{cm}}) + (\vec{r}_{\text{cm}} \times m_i\vec{u}_i) + (m_i\vec{r}_i' \times \vec{v}_{\text{cm}}) + (\vec{r}_i' \times m_i\vec{u}_i)$$

Summing both sides and factoring common terms out of the sums gives

$$\vec{L}_{\text{sys}} = \Sigma\vec{L}_i = \vec{r}_{\text{cm}} \times (\Sigma m_i)\vec{v}_{\text{cm}} + \vec{r}_{\text{cm}} \times (\Sigma m_i\vec{u}_i) + (\Sigma m_i\vec{r}_i') \times \vec{v}_{\text{cm}} + \Sigma(\vec{r}_i' \times m_i\vec{u}_i)$$

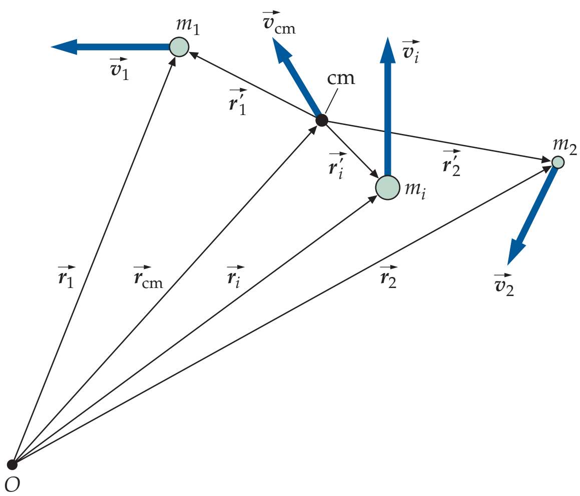

FIGURE 10-36

Because $\Sigma m_i\vec{r}_i'$ and $\Sigma m_i\vec{u}_i$ are both zero, and because $\Sigma m_i = M$ and $\Sigma(\vec{r}_i' \times m_i\vec{u}_i) = \vec{L}_{\rm cm}$, we have $\vec{L}_{\rm sys} = \vec{r}_{\rm cm} \times M\vec{v}_{\rm cm} + \vec{L}_{\rm cm}$ or

$$\vec{L}_{\rm sys} = \vec{L}_{\rm orbit} + \vec{L}_{\rm spin} \qquad \text{10-12}$$

where $\vec{L}_{\rm orbit} = \vec{v}_{\rm cm} \times M\vec{v}_{\rm cm}$ and

$$\vec{L}_{\rm spin} = \vec{L}_{\rm cm} = \Sigma(\vec{r}_i' \times m_i\vec{u}_i) \qquad \text{10-25}$$

DEFINITION: SPIN ANGULAR MOMENTUM

Proofs of Equations 10-14 and 10-15 We now take the z components of the vectors for the torque and the angular momentum about a point to obtain the formulas for the torque and angular momentum about a fixed axis. The angular momentum of a particle about the origin is $\vec{L} = \vec{r} \times \vec{p}$, so finding the z component of the angular momentum means finding the z component of the product $\vec{r} \times \vec{p}$. To do this, we express $\vec{r}$ and $\vec{p}$ as

$$\vec{r} = \vec{r}_{\rm rad} + \vec{r}_z \quad \text{and} \quad \vec{p} = \vec{p}_{xy} + \vec{p}_z$$

where $\vec{r}_{\rm rad}$, $\vec{r}_z$, $\vec{p}_{xy}$, and $\vec{p}_z$ are vector components (Figure 10-37) of $\vec{r}$ and $\vec{p}$.

Substituting for $\vec{r}$ and $\vec{p}$ gives

$$\vec{L} = \vec{r} \times \vec{p} = (\vec{r}_{\rm rad} + \vec{r}_z) \times (\vec{p}_{xy} \times \vec{p}_z)$$

and expanding the right side, we have

$$\vec{L} = (\vec{r}_{\rm rad} \times \vec{p}_{xy}) + (\vec{r}_{\rm rad} \times \vec{p}_z) + (\vec{r}_z \times \vec{p}_{xy}) + (\vec{r}_z \times \vec{p}_z)$$

The vector product of any two vectors is perpendicular to both vectors, so the product $\vec{r}_{\rm rad} \times \vec{p}_{xy}$ is parallel to the z axis. In each of the other three products at least one of the two vectors is parallel to the z axis, so the z component of each of these vector products is zero. Therefore,

$$\vec{L}_z = \vec{r}_{\rm rad} \times \vec{p}_{xy} \qquad \text{10-14}$$

ANGULAR MOMENTUM ABOUT z AXIS

The torque about the origin associated with a force acting on the particle is given by $\vec{\tau} = \vec{r} \times \vec{F}$ (Equation 10-1). Following the same procedure with the torque that we followed with the angular momentum gives

$$\vec{\tau}_z = \vec{r}_{\rm rad} \times \vec{F}_{xy} \qquad \text{10-15}$$

TORQUE ABOUT z AXIS

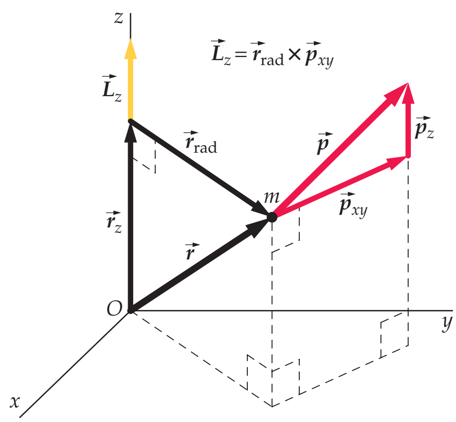

FIGURE 10-37 The vector components $\vec{r}_{\rm rad}$, $\vec{r}_z$, $\vec{p}_{xy}$, and $\vec{p}_z$ of $\vec{r}$ and $\vec{p}$ that are used for calculating the angular momentum about the z axis $\vec{L}_z$.

* 10-4 QUANTIZATION OF ANGULAR MOMENTUM

Angular momentum plays an important role in the description of atoms, molecules, nuclei, and elementary particles. If a particle is bound to one or more other particles, the particle is said to be a *bound particle.* The planets, the asteroids, the comets, and the Sun make up a *bound system,* called the solar system, and Earth is bound to the solar system. Like energy, the angular momentum of bound systems is **quantized,** that is, changes in angular momentum occur only in discrete amounts.

The angular momentum of a particle due to its orbital motion is its orbital angular momentum. The magnitude of the orbital angular momentum L of a bound particle can have only the values

$$L = \sqrt{\ell(\ell + 1)}\,\hbar \qquad \ell = 0, 1, 2, \ldots \tag{10-26}$$

where $\hbar$ (read "h-bar") is the **fundamental unit of angular momentum,** which is related to Planck's constant h:

$$\hbar = \frac{h}{2\pi} = 1.05 \times 10^{-34}\,\text{J}\cdot\text{s} \tag{10-27}$$

The component of orbital angular momentum along any direction in space is also quantized and can have only the values $\pm m\hbar$, where m is a nonnegative integer that is less than or equal to ℓ. For example, if $\ell = 2$, m can equal 2, 1, or 0.

Because the quantum of angular momentum $\hbar$ is so small, the quantization of angular momentum is not noticed in the macroscopic world. Consider a particle of mass $1.00\text{ g} = 1.00 \times 10^{-3}\text{ kg}$ moving in a circle of radius 1.00 cm with a period of 1.00 s. Its orbital angular momentum is

$$L = mvr = mr^2\omega = mr^2\frac{2\pi}{T} = (1.00 \times 10^{-3}\,\text{kg})(1.00 \times 10^{-2}\,\text{m})^2\frac{2\pi}{1.00\,\text{s}}$$
$$= 6.28 \times 10^{-7}\,\text{J}\cdot\text{s}$$

If we divide by $\hbar$, we obtain

$$\frac{L}{\hbar} = \frac{6.28 \times 10^{-7}\,\text{J}\cdot\text{s}}{1.05 \times 10^{-34}\,\text{J}\cdot\text{s}} = 6.00 \times 10^{27}$$

Thus, this typical macroscopic angular momentum contains 6.00×10^{27} units of the fundamental unit of angular momentum. Even if we could measure L to one part in a billion, we would never observe the quantization of this macroscopic angular-momentum value.

The quantization of orbital angular momentum leads to the quantization of rotational kinetic energy. Consider a molecule rotating about its center of mass with angular momentum L (Figure 10-38). Let I be its moment of inertia. Its kinetic energy is

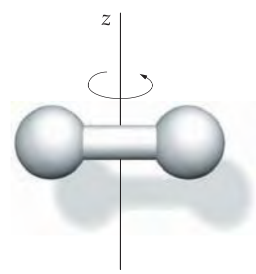

FIGURE 10-38 Model of a rigid diatomic molecule rotating about the z axis.

$$K = \frac{L^2}{2I} \tag{10-28}$$

But L^2 is quantized to the values $L^2 = \ell(\ell + 1)\hbar^2$, with $\ell = 0, 1, 2, \ldots$. Thus, the kinetic energy is quantized to the values K_ℓ given by

$$K_\ell = \frac{L^2}{2I} = \frac{\ell(\ell + 1)\hbar^2}{2I} = \ell(\ell + 1)E_{0r} \tag{10-29a}$$

where

$$E_{0r} = \frac{\hbar^2}{2I} \tag{10-29b}$$

Figure 10-39 shows an energy-level diagram for a rotating molecule with constant moment of inertia I. Note that, unlike the energy levels for a vibrating system (Section 7-4), the rotational energy levels are not equally spaced, and the lowest level is zero.

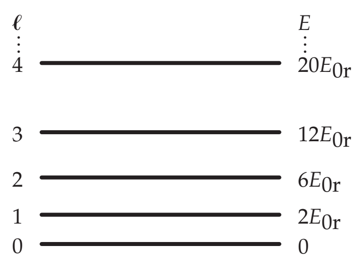

FIGURE 10-39 Energy-level diagram for a rotating molecule.

Example 10-11 Rotational Energy Levels

The characteristic rotational energy E_{0r} (Equation 10-29*b*) for the rotation of the N_2 molecule is 2.48×10^{-4} eV. Using this information, find the separation distance of the two nitrogen atoms.

PICTURE The characteristic rotational energy depends on the moment of inertia, and the moment of inertia depends on the separation distance.

SOLVE

1. The characteristic rotational energy is related to the moment of inertia (see Equation 10-29*b*):

$$E_{0r} = \frac{\hbar^2}{2I}$$

2. Model each nitrogen atom as a point mass at the center of its nucleus. The N_2 molecule then is modeled as two point masses rotating about the center of mass of the molecule. Calculate the moment of inertia about the axis through the center of mass and perpendicular to the line joining the molecules:

$$I = m_1 r_1^2 + m_2 r_2^2$$

3. The distance of each molecule from the center of mass is half of the separation distance d:

$$r_1 = r_2 = \frac{d}{2} \quad \text{and} \quad m_1 = m_2 = m$$

4. Calculate the moment of inertial in terms of d and m:

$$I = m\frac{d^2}{4} + m\frac{d^2}{4} = \frac{1}{2}md^2$$

5. Substitute for I in the step-1 result. The mass of a nitrogen atom is 14.00 u. (Atomic masses can be found in Appendix C):

$$E_{0r} = \frac{\hbar^2}{2I} = \frac{\hbar^2}{md^2}$$

where $m = (14.00\text{ u})(1.661 \times 10^{-27}\text{ kg/u}) = 2.325 \times 10^{-26}\text{ kg}$

and $E_{0r} = (2.48 \times 10^{-4}\text{ eV})(1.602 \times 10^{-19}\text{ J/eV}) = 3.973 \times 10^{-23}\text{ J}$

6. Solve for d:

$$d = \frac{\hbar}{\sqrt{mE_{0r}}} = \frac{1.055 \times 10^{-34}\text{ J}\cdot\text{s}}{\sqrt{(2.325 \times 10^{-26}\text{ kg})(3.973 \times 10^{-23}\text{ J})}}$$

$$= 1.097 \times 10^{-10}\text{ m} = \boxed{0.110\text{ nm}}$$

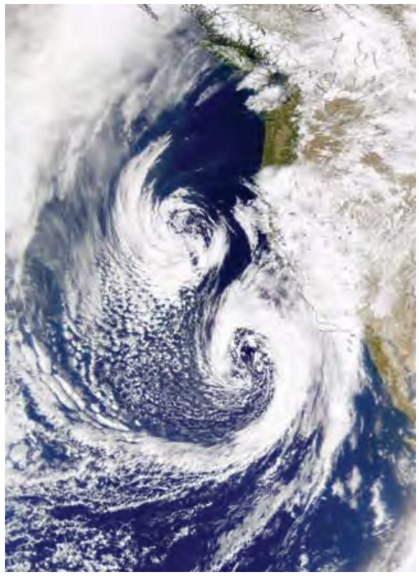
CHECK In 1911, the British physicist Ernest Rutherford (1871–1935) found the diameter of a nucleus to be $\sim 10^{-6}$ nm, and the diameter of an atom to be typically ~ 0.1 nm, which is approximately the same as our step-6 result. Is it plausible that the separation distance between atoms in N_2 is about equal to the diameter of an isolated atom? Yes. In a nitrogen molecule, the valence electrons are shared by the two atoms. This process, called covalent bonding, is discussed further in Chapter 37.

Stable matter contains just three kinds of particles: electrons, protons, and neutrons. In addition to orbital angular momentum, each of these particles also has an intrinsic angular momentum called **spin.** The spin angular momentum of a particle, like its mass and electric charge, is a fundamental property of the particle that cannot be changed. The magnitude of the spin angular-momentum vector for electrons, protons, and neutrons is $s = \sqrt{\frac{1}{2}(\frac{1}{2} + 1)}\,\hbar$, and the component of the spin angular momentum along any direction in space can have just two values: $+\frac{1}{2}\hbar$ and $-\frac{1}{2}\hbar$. Particles with the same spin angular momentum as electrons are called "spin-one-half" particles. Spin-one-half particles are called **fermions.** Other particles, called **bosons,** have zero spin or integral spin. (Photons and α particles are examples of bosons.) Curiously, spin is a quantum property of the particle that has nothing to do with the motion of the particle.

The picture of an electron as a spinning ball that orbits the nucleus in an atom (like the spinning Earth orbiting the Sun) is often a useful visualization. However, the angular momentum of a spinning ball can be increased or decreased, whereas the spin of the electron is a fixed property like its charge and mass. Furthermore, as far as we know, electrons are point particles that have no size. In addition, electrons do not orbit the nucleus as the planets orbit the Sun. The quantum mechanical model of an atom allows us to calculate the probability that an electron will be found in some specified volume of space.

Physics Spotlight

As the World Turns: Atmospheric Angular Momentum



Cloud patterns suggest two adjacent low pressure cells. *(SeaWiFS Project, NASA/Goddard Space Flight Center, and ORBIMAGE.)*

Air has measurable density, which varies both with the available moisture and the altitude within the atmosphere. Air also has measurable speed. Most surface winds are local, but masses of air higher in the atmosphere have measurable global circulation.

Over the years, increased computing power[*] has allowed scientists to calculate the total atmospheric angular momentum (AAM) for Earth. These calculations are available at the Special Bureau for the Atmosphere of the Global Geophysical Fluids Center.[†] They are based on measurements from meteorological services of several countries. Most measurements made between 10 and 50 kilometers high, in the upper *troposphere* and the *stratosphere,* are made with the help of weather balloons. AAM is calculated using the magnitude and direction of winds at various heights—wind vectors—and AAM Units, where $1\ \text{AAM Unit} = 10^{25}\ \text{kg} \cdot \text{m}^2/\text{s}$.[‡]

In the past few decades, the length of day (LOD) for Earth also has been measured to great precision,[#] calculated by astronomical measurements, and reckoned in solar time corrected for polar wobbling (UT1). The measurements use a combination of satellite laser ranging, very-long-baseline interferometry, recent data from GPS, and the Doppler Orbitography and Radio Positioning Integrated by Satellite (DORIS) system. Variations in LOD of tenths of a millisecond are routinely reported. That value is less than one part in a hundred million.

When variations in the LOD and the AAM are compared, they have striking similarity.[°] Both AAM and LOD have weekly, monthly, seasonal, yearly, and multiyear variations.[§] What is more, they correlate with each other to 95.4 percent and 98.02 percent,[¶] depending on the model for AAM. These correlations are not accidental. The spin angular momentum of the entire Earth–atmosphere system is conserved. Both Earth's spin angular momentum and AAM are in the same direction—from west to east. This means that when AAM speeds up, the angular momentum of Earth itself (excluding the atmosphere) slows down, and LOD increases.

The strongest confirmation of this result is El Niño weather patterns.[**] During El Niños, the southern Pacific Ocean warms and subtropical westerly winds speed up, while tropical easterly winds slow down. These wind patterns increase AAM. In 1984,[††] measurements at Goddard Space Flight Center showed that the day had lengthened by over a millisecond during El Niño. In 1997, the day grew by four-tenths of a millisecond[‡‡] during the El Niño event. When the AAM decreases, Earth speeds up, and days shorten. AAM is the strongest cause of variation in LOD for Earth. Other causes include solar flares, volcanic eruptions, and even core–mantle friction.[##]

Because precise measurements of Earth's AAM and LOD can be made, predictions about what changes in Earth's atmosphere, such as an increase in carbon dioxide,[°°] will mean for the angular momentum of the atmosphere can be made as well as studies of AAM of other planets.[§§]

Summary

1. Angular momentum is an important derived dynamic quantity in macroscopic physics. In microscopic physics, spin angular momentum is an intrinsic, fundamental property of elementary particles.
2. Conservation of angular momentum is a fundamental law of nature.
3. Quantization of angular momentum is a fundamental law of nature.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Vector Nature of Rotation	Right-hand rules are used to obtain the direction of the angular velocity and the torque.	
Angular velocity $\vec{\omega}$	The direction of the angular velocity $\vec{\omega}$ is along the axis of rotation in the direction given by the right-hand rule.	
Torque $\vec{\tau}$	$\vec{\tau} = \vec{r} \times \vec{F}$	10-1
2. Vector Product	$\vec{A} \times \vec{B} = AB\sin\phi\,\hat{n}$	10-2
	where ϕ is the angle between the vectors and $\hat{n}$ is a unit vector perpendicular to the plane of $\vec{A}$ and $\vec{B}$ in the direction given by the right-hand rule as $\vec{A}$ is rotated into $\vec{B}$.	
Properties	$\vec{A} \times \vec{A} = 0$	10-3
	$\vec{A} \times \vec{B} = -\vec{B} \times \vec{A}$	10-4
	$\frac{d}{dt}(\vec{A} \times \vec{B}) = \left(\vec{A} \times \frac{d\vec{B}}{dt}\right) + \left(\frac{d\vec{A}}{dt} \times \vec{B}\right)$	10-6
	$\hat{i} \times \hat{j} = \hat{k},\quad \hat{j} \times \hat{k} = \hat{i},\quad \text{and}\quad \hat{k} \times \hat{i} = \hat{j}$	10-7*a*
	$\hat{i} \times \hat{i} = \hat{j} \times \hat{j} = \hat{k} \times \hat{k} = 0$	10-7*b*
3. Angular Momentum		
For a point particle	$\vec{L} = \vec{r} \times \vec{p}$	10-8
For a system rotating about a symmetry axis	$\vec{L} = I\vec{\omega}$	10-9
For any system	The angular momentum about any point O is the angular momentum about the center of mass (spin angular momentum) plus the angular momentum associated with center-of-mass motion about O (orbital angular momentum). $\vec{L} = \vec{L}_{\text{orbit}} + \vec{L}_{\text{spin}} = \vec{r}_{\text{cm}} \times M\vec{v}_{\text{cm}} + \sum_i (\vec{r}_i' \times m_i\vec{u}_i)$	10-12
Newton's second law for angular motion	$\vec{\tau}_{\text{net ext}} = \frac{d\vec{L}}{dt}$	10-10
Conservation of angular momentum	If the net external torque remains zero, the angular momentum of the system is conserved. (If the component of the net external torque in a given direction remains zero, the component of the angular momentum of the system in that direction remains conserved.)	
Kinetic energy of an object rotating about a fixed axis	$K = \frac{1}{2}I\omega^2 = \frac{L^2}{2I}$	10-21
Quantization of angular momentum	The magnitude of the orbital angular momentum of a bound particle can have only the values $L = \sqrt{\ell(\ell+1)}\,\hbar \qquad \ell = 0, 1, 2, \ldots$	
*Quantization of any component of orbital angular momentum	The component of orbital angular momentum of a bound particle along any direction in space is also quantized and can have only the values $\pm m\hbar$, where m is a nonnegative integer that is less than or equal to ℓ.	
Spin	Electrons, protons, and neutrons have an intrinsic angular momentum called spin.	

Answers to Concept Check

Answers to Practice Problems

10-1 $K_i = 78.2\ \text{J}$, $K_f = 13.0\ \text{J}$

10-2 $r_N = r_0/\sqrt[3]{N}$

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimates.

For all problems, use 9.81 m/s^2 for the free-fall acceleration and neglect friction and air resistance unless instructed to do otherwise.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • True or false:
(*a*) If two vectors are exactly opposite in direction, their vector product must be zero.
(*b*) The magnitude of the vector product of two vectors is at a minimum when the vectors are perpendicular.
(*c*) Knowing the magnitude of the vector product of two nonzero vectors and the vectors' individual magnitudes uniquely determines the angle between them.

2 • Consider two nonzero vectors $\vec{A}$ and $\vec{B}$. Their vector product has the greatest magnitude if $\vec{A}$ and $\vec{B}$ are (*a*) parallel, (*b*) perpendicular, (*c*) antiparallel, (*d*) at an angle of 45° to each other.

3 • What is the angle between a force vector $\vec{F}$ and a torque vector $\vec{\tau}$ generated by $\vec{F}$?

4 • A point particle of mass m is moving with a constant speed v along a straight line that passes through point P. What can you say about the angular momentum of the particle relative to point P? (*a*) Its magnitude is mv. (*b*) Its magnitude is zero. (*c*) Its magnitude changes sign as the particle passes through point P. (*d*) Its magnitude increases as the particle approaches point P.

5 • A particle travels in a circular path, and point P is at the center of the circle. (*a*) If the particle's linear momentum $\vec{p}$ is doubled without changing the radius of the circle, how is the magnitude of its angular momentum about P affected? (*b*) If the radius of the circle is doubled but the speed of the particle is unchanged, how is the magnitude of its angular momentum about P affected? SSM

6 • A particle moves along a straight line at constant speed. How does the particle's angular momentum about any fixed point vary with time?

7 •• True or false: If the net torque on a rotating object is zero, the angular velocity of the object cannot change. If your answer is false, give an example of such a situation.

8 •• You are standing on the edge of a turntable with frictionless bearings that is initially rotating when you catch a ball that is moving in the same direction but faster than you are moving and on a line tangent to the edge of the turntable. Assume you do not move relative to the turntable. (*a*) Does the angular speed of the turntable increase, decrease, or remain the same during the catch? (*b*) Does the magnitude of your angular momentum (about the rotation axis of the table) increase, decrease, or remain the same during the catch? (*c*) How does the ball's angular momentum (about the rotation axis of the table) change after the catch? (*d*) How does the total angular momentum of the system, you–table–ball (above the rotation axis of the turntable), change after the catch?

9 •• If the angular momentum of a system about a fixed point P is constant, which one of the following statements must be true?
(*a*) No torque about P acts on any part of the system.
(*b*) A constant torque about P acts on each part of the system.
(*c*) Zero net torque about P acts on each part of the system.
(*d*) A constant external torque about P acts on the system.
(*e*) Zero net external torque about P acts on the system.

10 •• A block sliding on a frictionless table is attached to a string that passes through a narrow hole through the tabletop. Initially, the block is sliding with speed v_0 in a circle of radius r_0. A student under the table pulls slowly on the string. What happens as the block spirals inward? Give supporting arguments for your choice. (The term "angular momentum" refers to the angular momentum about a vertical axis through the hole.) (*a*) Its energy and angular momentum are conserved. (*b*) Its angular momentum is conserved and its energy increases. (*c*) Its angular momentum is conserved and its energy decreases. (*d*) Its energy is conserved and its angular momentum increases. (*e*) Its energy is conserved and its angular momentum decreases.

11 •• One way to tell if an egg is hardboiled or uncooked without breaking the egg is to lay the egg flat on a hard surface and try to spin it. A hardboiled egg will spin easily, an uncooked egg will not. However, once spinning, the uncooked egg may do something unusual: If you stop it with your finger, it may start spinning again. Explain the difference in the behavior of the two types of eggs. SSM

12 •• Explain why a helicopter with just one main rotor has a second smaller rotor mounted on a horizontal axis at the rear, as in Figure 10-40. Describe the resultant motion of the helicopter if this rear rotor fails during flight.

FIGURE 10-40 Problem 12
(Chris Sorenson/The Stock Market.)

13 •• The spin angular-momentum vector for a spinning wheel is parallel with its axle and is pointed east. To cause this vector to rotate toward the south, in which direction must a force be exerted on the east end of the axle? (*a*) up, (*b*) down, (*c*) north, (*d*) south, (*e*) east.

14 •• **CONTEXT-RICH** You are walking toward the north, and in your left hand you are carrying a suitcase that contains a massive spinning wheel mounted on an axle attached to the front and back of the case. The angular velocity of the gyroscope points north. You now begin to turn to walk toward the east. As a result, the front end of the suitcase will (*a*) resist your attempt to turn it and will try to maintain its original orientation, (*b*) resist your attempt to turn and will pull to the west, (*c*) rise upward, (*d*) dip downward, (*e*) show no effect whatsoever.

15 •• **ENGINEERING APPLICATION** The angular momentum of the propeller of a small single-engine airplane points forward. The propeller rotates clockwise if viewed from behind. (*a*) Just after liftoff, as the nose of the plane tilts upward, the airplane tends to veer to one side. To which side does it tend to veer and why? (*b*) If the plane is flying horizontally and suddenly turns to the right, does the nose of the plane tend to veer upward or downward? Why? SSM

16 •• **CONTEXT-RICH, ENGINEERING APPLICATION** You have designed a car that is powered by the energy stored in a single flywheel with a spin angular momentum $\vec{L}$. In the morning, you plug the car into an electrical outlet and a motor spins the flywheel up to speed, adding a huge amount of rotational kinetic energy to it—energy that will be changed into translational kinetic energy of the car during the day. Having taken a physics course involving angular momentum and torques, you realize that problems would arise during various maneuvers of the car. Discuss some of these problems. For example, suppose the flywheel is mounted so that $\vec{L}$ points vertically upward when the car is on a horizontal road. What would happen as the car travels over a hilltop? Through a valley? Suppose the flywheel is mounted so that $\vec{L}$ points forward or to one side when the car is on a horizontal road. Then what would happen if the car attempts to turn to the left or right? In each case that you examine, consider the direction of the torque exerted on the car by the road.

17 •• You are sitting on a spinning piano stool with your arms folded. (*a*) When you extend your arms out to your sides, what happens to your kinetic energy? What is the cause of this change? (*b*) Explain what happens to your moment of inertia, angular speed, and angular momentum as you extend your arms. SSM

18 •• A uniform rod of mass M and length L rests on a horizontal frictionless table. A blob of putty of mass $m = M/4$ moves along a line perpendicular to the rod, strikes the rod near its end, and sticks to the rod. Describe qualitatively the subsequent motion of the rod and putty.

ESTIMATION AND APPROXIMATION

19 •• An ice-skater starts her pirouette with arms outstretched, rotating at 1.5 rev/s. Estimate her rotational speed (in revolutions per second) when she brings her arms flat against her body. SSM

20 •• Estimate the ratio of angular velocities for the rotation of a diver between the full tuck position and the full layout position.

21 •• The days on Mars and Earth are of nearly identical length. Earth's mass is 9.35 times Mars's mass, Earth's radius is 1.88 times Mars's radius, and Mars is on average 1.52 times farther away from the Sun than Earth is. The Martian year is 1.88 times longer than Earth's year. Assume that they are both uniform spheres and that their orbits about the Sun are circles. Estimate the ratio (Earth to Mars) of (*a*) their spin angular momenta, (*b*) their spin kinetic energies, (*c*) their orbital angular momenta, and (*d*) their orbital kinetic energies.

22 •• The polar ice caps contain about 2.3×10^{19} kg of ice. This mass contributes negligibly to the moment of inertia of Earth because it is located at the poles, close to the axis of rotation. Estimate the change in the length of the day that would be expected if the polar ice caps were to melt and the water were distributed uniformly over the surface of Earth.

23 •• A 2.0-g particle moves at a constant speed of 3.0 mm/s around a circle of radius 4.0 mm. (*a*) Find the magnitude of the angular momentum of the particle. (*b*) If $L = \sqrt{\ell(\ell + 1)}\,\hbar$, where ℓ is an integer, find the value of $\ell(\ell + 1)$ and the approximate value of ℓ. (*c*) By how much does ℓ change if the particle's speed increases by one-millionth of a percent, and nothing else changes? Use your result to explain why the quantization of angular momentum is not noticed in macroscopic physics. SSM

24 ••• Astrophysicists in the 1960s tried to explain the existence and structure of *pulsars*—extremely regular astronomical sources of radio pulses whose periods ranged from seconds to milliseconds. At one point, these radio sources were given the acronym LGM (Little Green Men), a reference to the idea that they might be signals from extraterrestrial civilizations. The explanation given today is no less interesting. Consider the following. Our Sun, which is a fairly typical star, has a mass of 1.99×10^{30} kg and a radius of 6.96×10^{8} m. Although it does not rotate uniformly, because it is not a solid body, its average rate of rotation is about 1 rev/25 d. Stars larger than the Sun can expire in spectacular explosions called *supernovae,* leaving behind a collapsed remnant of the star called a *neutron star.* These neutron-stars have masses comparable to the original masses of the stars but radii of only a few kilometers! The high rotation rate are due to the conservation of angular momentum during the collapses. These stars emit beams of radio waves. Because of the rapid angular speed of the stars, the beam sweeps past Earth at regular, very short, intervals. To produce the observed radio-wave pulses, the star has to rotate at rates that range from about 1 rev/s to 1000 rev/s. (*a*) Using data from the textbook, estimate the rotation rate of the Sun if it were to collapse into a neutron star of radius 10 km. The Sun is not a uniform sphere of gas, and its moment of inertia is given by $I = 0.059MR^2$. Assume that the neutron star is spherical and has a uniform mass distribution. (*b*) Is the rotational kinetic energy of the Sun greater or smaller after the collapse? By what factor does it change, and where does the energy go to or come from?

25 •• The moment of inertia of Earth about its spin axis is approximately $8.03 \times 10^{37}\ \mathrm{kg \cdot m^2}$. (*a*) Because Earth is nearly spherical, assume that the moment of inertia can be written as $I = CMR^2$, where C is a dimensionless constant, $M = 5.98 \times 10^{24}$ kg is the mass of Earth, and $R = 6370$ km is its radius. Determine C. (*b*) If Earth's mass were distributed uniformly, C would equal 2/5. From the value of C calculated in Part (*a*), is Earth's density greater near its center or near its surface? Explain your reasoning.

26 ••• Estimate Timothy Goebel's initial takeoff speed, rotational velocity, and angular momentum when he performs a quadruple lutz (Figure 10-41). Make any assumptions you think reasonable, but justify them. Goebel's mass is about 60 kg and the height of the jump is about 0.60 m, Note that his angular speed will

change quite a bit during the jump, as he begins with arms outstretched and then pulls them in. Your answer should be accurate to within a factor of 2, if you are careful.

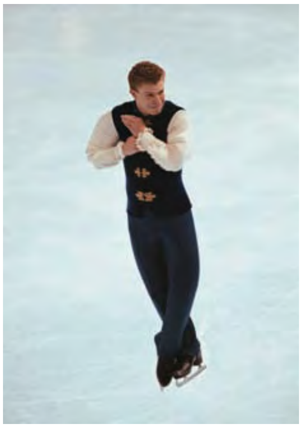

FIGURE 10-41
Problem 26
(Chris Trotman/DUOMO/Corbis.)

THE VECTOR PRODUCT AND THE VECTOR NATURE OF TORQUE AND ROTATION

27 • A force of magnitude F is applied horizontally in the $-x$ direction to the rim of a disk of radius R, as shown in Figure 10-42. Write $\vec{F}$ and $\vec{r}$ in terms of the unit vectors $\hat{\imath}$, $\hat{\jmath}$, and $\hat{k}$, and compute the torque produced by this force about the origin at the center of the disk. SSM

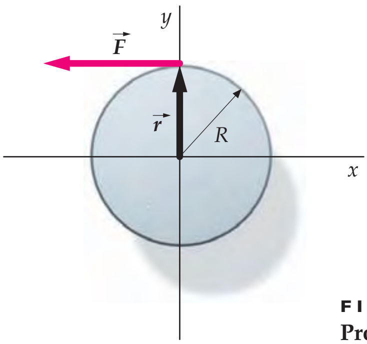

FIGURE 10-42
Problem 27

28 • Compute the torque about the origin of the gravitational force $\vec{F} = -mg\hat{\jmath}$ acting on a particle of mass m located at $\vec{r} = x\hat{\imath} + y\hat{\jmath}$, and show that this torque is independent of the y coordinate.

29 • Find $\vec{A} \times \vec{B}$ for the following choices: (*a*) $\vec{A} = 4\hat{\imath}$ and $\vec{B} = 6\hat{\imath} + 6\hat{\jmath}$, (*b*) $\vec{A} = 4\hat{\imath}$ and $\vec{B} = 6\hat{\imath} + 6\hat{k}$, and (*c*) $\vec{A} = 2\hat{\imath} + 3\hat{\jmath}$ and $\vec{B} = 3\hat{\imath} + 2\hat{\jmath}$.

30 •• For each case in Problem 29, compute $|\vec{A} \times \vec{B}|$. Compare it to $|\vec{A}||\vec{B}|$ to estimate which of the pairs of vectors are closest to being perpendicular. Verify your answers by calculating the angle using the dot product.

31 •• A particle moves in a circle that is centered at the origin. The particle has position $\vec{r}$ and angular velocity $\vec{\omega}$. (*a*) Show that its velocity is given by $\vec{v} = \vec{\omega} \times \vec{r}$. (*b*) Show that its centripetal acceleration is given by $\vec{a}_c = \vec{\omega} \times \vec{v} = \vec{\omega} \times (\vec{\omega} \times \vec{r})$.

32 •• You are given three vectors and their components in the form: $\vec{A} = a_x\hat{\imath} + a_y\hat{\jmath} + a_z\hat{k}$, $\vec{B} = b_x\hat{\imath} + b_y\hat{\jmath} + b_z\hat{k}$, and $\vec{C} = c_x\hat{\imath} + c_y\hat{\jmath} + c_z\hat{k}$. Show that the following equalities hold: $\vec{A} \cdot (\vec{B} \times \vec{C}) = \vec{C} \cdot (\vec{A} \times \vec{B}) = \vec{B} \cdot (\vec{C} \times \vec{A})$.

33 •• If $\vec{A} = 3\hat{\jmath}$, $\vec{A} \times \vec{B} = 9\hat{\imath}$, and $\vec{A} \cdot \vec{B} = 12$, find $\vec{B}$.

34 •• If $\vec{A} = 4\hat{\imath}$, $B_z = 0$, $|\vec{B}| = 5$, and $\vec{A} \times \vec{B} = 12\hat{k}$, determine $\vec{B}$.

35 ••• Given three noncoplanar vectors, $\vec{A}$, $\vec{B}$, and $\vec{C}$, show that $\vec{A} \cdot (\vec{B} \times \vec{C})$ is the volume of the parallelepiped formed by the three vectors.

36 ••• Using the vector product, prove the *law of sines* for the triangle shown in Figure 10-43. That is, if A, B, and C are the lengths of each side of the triangle, show that $A/\sin a = B/\sin b = C/\sin c$.

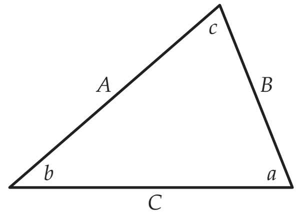

FIGURE 10-43
Problem 36

TORQUE AND ANGULAR MOMENTUM

37 • A 2.0-kg particle moves directly eastward at a constant speed of 4.5 m/s along an east–west line. (*a*) What is its angular momentum (including direction) about a point that lies 6.0 m north of the line? (*b*) What is its angular momentum (including direction) about a point that lies 6.0 m south of the line? (c) What is its angular momentum (including direction) about a point that lies 6.0 m directly east of the particle? SSM

38 • You observe a 2.0-kg particle moving at a constant speed of 3.5m/s in a clockwise direction around a circle of radius 4.0 m. (*a*) What is its angular momentum (including direction) about the center of the circle? (*b*) What is its moment of inertia about an axis through the center of the circle and perpendicular to the plane of the motion? (*c*) What is the angular velocity of the particle?

39 •• (*a*) A particle moving at constant velocity has zero angular momentum about a particular point. Use the definition of angular momentum to show that under this condition the particle is moving either directly toward or directly away from the point. (*b*) You are a right-handed batter and let a waist-high fastball go past you without swinging. What is the direction of the ball's angular momentum relative to your navel? (Assume that the ball travels in a straight, horizontal line as it passes you.)

40 •• A particle that has a mass m is traveling with a constant velocity $\vec{v}$ along a straight line that is a distance b from the origin O (Figure 10-44). Let dA be the area swept out by the position vector from O to the particle during a time interval dt. Show that dA/dt is constant and is equal to $L/2m$, where L is the magnitude of the angular momentum of the particle about the origin.

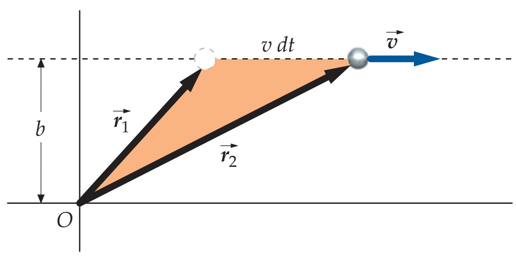

FIGURE 10-44 **Problem 40**

41 •• A 15-g coin that has a diameter equal to 1.5 cm is spinning at 10 rev/s about a fixed vertical axis. The coin is spinning on edge with its center directly above the point of contact with the tabletop. As you look down on the tabletop, the coin spins clockwise. (*a*) What is the angular momentum (including direction) of the coin about its center of mass? (To find the moment of inertia about the axis, see Table 9-1.) Model the coin as a cylinder of length L and take the limit as L approaches zero. (*b*) What is the coin's angular momentum (including direction) about a point on the tabletop 10 cm from the axis? (*c*) Now the coin's center of mass travels at 5.0 cm/s in a straight line east across the tabletop, while spinning the same way as in Part (*a*). What is the angular momentum (including direction) of the coin about a point on the line of motion of the center of mass? (*d*) When it is both spinning and sliding, what is the angular momentum of the coin (including direction) about a point 10 cm north of the line of motion of the center of mass?

42 •• **CONCEPTUAL** (*a*) Two stars of masses m_1 and m_2 are located at $\vec{r}_1$ and $\vec{r}_2$ relative to some origin O, as shown in Figure 10-45. They exert equal and opposite attractive gravitational forces on each other. For this two-star system, calculate the net torque exerted by these internal forces about the origin O and show that it is zero only if both forces lie along the line joining the particles. (*b*) The fact that the Newton's third-law pair of forces are not only equal and oppositely directed but also lie along the line connecting the two objects is sometimes called the strong form of Newton's third law. Why is it important to add that last phrase? *Hint: Consider what would happen to these two objects if the forces were offset from each other.*

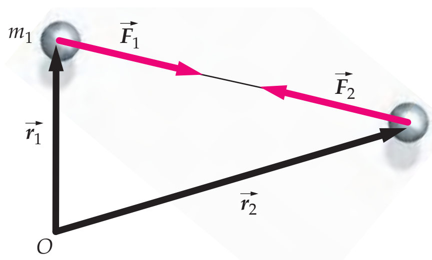

FIGURE 10-45 Problem 42

43 •• A 1.8-kg particle moves in a circle of radius 3.4 m. As you look down on the plane of its orbit, the particle is initially moving clockwise. If we call the clockwise direction positive, the particle's angular momentum relative to the center of the circle varies with time according to $L(t) = 10\,\mathrm{N\cdot m\cdot s} - (4.0\,\mathrm{N\cdot m})t$. (*a*) Find the magnitude and direction of the torque acting on the particle. (*b*) Find the angular velocity of the particle as a function of time.

44 •• **CONTEXT-RICH, ENGINEERING APPLICATION** You are designing a lathe motor, part of which consists of a uniform cylinder whose mass is 90 kg and whose radius is 0.40 m that is mounted so that it turns without friction on its axis, which is fixed. The cylinder is driven by a belt that wraps around its perimeter and exerts a constant torque. At $t = 0$, the cylinder's angular velocity is zero. At $t = 25$ s, its angular speed is 500 rev/min. (*a*) What is the magnitude of the cylinder's angular momentum at $t = 25$ s? (*b*) At what rate is the angular momentum increasing? (*c*) What is the magnitude of the torque acting on the cylinder? (*d*) What is the magnitude of the frictional force acting on the rim of the cylinder?

45 •• In Figure 10-46, the incline is frictionless and the string passes through the center of mass of each block. The pulley has a moment of inertia I and radius R. (*a*) Find the net torque acting on the system (the two masses, string, and pulley) about the center of the pulley. (*b*) Write an expression for the total angular momentum of the system about the center of the pulley. Assume the masses are moving with a speed v. (*c*) Find the acceleration of the masses by using your results for Parts (*a*) and (*b*) and by setting the net torque equal to the rate of change of the system's angular momentum. SSM

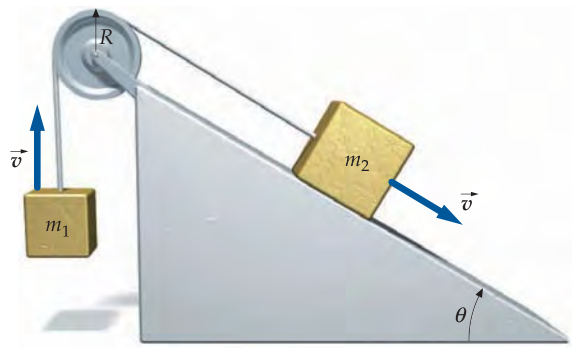

FIGURE 10-46 Problem 45

46 •• **CONTEXT-RICH, ENGINEERING APPLICATION** Figure 10-47 shows the rear view of a space capsule that was left rotating rapidly about its axis at 30 rev/min after a collision with another capsule. You are the flight controller and have just moments to tell the crew how to stop this rotation before they become ill from the rotation and the situation becomes dangerous. You know that they have access to two small jets mounted tangentially at a distance $R = 3.0$ m from the axis, as indicated in the figure. These jets can each eject 10 g/s of gas with a nozzle speed of 800 m/s. Determine the length of time these jets must run to stop the rotation. In flight, the moment of inertia of the ship about its axis (assumed constant) is known to be $4000\,\mathrm{kg\cdot m^2}$.

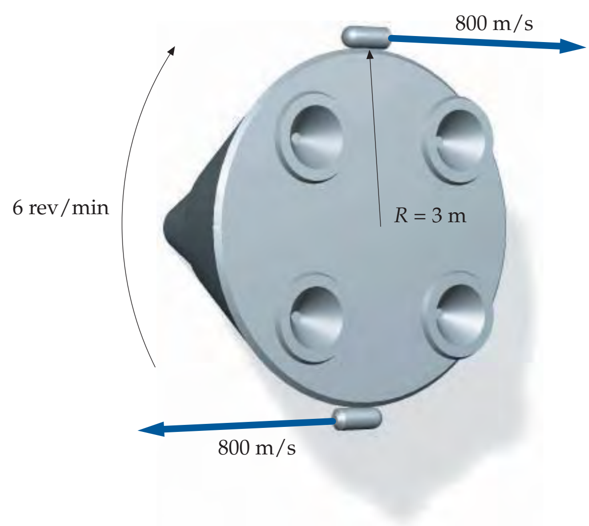

FIGURE 10-47 Problem 46

47 •• A projectile (mass M) is launched at an angle θ with an initial speed v_0. Considering the torque and angular momentum about the launch point, explicitly show that $dL/dt = \tau$. Ignore the effects of air resistance. (The equations for projectile motion are found in Chapter 3.)

CONSERVATION OF ANGULAR MOMENTUM

48 • A planet moves in an elliptical orbit about the Sun, with the Sun at one focus of the ellipse, as in Figure 10-48. (*a*) What is the torque about the center of the Sun due to the gravitational force of attraction of the Sun on the planet? (*b*) At position *A*, the planet has an orbital radius r_1 and is moving with a speed v_1 perpendicular to the line from the Sun to the planet. At position *B*, the planet has an orbital radius r_2 and is moving with speed v_2, again perpendicular to the line from the Sun to the planet. What is the ratio of v_1 to v_2 in terms of r_1 and r_2?

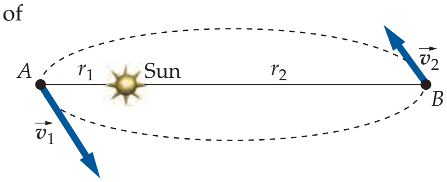

FIGURE 10-48 Problem 48

49 •• You stand on a frictionless platform that is rotating at an angular speed of 1.5 rev/s. Your arms are outstretched, and you hold a heavy weight in each hand. The moment of inertia of you, the extended weights, and the platform is $6.0\ \mathrm{kg \cdot m^2}$. When you pull the weights in toward your body, the moment of inertia decreases to $1.8\ \mathrm{kg \cdot m^2}$. (*a*) What is the resulting angular speed of the platform? (*b*) What is the change in kinetic energy of the system? (*c*) Where did this increase in energy come from? SSM

50 •• A small blob of putty of mass *m* falls from the ceiling and lands on the outer rim of a turntable of radius *R* and moment of inertia I_0 that is rotating freely with angular speed ω_0 about its vertical fixed-symmetry axis. (*a*) What is the postcollision angular speed of the turntable–putty system? (*b*) After several turns, the blob flies off the edge of the turntable. What is the angular speed of the turntable after the blob's departure?

51 •• A lazy Susan consists of a heavy plastic cylinder mounted on a frictionless bearing resting on a vertical shaft through its center. The cylinder has a radius $R = 15$ cm and mass $M = 0.25$ kg. A cockroach (mass $m = 0.015$ kg) is on the lazy Susan, at a distance of 8.0 cm from the center. Both the cockroach and the lazy Susan are initially at rest. The cockroach then walks along a circular path concentric with the axis of the lazy Susan at a constant distance of 8.0 cm from the axis of the shaft. If the speed of the cockroach with respect to the lazy Susan is 0.010 m/s, what is the speed of the cockroach with respect to the room? SSM

52 •• Two disks of identical mass but different radii (*r* and 2*r*) are spinning on frictionless bearings at the same angular speed ω_0, but in opposite directions (Figure 10-49). The two disks are brought slowly together. The resulting frictional force between the surfaces eventually brings them to a common angular velocity. (*a*) What is the magnitude of that final angular velocity in terms of ω_0? (*b*) What is the change in rotational kinetic energy of the system? Explain.

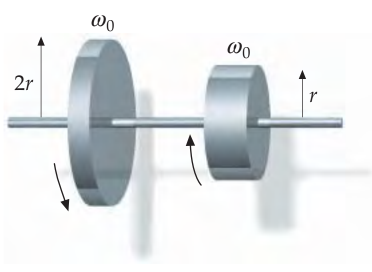

FIGURE 10-49 Problem 52

53 •• A block of mass *m* sliding on a frictionless table is attached to a string that passes through a narrow hole through the center of the table. The block is sliding with speed v_0 in a circle of radius r_0. Find (*a*) the angular momentum of the block, (*b*) the kinetic energy of the block, and (*c*) the tension in the string. (*d*) A student under the table now slowly pulls the string downward. How much work is required to reduce the radius of the circle from r_0 to $r_0/2$?

54 ••• A 0.20-kg point mass moving on a frictionless horizontal surface is attached to a rubber band whose other end is fixed at point *P*. The rubber band exerts a force whose magnitude is $F = bx$, where *x* is the length of the rubber band and *b* is an unknown constant. The rubber band force points inward toward *P*. The mass moves along the dotted line in Figure 10-50. When it passes point *A*, its velocity is 4.0 m/s, directed as shown. The distance *AP* is 0.60 m and *BP* is 1.0 m. (*a*) Find the speed of the mass at points *B* and *C*. (*b*) Find *b*.

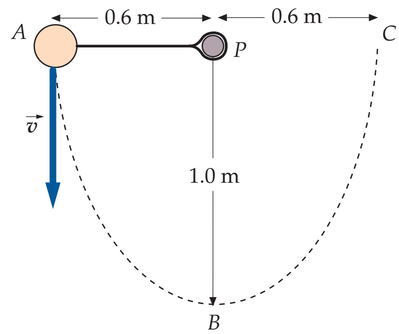

FIGURE 10-50 Problem 54

* QUANTIZATION OF ANGULAR MOMENTUM

55 •• The *z* component of the spin of an electron is $-\frac{1}{2}\hbar$, but the magnitude of the spin vector is $\sqrt{0.75}\,\hbar$. What is the angle between the electron's spin angular-momentum vector and the positive *z* axis? SSM

56 •• Show that the energy difference between one rotational state of a molecule and the next higher state is proportional to $\ell + 1$.

57 •• **CONTEXT-RICH, BIOLOGICAL APPLICATION** You work in a biochemical research lab, where you are investigating the rotational energy levels of the HBr molecule. After consulting the periodic chart, you know that the mass of the bromine atom is 80 times that of the hydrogen atom. Consequently, in calculating the rotational motion of the molecule, you assume, to a good approximation, that the Br nucleus remains stationary as the H atom (mass 1.67×10^{-27} kg) revolves around it. You also know that the separation between the hydrogen atom and bromine nucleus is 0.144 nm. Calculate (*a*) the moment of inertia of the HBr molecule about the bromine nucleus, and (*b*) the rotational energies for the bromine nucleus's *ground state* (lowest energy) $\ell = 0$, and the next two states of higher energy (called the first and second *excited states*) described by $\ell = 1$, and $\ell = 2$. SSM

58 ••• The equilibrium separation between the nuclei of the nitrogen molecule (N_2) is 0.110 nm and the mass of each nitrogen nucleus is 14.0 u, where $u = 1.66 \times 10^{-27}$ kg. For rotational energies, the total energy is due to rotational kinetic energy. (*a*) Approximate the nitrogen molecule as a rigid dumbbell of two equal point masses and calculate the moment of inertia about its center of mass. (*b*) Find the energy E_ℓ of the lowest three energy levels using $E_\ell = K_\ell = \ell(\ell + 1)\,\hbar^2/(2I)$. (*c*) Molecules emit a particle (or *quantum*) of light called a *photon* when they make a *transition* from a higher energy state to a lower one. Determine the energy of a photon emitted when a nitrogen molecule drops from the $\ell = 2$ to the $\ell = 1$ state. Visible-light photons each have between 2 and 3 eV of energy. Are these photons in the visible region?

59 ••• **CONCEPTUAL** Consider a *transition* from a lower energy state to a higher one—that is, the absorption of a quantum of energy, resulting in an increase in the rotational energy of an N_2 molecule (see Problem 58). Suppose such a molecule, initially in its ground rotational state, was exposed to photons, each with an energy equal to three times the energy of its first excited state. (*a*) Would the molecule be able to absorb this photon energy? Explain why or why not, and if it can, determine the energy level to which it goes. (*b*) To make a transition from its ground state to its second excited state requires how many times the energy of the first excited state?

COLLISIONS WITH ROTATIONS

60 •• A 16.0-kg, 2.40-m-long rod is supported at its midpoint on a knife edge. A 3.20-kg ball of clay drops from rest from a height of 1.20 m and makes a perfectly inelastic collision with the rod 0.90 m from the point of support (Figure 10-51). Find the angular momentum of the rod and clay system about the point of support immediately after the inelastic collision.

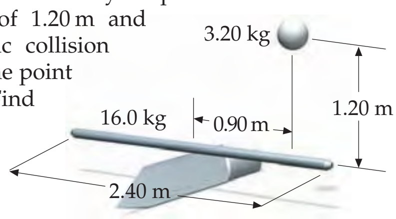

FIGURE 10-51 Problem 60

61 •• Figure 10-52 shows a thin, uniform bar of length L and mass M and a small blob of putty of mass m. The system is supported by a frictionless horizontal surface. The putty moves to the right with velocity $\vec{v}$, strikes the bar at a distance d from the center of the bar, and sticks to the bar at the point of contact. Obtain expressions for the velocity of the system's center of mass and for the angular speed following the collision. SSM

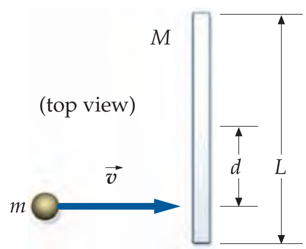

FIGURE 10-52 Problem 61

62 •• Figure 10-52 shows a thin, uniform bar whose length is L and mass is M and a compact hard sphere whose mass is m. The system is supported by a frictionless horizontal surface. The sphere moves to the right with velocity $\vec{v}$, and strikes the bar at a distance $\frac{1}{4}L$ from the center of the bar. The collision is elastic, and following the collision the sphere is at rest. Find the value of the ratio m/M.

63 •• Figure 10-53 shows a uniform rod whose length is L and mass is M pivoted at the top. The rod, which is initially at rest, is struck by a particle whose mass is m at a point $x = 0.8L$ below the pivot. Assume that the particle sticks to the rod. What must be the speed v of the particle so that following the collision the maximum angle between the rod and the vertical is 90°?

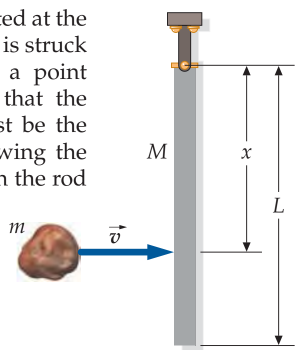

FIGURE 10-53 Problem 63

64 •• If, for the system of Problem 63, $L = 1.2$ m, $M = 0.80$ kg, $m = 0.30$ kg, and the maximum angle between the rod and the vertical following the collision is 60°, find the speed of the particle before impact.

65 •• A uniform rod is resting on a frictionless table when it is suddenly struck at one end by a sharp horizontal blow in a direction perpendicular to the rod. The mass of the rod is M and the magnitude of the impulse applied by the blow is J. Immediately after the rod is struck, (*a*) what is the velocity of the center of mass of the rod, (*b*) what is the velocity of the end that is struck, (*c*) and what is the velocity of the other end of the rod? (*d*) Is there a point on the rod that remains motionless?

66 •• A projectile of mass m_p is traveling at a constant velocity $\vec{v}_0$ toward a stationary disk of mass M and radius R that is free to rotate its axis (Figure 10-54). Before impact, the projectile is traveling along a line displaced a distance b below the axis. The projectile strikes the disk and sticks to point B. Model the projectile as a point mass. (*a*) Before impact, what is the total angular momentum L_0 of the disk–projectile system about the axis? Answer the following questions in terms of the symbols given at the start of this problem. (*b*) What is the angular speed ω of the disk–projectile system just after the impact? (*c*) What is the kinetic energy of the disk–projectile system after impact? (*d*) How much mechanical energy is lost in this collision?

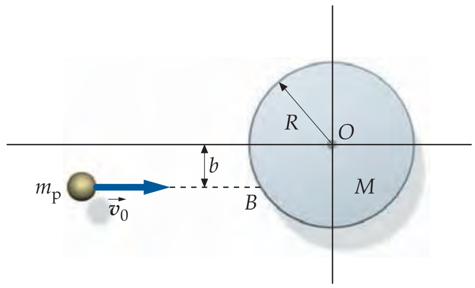

FIGURE 10-54 Problem 66

67 •• A uniform rod of length L_1 and mass M equal to 0.75 kg is attached to a hinge of negligible mass at one end and is free to rotate in the vertical plane (Figure 10-55). The rod is released from rest in the position shown. A particle of mass $m = 0.50$ kg is suspended from a thin string of length L_2 from the hinge. The particle sticks to the rod on contact. What should the ratio L_2/L_1 be so that $\theta_{max} = 60°$ after the collision? SSM

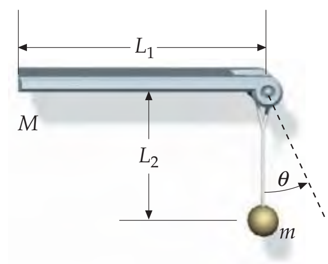

FIGURE 10-55 Problem 67

68 •• A uniform rod that has a length L_1 equal to 1.2 m and a mass M equal to 2.0 kg is attached to a hinge of negligible mass at one end and is free to rotate in the vertical plane (Figure 10-55). The rod is released from rest in the position shown. A particle whose mass is m is suspended from a thin string whose length L_2 is equal to 0.80 m from the hinge. The particle sticks to the rod on contact, and after the collision the rod continues to rotate until $\theta_{max} = 37°$. (*a*) Find m. (*b*) How much energy is dissipated during the collision? SSM

PRECESSION

69 •• A bicycle wheel that has a radius equal to 28 cm is mounted at the middle of a 50-cm-long axle. The tire and rim weigh 30 N. The wheel is spun at 12 rev/s, and the axle is then placed in a horizontal position with one end resting on a pivot. (*a*) What is the angular momentum due to the spinning of the wheel? (Treat the wheel as a hoop.) (*b*) What is the angular velocity of precession? (*c*) How long does it take for the axle to swing through 360° around the pivot? (*d*) What is the angular momentum associated with the motion of the center of mass, that is, due to the precession? In what direction is this angular momentum? SSM

70 •• A uniform disk, whose mass is 2.50 kg and radius is 6.40 cm, is mounted at the center of a 10.0-cm-long axle and spun at 700 rev/min. The axle is then placed in a horizontal position with one end resting on a pivot. The other end is given an initial horizontal velocity such that the precession is smooth with no nutation. (*a*) What is the angular velocity of precession? (*b*) What is the speed of the center of mass during the precession? (*c*) What is the acceleration (magnitude and direction) of the center of mass? (*d*) What are the vertical and horizontal components of the force exerted by the pivot on the axle?

GENERAL PROBLEMS

71 • A particle whose mass is 3.0 kg moves in the xy plane with velocity $\vec{v} = (3.0\text{ m/s})\hat{i}$ along the line $y = 5.3$ m. (*a*) Find the angular momentum $\vec{L}$ about the origin when the particle is at (12 m, 5.3 m). (*b*) A force $\vec{F} = (-3.9\text{ N})\hat{i}$ is applied to the particle. Find the torque about the origin due to this force as the particle passes through the point (12 m, 5.3 m). SSM

72 • The position vector of a particle whose mass is 3.0 kg is given by $\vec{r} = (4.0 + 3.0t^2)\hat{j}$, where $\vec{r}$ is in meters and t is in seconds. Determine the angular momentum and net torque about the origin acting on the particle.

73 •• Two ice-skaters, whose masses are 55 kg and 85 kg, hold hands and rotate about a vertical axis that passes between them, making one revolution in 2.5 s. Their centers of mass are separated by 1.7 m, and their center of mass is stationary. Model each skater as a point particle and find (*a*) the angular momentum of the system about their center of mass and (*b*) the total kinetic energy of the system.

74 •• A 2.0-kg ball attached to a string whose length is 1.5 m moves counterclockwise (as viewed from above) in a horizontal circle (Figure 10-56). The string makes an angle $\theta = 30°$ with the vertical. (*a*) Determine both the horizontal and vertical components of the angular momentum $\vec{L}$ of the ball about the point of support. (*b*) Find the magnitude of $d\vec{L}/dt$ and verify that it equals the magnitude of the torque exerted by gravity about the point of support.

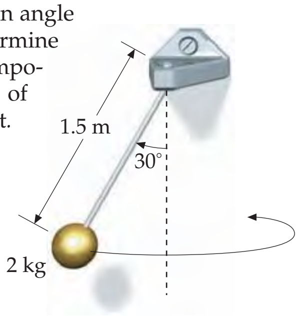

FIGURE 10-56 Problem 74

75 •• A compact object whose mass is m resting on a horizontal, frictionless surface is attached to a string that wraps around a vertical cylindrical post attached to the surface. Thus, when the object is set into motion, it follows a path that spirals inward. (*a*) Is the angular momentum of the object about the axis of the post conserved? Explain your answer. (*b*) Is the energy of the object conserved? Explain your answer. (*c*) If the speed of the object is v_0 when the unwrapped length of the string is r, what is its speed when the unwrapped length has shortened to $r/2$?

76 •• CONTEXT-RICH, ENGINEERING APPLICATION Figure 10-57 shows a hollow cylindrical tube that has a mass M, a length L, and a moment of inertia $ML^2/10$. Inside the cylinder are two disks, each of mass m and radius r, separated by a distance ℓ, and tied to a central post by a thin string. The system can rotate about a vertical axis through the center of the cylinder. You are designing this cylinder–disk apparatus to shut down the rotations by triggering an electronic "shutoff" signal (sent to the rotating motor) when the strings break as the disks hit the ends of the cylinder. During development, you notice that with the system rotating at some critical angular speed ω, the string suddenly breaks. When the disks reach the ends of the cylinder, they stick. Obtain expressions for the final angular speed and the initial and final kinetic energies of the system. Assume that the inside walls of the cylinder are frictionless.

77 •• CONTEXT-RICH, ENGINEERING APPLICATION Repeat Problem 76, but this time friction between the disks and the walls of the cylinder is not negligible. However, the coefficient of friction is not great enough to prevent the disks from reaching the ends of the cylinder. Can the final kinetic energy of the system be determined without knowing the coefficient of kinetic friction? SSM

78 •• CONTEXT-RICH, ENGINEERING APPLICATION Suppose that in Figure 10-57 $\ell = 0.60$ m, $L = 2.0$ m, $M = 0.80$ kg, and $m = 0.40$ kg. The string breaks when the system's angular speed approaches a critical angular speed ω_i at which time the tension in the string approaches 108 N. The masses then move radially outward until they undergo perfectly inelastic collisions with the ends of the cylinder. Determine the critical angular speed and the angular speed of the system after the inelastic collisions. Find the total kinetic energy of the system at the critical angular speed and again after the inelastic collisions. Assume that the inside walls of the cylinder are frictionless.

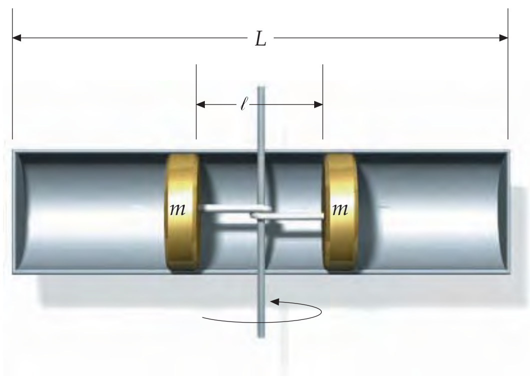

FIGURE 10-57 Problems 76, 77 and 78

79 •• Kepler's second law states: *The line from the center of the Sun to the center of a planet sweeps out equal areas in equal times.* Show that this law follows directly from the law of conservation of angular momentum and the fact that the force of gravitational attraction between a planet and the Sun acts along the line joining the centers of the two celestial objects. SSM

80 •• Consider a cylindrical turntable whose mass is M and radius is R, turning with an initial angular speed ω_1. (*a*) A parakeet of mass m, after hovering in flight above the outer edge of the turntable, gently lands on it and stays in one place on it, as shown in Figure 10-58. What is the angular speed of the turntable after the parakeet lands? (*b*) Becoming dizzy, the parakeet jumps off (not flies off) with a velocity $\vec{v}$ relative to the turntable. The direction of $\vec{v}$ is tangent to the edge of the turntable and in the direction of its rotation. What will be the angular speed of the turntable afterwards? Express your answer in terms of the two masses m and M, the radius R, the parakeet speed v, and the initial angular speed ω_1.

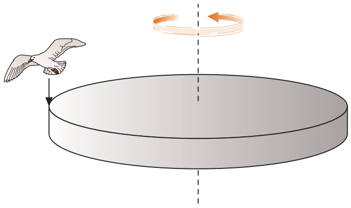

FIGURE 10-58 Problem 80

81 •• You are given a heavy but thin metal disk (like a coin, but larger; Figure 10-59) that has a mass of 0.500 kg and a radius of 0.125 m. (Objects like this are called *Euler disks.*) Placing the disk on a turntable, you spin the disk, on edge, about a vertical axis through a diameter of the disk and the center of the turntable. As you do this, you hold the turntable still with your other hand, letting it go immediately after you spin the disk. The turntable is a uniform solid cylinder with a radius equal to 0.250 m and a mass equal to 0.735 kg and rotates on a frictionless bearing. The disk has an initial angular speed of 30 rev/min. (*a*) The disk spins down and falls over, finally coming to rest on the turntable with its symmetry axis coinciding with the turntable. What is the final angular speed of the turntable? (*b*) What will be the final angular speed if the disk's symmetry axis ends up 0.100 m from the axis of the turntable?

FIGURE 10-59 **Problem 81** *(Courtesy of Tangent Toy Co.)*

82 •• (*a*) Assuming Earth to be a homogeneous sphere that has a radius r and a mass m, show that the period T (time for one daily rotation) of Earth's rotation about its axis is related to its radius by $T = br^2$, where $b = (4/5)\pi\, m/L$. Here L is the magnitude of the spin angular momentum of Earth. (*b*) Suppose that the radius r changes by a very small amount, Δr, due to some internal cause, such as thermal expansion. Show that the fractional change in the period ΔT is given approximately by $\Delta T/T = 2\Delta r/r$. (*c*) By how many kilometers would r need to increase for the period to change by 0.25 d/y, (so that leap years would no longer be necessary)?

83 •• The term *precession of the equinoxes* refers to the fact that Earth's spin axis does not stay fixed but sweeps out a cone once every 26,000 y. (This explains why our pole star, Polaris, will not remain the pole star forever.) The reason for this instability is that Earth is a giant gyroscope. The spin axis of Earth precesses because of the torques exerted on it by the gravitational forces of the Sun and moon. The angle between the direction of Earth's spin axis and the normal to the ecliptic plane (the plane of Earth's orbit) is 22.5 degrees. Calculate an approximate value for this torque, given that the period of rotation of Earth is 1.00 d and its moment of inertia is $8.03 \times 10^{37}\ \mathrm{kg \cdot m^2}$. SSM

84 •• As indicated in the text, according to the Standard Model of Particle Physics, electrons are pointlike particles having no spatial extent. (This assumption has been confirmed experimentally, and the radius of the electron has been shown to be less than 10^{-18} m.) The intrinsic spin of an electron could *in principle* be due to its rotation. Let us check to see if this conclusion is feasible. (*a*) Assuming that the electron is a uniform sphere whose radius is 1.00×10^{-18} m, what angular speed would be necessary to produce the observed intrinsic angular momentum of $\hbar/2$? (*b*) Using this value of angular speed, show that the speed of a point on the "equator" of a "spinning" electron would be moving faster than the speed of light. What is your conclusion about the spin angular momentum being analogous to a spinning sphere with spatial extent?

85 •• An interesting phenomenon occurring in certain *pulsars* (see Problem 24) is an event known as a "spin glitch," that is, a quick change in the spin rate of the pulsar due to a shift in mass location and a resulting rotational change in inertia. Imagine a pulsar whose radius is 10.0 km and whose period of rotation is 25.032 ms. The rotation period is observed to suddenly decrease from 25.032 ms to 25.028 ms. If that decrease was caused by a contraction of the star, by what amount would the pulsar radius have had to change?

86 ••• Figure 10-60 shows a pulley in the form of a uniform disk with a rope hanging over it. The circumference of the pulley is 1.2 m and its mass is 2.2 kg. The rope is 8.0 m long and its mass is 4.8 kg. At the instant shown in the figure, the system is at rest and the difference in height of the two ends of the rope is 0.60 m. (*a*) What is the angular speed of the pulley when the difference in height between the two ends of the rope is 7.2 m? (*b*) Obtain an expression for the angular momentum of the system as a function of time while neither end of the rope is above the center of the pulley. There is no slippage between rope and pulley wheel.

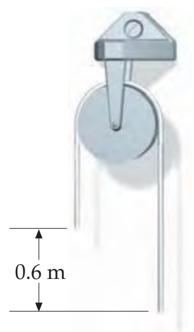

FIGURE 10-60 **Problem 86**

CHAPTER R

ABOARD THE SPACE SHUTTLE ORBITER, ASTRONAUTS REST IN BUNKS. THEY SLEEP STRAPPED IN SO THEY DO NOT FLOAT AROUND THE CABIN AND THEY DO NOT NEED SOFT MATTRESSES. WHEN THE SHUTTLE IS IN A LOW EARTH ORBIT, IT ORBITS EARTH ONCE EVERY 90 MIN AT A SPEED OF ABOUT 7 KM/S (4.9 MI/S). THIS SPEED IS A SMALL FRACTION OF THE SPEED OF LIGHT, WHICH IS 3.0×10^5 KM/S. *(NASA.)*

Special Relativity

? If an astronaut on a spaceship that is traveling at $0.6c$ relative to Earth takes a one-hour-long nap, does that nap take one hour according to observers on Earth? (See Example R-1.)

The theory of relativity consists of two rather different theories, the special theory and the general theory. The special theory, developed by Albert Einstein and others in 1905, concerns the comparison of measurements made in different inertial reference frames moving with constant velocity relative to one another. Its consequences, which can be derived with a minimum of mathematics, are applicable in a wide variety of situations encountered in physics and engineering. An application of the special theory can be seen in the development of the global positioning system (GPS), which is able to give your position coordinates (latitude, longitude, and altitude) to within a few meters. The system contains 24 satellites, each carrying an atomic clock and each broadcasting a time signal that can be picked up by any GPS receiver in the line of sight of the satellite. The relative arrival times of the signals from several satellites together with knowledge of the positions of the satellites enables the receiver to calculate its position coordinates. According to the special theory, the faster the speed of a clock, the slower it runs (Section R-3). The satellites are moving at about 3.9 km/s, and the effect of the clocks running more slowly at this speed is not negligible. However, the design of the system accounts for the slowing down of the orbiting clocks. (In addition, according to the general theory, the greater the gravitation potential energy of a clock, the faster it runs (Section 39-8). The design of the system also accounts for the speeding up of the clocks due to their high altitude.) The GPS is able to function only because it takes into account the effects of the special and general theories of relativity on the observed clock rates.

In this chapter, we concentrate on the special theory of relativity (often referred to as special relativity). You will see how this theory challenges our everyday experience of time and distance, as we describe the slowing down of moving clocks, the shortening of moving sticks, the relativity of simultaneity for events that occur in different locations, and the relativity of the momentum and energy relation.

R-1 THE PRINCIPLE OF RELATIVITY AND THE CONSTANCY OF THE SPEED OF LIGHT

The principle of relativity can be stated as follows:

> It is impossible to devise an experiment that determines whether you are at rest or moving uniformly.
>
> POSTULATE I: THE PRINCIPLE OF RELATIVITY

Moving uniformly means moving at constant velocity relative to an inertial reference frame. For example, suppose that you are in your seat on board a high-speed airplane moving uniformly relative to the surface of Earth. If you drop your fork, it will fall to the floor in the same way that it would if the plane were parked on a runway. When the airplane is in flight, you can consider yourself and the airplane to be at rest and the surface of Earth below you to be moving. There is nothing to distinguish whether you and the plane are moving and the surface of Earth is at rest, or vice versa.

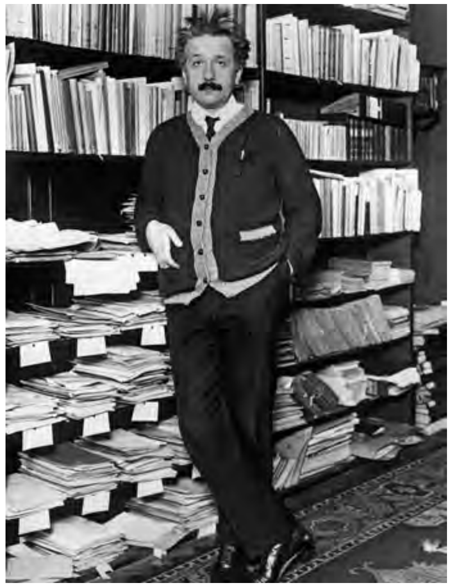
Any reference frame in which a particle with no forces acting on it moves with constant velocity is, by definition, an inertial reference frame.* The surface of Earth is, to a good approximation, an inertial reference frame. The airplane is also an inertial reference frame as long as it moves with constant velocity relative to the surface of Earth. As long as you remain seated or standing still on the airplane, you can consider yourself and the airplane to be at rest and the surface of Earth to be moving, or you can consider the surface of Earth to be at rest and yourself and the airplane to be moving.

In the nineteenth century, the existence of a preferred frame of reference that could be considered to be at rest was widely accepted. This reference frame was thought to be the reference frame of the *ether*, which is the medium filling all of space through which light was thought to propagate. (It was then accepted that light waves needed a medium to propagate through, just as it is now accepted that sound waves need air or some other medium through which to propagate.) The ether was considered to be the preferred "at rest" reference frame.

A carefully devised series of measurements to measure the orbital speed of Earth relative to the ether were carried out in 1887 by Albert Michelson and Edward Morley. These measurements were considered challenging because the

* Further discussion on inertial reference frames can be found in Chapter 4.

orbital speed of Earth is less than 1/10,000 the speed of light in vacuum. Much to the surprise of nearly everyone, the observations always found the speed of Earth relative to the ether to be zero. It was Albert Einstein who came up with a theory that was consistent with these observations. His explanation was that light is capable of traveling through empty space and that the ether was an unnecessary construct that did not exist. Einstein also postulated:



Albert Einstein.
(Underwood & Underwood/Corbis.)

> The speed of light is independent of the speed of the light source.
>
> POSTULATE II

Here the *speed of light* refers to the speed at which light travels through the vacuum of empty space.

A consequence of Postulate II and the principle of relativity (Postulate I) is that all inertial observers measure the same value for the speed of light. (An inertial observer is one that remains at rest relative to an inertial reference frame.) To establish that all inertial observers measure the same value for the speed of light, we consider inertial observers A and B, where observer A is moving relative to observer B. The principle of relativity states that it is impossible to devise an experiment that determines whether an inertial observer is at rest or moving uniformly. If observer A measures a different value for the speed of light than observer B, then observers A and B could not both consider themselves to be at rest—a result in direct contradiction with the principle of relativity. Thus, a consequence of both the principle of relativity and Postulate II (that the speed of light is independent of the speed of the source) leads to the **constancy of the speed of light:**

> The speed of light c is the same in any inertial reference frame.
>
> THE CONSTANCY OF THE SPEED OF LIGHT

That is, anything (not just light) that travels at speed c relative to one inertial reference frame travels at the same speed c relative to any inertial reference frame.

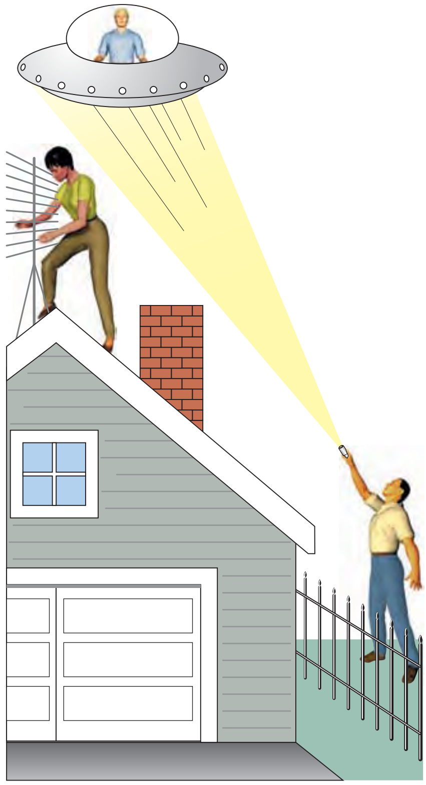


FIGURE R-1

Suppose you are in your backyard here on Earth and Bob is on a spaceship moving away from you at half the speed of light ($\frac{1}{2}c$) (Figure R-1). You point a flashlight in Bob's direction and turn it on. The light leaves the flashlight, traveling at speed c (relative to the flashlight), and passes by your neighbor Keisha, who is standing on the roof of her house next door. Keisha measures the speed of the light going by and finds it to be traveling at speed c. A few minutes later, the light travels past Bob and his spaceship. Like Keisha, Bob measures the speed of the light going by him and also finds it to be traveling at speed c. This surprises Bob because he expected the light to be traveling past him at speed $\frac{1}{2}c$ rather than at speed c—after all, Bob is moving at speed $\frac{1}{2}c$ relative to the source of the light (the flashlight in your backyard). Like many people, Bob finds the constancy of the speed of light to be counterintuitive. As a result, he is faced with a dilemma. Should he trust his measuring instruments or trust his intuition? It turns out that it is Bob's intuition that needs adjusting, not his instruments. Bob must change his concepts of both space and time.

Suppose that instead of pointing a flashlight, you point a high-speed particle beam in his direction, where by "high speed" we mean a speed very close to the speed of light, c. (A particle such as an electron or proton cannot travel at the speed of light, but it can travel at speeds that approach the speed of light.) If Keisha measures the particles going by her to be traveling at $0.9999c$ (relative to her), then how fast will Bob measure the particles going by him? Bob's intuition tells him that, because he is moving away from the source of the particles, they will be traveling past him at the slower speed of $0.4999c$, but that is not the case. When Bob measures the speed of the particles (relative to him) he finds it to be extremely close to $0.9999c$. (The actual value is $0.9997c$.)*

We tend to think of distances between cities as fixed. However, this too is not the case. According to a certain road map, the distance between Baltimore and Philadelphia is 160 km. However, if you travel from Baltimore to Philadelphia at a significant fraction of the speed of light, the distance between the two cities will be much shorter than it is if you travel at 100 km/h (62 mi/h). For someone driving at 100 km/h, the distance between Baltimore and Philadelphia is very close to 160 km. However, for someone traveling at a speed of $0.866c$ (relative to Earth's surface), the distance is only 80 km, and for someone traveling at $0.9999c$, the distance is only 2.2 km.

The fastest speed that a human being has ever traveled relative to Earth is only about 10 km/s $= 3.3 \times 10^{-5}c$. (During the Apollo missions to the moon, the capsule reached this speed on its return to Earth.) This speed is quite slow compared to the speed of light. For someone traveling at that speed from Baltimore to Philadelphia, the distance between those cities would be shorter than the distance for someone traveling at 100 km/h by less than the diameter of a human hair. The logic explaining how this is determined is presented in the next three sections.

R-2 MOVING STICKS

We wish to show that if a stick moves perpendicular to its length, its length does not change. We do this by showing that any increase or decrease in length would contradict the principle of relativity. Showing that a stick does not change its length may seem mundane. However, we show it because an immediate consequence is that moving clocks run slow.

Suppose that we have two identical metersticks, stick A and stick B. We verify that the sticks are identical in length by placing them side by side and comparing their lengths visually. We then give stick B to Bob just before he takes off on another trip in his spaceship. On this trip, Bob makes sure to hold the stick at right angles to the velocity of the spaceship relative to Earth. Stick A remains back on Earth with us. During the trip, is stick B shorter than stick A?

To answer this question we conduct a thought experiment. We attach felt-tipped marking pens to stick A, one at the 20-cm mark, the other at the 80-cm mark. Then Bob and his spaceship execute a flyby, during which Bob holds stick B out a porthole, keeping it at right angles to the ship's velocity. During the flyby, we hold up our stick (stick A), keeping it parallel with stick B. As the sticks pass by each other, two marks are drawn on stick B by the pens (Figure R-2). Bob then returns to Earth with stick B, the two sticks are again placed side by side (Figure R-3), and the distance between the two marks on stick B and the distance between the two marking pens on stick A are compared. Let us assume that a stick moving perpendicular to its length is shorter than is an identical stick that is stationary. Then, the distance between the two pens on A will be less than the distance between the two marks on B (Figure R-3)—clear evidence that during the flyby the moving stick (stick B) was shorter than the stationary stick. However, according to the principle of relativity it is equally valid to think of stick B as stationary and stick A as moving during the flyby. From this perspective, the same evidence (Figure R-3) demonstrates that the moving stick—now stick A—is longer than the stationary stick. Thus, our assumption—that a stick moving perpendicular to its length is shorter than an identical stationary stick—leads to a contradiction and must be rejected. The assumption that a stick moving perpendicular to its length is longer than is an iden-

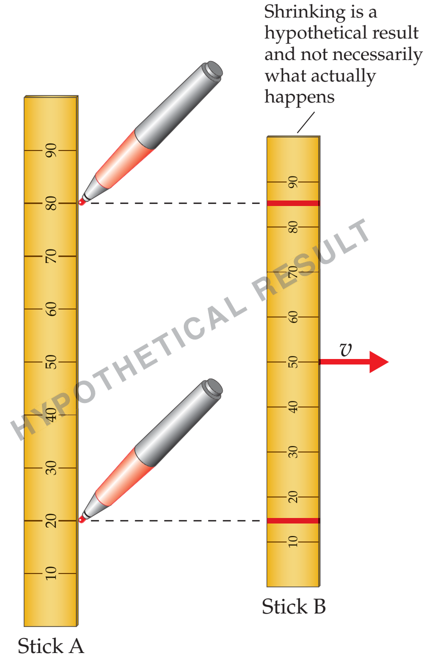

FIGURE R-2 During the flyby, marks like this would be made on stick B by marking pens attached to stick A, if the moving stick was shortened.

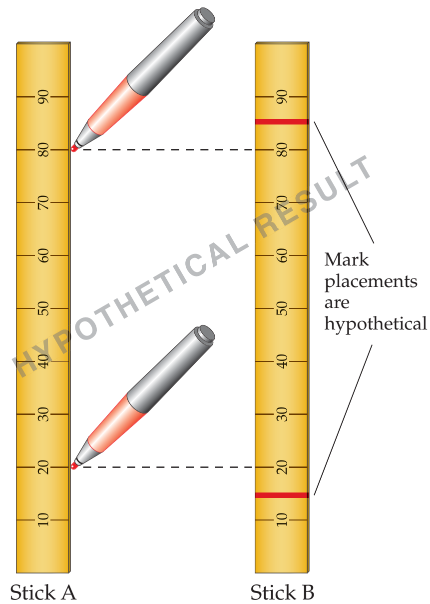

FIGURE R-3 If the distance between marks is greater than the distance between marker pens, this would demonstrate that stick B was shorter than stick A when the marks were made.

* Relative velocity in special relativity is covered in Chapter 39.

tical stationary stick also leads to a contradiction, as can be shown using an analogous argument. Thus, we conclude:

> A stick moving perpendicular to its length has the same length as an identical stick that is stationary.

This rule is established without any consideration of the material from which the two sticks are made. Thus, the rule does not reflect a property of sticks. Instead, it reflects a property of space.

The frame of reference in which the stick is at rest is called the **proper frame** or **rest frame** of the stick, and the length of a stick in its proper reference frame is called its **proper length** or **rest length.**

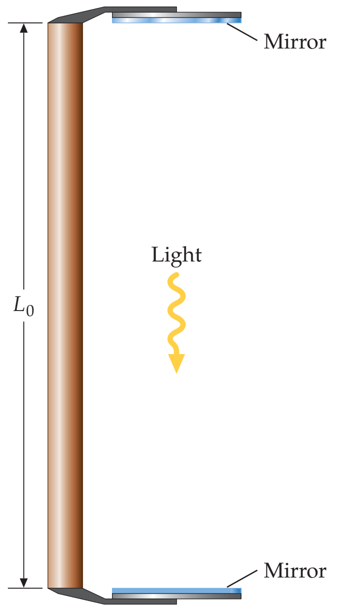

FIGURE R-4 The light clock ticks each time the light pulse reflects off the lower mirror.

R-3 MOVING CLOCKS

Clocks are used to measure time. In this section, we show that clocks moving at high speeds run slowly, so if a high-speed spaceship travels by us, we would observe that all the clocks on the ship run slower than our clocks. However, the people on the ship are free to consider themselves to be at rest and us to be moving, and they would observe that our clocks run slow compared to their clocks. Let us examine how these observations are consistent with the constancy of the speed of light and the principle of relativity.

We construct a clock, called a *light clock*, using a stick of proper length L_0 and two mirrors (Figure R-4). The two mirrors face each other, and a pulse of light bounces back and forth between them. Each time the light pulse strikes one of the mirrors, say the lower mirror, the clock is said to tick. Between successive ticks the light pulse travels a distance $2L_0$ in the proper reference frame of the clock. Thus, the time between ticks T_0 is related to L_0 by

$$2L_0 = cT_0 \qquad \text{R-1}$$

Next, we consider the time between ticks T of the same light clock, but this time we observe it from a reference frame in which the clock is moving perpendicular to the stick with speed v (Figure R-5). In this reference frame, the clock moves a distance vT between ticks and the light pulse moves a distance cT between ticks. The distance the pulse moves in traveling from the bottom mirror to the top mirror is $\sqrt{L_0^2 + (\frac{1}{2}vT)^2}$. The light pulse travels the same distance in traveling from the top mirror to the bottom mirror. Thus,

$$2\sqrt{L_0^2 + (\tfrac{1}{2}vT)^2} = cT \qquad \text{R-2}$$

Because the speed of light is the same in all inertial reference frames, we have used the same symbol c for the speed of light in Equations R-1 and R-2. Solving Equation R-1 for L_0 and substituting into Equation R-2 gives

$$\sqrt{(\tfrac{1}{2}cT_0)^2 + (\tfrac{1}{2}vT)^2} = \tfrac{1}{2}cT \qquad \text{R-3}$$

Solving for T gives

$$T = \frac{T_0}{\sqrt{1 - (v^2/c^2)}} \qquad \text{R-3}$$

TIME DILATION

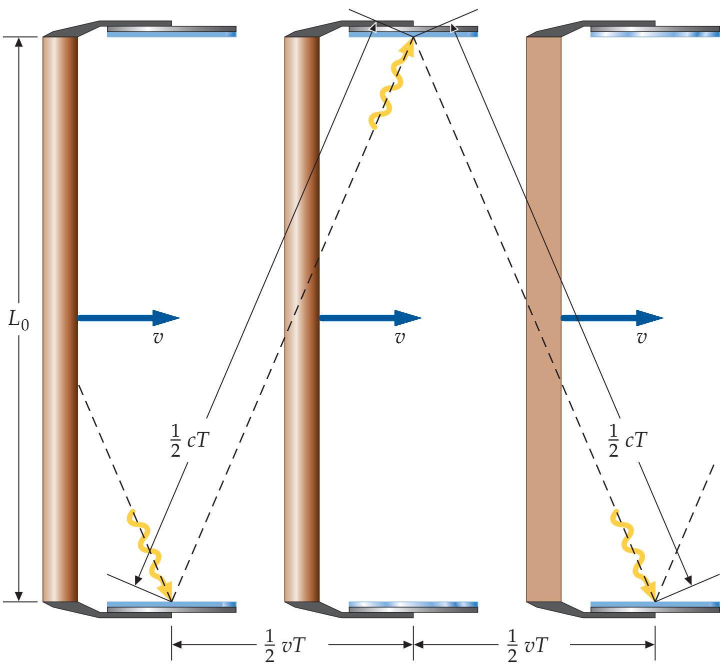

FIGURE R-5 The light clock moves with speed v.

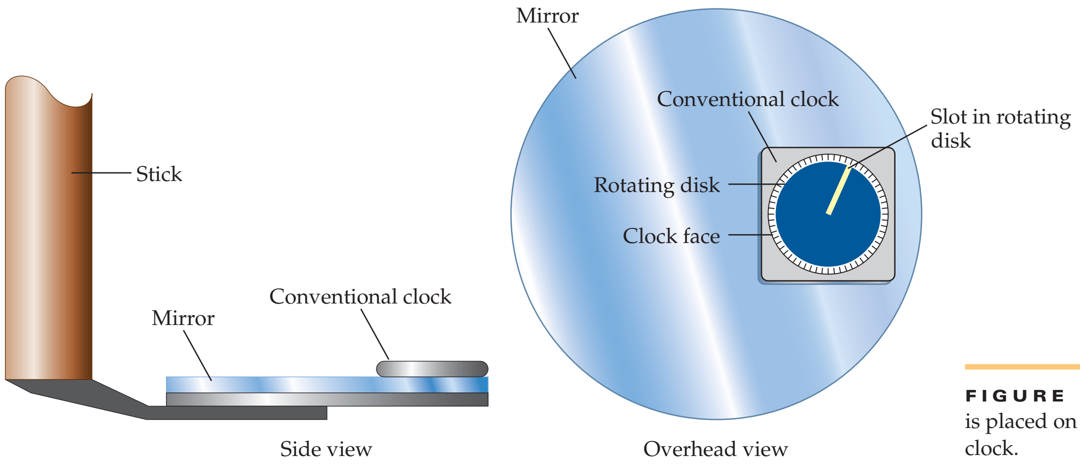

FIGURE R-6 A small conventional clock is placed on the lower mirror of the light clock.

According to Equation R-3, the time between ticks in the reference frame in which the clock moves at speed v is greater than the time between ticks in the proper reference frame of the clock.

This raises a question: Do other clocks run slow according to Equation R-3 when they move with speed v, or is Equation R-3 valid only for light clocks? To answer this question, we attach a conventional clock (with a conventional clock mechanism) to the lower mirror of the light clock (Figure R-6). The conventional clock has had the minute and hour hands removed. In place of a second hand, the clock has an opaque disk with a narrow slot to indicate the time. The clock's face contains 60 equal-spaced marks (called tick marks) around its perimeter—one for each second. The clock ticks each time the slot passes over one of the tick marks. We adjust the length L_0 of the light-clock stick so that the time between ticks of both clocks is the same in the proper reference frame of the clocks. Next, we synchronize the clocks so each tick of the light clock occurs simultaneously with a tick of the conventional clock. We then ask, "If the ticks of the two clocks occur simultaneously in the proper reference frame of the clocks, do they also occur simultaneously in a reference frame in which the clocks are moving at speed v?"

The answer is yes. To understand why this is so, consider the following thought experiment. In the proper reference frame of the clocks, the time between ticks of both clocks is exactly one second. A light-sensitive film is placed on the face of the conventional clock, behind the rotating disk. Each time the light pulse reflects off the lower mirror, a narrow region of the light-sensitive paper directly behind the slot gets exposed. These exposed regions will be aligned with the tick marks as shown in Figure R-7, and all observers must agree with this permanent record.

In reference frame A in which the clocks are both moving, the light pulse exposes the film behind the slot on the clock face each time the pulse reflects off the lower mirror. Because the light clock is moving, the time between these reflections is greater than 1 s, in accordance with Equation R-3. When an observer of reference frame A sees that the lines appearing where the film was exposed are aligned with the tick marks, she realizes that in her reference frame the conventional clock runs slow in exactly the same manner that the light clock runs slow—in accord with Equation R-3—and that this has nothing to do with the mechanism of the conventional clock. Thus, we conclude that all moving clocks run slow in exactly the same manner that a moving light clock runs slow. Because this is the case, we conclude that it is time itself that runs slow, a phenomenon known as **time dilation.**

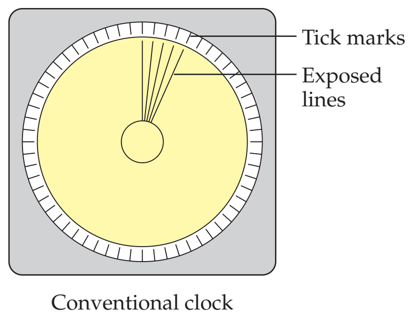

FIGURE R-7 The light striking the conventional clock that passes through the slot exposes the light-sensitive film behind the slot.

Something that occurs at a specific instant in time *and* at a specific location in space is called a **spacetime event,** or just an **event.** Each reflection of the light pulse off the lower mirror of the light clock is a spacetime event. If we call one of these reflections event 1, and the next reflection event 2, then the time between events 1 and 2 in a frame of reference in which the two events occur at the same location is called the **proper time interval** T_0 between the two events. Let T be the time between the same two events in a reference frame in which they occur at different locations. Equation R-3 relates the time T between two events to the proper time T_0 between the same two events.

Each time the light pulse reflects off the lower mirror, the slot (second hand) of the conventional clock is directly over a tick mark. In the proper frame of the two clocks, these two events—the arrival of the light pulse and the passing of the slot over a tick mark—occur at the same *time* and at the same place. Any two events that occur both at the same time and at the same place in one reference frame will occur both at the same time and at the same place in all reference frames. This is because such events can have lasting consequences—like producing lines on the light-sensitive film aligned with the tick marks on the clock face. We cannot have the marks aligned with the tick marks in one reference frame and not aligned with the tick marks in another reference frame. After all, there is only one clock face and one set of marks. This conclusion can be generalized into a principle called the principle of **invariance of coincidences:**

> If two events occur at the same time and at the same place in one reference frame, then they occur at the same time and at the same place in all reference frames.
>
> INVARIANCE OF COINCIDENCES

We can better visualize this principle by considering two automobiles passing through an intersection at the same time. The two events are (1) automobile A passes through the intersection, and (2) automobile B passes through the intersection. If these two events occur at the same time in one reference frame, then they must occur at the same time in all reference frames. Either a fender becomes dented or it does not. That is, if the automobiles collide, then there is no question that the two cars were in the intersection at the same time. The lasting evidence dictates that observers in all reference frames must agree on this fact. Any pair of events that occur at the same time *and* at the same location are referred to as a **spacetime coincidence.**

Example R-1 The Napping Astronauts *Context-Rich*

You work at space control and communicate regularly with astronauts in a spaceship traveling at $v = 0.600c$ relative to Earth. The astronauts sign off from space control, stating that they are going to nap for 1.00 h and then will call back. How long does their nap last according to you and other observers back on Earth?

PICTURE Clock S on the ship reads t_0 when the nap begins (a spacetime coincidence) and reads $t_0 + 1.00$ h when the nap ends (also a spacetime coincidence). Observers on the ship agree that, because clock S is stationary it does not run slow, so the nap lasted 1.00 h. In the reference frame of the ship, the two events (the beginning of the nap and the end of the nap) occur at the same location, so the time interval between the events is the proper time interval between them. You and other observers on Earth agree that clock S reads t_0 when the nap begins and it reads $t_0 + 1.00$ h when the nap ends. However, you and other observers on Earth also agree that because clock S is moving at speed v, it is running slow, so the nap lasted more than 1.00 h. In the reference frame of Earth, the ship is moving so the nap begins and ends at different locations. Therefore, in the reference frame of Earth, the time interval between the events is not the proper time interval between the events.

SOLVE

1. Event 1 is the beginning of the nap and event 2 is the end of the nap. Clock S on the ship advances 1.00 h between these events. Determine the proper time interval T_0 between these events:

$$T_0 = 1.00\text{ h}$$

2. Find the time interval T between events 1 and 2 for you and other observers on Earth:

$$T = \frac{T_0}{\sqrt{1 - (v^2/c^2)}} = \frac{1.00\text{ h}}{\sqrt{1 - \dfrac{(0.600c)^2}{c^2}}}$$

$$= \frac{1.00\text{ h}}{\sqrt{1 - 0.360}} = \frac{1.00\text{ h}}{\sqrt{0.640}} = \frac{1.00\text{ h}}{0.800} = \boxed{1.25\text{ h}}$$

CHECK The length of the nap is longer in the reference frame in which the napping person is moving, which is in accord with Equation R-3.

TAKING IT FURTHER Clock S is an unnecessary construct, as the astronauts themselves serve as clocks. What is necessary to realize is that the proper time between the beginning and the end of the nap is 1.00 h, so the time T *between* the same two events in a reference frame where the clocks (astronauts) are moving with speed v is given by Equation R-3.

PRACTICE PROBLEM R-1 A pion* has a mean proper lifetime of 26 ns ($1\text{ ns} = 1 \times 10^{-9}\text{ s}$) (measured when the pion is at rest). What is the mean pion lifetime if measured when the pion is moving at $0.995c$?

PRACTICE PROBLEM R-2 A beam of pions (see Practice Problem R-1) moving at $0.995c$ passes point P. How far from P do the pions travel before only half of the pions in the beam remain?

R-4 MOVING STICKS AGAIN

In Section R-2 the length of a stick moving perpendicular to its length and the length of an identical stationary stick are compared and found to be equal. However, the technique used for this comparison works only if the velocity of the moving stick is perpendicular to the length of the stick. Here we apply a different technique to compare the length of a stick at rest to its length when the stick is moving parallel to its length.

A light clock is shown in its proper frame in Figure R-8. This clock ticks each time the light pulse reflects off the mirror on the left. In its proper reference frame, the length of the clock is L_0 and the time between ticks is $T_0 = 2L_0/c$ (Equation R-1). To find the length of the clock in a reference frame in which it is moving to the right at speed v we consider three sequential events:

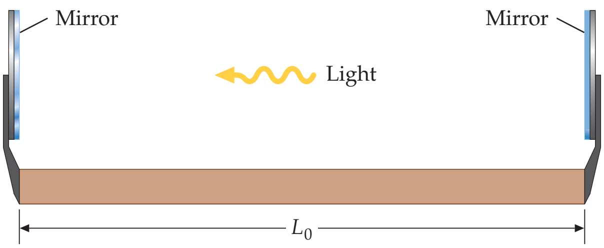

FIGURE R-8

Event 0 Light pulse reflects off the mirror at the left end.
Event 1 Light pulse reflects off the mirror at the right end.
Event 2 Light pulse reflects off at the mirror at the left end.

In Figure R-9, the clock is shown at the time of each of these events in a reference frame in which the clock moves to the right with speed v. (The clock is drawn lower down the page at later times to avoid visual overlap.) The times of occurrence for events 0, 1, and 2 in this reference frame are t'_0, t'_1, and t'_2, respectively. In the time between events 0 and 1, the clock moves a distance $v(t'_1 - t'_0)$ and the light pulse travels a distance $c(t'_1 - t'_0)$. Thus,

$$c(t'_1 - t'_0) = L + v(t'_1 - t'_0) \qquad \text{R-4}$$

* A pion (short for pi meson) is a subatomic particle.

In the time between events 1 and 2 the clock moves a distance $v(t'_2 - t'_1)$ and the light pulse travels a distance $c(t'_2 - t'_1)$, so

$$c(t'_2 - t'_1) = L - v(t'_2 - t'_1) \qquad \text{R-5}$$

Eliminating t'_1 by solving Equation R-4 for t'_1, substituting the result into Equation R-5, and then solving for $t'_2 - t'_0$ gives

$$t'_2 - t'_0 = \frac{2L/c}{1 - (v^2/c^2)} \qquad \text{R-6}$$

The time interval $t'_2 - t'_0$ is related to the proper time interval $t_2 - t_0$ between events 0 and 2 (Equation R-3) by

$$t'_2 - t'_0 = \frac{t_2 - t_0}{\sqrt{1 - (v^2/c^2)}} \qquad \text{R-7}$$

where $t_2 - t_0 = 2L_0/c$ (Equation R-1). Substituting $2L_0/c$ for $t_2 - t_0$ gives

$$t'_2 - t'_0 = \frac{2L_0/c}{\sqrt{1 - (v^2/c^2)}} \qquad \text{R-8}$$

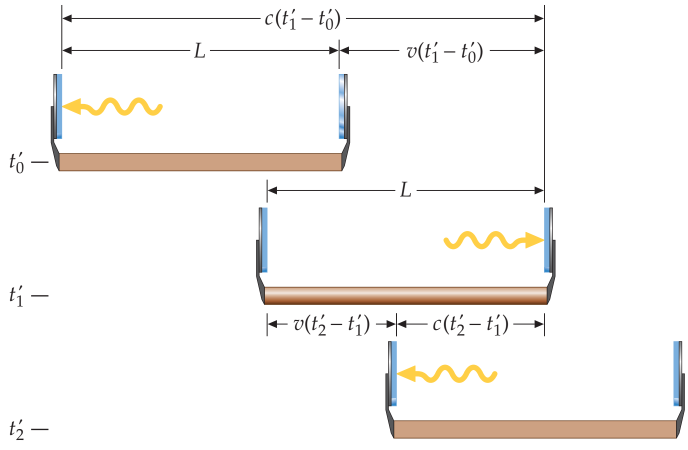

FIGURE R-9 A light clock moving to the right at speed v is shown at times t_0, t_1, and t_2.

Equating the right sides of Equations R-6 and R-8, and then solving for L gives

$$L = L_0\sqrt{1 - (v^2/c^2)} \qquad \text{R-9}$$

LENGTH CONTRACTION

Establishing this result did not involve any properties of the stick. Thus, Equation R-9 reflects the nature of space and time, and not the nature of the sticks.

Example R-2 The Length of a Railroad Car

Keisha is on a train that is moving at $0.80c$ relative to the station. She measures the length of the railroad car she is in, and finds its length to be 40 m. Bob is standing on the station platform as the train streaks by. Bob measures the time it takes for the car to pass him and multiplies this time by $0.80c$ to determine the length of the car. What is the length of the car according to Bob's calculation?

PICTURE The car is at rest in Keisha's reference frame, so 40 m is the proper length of the car.

SOLVE

The car is at rest in Keisha's frame, so 40 m is its proper length. In Bob's frame the train is moving at $0.8c$. Use Equation R-9 to find the length of the car in Bob's frame:

$$L = L_0\sqrt{1 - (v^2/c^2)} = 40\text{ m}\sqrt{1 - 0.80^2} = \boxed{24\text{ m}}$$

CHECK As expected, the car is shorter in the reference frame in which it is moving.

R-5 DISTANT CLOCKS AND SIMULTANEITY

We have established three useful relations: (1) that the length of a stick moving perpendicular to its length is the same as its rest length; (2) that the time T *between* two ticks of a moving clock is greater than the proper time between the two ticks of the same clock according to $T = T_0/\sqrt{1 - (v^2/c^2)}$; and (3) that the length L of a stick moving parallel to its length is less than its rest length L_0 according to $L = L_0\sqrt{1 - (v^2/c^2)}$. But in order to analyze events from the perspective of observers in reference frames moving at different velocities, we need one more relation, one that concerns clocks at different locations.

Clocks A and B (Figure R-10*a*) are at rest relative to each other, and in their rest frame the clocks are separated by a distance L_0. To synchronize these clocks there is a flashlamp on clock A and a light-sensitive film on the face of clock B. The alarm on clock A is set to energize the flashlamp when the second hand on clock A passes zero. Like the conventional clock described in Section R-3, clock B has only a second hand, a rotating opaque disk with a slot to indicate the time. Behind the disk is a light-sensitive film. When the light from the flash reaches clock B, the film is illuminated on the narrow region behind the slot. This provides a lasting record of the reading on clock B when the light from the flashlamp reaches it. Let this reading be t_1. In the rest frame of the clocks, the time for the light to travel at speed c from clock A to clock B is L_0/c, so when the light arrives at clock B, clock A reads L_0/c and clock B reads t_1. To synchronize the two clocks, we turn clock B back by $\Delta t = t_1 - L_0/c$.

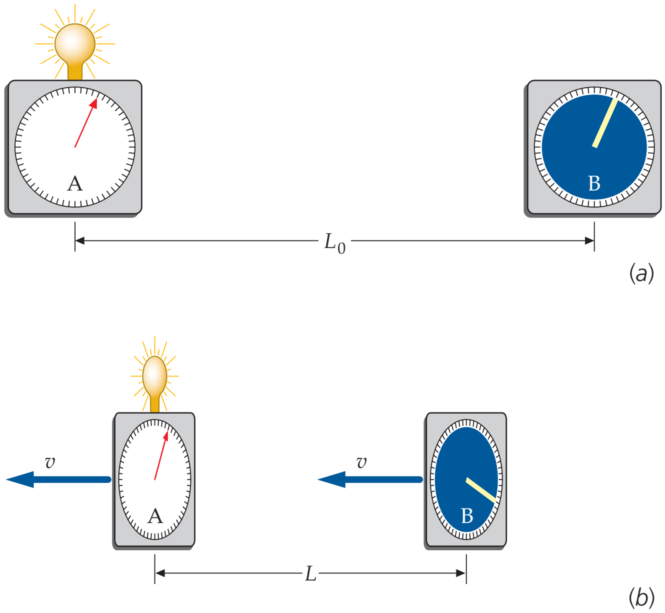

FIGURE R-10 (*a*) The clocks are synchronized in the reference frame in which they are at rest. (*b*) Are the clocks also synchronized in the reference frame in which they are moving with speed v parallel to the line joining them?

With the two clocks synchronized in their rest frame (frame 1), we then determine whether they are also synchronized in a reference frame (frame 2) in which they are moving at speed v parallel to the line joining them (shown in Figure R-10*b*). We reset the alarm to energize the flashlamp when clock A next reads zero. These two events—clock A reads zero and the lamp flashes—are a spacetime coincidence, so we know they occur simultaneously in all reference frames. Also, the light reaching clock B and clock B reading L_0/c, are a spacetime coincidence, so we know they occur simultaneously in all reference frames.

In frame 2, the distance L between the clocks is given by

$$L = L_0\sqrt{1 - (v^2/c^2)}$$

and clock B is moving toward the flashlamp. In this frame, the light traveling from clock A to clock B travels a distance $L - vt$, where t is the time required for the light to travel this distance. Thus, the time t, the distance L, and the speed v are related by

$$ct = L - vt$$

Solving for the time gives $t = L/(c + v)$.

Moving clocks run slow, so during time t the readings on both clocks advance not by t but $t\sqrt{1 - (v^2/c^2)}$, where $t = L/(c + v)$. This advance is equal to

$$\frac{L}{c + v}\sqrt{1 - (v^2/c^2)} = \frac{L_0\sqrt{1 - (v^2/c^2)}}{c + v}\sqrt{1 - (v^2/c^2)}$$

$$= \frac{L_0}{(c + v)}\frac{(c + v)(c - v)}{c^2} = \frac{L_0}{c} - \frac{vL_0}{c^2}$$

Thus, when the light arrives at clock B, clock B reads L_0/c and clock A reads $L_0/c - vL_0/c^2$. Therefore, in frame 2, clock B is ahead of clock A by vL_0/c^2:

> If two clocks that are moving with the same velocity are synchronized in their rest frame, then in a frame where they move with speed v parallel to the line joining them, the clock in the rear is ahead of the clock in front by vL_0/c^2.
>
> THE RELATIVITY OF SIMULTANEITY

In this case, L_0 is the distance between the clocks in their rest frame. It is also true that if two clocks are synchronized in their rest frame, they are also synchronized in any frame in which they are moving perpendicular to the line joining them. This condition follows from the symmetry of the situation. (For one thing, there is no way to state a rule specifying which of the two clocks is ahead.)

APPLYING THE RULES

Example R-3 A Train Through a Tunnel

A high-speed train is about to enter a tunnel through a mountain. The tunnel has a proper length of 1.2 km. The length of the train in the reference frame of the mountain is also 1.2 km, and the proper length of the train is 2.0 km. Clock A is attached to the mountain at the entrance to the tunnel, and clock B is attached to the mountain at the exit to the tunnel. In the reference frame of the mountain, at the instant the front of the train enters the tunnel both clocks read zero. (*a*) In the reference frame of the mountain, what is the speed of the train, and what is the reading of both clocks at the instant the front of the train exits the tunnel (Figure R-11*a*)? (*b*) In the reference frame of the train, what is the length of the tunnel, what is the reading of both clocks at the instant the front of the train enters the tunnel (Figure R-11*b*), and what is the reading of both clocks at the instant the front of the train exits the tunnel? (*c*) For a passenger on the train, how long does it take for the front of the train to pass through the tunnel?

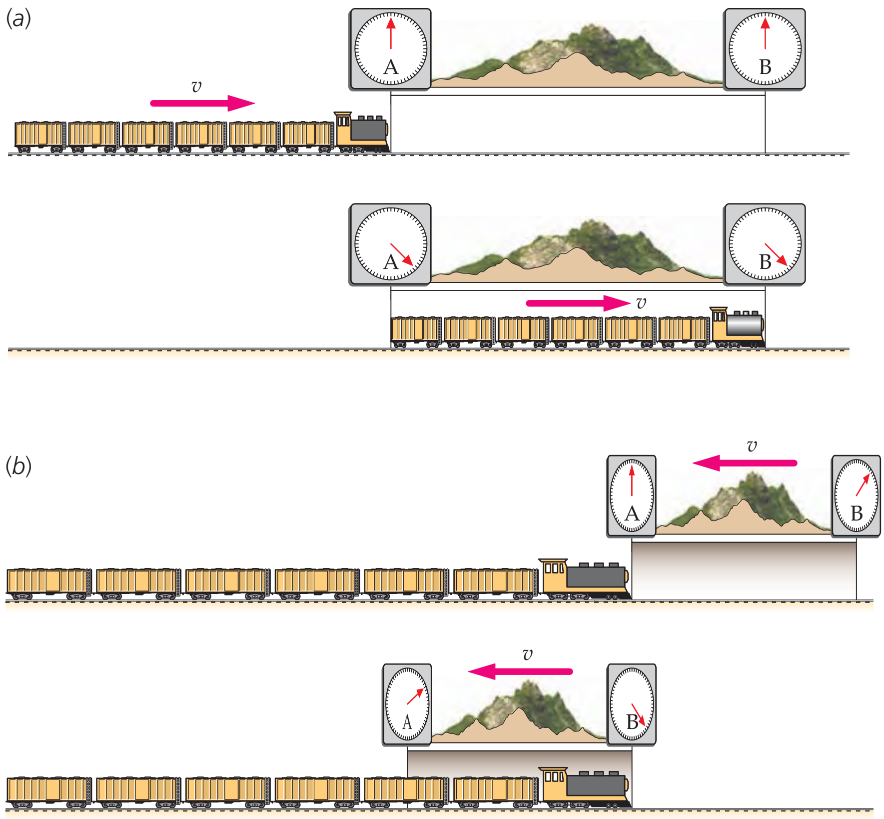

FIGURE R-11 (*a*) In the reference frame of the mountain, the train approaches the tunnel at high speed. The clocks are synchronized in this reference. (*b*) In the reference frame of the train, the tunnel (and the mountain) approaches at high speed. Clock B is ahead of clock A in this reference frame.

PICTURE The speed of the train and the length of the train are related by the length-contraction formula. Some of the clock readings in the two reference frames can be equated because they are event pairs that form spacetime coincidences. Other clock readings can be related by the relativity-of-simultaneity relation.

SOLVE

(*a*) 1. Using the length-contraction formula, solve for the speed of the train:

$$L = L_0\sqrt{1-(v^2/c^2)}$$

$$1.2\text{ km} = 2.0\text{ km}\sqrt{1-(v^2/c^2)}$$

$$\text{so}\quad v = 0.80c = 0.80(3.00\times10^8\text{ m/s}) = \boxed{2.4\times10^8\text{ m/s}}$$

2. The length of the tunnel equals its proper length, and because the clocks are not moving, they do not run slow. The reading on both clocks is the time t that it takes for the front of the train to travel the length of the tunnel:

$$L_{\text{tunnel }0} = vt$$

$$\text{so}\quad t = \frac{L_{\text{tunnel }0}}{v} = \frac{1.2\times10^3\text{ m}}{2.4\times10^8\text{ m/s}} = 5.0\times10^{-6}\text{ s} = \boxed{5.0\ \mu\text{s}}$$

3. The clocks are synchronized, so when the front of the train exits the tunnel, both clocks read 5 μs:

$$\text{Clock A reading} = \text{Clock B reading} = \boxed{5.0\ \mu\text{s}}$$

(*b*) 1. In this frame, the mountain is moving at 0.80c. Using the length-contraction formula, solve for the length of the tunnel:

$$L_{\text{tunnel}} = L_{\text{tunnel }0}\sqrt{1-(v^2/c^2)} = 1.2\text{ km}\sqrt{1-\frac{(0.80c)^2}{c^2}}$$

$$= 1.2\text{ km}\sqrt{1-0.80^2} = \boxed{0.72\text{ km} = 720\text{ m}}$$

2. The front of the train entering the tunnel and a zero reading on clock A are a spacetime coincidence:

$$\boxed{\text{Clock A reads zero}}$$

3. The two clocks are moving toward the train with clock B in the rear, so clock B is ahead of clock A by vL_0/c^2. When the train enters the tunnel, clock A reads zero, so clock B reads vL_0/c^2:

$$\text{Clock B reading} = \frac{vL_{\text{tunnel }0}}{c^2} = \frac{0.80L_{\text{tunnel }0}}{c}$$
$$= \frac{0.80(1.2 \times 10^3\text{ m})}{3.0 \times 10^8\text{ m/s}} = \boxed{3.2\ \mu\text{s}}$$

4. The front of the train exiting the tunnel and a 5.0-μs reading of clock B are a spacetime coincidence:

$$\text{Clock B reads} = \boxed{5.0\ \mu\text{s}}$$

5. Clock B is in the rear, so clock A lags behind clock B by vL_0/c^2.

$$\text{Clock A reading} = \text{clock B reading} - \frac{vL_{\text{tunnel }0}}{c^2}$$
$$= 5.0\ \mu\text{s} - 3.2\ \mu\text{s} = \boxed{1.8\ \mu\text{s}}$$

(*c*) For an observer in the reference frame of the train, the mountain is traveling at 0.80*c* and the tunnel is 720-m long:

$$L_{\text{tunnel}} = vt$$
$$\text{so}\quad t = \frac{L_{\text{tunnel}}}{v} = \frac{L_{\text{tunnel}}}{0.80c} = \frac{720\text{ m}}{2.4 \times 10^8\text{ m/s}} = \boxed{3.0\ \mu\text{s}}$$

CHECK Our Part (*c*) result of 3.0 μs is less than the Part-(*a*) step-2 result of 5 μs. This result is as expected. After all, the train is 1.2-km long in Part (*a*) and the tunnel is only 720-m long in Part (*c*).

TAKING IT FURTHER In the reference frame of the train, the train is longer than the tunnel so at no time is the entire train within the tunnel.

CONCEPT CHECK R-1

Event 1 is the front of the train entering the tunnel, and event 2 is the front of the train exiting the tunnel. (*a*) In which reference frame do these two events occur at the same location? (*b*) What is the proper time interval between events 1 and 2?

It is often convenient to measure large distances in light-years, where a light-year is the distance traveled when traveling at the speed of light for a time of one year. That is,

$$1\text{ light-year} = 1\ c\cdot\text{y}$$

where $1\ c\cdot\text{y} = c\cdot(1\text{ y})$. This notation is particularly convenient when distances are divided by speeds. For example, the time T for a particle traveling at $v = 0.10c$ to travel a distance of $L = 25$ light-years is

$$T = \frac{L}{v} = \frac{25\ c\cdot\text{y}}{0.10c} = 250\text{ y}$$

where the c's cancel.

PRACTICE PROBLEM R-3

In the reference frame of Earth, it takes 8 minutes for light to travel from the Sun to Earth, so the distance between the Sun and Earth is $8.3c\cdot\text{min}$. How many minutes does it take a particle from the Sun to reach Earth if the particle travels at 0.10*c*?

R-6 RELATIVISTIC MOMENTUM, MASS, AND ENERGY

MOMENTUM AND MASS

In special relativity, both momentum and energy are conserved, just as they are in classic physics. The laws of conservation of momentum and energy are essential to analyzing the high-speed collisions that take place in high-energy physics laboratories. However, the classic equations for conserving momentum and energy are not adequate for the analysis of high-speed collisions. Here, we present the relativistically correct form of these conservation equations. The momentum of a particle moving with velocity v is given by

$$p = \frac{mv}{\sqrt{1 - (v^2/c^2)}} \qquad \text{R-10}$$

RELATIVISTIC MOMENTUM

where m is the mass of the particle.* The relativity of momentum is discussed further in Chapter 39.

ENERGY

In relativistic mechanics, as in classic mechanics, the net force on a particle is equal to the time rate of change of the momentum of the particle. Considering one-dimensional motion only, we have

$$F_{\text{net}} = \frac{dp}{dt} \qquad \text{R-11}$$

We wish to find an expression for the kinetic energy. To do this, we multiply both sides of Equation R-11 by the displacement $d\ell$. This gives

$$F_{\text{net}}\, d\ell = \frac{dp}{dt}\, d\ell \qquad \text{R-12}$$

where we identify the term on the left as the work and the term on the right as the change in kinetic energy dK. Substituting $v\,dt$ for $d\ell$ in the term on the right we obtain

$$dK = \frac{dp}{dt} v\, dt = v\, dp$$

Integrating both sides gives

$$K = \int_0^{p_\text{f}} v\, dp \qquad \text{R-13}$$

To evaluate this integral, we first change the integration variable from p to v. Using Equation R-10 and the quotient rule, we have

$$dp = d\left(\frac{v}{\sqrt{1 - (v^2/c^2)}}\right)$$

$$= \frac{[1 - (v^2/c^2)]^{1/2} dv - v\dfrac{1}{2}[1 - (v^2/c^2)]^{-1/2}\left(-\dfrac{2v dv}{c^2}\right)}{1 - (v^2/c^2)} = \frac{dv}{[1 - (v^2/c^2)]^{3/2}}$$

Substituting for dp in Equation R-13 gives

$$K = \int_0^{p_\text{f}} v dp = m\int_0^{v_\text{f}} \frac{v dv}{[1 - (v^2/c^2)]^{3/2}} = mc^2\left(\frac{1}{\sqrt{1 - (v_\text{f}^2/c_2)}} - 1\right)$$

so

$$K = \frac{mc^2}{\sqrt{1 - (v^2/c^2)}} - mc^2 \qquad \text{R-14}$$

(In this expression, because the only speed is v_f, the subscript f is not needed.)

---

* Equation R-10 is sometimes written $p = m_\text{r} v$, where m_r is called the *relativistic mass*: $m_\text{r} = m/\sqrt{1 - (v^2/c^2)}$. In the rest frame of the particle, $v = 0$ and $m_\text{r} = m$. (The mass m is sometimes called the *rest mass* to differentiate it from the relativistic mass.)

Defining $mc^2/\sqrt{1-(v^2/c^2)}$ as the **total relativistic energy** E, Equation R-14 can be written

$$E = K + mc^2 = \frac{mc^2}{\sqrt{1-(v^2/c^2)}} \qquad \text{R-15}$$

where mc^2, called the **rest energy** E_0, is energy the particle has when it is at rest.

By multiplying both sides of Equation R-10 by c and then dividing the resulting equation by Equation R-15, we obtain

$$\frac{v}{c} = \frac{pc}{E} \qquad \text{R-16}$$

which can be useful when trying to solve for the speed v. Eliminating v from Equations R-10 and R-16, and solving for E^2, gives

$$E^2 = p^2c^2 + m^2c^4 \qquad \text{R-17}$$

The relation between mass and energy is briefly discussed in Section 4 of Chapter 7.

See **Math Tutorial** *for more information on the* **Binomial Expansion**

Example R-4 Momentum and Energy

A proton has kinetic energy of 1100 MeV and a mass of 938 MeV/c^2. What is its momentum? What is its speed?

PICTURE Equations R-15 and R-17 relate the momentum to the total energy, the kinetic energy and the mass. Equation R-16 relates the speed to the momentum and the total energy.

SOLVE

1. The momentum is related to the total energy by Equation R-17, and the total energy is related to the kinetic energy by Equation R-15:
   $E^2 = p^2c^2 + m^2c^4$
   $E = K + mc^2$
2. Substitute for E in the first step-1 equation and solve for p^2c^2:
   $(K + mc^2)^2 = p^2c^2 + m^2c^4$
   so $p^2c^2 = (K + mc^2)^2 - m^2c^4$
3. Calculate the value of p^2c^2:
   $p^2c^2 = (1100\text{ MeV} + 938\text{ MeV})^2 - (938\text{ MeV})^2 = 3.27 \times 10^6\ (\text{MeV})^2$
4. Solve for p:
   $p = \sqrt{3.27 \times 10^6}\ \text{MeV}/c = 1.81 \times 10^3\ \text{MeV}/c = \boxed{1.8 \times 10^3\ \text{MeV}/c}$
5. Using Equation R-16 solve for the speed:
   $\frac{v}{c} = \frac{pc}{E} = \frac{pc}{K + mc^2} = \frac{1.81 \times 10^3\text{ MeV}}{1100\text{ MeV} + 938\text{ MeV}} = 0.888$
   so $\boxed{v = 0.888c = 0.89c}$

CHECK As expected, the speed is greater than zero and less than c. In addition, the kinetic energy is greater than the rest energy (938 MeV), so we expect the speed to be a significant fraction of c.

Example R-5 Colliding Particles *Conceptual*

Two identical particles, each with mass m, travel in opposite directions, each with a total energy equal to twice its rest energy. They undergo a perfectly inelastic head-on collision and stick together to form a single particle of mass M. Find M.

PICTURE Use conservation of momentum to determine the speed of the mass-M particle. Use conservation of energy to find the mass of the mass-M particle.

SOLVE

1. The identical particles have the same mass, m, and the same total energy, E, so they have the same speed. They are traveling in opposite directions, so the momentum of one is equal and opposite to the momentum of the other. The total momentum of the two-particle system is zero.

Conservation of momentum tells us that the momentum, and thus the speed, of the mass-M particle is zero.

2. The particle of mass M is at rest, so its total energy is equal to its rest energy Mc^2. For each mass-m particle, the total energy is twice the rest energy mc^2. *Conservation of energy* tells us that the total energy in the same before and after the collision.

$E_f = E_i$

$Mc^2 = 2mc^2 + 2mc^2$

$\therefore \boxed{M = 4m}$

CHECK The kinetic energies of the two mass-m particles is transformed into the rest energy of the mass-M particle. Because the kinetic energy of each mass-m particle is equal to its rest energy, the mass of the mass-M particle is equal to $4m$.

! Do not think during an inelastic collision mass is conserved. It is not. Mass is proportional to rest energy. If kinetic energy is transformed into rest energy, then the mass increases.

Summary

1. The principle of relativity is a *fundamental law of physics.*

2. That the speed of light in a vacuum is independent of the speed of the source is a *fundamental law of physics.*

TOPIC	RELEVANT EQUATIONS AND REMARKS
1. Postulates of Special Relativity	
Postulate I: Principle of relativity	It is impossible to devise an experiment that determines whether you are at rest or moving uniformly, where moving uniformly means moving at constant velocity relative to an inertial reference frame.
Postulate II	The speed of light is independent of the speed of the source.
Constancy of the speed of light	It follows that the speed of light is the same in any inertial reference frame.
2. Moving Sticks	The length of a stick moving perpendicular to its length is equal to its proper length. The length of a stick moving with speed v parallel to its length is shorter than its proper length according to $$L = L_0\sqrt{1-(v^2/c^2)} \quad \text{R-9}$$
3. Moving Clocks	
Time dilation	The time between ticks of a clock moving with speed v is longer than the proper time between ticks of the same clock by $$T = \frac{T_0}{\sqrt{1-(v^2/c^2)}} \quad \text{R-3}$$
Relativity of simultaneity	If two clocks that move with the same velocity are synchronized in their rest frame, in a frame where they move with speed v parallel to the line joining them, the clock in the rear is ahead of the clock in front by vL_0/c^2, where L_0 is the distance between them in their rest frame. If two clocks that move with the same velocity are synchronized in their rest frame they are also synchronized in any frame where they are moving perpendicular to the line joining them.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
4. Spacetime Coincidence	If two events occur both at the same time *and* at the same place in one reference frame, they occur both at the same time and at the same place in any reference frame.	
5. Momentum, Mass, and Energy		
Momentum	The momentum of a particle is given by $$p = \frac{m_0 v}{\sqrt{1-(v^2/c^2)}}$$	R-10
Kinetic energy	$$K = \left(\frac{1}{\sqrt{1-(v^2/c^2)}} - 1\right)mc^2$$	R-14
Mass and energy	The total relativistic energy E of a particle equals its rest energy plus its kinetic energy. $$E = K + mc^2 = \frac{mc^2}{\sqrt{1-(v^2/c^2)}}$$ where mc^2 is the rest energy E_0.	R-15

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • **CONTEXT-RICH** You are standing on a corner when you see a friend drive past you in a car. Each of you is wearing a wristwatch. Both of you note the times when the car passes two different intersections and determine from your watch readings the time that elapses between the two events. Have either of you determined the proper time interval? Explain your answer.

2 • **CONTEXT-RICH** In Problem 1, suppose your friend in the car measures the width of the car door to be 90 cm. You also measure the width as he goes by you. (*a*) Does either of you measure the proper width of the door? Explain your answer. (*b*) How will your value for the door width compare to his? (1) Your value will be smaller. (2) Your value will be larger. (3) Your value will be the same. (4) You cannot compare the widths, as the answer depends on the car's speed.

3 • If event A occurs at a different location than event B in some reference frame, might it be possible for there to be a second reference frame in which they occur at the same location? If so, give an example. If not, explain why not. SSM

4 • If event A occurs prior to event B in some reference frame, might it be possible for there to be a second reference frame in which event B occurs prior to event A? If so, give an example. If not, explain why not.

5 • Two events are simultaneous in a reference frame in which they also occur at the same location. Are they simultaneous in all other reference frames? SSM

6 • Two inertial observers are in relative motion. Under what circumstances can they agree on the simultaneity of two different events?

7 • The approximate total energy of a particle of mass m moving at speed $v \ll c$ is (*a*) $mc^2 + \frac{1}{2}mv^2$, (*b*) mv^2, (*c*) cmv, (*d*) $\frac{1}{2}mc^2$.

8 • True or false:
(*a*) The speed of light is the same in all reference frames.
(*b*) The proper time interval is the shortest time interval between two events.
(*c*) Absolute motion can be determined by means of length contraction.
(*d*) The light-year is a unit of distance.
(*e*) For two events to form a spacetime coincidence, they must occur at the same place.
(*f*) If two events are not simultaneous in one reference frame, they cannot be simultaneous in any other reference frame.

9 •• (*a*) Show that pc has dimensions of energy. (*b*) There is a geometrical interpretation of Equation R-17 based on the Pythagorean theorem. Draw a picture of a triangle illustrating this interpretation.

10 •• A wad of putty of mass m_1 strikes and sticks to a second wad of putty of mass m_2, which is initially at rest. Do you expect that after the collision the combined putty mass will be (*a*) greater than, (*b*) less than, (*c*) the same as $m_1 + m_2$? Explain your answer.

11 •• **Biological Application** Many nuclei of atoms are unstable; for example, ^{14}C, an isotope of carbon, has a half-life of 5700 years. (By definition, the *half-life* is the time it takes for any given number of unstable particles to decay to half that number of particles.) This fact is used extensively for archeological and biological dating of old artifacts. Such unstable nuclei decay into several decay products, each with significant kinetic energy. Which of the following is true? (*a*) The mass of the unstable nucleus is larger than the sum of the masses of the decay products. (*b*) The mass of the unstable nucleus is smaller than the sum of the masses of the decay products. (*c*) The mass of the unstable nucleus is the same as the sum of the masses of the decay products. Explain your choice. SSM

12 •• **Biological Application** Positron emission tomography (PET) scans are common in modern medicine. During this procedure, positrons (a positron has the same mass but the opposite charge of an electron) are emitted by radioactive nuclei that have been introduced into the body. Assume that an emitted positron, traveling slowly (with negligible kinetic energy), collides with an electron traveling at the same slow speed in the opposite direction. They undergo annihilation and two quanta of light (photons) are formed. You are in charge of designing detectors to receive these photons and measure their energies. (*a*) Explain why you would expect these two photons to come off in exactly opposite directions. (*b*) In terms of the electron mass m_e, how much energy would each photon have? (1) less than mc^2, (2) greater mc^2, (3) exactly mc^2. Explain your choice.

ESTIMATION AND APPROXIMATION

13 •• In 1975, an airplane carrying an atomic clock flew back and forth at low altitude for 15 hours at an average speed of 140 m/s as part of a time-dilation experiment. The time on the clock was compared to the time on an atomic clock kept on the ground. What is the time difference between the atomic clock on the airplane and the atomic clock on the ground? (Ignore any effects that accelerations of the airplane have on the atomic clock that is on the airplane. Also assume that the airplane travels at costant speed.) SSM

14 •• (*a*) By making any necessary assumptions and finding certain stellar distances, estimate the speed at which a spaceship would have to travel for its passengers to make a trip to the nearest star (not the Sun!) and back to Earth in 1.0 Earth years, as measured by an observer on the spaceship. Assume that the passengers make the outgoing and return trips at constant speed, and ignore any effects due to the spaceship stopping and starting. (*b*) How much time would elapse on Earth during their round-trip? Include 2.0 Earth years for a low-speed exploration of the planets in the vicinity of the star.

15 •• (*a*) Compare the kinetic energy of a moving car to its rest energy. (*b*) Compare the total energy of a moving car to its rest energy. (*c*) Estimate the error made in computing the kinetic energy of a moving car using nonrelativistic expressions compared to the relativistically correct expressions. *Hint: Use of the binomial expansion may help.*

LENGTH CONTRACTION AND TIME DILATION

16 • The proper average (or mean) lifetime of a pion (a subatomic particle) is 2.6×10^{-8} s. (A neutral pion has a much shorter lifetime. See Chapter 41.) A beam of pions has a speed of 0.85c relative to a laboratory. (*a*) What would be their mean lifetime as measured in that laboratory? (*b*) On average, how far would they travel in that laboratory before they decay? (*c*) What would your answer to Part (*b*) be if you had neglected time dilation?

17 • In the reference frame of a pion in Problem 16, how far does the laboratory travel in 2.6×10^{-8} s? SSM

18 • The proper average (or mean) lifetime of a muon (a subnuclear particle) is 2.20 μs. Muons in a beam are traveling at 0.999c relative to a laboratory. (*a*) What is their lifetime as measured in that laboratory? (*b*) On average, how far do they travel in that laboratory before they decay?

19 • In the reference frame of the muon in Problem 18, how far does the laboratory travel in 2.20 μs?

20 • **Context-Rich** You have been posted to a remote region of space to monitor traffic. Toward the end of a quiet shift, a spacecraft goes by and you measure its length using a laser device. This device reports a length of 85.0 m. You flip open your handy reference catalog and identify the craft as a CCCNX-22, which has a proper length of 100 m. When you phone in your report, what speed should you give for this spacecraft?

21 • A spaceship travels from Earth to a star 95 light-years away at a speed of 2.2×10^8 m/s. How long does the spaceship take to get to the star (*a*) as measured on Earth and (*b*) as measured by a passenger on the a spaceship? SSM

22 • The average lifetime of a beam of subatomic particles called pions (see Problem 16 for details on these particles) traveling at high speed is measured to be 7.5×10^{-8} s. Their average lifetime at rest is known to be 2.6×10^{-8} s. How fast is this pion beam traveling?

23 • A meterstick moves with speed 0.80c relative to you in the direction parallel to the stick. (*a*) Find the length of the stick as measured by you. (*b*) How long does it take for the stick to pass you?

24 • Recall that the half-life is the time it takes for any given amount of unstable particles to decay to half that amount of particles. The proper half-life of a species of charged subatomic particles called pions is 1.80×10^{-8} s. (See Problem 16 for details on pions.) Suppose a group of these pions are produced in an accelerator and emerge with a speed of 0.998c. How far do these particles travel in the accelerator's laboratory before half of them have decayed?

25 •• Your friend, who is the same age as you, travels to the star Alpha Centauri, which is 4.0 light-years away, and returns immediately. He claims that the entire trip took just 6.0 y. What was his speed? Ignore any accelerations of your friend's spaceship and assume that the spaceship traveled at the same speed during the entire trip. SSM

26 •• Two spaceships pass each other traveling in opposite directions. A passenger in ship A, knows that her ship is 100 m long. She notes that ship B is moving with a speed of $0.92c$ relative to ship A and that the length of B is 36 m. What are the lengths of the two spaceships as measured by a passenger in ship B?

27 •• Supersonic jets achieve maximum speeds of about $3.00 \times 10^{-6}c$. (*a*) By what percentage would a jet traveling at this speed contract in length? (*b*) During a time of exactly one year or 3.15×10^7 s on your clock, how much time would elapse on the pilot's clock? How many minutes are lost by the pilot's clock in one year of your time? Assume that you are on the ground and the pilot is flying at the specified speed for the entire year.

28 •• The proper mean lifetime of a muon (see Problems 18 and 19 for details regarding muons) is 2.20 μs. Consider a muon, created in Earth's upper atmosphere, speeding toward the surface 8.00 km below, at a speed of $0.980c$. (*a*) What is the likelihood that the muon will survive its trip to Earth's surface before decaying? The probability of a muon decaying is given by $P = 1 - e^{-\Delta t/\tau}$, where Δt is the time interval as measured in the reference frame in question. (*b*) Calculate the probability from the point of view of an observer moving with the muon. Show that the answer is the same from the point of view of an observer on Earth.

29 •• A spaceship commander traveling to the Magellanic Clouds travels at a uniform speed of $0.800c$. When leaving the Kuiper belt, whose outer edge is 50.0 AU from Earth (*Note:* 1 AU = 150,000,000 km and represents the average distance between Earth and the Sun; AU = astronomical unit), he sends a message to ground control in Houston, Texas, saying that he is fine. Fifteen minutes later (according to him), he realizes he has made a typo, so he sends a correction. How much time passes at Houston between the receipt of his initial message and the receipt of second message?

THE RELATIVITY OF SIMULTANEITY

Problems 30 through 34 refer to the following situation: Mary is a worker on a large space platform. She places clock A at point A and clock B at point B, which is 100 light-minutes from point A (Figure R-12). She also places a flashbulb at a point midway between points A and B. Jamal, a worker on a different platform, is standing next to clock C. Each clock immediately starts at zero when the flash reaches it. Mary's platform moves at speed of $0.600c$ to the left relative to Jamal's. As Mary's platform passes by, clock B, then the flashbulb, and then clock A pass directly over clock C—just missing it as they go by. As the flashbulb passes next to clock C, it flashes and clock C immediately starts at zero.

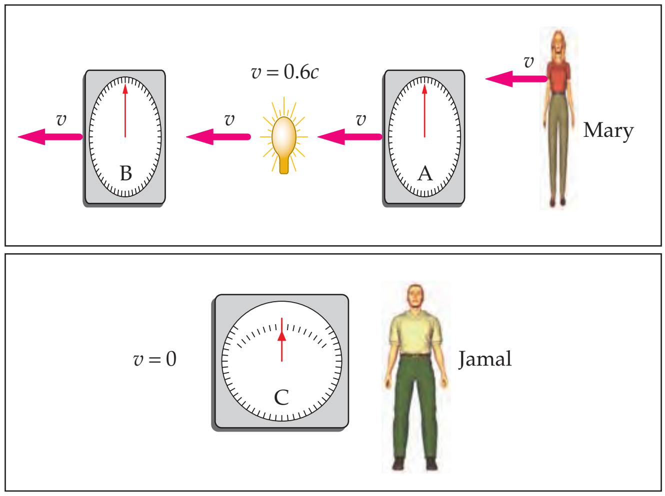

FIGURE R-12 Problems 30–34

30 •• According to Jamal: (*a*) What is the distance between the flashbulb and clock A? (*b*) How far does the flash travel to reach clock A? (*c*) How far does clock A travel while the flash is traveling from the flashbulb to it?

31 •• According to Jamal, how long does it take the flash to travel to clock A, and what does clock C read as the flash reaches clock A.

32 •• Show that clock C reads 100 min as the light flash reaches clock B, which is traveling away from clock C with speed $0.600c$.

33 •• According to Jamal, the reading on clock C advances from 25 min to 100 min between the reception of the flashes by clocks A and B in Problems 31 and 32. According to Jamal, how much will the reading on clock A advance during this 75-min interval?

34 •• According to Jamal, the advance of clock A calculated in Problem 33 is the amount that clock A leads clock B. Compare this result with vL_0/c^2, where $v = 0.600c$.

35 •• In an inertial reference frame *S*, event B occurs 2.00 μs after and 1.50 km distant from event A. How fast must an observer be moving along the line joining the two events so that the two events occur simultaneously? For an observer traveling fast enough, is it possible for event B to precede event A? SSM

36 •• A large flat space platform has an x axis painted on it. A firecracker explodes on the x axis at x_1 = 480 m, and a second firecracker explodes on the x axis 5.00 μs later at x_2 = 1200 m. In the reference frame of a train traveling alongside the x axis at speed v relative to the platform, these two explosions occur at the same place on that axis. What is the separation in time between the two explosions in the reference frame of the train?

37 •• Herb and Randy are twin jazz musicians who perform as a trombone-saxophone duo. At the age of twenty, however, Randy got an irresistible offer to perform on a star 15 light-years away. To celebrate his good fortune, he bought a new vehicle for the trip—a deluxe space-coupé that travels at $0.99c$. Each of the twins promises to practice diligently, so they can reunite afterward. However, Randy's gig goes so well that he stays for a full 10 years before returning to Herb. After their reunion, (*a*) how many years of practice will Randy have had, and (*b*) how many years of practice will Herb have had?

38 •• Al and Bert are twins. Al travels at $0.600c$ to Alpha Centauri (which is $4.00\ c \cdot y$ from Earth, as measured in the reference frame of Earth) and returns immediately. Each twin sends the other a light signal every 0.0100 y, as measured in his own reference frame. (*a*) At what rate does Bert receive signals as Al is moving away from him? (*b*) How many signals does Bert receive at this rate? (*c*) How many total signals are received by Bert before Al returns to Earth? (*d*) At what rate does Al receive signals as Bert is moving away from him? (*e*) How many signals does Al receive at this rate? (*f*) How many total signals are received by Al before Al returns to Earth? (*g*) Which twin is younger at the end of the trip and by how many years?

RELATIVISTIC ENERGY AND MOMENTUM

39 • Find the ratio of the total energy to the rest energy of a particle of mass m moving with speed (*a*) $0.100c$, (*b*) $0.500c$, (*c*) $0.800c$, and (*d*) $0.990c$.

40 • A proton of rest energy 938 MeV has a total energy of 1400 MeV. (*a*) What is its speed? (*b*) What is its momentum?

41 • How much energy would be required to accelerate a particle of mass m from rest to (*a*) $0.500c$, (*b*) $0.900c$, and (*c*) $0.990c$? Express your answers as multiples of the rest energy, mc^2. SSM

42 • If the kinetic energy of a particle equals its rest energy, what percentage error is made by using $p = mv$ for its momentum? Is the nonrelativistic expression always smaller or larger than the relativistically correct expression for momentum?

43 • What is the total energy of a proton whose momentum is $3mc$?

44 •• **Spreadsheet, Estimation** Using a spreadsheet program or graphing calculator, make a graph of the kinetic energy of a particle with rest energy of 100 MeV for speeds between 0 and c. On the same graph, plot $\frac{1}{2}mv^2$ by way of comparison. Using the graph, estimate what speed of the nonrelativistic expression is no longer a good approximation of the kinetic energy. As a suggestion, plot the energy in units of MeV and the speed in the dimensionless form v/c.

45 •• (*a*) Show that the speed v of a particle of mass m and total energy E is given by $v/c = [1 - ((mc^2)^2/E^2)]^{1/2}$, and that when E is much greater than mc^2, this can be approximated by $(v/c) \approx 1 - ((mc^2)/2E^2)$. Find the speed of an electron with kinetic energy of (*b*) 0.510 MeV, and (*c*) 10.0 MeV. SSM

46 •• Use the binomial expansion and Equation R-17 to show that when $pc \ll mc^2$, the total energy is given approximately by $E \approx mc^2 + (p^2/2m)$.

47 •• Derive the equation $E^2 = p^2c^2 + m^2c^4$ (Equation R-17) by eliminating v from Equations R-10 and R-16.

48 •• The rest energy of a proton is about 938 MeV. If its kinetic energy is also 938 MeV, find (*a*) its momentum, and (*b*) its speed.

49 •• What percentage error is made in using $\frac{1}{2}m_0v^2$ for the kinetic energy of a particle if its speed is (*a*) $0.10c$, and (*b*) $0.90c$?

GENERAL PROBLEMS

50 • A spaceship departs from Earth for the star Alpha Centauri, which is $4.0\ c \cdot y$ away in the reference frame of Earth. The spaceship travels at $0.75c$. How long does it take to get there (*a*) as measured on Earth, and (*b*) as measured by a passenger on the spaceship?

51 • The total energy of a particle is three times its rest energy. (*a*) Find v/c for the particle. (*b*) Show that its momentum is given by $p = \sqrt{8}mc$.

52 • A spaceship travels past Earth moving at $0.70c$ relative to Earth. Five minutes after the spaceship is closest to Earth, a message is sent from the control center at Houston, Texas, to the craft. (Ignore any effects of the rotational motion of Earth.) (*a*) How long does it take for the signal to arrive? (*b*) The spaceship and the control center agree on the time when the ship is closest to Earth. Five minutes after the message is received aboard the ship, a return message is sent by the ship back to Houston. What is the time interval in Houston between the time their message is sent, and the time the return message is received?

53 •• Particles called muons traveling at $0.99995c$ are detected at the surface of Earth. One of your fellow students claims that the detected muons might have originated from the Sun. Prove him wrong. (The proper mean lifetime of the muon is 2.20 μs.) SSM

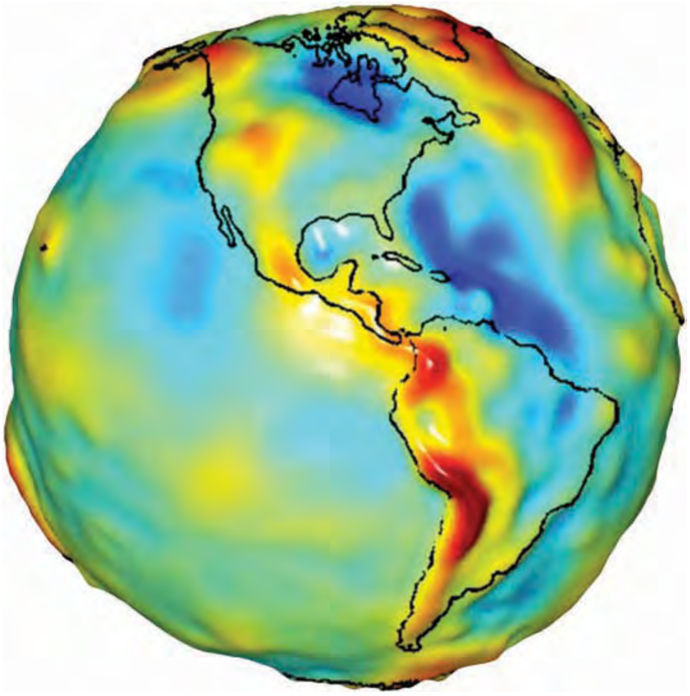
54 •• (*a*) How tall is Mount Everest in a reference frame traveling with a cosmic ray muon that is traveling straight down, relative to Earth, at $0.99c$? Take the height of Mount Everest according to an Earth-based observer to be 8846 m. (*b*) How long does it take the muon to travel the height of the mountain from the reference frame traveling with the muon? (*c*) How long does it take the muon to travel the height of the mountain from the Earth-based reference frame?

55 ••• A gold nucleus has a radius of 3.00×10^{-14} m, and a mass of 197 AMU. (One AMU has a rest energy of 932 MeV.) During experiments at Brookhaven National Laboratory, these nuclei are routinely accelerated to a kinetic energy of 3.35×10^4 GeV. (*a*) How much less than the speed of light are they traveling? (*b*) At these energies, how long does it take them to travel 100 m in the laboratory reference frame?

56 ••• **Approximation** Consider the flight of a beam of neutrons produced in a nuclear reactor. These neutrons have kinetic energies of up to 1.00 MeV. The rest energy of a neutron is 939 MeV. (*a*) What is the speed of 1.00 MeV neutrons? Express your answer

in terms of v/c. (*b*) If the average lifetime of such a neutron is 15.0 min (in the laboratory reference frame), what is the maximum length of a beam of such neutrons (in a vacuum, in the absence of any interactions between the neutrons and other material)? Estimate this maximum range by calculating the length corresponding to five mean lifetimes. After five mean lifetimes, only e^{-5} or 0.007 (0.7%) of the neutrons remain. (*c*) Compare this range to the range of so-called "thermally moderated" neutrons, whose kinetic energies are around 0.025 eV. Express your answer as a percentage. That is, what percent of the 1.00 MeV-neutron range is the thermally moderated-neutron range? (Note that our assumption of a vacuum continues; however, in reality neutrons of this energy interact readily with matter, such as air or water, and "real" ranges are much shorter.)

57 ••• **CONTEXT-RICH** You and Ernie are trying to fit a 15-ft-long ladder into a 10-ft-long shed with doors at each end. You suggest to Ernie that you open the front door to the shed and that he run toward it with the ladder at a speed such that the length contraction of the ladder shortens it enough so that it fits in the shed. As soon as the back end of the ladder passes through the door, you will slam it shut. (*a*) What is the minimum speed at which Ernie must run to fit the ladder into the shed? Express it as a fraction of the speed of light. (*b*) As Ernie runs toward the shed at a speed of $0.866c$, he realizes that in the reference frame of the ladder, it is the *shed* that is shorter, not the ladder. How long is the shed in the rest frame of the ladder? (*c*) In the reference frame of the ladder, is there any instant that both ends of the ladder are simultaneously inside the shed? Examine this from the point of view of relativistic simultaneity.



CHAPTER 11

THIS EXAGGERATED GRAVITY MAP OF THE WESTERN HEMISPHERE WAS PRODUCED AS PART OF THE GRACE MISSION, A MISSION JOINTLY UNDERTAKEN BY DLR OF GERMANY AND NASA OF THE UNITED STATES. THE STRENGTH OF THE GRAVITATIONAL FIELD VARIES SLIGHTLY FROM LOCATION TO LOCATION. (THE VARIATIONS ON THIS MAP ARE EXAGGERATED.) THE DATA FOR THIS MAP WERE ACQUIRED BY ACCURATELY MONITORING THE DISTANCE BETWEEN A PAIR OF ORBITING SATELLITES. *(NASA/University of Texas Center for Space Research.)*

Gravity

An understanding of gravity and its role in how celestial bodies move and interact, galaxies expand and contract, and black holes develop is well understood. The gravitational force exerted by Earth on us and on the objects around us is a fundamental part of our experience. It is gravity that binds us to Earth and keeps Earth and the other planets within the solar system. However, the variations in gravity are often too small to notice on the surface of Earth. But these minuscule variations should not be completely disregarded. Geophysicists have found ways to use these small variations in gravity to determine the location of oil and mineral deposits.

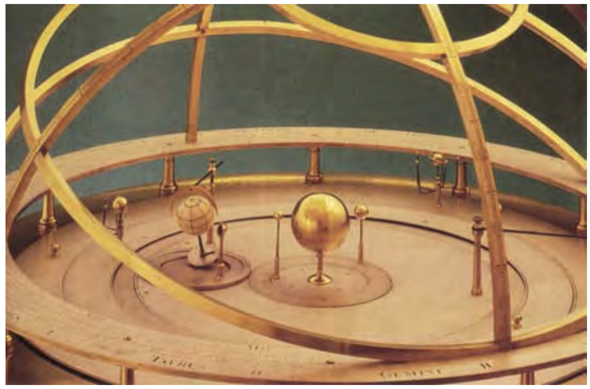
During the time of Newton, many believed that nature followed different rules in other parts of the universe than here on Earth. Newton's law of universal gravity, along with his three laws of motion, revealed that nature follows the same rules everywhere, and this revelation has had a profound effect on our view of the universe.

? Using two satellites, how might you use your understanding of gravity to detect a region of increased gravitation-field strength? (See Example 11-9.)

In this chapter, we use the tools of conservation of angular momentum, conservation of energy, Newton's laws of motion, and Newton's law of gravity to predict the motion of the planets and other celestial bodies, including satellites that we have put in space.

11-1 KEPLER'S LAWS

The nighttime sky with its myriad stars and shining planets has always fascinated people. Toward the end of the sixteenth century, the astronomer Tycho Brahe studied the motions of the planets and made observations that were considerably more accurate than those previously available. Using Brahe's data, Johannes Kepler discovered that the paths of the planets about the Sun are ellipses (Figure 11-1). He also showed that each planet moves faster when its orbit brings it closer to the Sun and slower when its orbit takes it farther away. Finally, Kepler developed a precise mathematical relation between the orbital period of a planet and its average distance from the Sun (Table 11-1). He stated these results in three empirical laws of planetary motion. Ultimately, these laws provided the basis for Newton's discovery of the law of gravity. Kepler's three laws follow.



A mechanical model of the solar system, called an *orrery*, in the collection of Historical Scientific Instruments at Harvard University. *(Collection of Historical Scientific Instruments, Harvard University.)*

> Law 1. All planets move in elliptical orbits with the Sun at one focus.

An ellipse is the locus of points for which the sum of the distances from two fixed points, called foci F, is constant, as shown in Figure 11-2. Figure 11-3 shows a planet following an elliptical path with the Sun at one focus. Earth's orbit is nearly circular, with the distance to the Sun at perihelion (closest point) being 1.48×10^{11} m and at aphelion (farthest point) being 1.52×10^{11} m. The semimajor axis equals the mean of these two distances, which is 1.50×10^{11} m (93 million miles) for Earth's orbit. This mean distance defines the astronomical unit (AU):

$$1\text{ AU} = 1.50 \times 10^{11}\text{ m} = 93.0 \times 10^{6}\text{ mi} \qquad 11\text{-}1$$

The AU is used frequently in problems dealing with the solar system.

Table 11-1 Mean Orbital Radii and Orbital Periods for the Planets

Planet	Mean Radius r ($\times 10^{10}$ m)	Period T (y)
Mercury	5.79	0.241
Venus	10.8	0.615
Earth	15.0	1.00
Mars	22.8	1.88
Jupiter	77.8	11.9
Saturn	143	29.5
Uranus	287	84
Neptune	450	165
Pluto	590	248

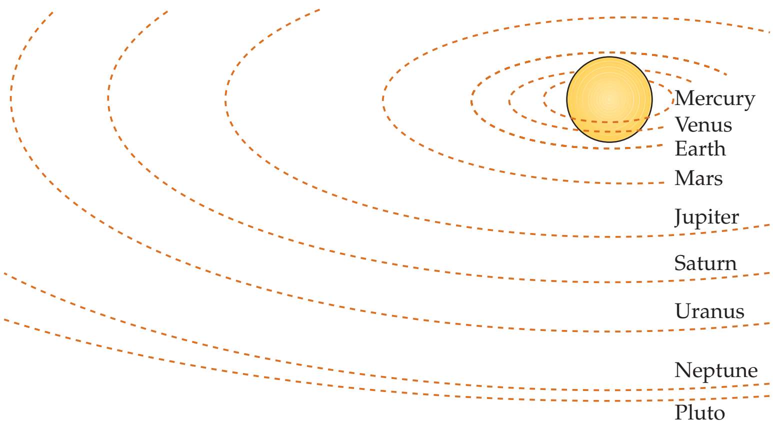


FIGURE 11-1 Orbits of the planets around the Sun. (The sizes are not to scale.) In 2006, the International Astronomical Union passed a new definition of planet that excludes Pluto and puts it in a new category of "dwarf planet."

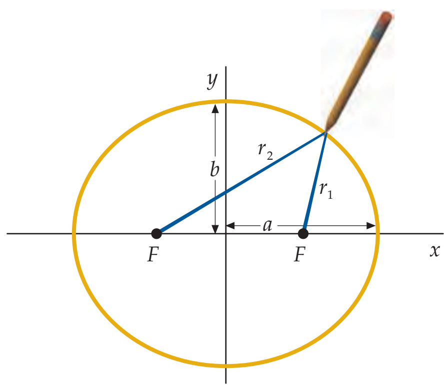

FIGURE 11-2 An ellipse is the locus of points for which $r_1 + r_2$ = constant. The distance a is called the semimajor axis, and b is the semiminor axis. You can draw an ellipse with a piece of string by fixing each end at a focus F and using it to guide the pencil. Circles are special cases in which the two foci coincide.

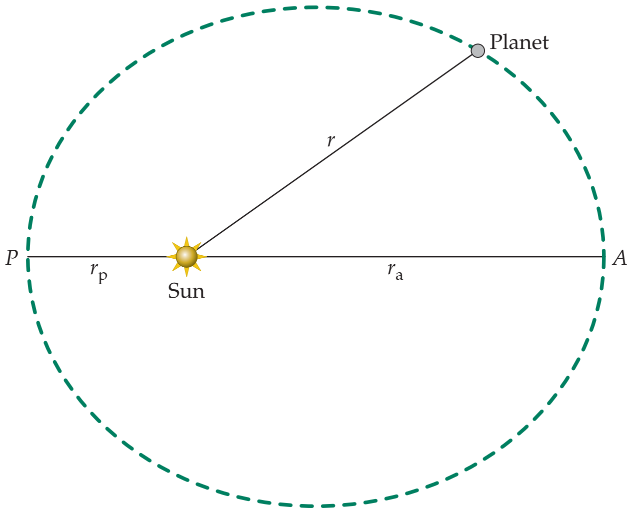

FIGURE 11-3 The elliptical path of a planet with the Sun at one focus. Point P, where the planet is closest to the Sun, is called the *perihelion*, and point A, where it is farthest from the Sun, is called the *aphelion*. The average distance between the planet and the Sun, defined as $(r_p + r_a)/2$, is equal to the semimajor axis. (The known planets travel along more circular paths than the orbit shown here.)

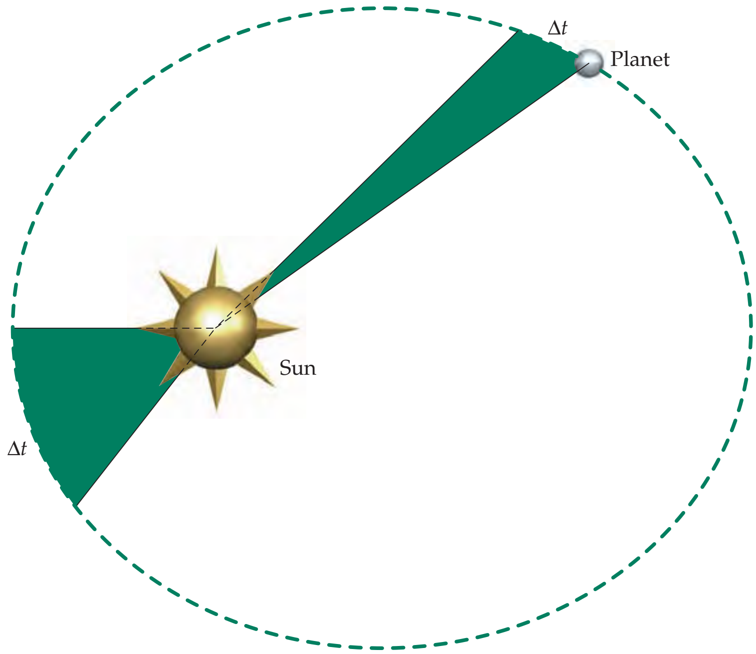

FIGURE 11-4 When a planet is close to the Sun, it moves faster than when it is farther away. The areas swept out by the line joining the centers of the Sun and the planet during a given time interval are equal.

Law 2. A line joining any planet to the Sun sweeps out equal areas in equal times.

Figure 11-4 illustrates Kepler's second law, the law of equal areas. A planet moves so that the area swept out by the line joining the centers of the Sun and the planet during a given time interval is the same throughout the orbit. The law of equal areas is a consequence of the conservation of angular momentum, as we will see in the next section.

Law 3. The square of the period of any planet is proportional to the cube of the semimajor axis of its orbit.

Kepler's third law relates the period of any planet to its mean distance from the Sun, which equals the semimajor axis of its elliptical path. In algebraic form, if r is the mean orbital radius* and T is the period of revolution, Kepler's third law states that

$$T^2 = Cr^3 \qquad \text{11-2}$$

where the constant C has the same value for all the planets. This law is a consequence of the fact that the force exerted by the Sun on a planet varies inversely with the square of the distance from the Sun to the planet. We will demonstrate this in Section 11-2 for the special case of a circular orbit.

* By *mean orbital radius* we refer to the average of the perihelion and aphelion distances.

Example 11-1 Jupiter's Orbit

Jupiter's mean orbital radius is 5.20 AU. What is the period of Jupiter's orbit around the Sun?

PICTURE We use Kepler's third law to relate Jupiter's period to its mean orbital radius. The constant C can be obtained from Earth's known mean orbital radius and period.

SOLVE

1. Kepler's third law relates Jupiter's period T_J and mean orbital radius r_J: $T_J^2 = Cr_J^3$
2. Apply Kepler's third law to Earth to obtain a second equation relating the same constant C to T_E and r_E: $T_E^2 = Cr_E^3$
3. Divide the two equations, eliminating C, and solve for T_J:

$$\frac{T_J^2}{T_E^2} = \frac{r_J^3}{r_E^3}$$

so

$$T_J = T_E\left(\frac{r}{r_E}\right)^{3/2} = (1\text{ y})\left(\frac{5.20\text{ AU}}{1\text{ AU}}\right)^{3/2} = \boxed{11.9\text{ y}}$$

CHECK The step-3 result agrees with the orbital period of Jupiter listed in Table 11-1.

TAKING IT FURTHER The periods of the planets Earth, Jupiter, Saturn, Uranus, and Neptune are plotted in Figure 11-5 as functions of their mean orbital radii. In Figure 11-5*a*, periods are plotted versus mean orbital radii. In Figure 11-5*b*, the squares of the periods are plotted versus the cubes of the mean orbital radii. Here, the points fall on a straight line.

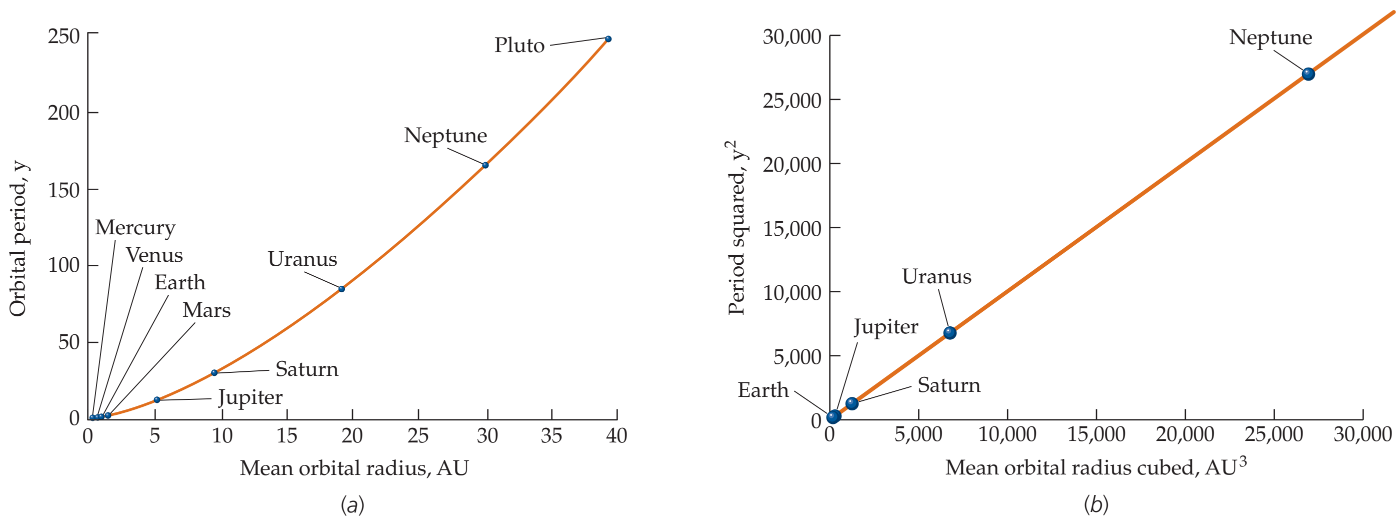

FIGURE 11-5

PRACTICE PROBLEM 11-1 The period of Neptune is 164.8 y. What is its mean orbital radius?

PRACTICE PROBLEM 11-2 If the logarithms of the periods of the planets Earth, Jupiter, Saturn, Uranus, and Neptune are plotted versus the logarithms of their mean orbital radii, the points fall on a curve. What is the shape of this curve?

11-2 NEWTON'S LAW OF GRAVITY

Although Kepler's laws were an important first step in understanding the motion of planets, they were nothing more than empirical rules obtained from the astronomical observations of Brahe. It remained for Newton to take the next giant step by attributing the acceleration of a planet in its orbit to a specific force exerted on it by the Sun. Using his second law, Newton proved that an attractive force that varies inversely with the square of the distance between the Sun and a planet would result in an elliptical orbit, as observed by Kepler. He then made the bold assumption that this attractive force acts between any two objects in the universe. Before Newton, it was not widely believed that the laws of physics observed on Earth were applicable to the heavenly bodies. Newton changed our understanding of the nature of the nonterrestrial realm by showing that the laws of physics apply equally well to both terrestrial and nonterrestrial objects. **Newton's law of gravity** postulates that there is a force of attraction between each pair of point particles that is proportional to the product of the masses of the particles and inversely proportional to the square of the distance separating them. Let m_1 and m_2 be the masses of point particles 1 and 2 (at positions $\vec{r}_1$ and $\vec{r}_2$, respectively) and $\vec{r}_{12}$ be the position of particle 2 relative to particle 1 (Figure 11-6*a*).

The gravitational force $\vec{F}_{12}$ exerted by particle 1 on particle 2 is then

$$\vec{F}_{12} = -\frac{Gm_1m_2}{r_{12}^2}\hat{r}_{12} \qquad 11\text{-}3$$

NEWTON'S LAW OF GRAVITY

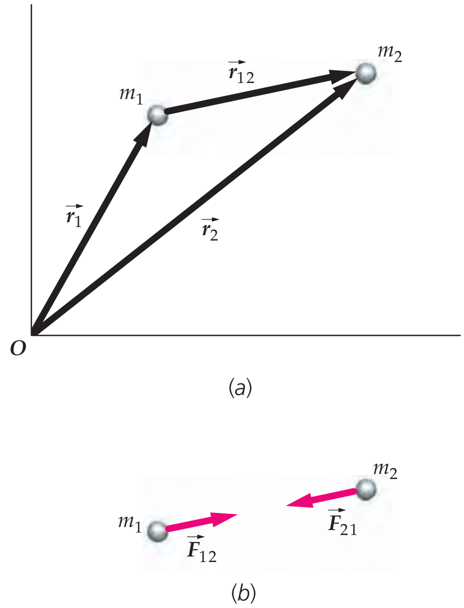

FIGURE 11-6 (*a*) Particles at $\vec{r}_1$ and $\vec{r}_2$. (*b*) The particles exert equal and opposite forces on each other.

where $\hat{r}_{12} = \vec{r}_{12}/r_{12}$ is a unit vector in the direction from 1 toward 2 and G is the **universal gravitational constant,** which has the value

$$G = 6.67 \times 10^{-11}\,\mathrm{N \cdot m^2/kg^2} \qquad 11\text{-}4$$

The force $\vec{F}_{21}$ exerted by 2 on 1 is equal and opposite to $\vec{F}_{12}$, in accord with Newton's third law (Figure 11-6*b*). The magnitude of the gravitational force exerted by a point particle of mass m_1 on a point particle of mass m_2 a distance r away is thus given by

$$F_g = \frac{Gm_1m_2}{r^2} \qquad 11\text{-}5$$

Newton published his theory of gravitation in 1686, but it was not until a century later that an accurate experimental determination of G was made by Henry Cavendish, as is discussed in Section 11-4.

We can use the known value of G to compute the gravitational attraction between two ordinary objects.

PRACTICE PROBLEM 11-3

Show that the gravitational force that attracts a 65-kg man to a 50-kg woman when they are 0.50 m apart is 8.7×10^{-7} N. (Model them as point particles for the purpose of this calculation.)

This calculation demonstrates that the gravitational force exerted by an object of ordinary size on another such object is so small as to be unnoticeable. For comparison, a mosquito weighs about 1×10^{-7} N so the force of attraction is equal to the weight of 9 mosquitos. The weight of a 50-kg woman is about 490 N—*half a billion* times greater than the force of attraction calculated in Practice Problem 11-3! Gravitational attraction is easily noticed only when at least one of the objects is astronomically massive. The gravitational attraction between the woman and Earth for example, is readily apparent.

To check the validity of the inverse-square nature of the gravitational force, Newton compared the acceleration of the moon in its orbit with the free-fall acceleration of objects near the surface of Earth (such as the legendary apple). He reasoned that the gravitational attraction due to Earth causes both accelerations. He first assumed that Earth and the moon could be treated as point particles with their total masses concentrated at their centers. The force on a particle of mass m a distance r from the center of Earth is

$$F_g = \frac{GM_E m}{r^2} \tag{11-6}$$

where M_E is the mass of Earth. If this is the only force acting on the particle, then its acceleration is

$$a = \frac{F_g}{m} = \frac{GM_E}{r^2} \tag{11-7}$$

For objects near the surface of Earth, $r \approx R_E$ and the free-fall acceleration is g:

$$g = \frac{GM_E}{R_E^2} \tag{11-8}$$

where R_E is the radius of Earth. The distance to the moon is about 60 times the radius of Earth ($r = 60R_E$). Substituting this into Equation 11-7 gives $a = g/60^2 = g/3600$, so the acceleration of the moon in its near-circular orbit is the free-fall acceleration g at the surface of Earth divided by 60^2. That is, the acceleration of the moon a_m should be $(9.81/3600)\ \mathrm{m/s^2}$. The moon's acceleration can be calculated from its known distance from the center of Earth, $r = 3.84 \times 10^8$ m, and its known period $T = 27.3\ \mathrm{d} = 2.36 \times 10^6$ s:

$$a_m = \frac{v^2}{r} = \frac{(2\pi r/T)^2}{r} = \frac{4\pi^2 r}{T^2} = \frac{4\pi^2(3.84 \times 10^8\ \mathrm{m})}{(2.36 \times 10^6\ \mathrm{s})^2} = 2.72 \times 10^{-3}\ \mathrm{m/s^2}$$

Then

$$\frac{g}{a_m} = \frac{9.81\ \mathrm{m/s^2}}{2.72 \times 10^{-3}\ \mathrm{m/s^2}} = 3607 \approx 3600$$

In Newton's words, "I thereby compared the force requisite to keep the Moon in her orb with the force of gravity at the surface of the Earth, and found them answer pretty nearly."

The assumption that Earth and the moon can be treated as point particles in the calculation of the force on the moon is reasonable because the Earth-to-moon distance is large compared with the radius of either Earth or the moon, but such an assumption is certainly questionable when applied to an object near Earth's surface. After considerable effort, Newton was able to mathematically demonstrate that the force exerted by any object with a spherically symmetric mass distribution on a point mass either on or outside its surface is the same as if all the mass of the object were concentrated at its center. (This calculation is the subject of Section 11-5.) The proof involves integral calculus, which Newton developed to solve this problem.

Because $g = 9.81\ \mathrm{m/s^2}$ is readily measured and the radius of Earth is known, Equation 11-8 can be used to determine the value of the product GM_E. Newton estimated the value of G from an estimation of the average density of Earth. When Cavendish determined G to within one percent some 100 years later by measuring the force between small spheres of known mass and separation, he called his experiment "weighing Earth." Knowing the value of G meant that the mass of the Sun and the mass of any planet with a satellite could be determined. The method for doing this is described in Section 11-4.

Earth as seen from *Apollo 11* orbiting the Moon on July 16, 1969. *(NASA.)*

Example 11-2 Falling to Earth

What is the free-fall acceleration of an object at the altitude of the space shuttle's orbit, about 400 km above Earth's surface?

(NASA.)

PICTURE The only force acting on an object in freefall is the force of gravity.

SOLVE

1. The free-fall acceleration is given by $a = F_g/m$: $\quad a = \dfrac{F_g}{m} = \dfrac{GmM_E/r^2}{m} = \dfrac{GM_E}{r^2}$

2. The distance r is related to the radius of Earth R_E and the altitude h: $\quad r = R_E + h = 6370\text{ km} + 400\text{ km} = 6770\text{ km}$

3. The acceleration is then:

$$a = \frac{GM_E}{r^2} = \frac{(6.67 \times 10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2)(5.98 \times 10^{24}\,\text{kg})}{(6.77 \times 10^6\,\text{m})^2} = \boxed{8.70\,\text{m/s}^2}$$

CHECK The altitude of 400 km is 6% of the radius of Earth (6370 km), and the free-fall acceleration of 8.70 m/s^2 is 11% less than 9.81 m/s^2. A free-fall acceleration that is only 11% less than 9.81 m/s^2 is plausible because the altitude is only 6% of Earth's radius.

TAKING IT FURTHER The acceleration of both the shuttle and the shuttle astronauts as they accelerate in their near circular orbit is 8.70 m/s^2.

CONCEPT CHECK 11-1

How is it that the astronauts in the orbiting shuttle are said to be weightless, even though the force of gravity on them is only 11 percent less than it is on Earth's surface?

The calculation in Example 11-2 can be simplified by using Equation 11-8 to eliminate GM_E from Equation 11-7. Then the acceleration at a distance r is

$$a = \frac{F_g}{m} = \frac{GM_E}{r^2} = g\frac{R_E^2}{r^2} \qquad \text{11-9}$$

PRACTICE PROBLEM 11-4

At what distance h above the surface of Earth is the free-fall acceleration half its value at sea level?

MEASUREMENT OF *G*

The universal gravitational constant G was first measured in 1798 by Henry Cavendish, who used the apparatus shown in Figure 11-7. Cavendish's measurement of G has been repeated by other experimenters with various improvements and refinements. All measurements of G are difficult because of the extreme

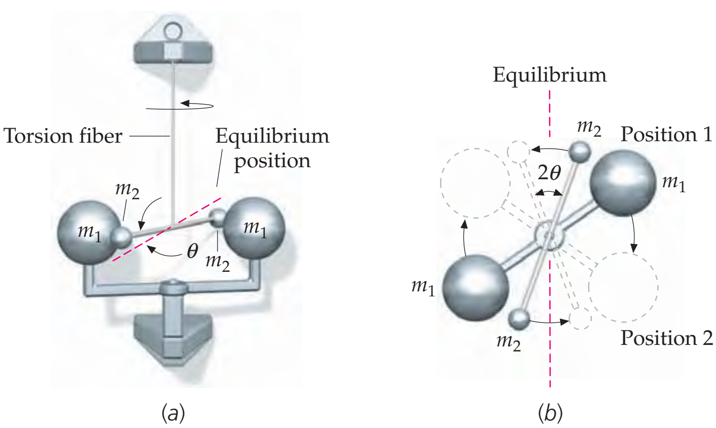

FIGURE 11-7 (*a*) Two small spheres, each of mass m_2, are at the ends of a light rod that is suspended by a fine fiber. Careful measurements determine the torque required to turn the fiber through a given angle. Two large spheres, each of mass m_1, are then placed near the small spheres. Because of the gravitational attraction of the large spheres of mass m_1 for the small spheres, the fiber is twisted through a very small angle θ from its equilibrium position. (*b*) The apparatus as seen from above. After the apparatus comes to rest, the positions of the large spheres are reversed, as shown by the dashed lines, so that they are at the same distance from the equilibrium position of the balance, but on the other side. If the apparatus is again allowed to come to rest, the fiber will turn through angle 2θ in response to the reversal of the torque. Once the torsion constant has been determined, the forces between the masses m_1 and m_2 can be determined from the measurement of this angle. Because the masses and their separations are known, G can be calculated. Cavendish obtained a value for G within about 1 percent of the currently accepted value given by Equation 11-4.

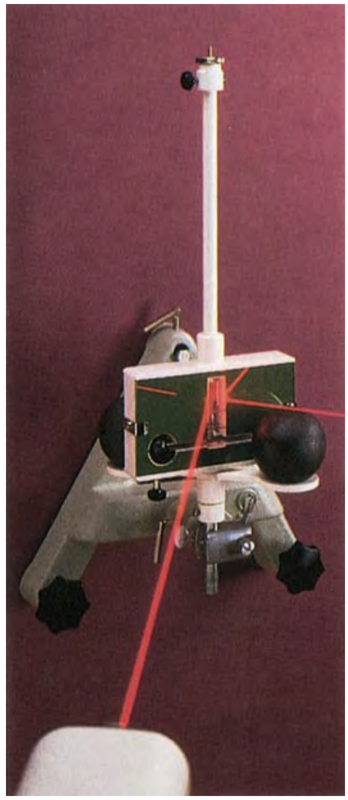
weakness of the gravitational attraction. Consequently, the value of G is known today only to about 1 part in 10,000. Although G was one of the first physical constants ever measured, it remains one of the least accurately known.



Gravitational torsional balance used in student labs for the measurement of G. A tiny angular deflection of the balance results in a large angular deflection of the laser beam that reflects from a mirror on the balance. *(Courtesy of Central Scientific Company.)*

GRAVITATIONAL AND INERTIAL MASS

The property of an object that is responsible for the gravitational force the object exerts on another object, or for the gravitational force another object exerts on it, is its *gravitational* mass. On the other hand, *inertial* mass is the property of an object that measures the object's resistance to acceleration. We have used the same symbol m for these two properties because, experimentally, they are proportional. For convenience, units are judiciously defined to make the proportionality constant one. The fact that the gravitational force exerted on an object is proportional to its inertial mass is a characteristic unique to the force of gravity. One consequence is that all objects near the surface of Earth fall with the same acceleration if air resistance is neglected. The well-known story of Galileo dropping objects from the Leaning Tower of Pisa to demonstrate that the free-fall acceleration is the same for objects with different inertial masses is just one example of the excitement this discovery aroused in the sixteenth century.

We could easily imagine that the gravitational and inertial masses of an object were not the same. Suppose we write m_G for the gravitational mass and m for the inertial mass. The force exerted by Earth on an object near its surface would then be

$$F_g = \frac{GM_E m_G}{R_E^2} \qquad 11\text{-}10$$

where M_E is the gravitational mass of Earth. The free-fall acceleration of the object near Earth's surface would then be

$$a = \frac{F_g}{m} = \left(\frac{GM_E}{R_E^2}\right)\frac{m_G}{m} \qquad 11\text{-}11$$

If gravity were just another property of matter, like porosity or hardness, it might be reasonable to expect that the ratio m_G/m would depend on such things as the chemical composition of the object or its temperature. The free-fall acceleration would then be different for different objects. The experimental evidence, however, is that a is the same for all objects. Thus, we need not maintain the distinction between m_G and m, and can set $m_G = m$. We must keep in mind, however, that the equivalence of gravitational and inertial mass is an empirical law that is limited by the accuracy of experiment. Experiments testing this equivalence were carried out by Simon Stevin in the 1580s. Galileo publicized this law widely, and his contemporaries made considerable improvements in the experimental accuracy with which the law was established.

! Free-fall acceleration is the same for all objects.

The most precise early comparisons of gravitational and inertial mass were made by Newton. Through experiments using simple pendulums rather than falling bodies, Newton was able to establish the equivalence between gravitational and inertial mass to an accuracy of about 1 part in 1000. Experiments comparing gravitational and inertial mass have improved steadily over the years. Their equivalence is now established to about 1 part in 5×10^{13}. Thus, the equivalence of gravitational and inertial mass is one of the best established of all physical laws. It is the basis for the principle of equivalence, which is the foundation of Einstein's general theory of relativity.

CONCEPT CHECK 11-2

What is the difference between gravitational mass and inertial mass?

DERIVATION OF KEPLER'S LAWS

Newton used his second law of motion to show that a particle moving under the influence of an attractive force that varies inversely with the square of the distance from a fixed point moves along a path the shape of a conic section (an ellipse, a parabola, or a hyperbola) with a focus located at the fixed point. He inferred from this result and Kepler's laws that the planets (and comets) are attracted to the center of the Sun by a force that varies inversely with the square of their distances from the center of the Sun. The parabolic and hyperbolic paths apply to objects that make one pass by the Sun and never return. Such orbits are not closed. The only closed orbits are those of objects that follow elliptical paths. Thus, Kepler's first law is a direct consequence of Newton's law of gravity. Kepler's second law, the law of equal areas, follows from the fact that the force exerted by the Sun on a planet is directed toward a force center—the center of the Sun. Such a force is called a **central force.** Figure 11-8*a* shows a planet moving in an elliptical orbit around the Sun. In time dt, the planet moves a distance $v\,dt$ and the radius vector $\vec{r}$ sweeps out the area shaded in the figure. This is half the area of the parallelogram formed by the vectors $\vec{r}$ and $\vec{v}\,dt$, which is $|\vec{r} \times \vec{v}\,dt|$. Thus, the area dA swept out by the radius vector $\vec{r}$ in time dt is given by

$$dA = \frac{1}{2}|\vec{r} \times \vec{v}\,dt| = \frac{|\vec{r} \times m\vec{v}|}{2m}\,dt$$

or

$$\frac{dA}{dt} = \frac{L}{2m} \qquad 11\text{-}12$$

where $L = |\vec{r} \times m\vec{v}|$ is the magnitude of the orbital angular momentum of the planet about the Sun. The area dA swept out in a given time interval dt is therefore proportional to the magnitude of the orbital angular momentum L. Because the force on a planet is along the line from the planet to the Sun, it exerts no torque about the Sun. Thus, the orbital angular momentum of the planet is constant; that is, L is constant. Therefore, the rate at which the area is swept out is the same for all parts of the orbit, which is Kepler's second law. Also, the fact that L is constant means that $rv \sin \phi$ is constant. At aphelion and perihelion $\phi = 90°$ (Figure 11-8*b*), so $r_a v_a = r_p v_p$.

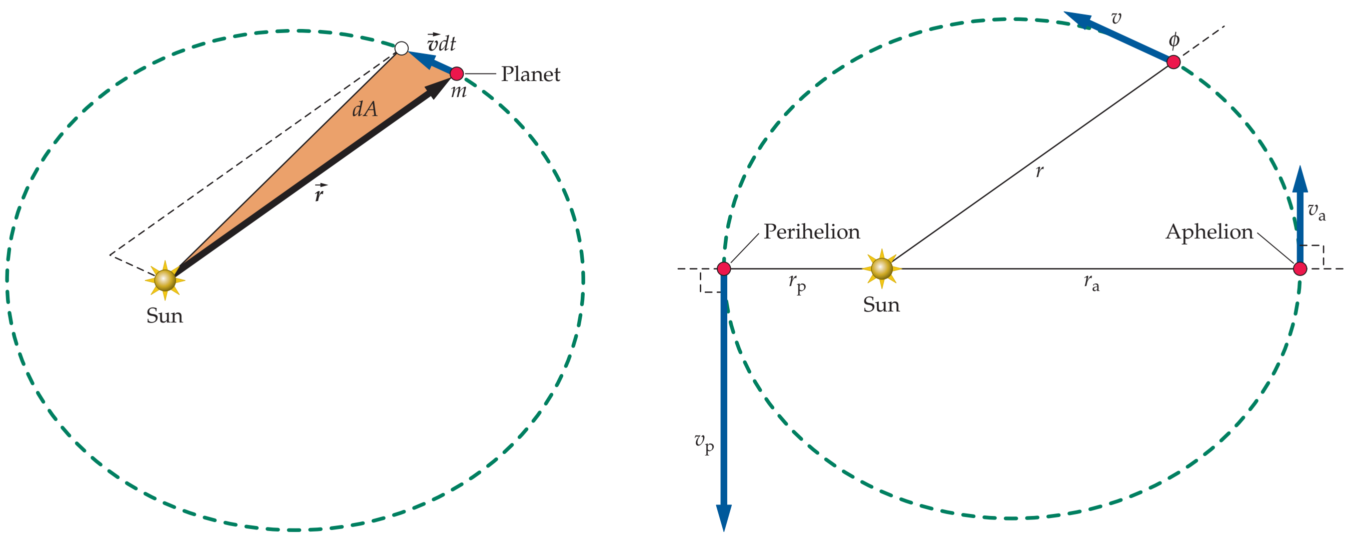


FIGURE 11-8 (*a*) The area dA swept out in time dt equals $\frac{1}{2}|\vec{r} \times \vec{v}\,dt| = \frac{1}{2m}L\,dt$, where $\vec{L} = \vec{r} \times m\vec{v}$. Because $\vec{L}$ remains constant, dA/dt remains constant. (*b*) The magnitude of the angular momentum, given by $L = mvr \sin \phi$, remains constant, so $rv \sin \theta$ remains constant. In addition, $\phi = 90°$ at both perihelion and aphelion, so $r_a v_a = r_p v_p$.

We now show that Newton's law of gravity implies Kepler's third law for the special case of a circular orbit. Consider a planet moving with speed v in a circular orbit of radius r about the Sun. The gravitational force on the planet by the Sun provides the centripetal acceleration v^2/r. Applying Newton's second law ($F = ma$) to the planet gives

$$\frac{GM_S M_P}{r^2} = M_P \frac{v^2}{r} \qquad 11\text{-}13$$

where M_S is the mass of the Sun and M_P is that of the planet. Solving for v^2 gives

$$v^2 = \frac{GM_S}{r} \qquad 11\text{-}14$$

Because the planet moves a distance $2\pi r$ in time T, its speed is related to the period by

$$v = \frac{2\pi r}{T} \qquad 11\text{-}15$$

Substituting $2\pi r/T$ for v in Equation 11-14, we obtain

$$\frac{4\pi^2 r^2}{T^2} = \frac{GM_S}{r}$$

or

$$T^2 = \frac{4\pi^2}{GM_S} r^3 \qquad 11\text{-}16$$

KEPLER'S THIRD LAW

Equation 11-16 is a version of Kepler's third law. Equation 11-16 is the same as Equation 11-2 with $C = 4\pi^2/GM_S$. Equation 11-16 also applies to the orbits of the satellites of any planet if we replace the mass of the Sun M_S with the mass of the planet.

(NASA.)

Example 11-3 The Orbiting Space Station

Context-Rich

You are trying to view the International Space Station (ISS), which travels in a roughly circular orbit around Earth. If its altitude is 385 km above Earth's surface, how long do you have to wait between sightings?

PICTURE The sightings occur only at night, and then only if the space station is above the horizon at your location. Thus, the minimum time between sightings is approximately equal to the orbital period. To find the orbital period we apply Newton's second law to the space station and use distance equals speed multiplied by time.

SOLVE

1. For a circular orbit, the orbital period T and orbital speed v can be related to the orbital radius r by using distance equals speed multiplied by time.

$$2\pi r = vT$$

2. To obtain a second equation relating v and r we apply Newton's second law to the space station of mass m:

$$F_g = ma$$

$$\frac{GM_E m}{r^2} = m\frac{v^2}{r}$$

3. Substituting $2\pi r/T$ for v (from our step-1 result) gives:

$$\frac{GM_E}{r^2} = \frac{4\pi^2 r}{T^2}$$

4. Solving for T^2, we obtain:

$$T^2 = \frac{4\pi^2}{GM_E}r^3$$

5. At an altitude $h = 385$ km, $r = R_E + h = 6760$ km. Substitute $r = R_E + h$ and solve for the period:

$$T^2 = \frac{4\pi^2}{GM_E}(R_E + h)^3$$

$$= \frac{4\pi^2}{(6.67 \times 10^{-11}\,\mathrm{N \cdot m^2/kg^2})(5.98 \times 10^{24}\,\mathrm{kg})}(6.76 \times 10^6\,\mathrm{m})^3$$

$$= 30.56 \times 10^6\,\mathrm{s^2}$$

$$\text{so} \quad T = 5528\,\mathrm{s} = \boxed{92.1\,\mathrm{min}}$$

CHECK An Internet search for "NASA orbital period ISS" tells us that the orbital period is 91.5 min, so our step-2 result is in the right ballpark. In addition, our step-3 result is Kepler's third law (Equation 11-16) for a satellite orbiting Earth.

TAKING IT FURTHER Kansas City is due west of New York City by 23 degrees of longitude. The plane of the near-circular orbit of the ISS, which is inclined $\approx 52°$ to the equatorial plane, does not rotate with Earth. If the ISS is directly over your home at time t, 92.1 min later it will be directly over a location 23.0° due west of your home. If the ISS passes over your home in New York City at midnight Eastern Time, you could tell your friend in Kansas City that it will pass over Kansas City at 12:32 A.M. Central Time (1:32 A.M. Eastern Time).

PRACTICE PROBLEM 11-5 How many degrees does Earth rotate in one hour? *Hint: How many degrees does Earth rotate in 24 h?*

PRACTICE PROBLEM 11-6 Find the radius of the circular orbit of a satellite that orbits Earth with a period of 1.00 d.

Because G is known, we can determine the mass of an astronomical object by measuring the orbital period T and the mean orbital radius r of a satellite orbiting it and by substituting these values into Equation 11-16. In establishing Equation 11-16, the mass of the satellite was assumed negligible compared to the mass of the central object. This means that the central object remains stationary as the satellite revolves around it. In fact, the central object and satellite both revolve around a common point, their center of mass. If the mass of the satellite is not assumed negligible, the result is

$$T^2 = \frac{4\pi^2}{G(M_1 + M_2)}r^3 \qquad \text{11-17}$$

where r is the center-to-center separation of the objects. (The derivation of Equation 11-17 for circular orbits is left to Problem 11-93. For the more general elliptical orbits, the math is more challenging, but the result is the same, only r is replaced by the mean of the maximum and minimum center-to-center distances between the objects.) If the mass of the satellite is not negligible, as is the case with most binary star systems, then only the sum of the masses is determined, as revealed by Equation 11-17. The moon, along with planets Mercury and Venus, have no natural satellites, so their masses were not well known until the 1960s when artificial satellites were first placed in orbit around them.

PRACTICE PROBLEM 11-7

The Martian moon Phobos has a period of 460 min and a mean orbital radius of 9400 km. What is the mass of Mars?

CONCEPT CHECK 11-3

Kepler's first law is that the planets all follow elliptical paths with the center of the Sun and a focus of each ellipse. Newton inferred from Kepler's first law that the planets are all attracted to the center of the Sun by a force that varies inversely with the square of the distance. What led him to this inference?

11-3 GRAVITATIONAL POTENTIAL ENERGY

Near the surface of Earth, the gravitational force exerted by Earth on an object is essentially uniform because the distance to the center of Earth, $r = R_E + h$, is always approximately R_E for $h \ll R_E$. The potential energy of an object near Earth's surface is $mgh = mg(r - R_E)$, where we have chosen $U = 0$ at Earth's surface, $r = R_E$. When we are far from the surface of Earth, we must take into account the fact that the gravitational force exerted by Earth is not uniform, but decreases as $1/r^2$. The general definition of potential energy (Equation 7-1) is

$$dU = -\vec{F} \cdot d\vec{\ell}$$

where $\vec{F}$ is a conservative force on a particle and $d\vec{\ell}$ is a general displacement of the particle. For the gravitational force $\vec{F}_g$ given by Equation 11-6 (Figure 11-9), we have

$$dU = -\vec{F}_g \cdot d\vec{\ell} = -(-F_g \hat{r}) \cdot d\vec{\ell} = F_g \hat{r} \cdot d\vec{\ell} = \frac{GM_E m}{r^2} dr \qquad 11\text{-}18$$

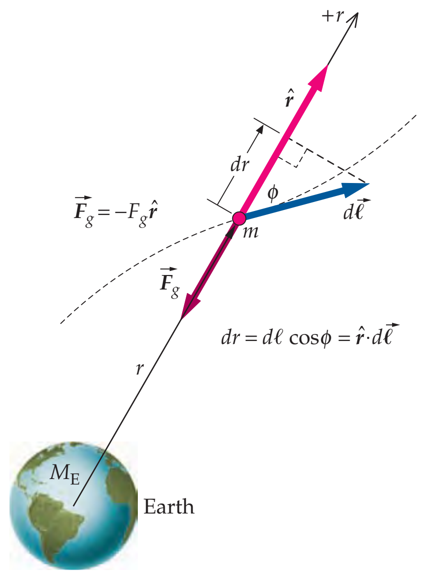

FIGURE 11-9 The distance r of the particle from Earth increases by dr when the particle undergoes displacement $d\vec{\ell}$. In the figure the length of $d\vec{\ell}$ has been exaggerated.

where we have used $\vec{F}_g = -F_g \hat{r}$ and $\hat{r} \cdot d\vec{\ell} = d\ell \cos\phi = dr$. Integrating both sides of Equation 11-18 we obtain

$$U = GM_E m \int r^{-2}\, dr = -\frac{GM_E m}{r} + U_0 \qquad 11\text{-}19$$

where U_0 is a constant of integration. The expression for U is algebraically simplest if we choose $U_0 = 0$. Then

$$U(r) = -\frac{GMm}{r} \qquad 11\text{-}20$$

Thus, a choice of zero for U_0 means that U approaches zero as r approaches infinite. At first this may seem like a strange choice, because for finite values of r all values of U are negative. This just means, however, that the potential energy is maximum when Earth and the particle are at infinite separation. Negative potential energy is nothing new. When we use the potential-energy function $U = mgh$, where h is the height above some reference point on a tabletop, the potential energy is negative any time the particle of mass m is anywhere below the level of the tabletop. This reflects the fact that when the particle is below the level of the tabletop the potential energy is less than it is when the particle is at the level of the tabletop.

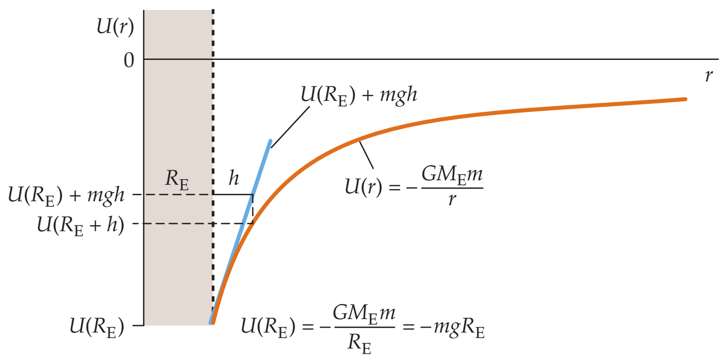

FIGURE 11-10

Figure 11-10 is a plot of $U(r)$ versus r for $U(r) = -GM_E m/r$ for $R_E \le r < \infty$. This plot begins at the negative value $U = -GM_E m/R_E$ at Earth's surface and increases as r increases, approaching zero as r approaches infinity. The slope of this curve at $r = R_E$ is $GM_E m/R_E^2 = mg$. (Recall that $g = GM_E m/R_E^2$.) The equation of the tangent line, drawn in blue, is $f(h) = U(R_E) + mgh$, where $h = r - R_E$ is the distance above Earth's surface. From the figure, you can see that for small h, $U(R_E) + mgh \approx U(r)$.

ESCAPE SPEED

Since the mid-1950s, the idea of escaping from Earth's gravity has changed from fantasy to reality. Space probes have been sent out to the far reaches of the solar system. Many of these probes orbit the Sun, while a few leave the solar system and drift on into outer space. We will see that a minimum initial speed, called the **escape speed**, is required for a projectile to escape from Earth.

If we project an object upward from the surface of Earth with some initial kinetic energy, the kinetic energy decreases and the potential energy increases as the object rises. But the maximum increase in potential energy is GM_Em/R_E. Therefore, this amount is the most that the kinetic energy can decrease. If the initial kinetic energy is greater than GM_Em/R_E, then the total energy E will be greater than zero (E_2 in Figure 11-11), and the object will still have some kinetic energy when r is very large (even if r approaches infinity). Thus, if the initial kinetic energy is greater than GM_Em/R_E, the object is said to escape from Earth. Because the potential energy at Earth's surface is $-GM_Em/R_E$, the total energy $E = K + U$ must be greater than or equal to zero in order for the object to escape Earth. The speed near Earth's surface corresponding to zero total energy is called the escape speed v_e. It is found from

$$K_f + U_f = K_i + U_i$$

$$0 + 0 = \frac{1}{2}mv_e^2 - \frac{GM_Em}{R_E}$$

so

$$v_e = \sqrt{\frac{2GM_E}{R_E}} \qquad 11\text{-}21$$

ESCAPE SPEED

(NASA.)

Using $G = 6.67 \times 10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2$, $M_E = 5.98 \times 10^{24}\,\text{kg}$, and $R_E = 6.37 \times 10^6\,\text{m}$, we obtain

$$v_e = \sqrt{2(9.81\,\text{m/s}^2)(6.37 \times 10^6\,\text{m})} = 11.2\,\text{km/s}$$

This speed is about 7 mi/s or 25,000 mi/h. An object that has this speed will escape Earth, but it will not escape the solar system because we have neglected the gravitational attraction of the Sun and other planets (see Problem 50).

The escape speed for a planet or moon relative to the thermal speeds of gas molecules determines the kind of atmosphere a planet or moon can have. The average kinetic energy of gas molecules, $(\frac{1}{2}mv^2)_{av}$, is proportional to the absolute temperature T (Chapter 18). Near the surface of Earth, the speeds of nearly all of the oxygen and nitrogen molecules are much much lower than the escape speed, so these gases are retained in our atmosphere. For the lighter molecules hydrogen and helium, however, a significant fraction of them have speeds greater than the escape speed. Hydrogen and helium gases are therefore not found in our atmosphere. The escape speed at the surface of the moon is 2.3 km/s, which can be calculated from Equation 11-21 using the mass and radius of the moon instead of M_E and R_E. This speed is considerably smaller than the escape speed for Earth and, in fact, is too small for any atmosphere to exist.

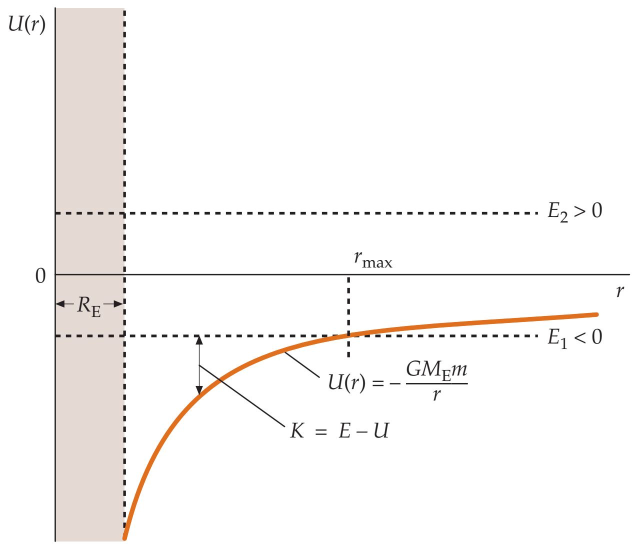

FIGURE 11-11 The kinetic energy of an object at a distance r from the center of Earth is $E - U(r)$. When the total energy is less than zero (E_1 in the figure), the kinetic energy K is zero at $r = r_{max}$ and the object is bound to Earth. When the total energy is greater than zero (E_2 in the figure), the object can escape Earth.

PRACTICE PROBLEM 11-8

Find the escape speed at the surface of Mercury, which has a mass $M = 3.31 \times 10^{23}\,\text{kg}$ and a radius $R = 2440\,\text{km}$.

CLASSIFICATION OF ORBITS BY ENERGY

In Figure 11-11, two possible values for the total energy E are indicated on a graph of $U(r)$ versus r: E_1, which is negative, and E_2, which is positive. A negative total energy simply means that the kinetic energy at Earth's surface is less than GM_Em/R_E, so that $K + U$ is never greater than zero. From this figure we see that, if the total energy is negative, the total-energy line intersects the potential-energy curve at some maximum separation r_{max} and the system is bound. On the other hand, if the total energy is zero or positive, there is no such intersection and the system is unbound. The criteria for a bound or unbound system are simply stated:

If $E < 0$, the system is bound.
If $E \geq 0$, the system is unbound.

When E is negative, its absolute value $|E|$ is called the *binding energy*. The binding energy is the energy that must be added to the system to bring the total energy up to zero.

The potential energy of an object such as a planet or comet of mass m at a distance r from the Sun is

$$U(r) = -\frac{GM_S m}{r} \qquad 11\text{-}22$$

where M_S is the mass of the Sun. The kinetic energy of the object is $\frac{1}{2}mv^2$. If the total energy, kinetic plus potential, is less than zero, then the orbit will be an ellipse (possibly a circle), and the object will be bound to the Sun. If, instead, the total energy is positive, then the orbit will be a hyperbola, and the object will make one trip around the Sun and leave the solar system, never to return. If the total energy is exactly zero, the orbit will be a parabola, and again the object will make one trip and then escape the solar system. To summarize, when the total energy is zero or positive the object is not bound to the Sun, but will escape. Curiously, there have not been any measurements of the energy E of a comet or an asteroid that are definitely nonnegative. Thus, all observed comets and asteroids appear to be bound to the solar system.

Example 11-4 Height of a Projectile

A projectile is fired straight up from the south pole of Earth with an initial speed $v_i = 8.0$ km/s. Find the maximum height it reaches, neglecting effects due to air resistance.

PICTURE The maximum height is found using energy conservation. We are neglecting air resistance, so mechanical energy remains constant.

SOLVE

1. Mechanical energy remains constant. At the maximum height the speed is zero. Projectile is launched from the surface of Earth, so $r_i = R_E$.

$$K_f + U_f = K_i + U_i$$

$$\frac{1}{2}mv_f^2 - \frac{GM_E m}{r_f} = \frac{1}{2}mv_i^2 - \frac{GM_E m}{r_i}$$

$$0 - \frac{GM_E m}{r_f} = \frac{1}{2}mv_i^2 - \frac{GM_E m}{R_E}$$

2. Multiply through by $-1/(GM_E m)$ and solve for r_f:

$$\frac{1}{r_f} = -\frac{v_i^2}{2GM_E} + \frac{1}{R_E}$$

$$= \frac{-(8000\ \mathrm{m/s})^2}{2(6.67 \times 10^{-11}\ \mathrm{N \cdot m^2/kg^2})(5.98 \times 10^{24}\ \mathrm{kg})} + \frac{1}{6.37 \times 10^6\ \mathrm{m}}$$

$$= 7.68 \times 10^{-8}\ \mathrm{m^{-1}}$$

so $r_f = 1/(7.68 \times 10^{-8}\ \mathrm{m^{-1}}) = 1.30 \times 10^7\ \mathrm{m}$

3. Solve for h_f, where $h_f = r_f - R_E$:

$$h = r_f - R_E = 1.30 \times 10^7\ \mathrm{m} - 6.37 \times 10^6\ \mathrm{m} = \boxed{6.7 \times 10^6\ \mathrm{m}}$$

CHECK If g remained equal to $9.81\ \mathrm{m/s^2}$, then the maximum height h could be calculated from $mgh = \frac{1}{2}mv_i^2$. Solving this for h gives $h = v_i^2/(2g) = (8000\ \mathrm{m/s})^2/(19.6\ \mathrm{m/s^2}) = 3.3 \times 10^6$ m. Our step-3 result is greater than this value—as expected.

TAKING IT FURTHER Our step-3 result is 4.5% greater than the radius of Earth.

Example 11-5 Speed of a Projectile

Try It Yourself

A projectile is fired straight up from the south pole of Earth with an initial speed $v_i = 15$ km/s. Find the speed of the projectile when it is very far from Earth, neglecting effects due to air resistance.

PICTURE The maximum height is found using energy conservation. We are neglecting effects due to air resistance, so mechanical energy remains constant. The initial speed of 15 m/s is greater than the escape speed of 11.2 km/s, so the total energy of the projectile is positive and the projectile will retain some kinetic energy when it is very far from Earth.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. Mechanical energy remains constant. Note that $r_f \to \infty$, so $U_f \to 0$.	$\frac{1}{2}mv_f^2 + 0 = \frac{1}{2}mv_i^2 - \frac{GM_E m}{R_E}$
2. Solve for v_f^2.	$v_f^2 = v_i^2 - \frac{2GM_E}{R_E}$
3. Calculate v_f.	$v_f = \boxed{1.0 \times 10^4 \text{ m/s}}$

CHECK The initial speed is just slightly less than $\sqrt{2}$ times the escape speed, so the initial kinetic energy is almost twice that needed to escape with zero final speed. This means the final kinetic energy will be slightly less than that of the projectile if it were moving at the escape speed of 11 km/s. Our step-3 result of 10 km/s is, as expected, slightly less than 11 km/s.

TAKING IT FURTHER In Figure 11-12, the speed of the projectile in kilometers per second is plotted versus h/R_E, where h is the height above Earth's surface. At very large values of h/R_E, the speed of the projectile approaches the horizontal line $v = 10$ km/s.

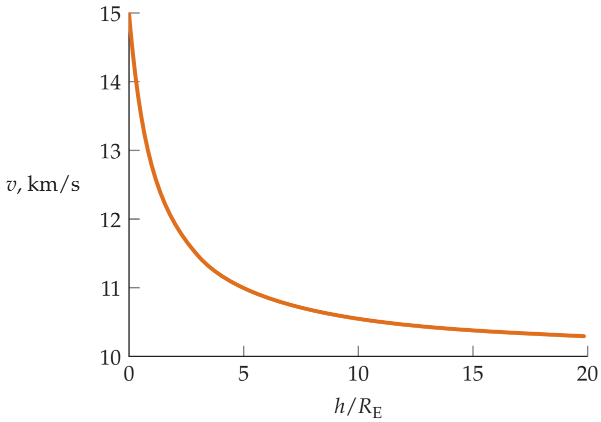

FIGURE 11-12

Example 11-6 Total Energy of a Satellite

Show that the total energy of a satellite in a circular orbit about Earth is equal to half of the potential energy.

PICTURE The total energy of a satellite is the sum of its potential and kinetic energies, $E = U + K$. Newton's second law allows us to relate the speed v of the satellite to its orbital radius r. The kinetic energy depends on the speed, so we can find the kinetic energy in terms of r.

SOLVE

1. Write the total energy equal to the sum of the potential energy and the kinetic energy.

$$E = K + U = \frac{1}{2}mv^2 - \frac{GM_E m}{r}$$

2. Apply Newton's second law to the satellite and solve for the square of the speed.

$$F = ma$$

$$\frac{GM_E m}{r^2} = m\frac{v^2}{r}$$

$$\text{so} \quad v^2 = \frac{GM_E}{r}$$

3. Substitute into the step-1 result and simplify.

$$E = \frac{1}{2}m\frac{GM_E}{r} - \frac{GM_E m}{r} = -\frac{GM_E m}{2r}$$

4. Compare the step-3 result with U in step 1.

$$E = -\frac{GM_E m}{2r} = \frac{1}{2}\left(-\frac{GM_E m}{r}\right) = \boxed{\frac{1}{2}U}$$

CHECK $E = K + U$, so $K = E - U$. Because K is positive, this means that E is greater than U. Because U is negative, $U//2$ is greater than U. Thus, our step-4 result correctly meets the expectation that E is greater than U.

PRACTICE PROBLEM 11-9 A satellite of mass 450 kg orbits Earth in a circular orbit at 6830 km above Earth's surface. The potential energy is zero at infinite separation from Earth. Find (*a*) the potential energy, (*b*) the kinetic energy, and (*c*) the total energy of the satellite.

(NASA.)

11-4 THE GRAVITATIONAL FIELD

The gravitational force exerted by a point particle of mass m_1 on a second point particle of mass m_2 a distance r_{12} away is given by

$$\vec{F}_{12} = -\frac{Gm_1m_2}{r_{12}^2}\hat{r}_{12}$$

where $\hat{r}_{12} = \vec{r}_{12}/r_{12}$ is a unit vector directed away from particle 1 toward particle 2. The **gravitational field** at point P is determined by placing a point particle of mass m at P and calculating the gravitational force $\vec{F}_g$ on it due to all other particles. The gravitational force $\vec{F}_g$ divided by the mass m is the gravitational field $\vec{g}$ at P:

$$\vec{g} = \frac{\vec{F}_g}{m} \tag{11-23}$$

DEFINITION—GRAVITATIONAL FIELD

The point P is called a **field point.** The gravitational field at a field point due to the masses of a collection of point particles is the vector sum of the fields due to the individual masses:

$$\vec{g} = \sum_i \vec{g}_i \tag{11-24a}$$

The locations of these point particles are called **source points.** To find the gravitational field at a field point due to a continuous object, we find the field $d\vec{g}$ due to a small element of volume with mass dm and integrate over the entire mass distribution of the object (the entire set of source points).

$$\vec{g} = \int d\vec{g} \tag{11-24b}$$

The gravitational field of Earth at a distance $r \geq R_E$ points toward Earth and has the magnitude $g(r)$ given by

$$g(r) = \frac{F_g}{m} = \frac{GM_E}{r^2} \tag{11-25}$$

GRAVITATIONAL FIELD OF EARTH

The following Problem-Solving Strategy and two examples involve calculations of the gravitational field produced by rather artificial distributions of mass. We present these here because the skills needed to accomplish these calculations are also needed in many other areas of physics. More specifically, these skills will be used extensively in Chapters 21 and 22 where the task at hand is to calculate the electric field produced by distributions of electric charge.

PROBLEM-SOLVING STRATEGY

Calculating a Gravitational Field

PICTURE Making a sketch of the mass or masses described by a problem is crucial in determining where the field point and source points are. These locations are needed to find both the magnitude and the direction of the gravitational field.

SOLVE

1. Draw a diagram that describes the situation given in the problem statement. Do not forget to identify the field point and the source points. The placement of these points must be accurate because their locations will help you solve the problem.
2. Determine r or the distance between the field point and the source points. You may have to use geometry or trigonometry to determine r.
3. Use the equation $g(r) = (GM/r^2)$ to determine the magnitude of the gravitational field. The direction can be obtained by using your diagram.

CHECK Do not forget that gravitational fields are vector fields, so your answers for these fields must include both their magnitudes and their directions.

Example 11-7 Gravitational Field of Two Point Particles

Two point particles, each of mass M, are fixed in position on the y axis at $y = +a$ and $y = -a$. Find the gravitational field at all points on the x axis as a function of x.

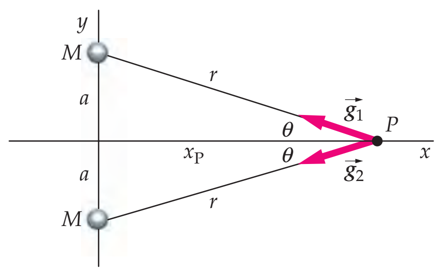

FIGURE 11-13 The particles are each located at a source point, and point P is a field point.

PICTURE Make a sketch of the two particles and the coordinate axis (Figure 11-13). Two particles of mass M each produce a gravitational field at point P located at $x = x_P$. The distance r between P and either particle is $\sqrt{x_P^2 + a^2}$. The resultant field $\vec{g}$ is the vector sum of the fields $\vec{g}_1$ and $\vec{g}_2$ due to each particle.

SOLVE

1. Calculate the magnitude of $\vec{g}_1$ and $\vec{g}_2$:

$$g_1 = g_2 = \frac{GM}{r^2}$$

2. The y component of the resultant field, the sum of g_{1y} and g_{2y}, is zero. The x component is the sum of g_{1x} and g_{2x}:

$$g_y = g_{1y} + g_{2y} = g_1 \sin\theta - g_2 \sin\theta = 0$$

$$g_x = g_{1x} + g_{2x} = g_1 \cos\theta + g_2 \cos\theta = 2g_1 \cos\theta = \frac{2GM}{r^2}\cos\theta$$

3. Express $\cos\theta$ in terms of x_P and r from the figure:

$$\cos\theta = \frac{x_P}{r}$$

4. Combining the last two results yields $\vec{g}$. To express $\vec{g}$ as a function of x_P, substitute $(x_P^2 + a^2)^{1/2}$ for r:

$$\vec{g} = g_x\hat{i} = -\frac{2GM}{r^2}\frac{x_P}{r}\hat{i} = -\frac{2GMx_P}{r^3}\hat{i} = -\frac{2GMx_P}{(x_P^2 + a^2)^{3/2}}\hat{i}$$

5. x_P is an arbitrary point on the x axis. For simplicity, we replace it with x:

$$\vec{g} = \boxed{-\frac{2GMx}{(x^2 + a^2)^{3/2}}\hat{i}}$$

CHECK: For $x < 0$, $\vec{g}$ is in the positive x direction and for $x > 0$, $\vec{g}$ is in the negative direction, as expected. If $x = 0$, we find that $\vec{g} = 0$; the fields $\vec{g}_1$ and $\vec{g}_2$ are equal and opposite at $x = 0$, and hence they cancel.

TAKING IT FURTHER For $x \gg a$, $\vec{g} \approx -(2GM/x^2)\hat{i}$. The field is the same as if a single particle of mass $2M$ were at the origin.

Example 11-8 Gravitational Field of a Uniform Rod

A thin uniform rod of mass M and length L is centered at the origin and lies along the x axis. Find the gravitational field due to the rod at all points on the x axis in the region $x > L/2$.

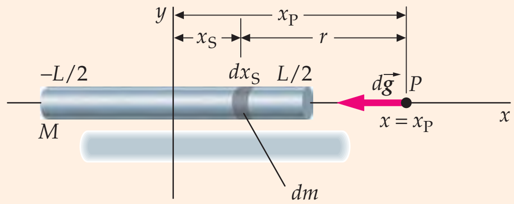

FIGURE 11-14 All points on x axis in the range $-L/2 < x < L/2$ are source points, and point P is a field point.

PICTURE Make a sketch of the rod (Figure 11-14). Identify a mass element dm of length dx_S at $x = x_S$, where $-L/2 < x_S < L/2$, and choose a field point P on the x axis at $x = x_P$, where $x_P > L/2$. Each mass element of the rod produces a gravitational field at P that points in the negative x direction. We can calculate the total field at P by integrating the field due to the mass element over the length of the rod.

SOLVE

1. Find the x component of the field at P due to the mass element dm:
$$dg_x = -\frac{G\,dm}{r^2}$$

2. Because the rod is uniform, the mass per unit length λ is constant and equal to the total mass divided by the total length. The mass dm of an element of length dx_S is equal to the mass per unit length times the length dx_S:
$$dm = \lambda\,dx$$
where $\lambda = \dfrac{M}{L}$

3. Write the distance r between dm and point P in terms of x_S and x_P:
$$r = x_P - x_S$$

4. Substitute these results to express dg in terms of x:
$$dg_x = -\frac{G\,dm}{r^2} = -\frac{G\lambda\,dx_S}{(x_P - x_S)^2}$$

5. Integrate to find the x component of the resultant field:
$$g_x = \int dg_x = -G\lambda \int_{-L/2}^{L/2} \frac{dx_S}{(x_P - x_S)^2} = -\frac{GM}{x_P^2 - (L/2)^2}$$

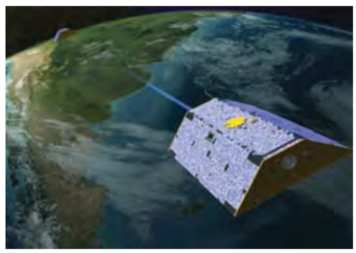
6. Express the resultant field as a vector:
$$\vec{g} = g_x\hat{i} = -\frac{GM}{x_P^2 - (L/2)^2}\hat{i}$$

7. Here x_P is an arbitrary point on the x axis in the region $x > L/2$. For simplicity, we replace it with x:
$$\vec{g} = \boxed{-\frac{GM}{x^2 - (L/2)^2}\hat{i} \qquad x > L/2}$$

CHECK For $x \gg L/2$, the field approaches that of a point particle of mass M, $\vec{g} = -(GM/x^2)\hat{i}$.

Example 11-9 A Gravity Map of Earth *Conceptual*

Twin satellites, launched in March 2002, are making detailed measurements of Earth's gravitational field. They are in identical orbits, with one satellite directly in front of the other by about 220 km. The distance between the satellites is continuously monitored with micrometer accuracy using onboard microwave telemetry equipment. How does the distance between the two satellites change as the satellites approach a region of increased mass?



Twin satellites monitoring the distance between them and measuring variations in Earth's gravitational field. *(NASA and DLR under the NASA Earth System Science Pathfinder Program.)*

PICTURE Earth's gravitational-field strength varies because the mass of Earth is not uniformly distributed. For example, rock is denser than water, so the gravitational field is stronger over a region of dense rock than it is over water.

SOLVE

As the twin satellites approach a region where there is excess mass, the increased gravitational-field strength due to the excess mass pulls them forward (toward the excess mass). The pull on the leading satellite is greater than the pull on the trailing satellite because the leading satellite is closer to the excess mass. Consequently, the leading satellite is gaining speed more rapidly than is the trailing satellite. This results in an increase in the separation distance between the satellites. Thus, the separation distance increases as the satellites approach a region of increased mass.

The distance between them gets larger.

TAKING IT FURTHER A map of the gravitational field is also a map of the mass distribution both at and below the surface of Earth. The buildup of water in the western Pacific during an El Niño can be detected by mapping the gravitational field of Earth with the twin satellites. Gravitational maps provide information that is often useful in the search for underground resources, such as water and oil.

CONCEPT CHECK 11-4

When the twin satellites *straddle* a region of increased mass, with the leading satellite leaving the region and the trailing satellite entering the region, is the distance between the twin satellites changing? If so, is it increasing or decreasing?

$\vec{g}$ OF A SPHERICAL SHELL AND OF A SOLID SPHERE

One of Newton's motivations for developing calculus was to prove that the gravitational field outside a solid sphere is the same as if all the mass of the sphere were concentrated at its center. (This statement is correct only if the mass density of the sphere is uniform or if it varies only with distance from the center of the sphere.) A proof of this statement is in Section 11-5. Here, we merely discuss the consequences of this proof. We first consider a uniform thin spherical shell of mass M and radius R (Figure 11-15). We will show that the gravitational field due to the shell a distance r from the center of the shell is given by

$$\vec{g} = -\frac{GM}{r^2}\hat{r} \qquad r > R \qquad \text{11-26}a$$

$$\vec{g} = 0 \qquad r < R \qquad \text{11-26}b$$

GRAVITATIONAL FIELD OF A UNIFORM THIN SPHERICAL SHELL

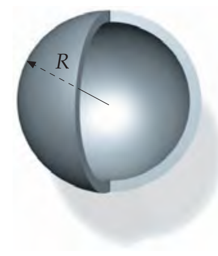


FIGURE 11-15 A uniform spherical shell of mass M and radius R.

From Figure 11-16, which shows a point mass m_0 inside a uniform spherical shell, we can understand the result that $\vec{g} = 0$ inside the shell. In this figure, the shell segments with masses m_1 and m_2 are proportional to the areas A_1 and A_2, respectively, and the areas A_1 and A_2 are proportional to the squares of radii r_1 and r_2, respectively. It follows that

$$\frac{m_1}{m_2} = \frac{A_1}{A_2} = \frac{r_1^2}{r_2^2} \quad \text{so} \quad \frac{m_1}{r_1^2} = \frac{m_2}{r_2^2}$$

Because the gravitational force falls off inversely as the square of the distance, the force on m_0 due to the smaller mass m_1 on the left is exactly balanced by that due to the more distant, larger mass m_2 on the right.

The gravitational field outside a uniform solid sphere is a simple extension of Equation 11-26*a*. We merely consider the solid sphere to consist of a continuum of concentric uniform spherical shells. Because the field due to each shell is the same as if its mass were concentrated at the center of the shell, the field due to the entire sphere is the same as if the entire mass of the sphere were concentrated at its center:

$$g_r = -\frac{GM}{r^2} \qquad r > R \qquad \text{11-27}$$

This result holds whether or not the sphere has uniform density, as long as the density depends only on r.

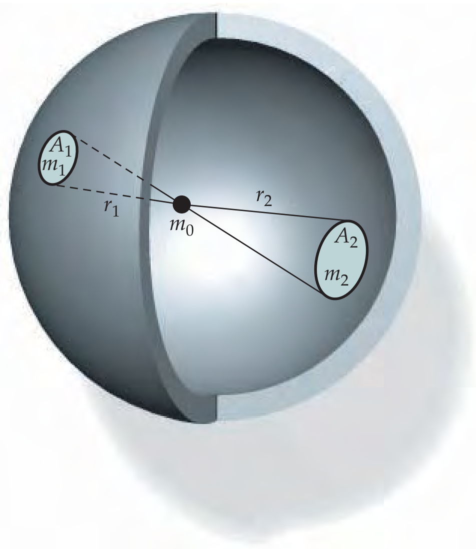

FIGURE 11-16 A point mass m_0 inside a uniform spherical shell feels no net force.

$\vec{g}$ INSIDE A SOLID SPHERE

We now use Equations 11-26*a* and 11-26*b* to find the gravitational field inside a solid sphere of uniform density at a point a distance r from the center, where r is less than the radius R of the sphere. This would apply, for example, to finding the gravitational force on an object at the bottom of a deep mine shaft. As we have seen, the field inside a spherical shell is zero. Thus, in Figure 11-17 the mass of that part of the sphere outside r exerts no force at or inside r.

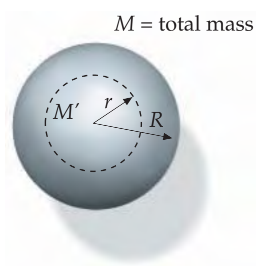

FIGURE 11-17 A uniform solid sphere of radius R and mass M. Only the mass M', which is inside the sphere of radius r, contributes to the gravitational field at the distance r.

Therefore, only the mass M' within the radius r contributes to the gravitational field at r. This mass produces a field equal to that of a point mass M' at the center of the sphere. For a uniform sphere, the fraction of the total mass of the sphere within radius r is equal to the ratio of the volume of a sphere of radius r to that of a sphere of radius R. Thus, if M is the total mass of the sphere, M' is given by

$$M' = \frac{\frac{4}{3}\pi r^3}{\frac{4}{3}\pi R^3}M = \frac{r^3}{R^3}M \qquad \text{11-28}$$

The gravitational field at the distance r is thus

$$g_r = -\frac{GM'}{r^2} = -\frac{GM}{r^2}\frac{r^3}{R^3} \qquad r \le R$$

or

$$g_r = -\frac{GM}{R^3}r \qquad r \le R \qquad \text{11-29}$$

The magnitude of the field is zero at the center and increases linearly with distance r inside the uniform sphere. Figure 11-18 shows a plot of the field g_r as a function of r for a solid sphere of uniform mass density.

See **Math Tutorial** *for more information on* **Geometry**

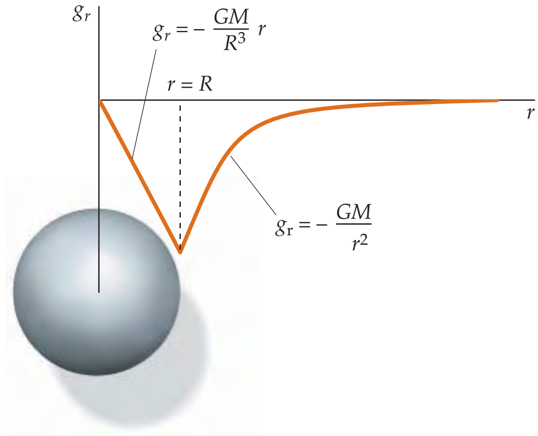

FIGURE 11-18 A plot of g_r versus r for a uniform solid sphere of mass M. The magnitude of the field increases linearly with r inside the sphere and decreases as $1/r^2$ outside the sphere.

Example 11-10 A Hollow Planet

A planet that has a hollow core consists of a uniform spherical shell with mass M, outer radius R, and inner radius $R/2$. (*a*) What amount of mass is closer than $\frac{3}{4}R$ to the center of the planet? (*b*) What is the gravitational field a distance $\frac{3}{4}R$ from the center?

PICTURE The mass M' of that part of the spherical shell that is closer to the center than $\frac{3}{4}R$ is the density times the volume of the spherical shell with outer radius $\frac{3}{4}R$ and inner radius $\frac{1}{2}R$. First, find the density and volume, then find the mass. The gravitational field at $r = \frac{3}{4}R$ is due only to the mass closer to the center than $\frac{3}{4}R$.

SOLVE

(*a*) 1. The mass M' (the mass of the spherical shell with outer radius $\frac{3}{4}R$ and inner radius $\frac{1}{2}R$) is the density ρ times the volume V':

$$M' = \rho V'$$

2. The density is the total mass M divided by the total volume V:

$$\rho = \frac{M}{V} = \frac{M}{\frac{4}{3}\pi R^3 - \frac{4}{3}\pi(\frac{1}{2}R)^3} = \frac{M}{\frac{7}{6}\pi R^3} = \frac{6M}{7\pi R^3}$$

3. Find the volume V' of the thick shell with outer radius $\frac{3}{4}R$ and inner radius $\frac{1}{2}R$:

$$V' = \frac{4}{3}\pi\left(\frac{3R}{4}\right)^3 - \frac{4}{3}\pi\left(\frac{R}{2}\right)^3 = \frac{19}{48}\pi R^3$$

4. Find the mass M':

$$M' = \rho V' = \frac{6M}{7\pi R^3}\frac{19}{48}\pi R^3 = \boxed{\frac{19}{56}M}$$

(*b*) The gravitational field at $r = \frac{3}{4}R$ is due only to the mass M':

$$\vec{g} = -\frac{GM'}{r^2}\hat{r} = -\frac{G\frac{19}{56}M}{(\frac{3}{4}R)^2}\hat{r} = \boxed{-\frac{38}{63}\frac{GM}{R^2}\hat{r}}$$

CHECK The volume V' (step 3) is less than half the volume V (step 2), so we expect M' to be less than half M. Our step-4 result meets this expectation.

Example 11-11 Radially Dependent Density

A solid sphere of radius R and mass M is spherically symmetric but not uniform. Its density ρ, defined as its mass per unit volume, is proportional to the distance r from the center for $r \le R$. That is, $\rho = Cr$ for $r \le R$, where C is a constant. (*a*) Find C. (*b*) Find $\vec{g}$ for all $r \ge R$. (*c*) Find $\vec{g}$ at $r = \frac{1}{2}R$.

PICTURE (*a*) You can find C by integrating the density over the volume of the sphere and setting the result equal to M. For a volume element, take a spherical shell of radius r and thickness dr (Figure 11-19). Its volume is $4\pi r^2\,dr$ and its mass is $dM = \rho\,dV = Cr(4\pi r^2\,dr)$. (*b*) The field outside the sphere ($r \ge R$) is the same as if the total mass M were at the center of the sphere. (*c*) The field at $r = \frac{1}{2}R$ is the same as if mass M' were at the center of the sphere, where M' is the amount of mass within the sphere of radius $\frac{1}{2}R$. The mass between $r = \frac{1}{2}R$ and $r = R$ produces zero field at $r = \frac{1}{2}R$.

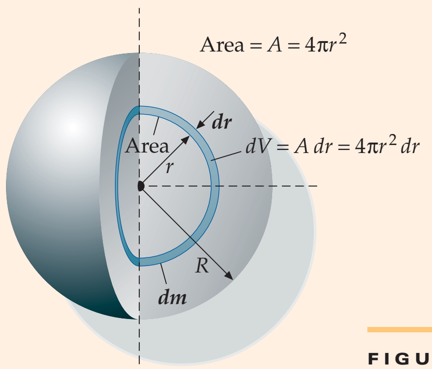

FIGURE 11-19

SOLVE

(*a*) 1. Integrate $dM = \rho\,dV$ to relate C to the mass M, where $dV = 4\pi r^2\,dr$. ($4\pi r^2$ is the area of a sphere of radius r so $4\pi r^2\,dr$ is the volume of a spherical shell of radius r and thickness dr):

$$M = \int dM = \int \rho\,dV$$
$$= \int_0^R Cr(4\pi r^2\,dr) = C\pi R^4$$

2. Solve for C in terms of the given quantities M and R.

$$C = \boxed{\frac{M}{\pi R^4}}$$

(*b*) Write an expression for the field outside the sphere in terms of the mass M, the distance r from the center, and the unit vector $\hat{r}$. The unit vector $\hat{r}$ is in the direction of increasing r:

$$\vec{g} = \boxed{-\frac{GM}{r^2}\hat{r}} \quad (r > R)$$

(*c*) 1. Compute the mass M' that is within the radius $\frac{1}{2}R$ by integrating $dm = \rho\,dV$ from $r = 0$ to $\frac{1}{2}R$ and use the value of C found in Part (*a*), step 2.

$$M' = \int \rho\,dV = \int_0^{R/2} Cr(4\pi r^2\,dr) = C\pi R^4/16$$
$$M' = \frac{M}{16}$$

2. Write an expression for the field at $r = \frac{1}{2}R$ in terms of M and R.

$$\vec{g} = -\frac{GM'}{r^2}\hat{r} = \boxed{-\frac{GM}{4R^2}\hat{r} \quad \text{at} \quad r = \tfrac{1}{2}R}$$

CHECK For a uniform sphere, Equation 11-29 gives the field at $r = \frac{1}{2}R$ as $g_r = -GM/(2R^2)$, which is twice as large as our Part-(*c*) result. We expected a larger value for a uniform sphere, because a uniform sphere has a larger fraction of its total mass in the region $0 < r < \frac{1}{2}R$ than does the sphere in Example 11-11.

TAKING IT FURTHER Note that the units for C are kg/m^4, so the units for ρ are kg/m^3, which is mass per volume.

* 11-5 FINDING THE GRAVITATIONAL FIELD OF A SPHERICAL SHELL BY INTEGRATION

We now derive the equation for the gravitational field of a uniform thin spherical shell. First, we find the gravitational field on the axis of a thin ring of uniform mass. We then apply our result to a thin spherical shell, which we treat as a continuum of thin coaxial rings.

Figure 11-20 shows a thin ring of total mass m and radius a and a field point P on the axis of the ring a distance x from its center. We choose an element with mass dm on the ring that is small enough to be considered a point particle. The distance from the element to P is s, and the line joining the element and P makes an *angle* α with the axis of the ring.

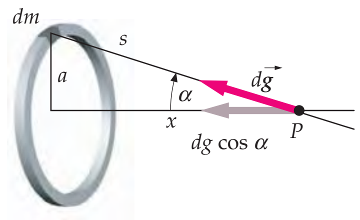

FIGURE 11-20 The gravitational field at a point P a distance x from a thin uniform ring. The field due to the element with a mass equal to dm points toward the element.

The field at P, which is due to the element dm, is toward the element and has magnitude dg given by

$$dg = \frac{G\,dm}{s^2}$$

From the symmetry of the figure, we can see that when we sum over all the elements of the ring, the net field will be along the axis of the ring; that is, the components of $\vec{g}$ perpendicular to the x axis will sum to zero. For example, the perpendicular component of the field shown in the figure will be canceled by the perpendicular component of the field due to another element of the ring directly opposite the one shown. The net field will therefore be in the $-x$ direction. The x component of the field due to the element dm is

$$dg_x = -dg\cos\alpha = -\frac{G\,dm}{s^2}\cos\alpha$$

We obtain the total field by integrating both sides of this equation:

$$g_x = -\int \frac{G\cos\alpha}{s^2}\,dm$$

See Math Tutorial *for more information on* Integrals

Because s and α are the same for all points on the ring, they are constants as far as this integration is concerned. Thus,

$$g_x = -\frac{G\cos\alpha}{s^2}\int dm = -\frac{Gm}{s^2}\cos\alpha \qquad 11\text{-}30$$

where $m = \int dm$ is the total mass of the ring.

We now use this result to calculate the gravitational field of a thin uniform spherical shell of mass M and radius R at a point a distance r from the center of the shell. We first consider the case in which the field point P is outside the shell, as in Figure 11-21. By symmetry, the field must be directed toward the center of the spherical shell. We choose for our element of mass the strip shown, which can be considered to be a thin ring of mass dM. The field due to this strip is given by Equation 11-30 with m replaced by dM:

$$dg_r = -\frac{G\,dM}{s^2}\cos\alpha \qquad 11\text{-}31$$

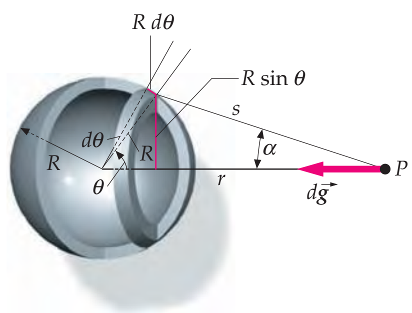

FIGURE 11-21 A uniform thin spherical shell of radius R and total mass M. The strip shown can be considered to be a ring of width $R\,d\theta$ and circumference $2\pi R\sin\theta$.

The mass dM is proportional to the area of the strip dA, which equals the circumference times the width. The radius of the strip is $R\sin\theta$, so the circumference is $2\pi R\sin\theta$. The width is $R\,d\theta$. If M is the total mass of the shell and $A = 4\pi R^2$ is its total area, the mass of the strip of area dA is

$$dM = \frac{M}{A}\,dA = \frac{M}{4\pi R^2}2\pi R^2\sin\theta\,d\theta = \frac{1}{2}M\sin\theta\,d\theta \qquad 11\text{-}32$$

Substituting this result into Equation 11-31 gives

$$dg_r = -\frac{G\,dM}{s^2}\cos\alpha = -\frac{GM\sin\theta\,d\theta}{2s^2}\cos\alpha \qquad \text{11-33}$$

The right-hand term of Equation 11-33 contains three variables (s, θ, and α). Before integrating this term we must express it as a function of a single variable. It turns out to be easiest if we express it in terms of s. By the law of cosines, we have

$$s^2 = r^2 + R^2 - 2rR\cos\theta$$

Differentiating gives

$$2s\,ds = +2rR\sin\theta\,d\theta$$

so

$$\sin\theta\,d\theta = \frac{s\,ds}{rR}$$

An expression for cos α can be obtained by again applying the law of cosines to the same triangle. We have

$$R^2 = s^2 + r^2 - 2sr\cos\alpha$$

so

$$\cos\alpha = \frac{s^2 + r^2 - R^2}{2sr}$$

Substituting these results into Equation 11-33 gives

$$\begin{aligned} dg_r &= -\frac{GM\sin\theta\,d\theta}{2s^2}\cos\alpha = -\frac{GM}{2s^2}\left(\frac{s\,ds}{rR}\right)\frac{s^2 + r^2 - R^2}{2sr} \\ &= -\frac{GM\,ds}{4s^2r^2R}(s^2 + r^2 - R^2) = -\frac{GM}{4r^2R}\left(1 + \frac{r^2 - R^2}{s^2}\right)ds \end{aligned} \qquad \text{11-34}$$

To find the field at P, we integrate over the entire shell. The integration limits for this step depend on whether the field point P lies outside the shell or inside it. For P outside the shell, s varies from $r - R$ (at $\theta = 0$) to $s = r + R$ (at $\theta = 180°$), so the field due to the entire shell is found by integrating from $s = r - R$ to $s = r + R$.

$$g_r = -\frac{GM}{4r^2R}\int_{r-R}^{r+R}\left(1 + \frac{(r-R)(r+R)}{s^2}\right)ds = -\frac{GM}{4r^2R}\left[s - \frac{(r-R)(r+R)}{s}\right]_{r-R}^{r+R}$$

Substituting the upper and lower limits for s yields $4R$ for the quantity in the square brackets. Thus,

$$g_r = -\frac{GM}{r^2} \qquad \text{for} \quad r > R$$

which is the same result as for Equation 11-26*a*.

If the field point P is inside the shell (Figure 11-22), the calculation is identical except that s now varies from $R - r$ to $R + r$. Thus,

$$g_r = -\frac{GM}{4r^2R}\left[s - \frac{(r-R)(r+R)}{s}\right]_{R-r}^{R+r}$$

Substituting these upper and lower limits for s yields $g_r = 0$. Therefore,

$$g_r = 0 \qquad \text{for} \quad r < R$$

which is the same as Equation 11-26*b*.

Applying these results to find the gravitational field due to a uniform spherical shell of finite thickness is the topic of Problem 11-99.

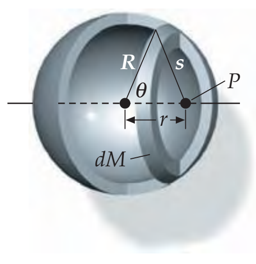

FIGURE 11-22

Physics Spotlight

Gravitational Lenses: A Window on the Universe

In 1919, Arthur Eddington took photographs during a 1919 solar eclipse which showed stars where they should not be. The starlight had been "bent" by the mass of the Sun. This verified a key prediction of Einstein's 1915 theory of general relativity, namely, space is warped by massive objects. The degree of curvature of space depends on the object's mass.

The bent light was mostly a curiosity for many years after 1919. Years later, many astronomers started studying quasars, star-sized objects that gave off more light than most galaxies. In 1979, twin images of a distant quasar were seen. These images had been formed when the quasar's light was bent by a cluster of galaxies[*] between the quasar and Earth.

The central reddish-white blobs are giant elliptical galaxies, and the thin blue light ringing these blobs comes from galaxies twice as far away and directly behind the giant elliptical galaxies. The light from the more distant galaxies is distorted into circular shapes by the gravitation field of the giant elliptical galaxies. *(NASA, ESA, A. Bolton (Harvard-Smithsonian CfA), & the SLACS Team.)*

Clusters of galaxies are massive objects. Space in and around them warps, and thus curves the light from distant objects that travels through and near them on its journey toward Earth. The region of warped space near a massive object is called a *gravitational lens*. Gravitational lenses can brighten the light of distant objects, just as light shining through a drop of water can be brightened. Gravitational lenses are now used to study very distant quasars and galaxies. Because the lenses magnify faint light, they help determine the age and expansion of the universe.[†]

Calculations using gravitational lenses are based on the images of the distant object. To get a precise description for an object, the distance, mass, and shape of the intervening gravitational lens must be determined. A lens formed by a uniform circular mass directly between the distant object and Earth would create a uniform circular image—an *Einstein ring*—with easily calculated values.[‡,#] But gravitational lenses create multiple[°] or strangely distorted images much more often than they create perfect rings. The strongest lenses are formed by clusters of galaxies.[§] These galaxies are difficult to model, and their detectable energy cannot account for all of the distorting mass. Calculations show that the galaxies must have a large halo of unseen mass. Gravitational lenses confirm that most of the universe's mass is *dark matter*, matter that does not emit detectable energy.[¶,**]

A weak lens, or *microlens*, does not create multiple images of a distant object, but brightens the image of a known object for a short time. This type of lens is formed by a massive compact halo object (macho), which passes between the known object and Earth.[††] The changes in brightness reveal much about the shape and mass of the macho. One microlens was determined to be a red dwarf, orbited by the smallest planet known outside of our solar system.[‡‡]

Gravitational lenses have enabled the discovery of objects from galaxies[##] produced less than a billion years after the start of the universe, to the smallest known objects outside of our solar system. These lenses have defined questions about matter and energy in the universe. Gravitational lenses have come full circle—the curve of light is now used to measure things that have not yet been seen.

Summary

1. Kepler's laws are *empirical* observations. They can also be derived from Newton's laws of motion and Newton's law of gravity.
2. Newton's law of gravity is a *fundamental law* of physics, and G is a fundamental *universal* physical constant.
3. The gravitational potential energy of a two-particle system, relative to $U = 0$ at infinite separation, is given by $U = 2Gm_1m_2/r$. If the system is bound, its total energy is negative.
4. The gravitational field is a *fundamental physical concept* that describes the condition in space set up by a mass distribution.

TOPIC	RELEVANT EQUATIONS AND REMARKS

1. Kepler's Three Laws

Law 1. All of the planets move in elliptical orbits with the Sun at one focus.

Law 2. A line joining any planet to the Sun sweeps out equal areas in equal times.

Law 3. The square of the period of any planet is proportional to the cube of the planet's mean distance from the Sun:

$$T^2 = Cr^3 \qquad \text{11-2}$$

where C has almost the same value for all planets; from Newton's law of gravity, C can be shown to be $4\pi^2/[G(M_S + M_p)]$. If $M_S \gg M_p$, this can be expressed as

$$T^2 = \frac{4\pi^2}{GM_S}r^3 \qquad \text{11-16}$$

Kepler's laws can be derived from Newton's law of gravity. The first and third of Kepler's laws follow from the fact that the force exerted by the Sun on the planets varies inversely as the square of the separation distance. The second law follows from the fact that the force exerted by the Sun on a planet is along the line joining them, so the orbital angular momentum of the planet is conserved. Kepler's laws also hold for any object orbiting another in an inverse-square gravitational field, such as a satellite orbiting a planet.

2. Newton's Law of Gravity

Every point particle exerts an attractive force on every other point particle that is proportional to the masses of the two particles and inversely proportional to the square of the distance separating them:

$$\vec{F}_{12} = -\frac{Gm_1m_2}{r_{12}^2}\hat{r}_{12} \qquad \text{11-3}$$

Universal gravitational constant

$$G = 6.67 \times 10^{-11}\ \mathrm{N \cdot m^2/kg^2} \qquad \text{11-4}$$

3. Gravitational Potential Energy

The gravitational potential energy U for a system consisting of a particle of mass m outside a spherically symmetric object of mass M and at a distance r from its center is

$$U(r) = -\frac{GMm}{r} \qquad \text{11-20}$$

This potential-energy function approaches zero as r approaches infinity.

4. Mechanical Energy

The mechanical energy E for a system consisting of a particle of mass m outside a spherically symmetric object of mass M and at a distance r from its center is

$$E = \frac{1}{2}mv^2 - \frac{GMm}{r}$$

Escape speed

For a given value of r, the speed of the particle for which $E = 0$ is called the escape speed v_e. That is, if $v = v_e$, then $E = 0$.

5. Classification of Orbits

If $E < 0$, the system is bound and the orbit is an ellipse (or circle, which is a type of ellipse).

If $E \geq 0$, the system is unbound and the orbit is a hyperbola (or a parabola for $E = 0$).

6. Gravitational Field		
Definition	$\vec{g} = \dfrac{\vec{F}_g}{m}$	11-23
Due to Earth	$\vec{g}(r) = \dfrac{\vec{F}_g}{m} = -\dfrac{GM_E}{r^2}\hat{r} \quad (r \geq R_E)$	11-29
Due to a thin, spherical shell	Outside the shell, the gravitational field is the same as if all the mass of the shell were concentrated at the center. The field inside the shell is zero.	
	$\vec{g} = -\dfrac{GM}{r^2}\hat{r} \quad \text{for} \quad r > R$	11-26*a*
	$\vec{g} = 0 \quad \text{for} \quad r < R$	11-26*b*

Answers to Concept Checks

11-1 An orbiting astronaut is said to be weightless because both he and the orbiting shuttle are in free-fall with the same acceleration, so if an astronaut would stand on a scale that is attached to the shuttle, the scale would read zero. An orbiting astronaut is not actually weightless because we have defined weight to be the magnitude of the gravitational force.

11-2 The property of an object responsible for the gravitational force it exerts on another object, or for the gravitational force another object exerts on it, is its *gravitational* mass. On the other hand, the property of an object that measures its inertial resistance to acceleration is its *inertial* mass.

11-3 Using his second law, Newton proved that an attractive force that varies inversely with the square of the distance between the Sun and a planet would result in an elliptical orbit with the center of the Sun at a focus of the ellipse.

11-4 The distance between the satellites is decreasing.

Answers to Practice Problems

11-1 30.1 AU

11-2 A straight line that has a slope of 1.5

11-3 8.67×10^{-7} N

11-4 2640 km

11-5 Earth rotates 360° in 24 h, so in 1 h Earth rotates 15°. Because of Earth's orbital motion, the direction of the Sun relative to Earth changes by (1/365.25) rev each 24 h. As a result, Earth rotates through 1 rev in about 4 min less than 24 h. The time for 1 rev is called the sidereal day.

11-6 $r = 6.63R_E = 4.22 \times 10^7$ m $= 26{,}200$ mi. If such a satellite is in orbit over the equator and moves in the same direction as the rotation of Earth, it appears stationary relative to Earth. Many communication satellites are "parked" in such orbits, called *geosynchronous orbits*.

11-7 6.45×10^{23} kg $= 0.108\, M_E$

11-8 $v_e = 4.25$ km/s

11-9 (Note that $r = R_E + h = 13{,}200$ km.) (*a*) $U = -13.6 \times 10^9$ J, (*b*) $K = 6.80 \times 10^9$ J, (*c*) $E = -6.80 \times 10^9$ J

PROBLEMS

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimates.

For all problems, use 9.81 m/s² for the free-fall acceleration and neglect friction and air resistance unless instructed to do otherwise.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • True or false:

(*a*) For Kepler's law of equal areas to be valid, the force of gravity must vary inversely with the square of the distance between a given planet and the Sun.
(*b*) The planet closest to the Sun has the shortest orbital period.
(*c*) Venus's orbital speed is larger than the orbital speed of Earth.
(*d*) The orbital period of a planet allows accurate determination of that planet's mass. SSM

2 • If the mass of a small Earth-orbiting satellite is doubled, the radius of its orbit can remain constant if the speed of the satellite (*a*) increases by a factor of 8, (*b*) increases by a factor of 2, (*c*) does not change, (*d*) is reduced by a factor of 8, (*e*) is reduced by a factor of 2.

3 • During what season in the northern hemisphere does Earth attain its maximum orbital speed about the Sun? In what season does it attain its minimum orbital speed? *Hint: Earth is at perihelion in early January.* SSM

4 • Haley's comet is in a highly elliptical orbit about the Sun with a period of about 76 y. Its last closest approach to the Sun occurred in 1987. In what years of the twentieth century was it traveling at its fastest or slowest orbital speed about the Sun?

5 • Venus has no natural satellites. However, artificial satellites have been placed in orbit around it. To use one of their orbits to determine the mass of Venus, what orbital parameters would you have to measure? How would you then use these parameters to do the mass calculation?

6 • A majority of the asteroids are in approximately circular orbits in a "belt" between Mars and Jupiter. Do they all have the same orbital period about the Sun? Explain.

7 • At the moon's surface, the acceleration due to the gravity of the moon is a. At a distance from the moon's center equal to four times the radius of the moon, the acceleration due to the gravity of the moon is (*a*) $16a$, (*b*) $a/4$, (*c*) $a/3$, (*d*) $a/16$, (*e*) None of the above. SSM

8 • At a depth equal to half the radius of Earth, the acceleration due to gravity is about (*a*) g (*b*) $2g$ (*c*) $g/2$, (*d*) $g/4$, (*e*) $g/8$, (*f*) You cannot determine the answer based on the data given.

9 •• Two stars orbit their common center of mass as a *binary* star system. If each of their masses were doubled, what would have to happen to the distance between them in order to maintain the same gravitational force? The distance would have to (*a*) remain the same, (*b*) double, (*c*) quadruple, (*d*) be reduced by a factor of 2, (*e*) You cannot determine the answer based on the data given.

10 •• **CONTEXT-RICH** If you had been working for NASA in the 1960s and planning the trip to the moon, you would have determined that a unique location exists somewhere between Earth and the moon, where a spaceship is, for an instant, truly weightless. (Consider only the moon, Earth, and the Apollo spaceship, and neglect other gravitational forces.) Explain this phenomenon and explain whether this location is closer to the moon, midway on the trip, or closer to Earth.

11 •• Suppose the escape speed from a planet is only slightly larger than the escape speed from Earth, yet the planet is considerably larger than Earth. How would the planet's (average) density compare to Earth's (average) density? (*a*) It must be denser, (*b*) It must be less dense. (*c*) It must be the same density. (*d*) You cannot determine the answer based on the data given. SSM

12 •• Suppose that, using a telescope in your backyard, you discovered a distant object approaching the Sun, and were able to determine both its distance from the Sun and its speed. How would you be able to predict whether the object will remain "bound" to the solar system, or if it is an interstellar interloper that would come in, turn around, and escape, never to return?

13 •• **CONTEXT-RICH, ENGINEERING APPLICATION** Near the end of their useful lives, several large Earth-orbiting satellites have been maneuvered so they burn up as they enter Earth's atmosphere. These maneuvers have to be done carefully so large fragments do not impact populated land areas. You are in charge of such a project. Assuming a satellite of interest has on-board propulsion, in what direction would you fire the rockets for a short burn time to start this downward spiral? What would happen to the kinetic energy, gravitational potential energy, and total mechanical energy following the burn as the satellite came closer and closer to Earth? SSM

14 •• **ENGINEERING APPLICATION** During a trip back from the moon, the Apollo spacecraft fires its rockets to leave its lunar orbit. Then, it coasts back to Earth where it enters the atmosphere at high speed, survives a blazing reentry, and parachutes safely into the ocean. In what direction do you fire the rockets to initiate this return trip? Explain the changes in kinetic energy, gravitational potential, and total mechanical energy that occur to the spacecraft from the beginning to the end of this journey.

15 •• Explain why the gravitational field inside a solid sphere of uniform mass is directly proportional to r rather than inversely proportional to r.

16 •• In the movie *2001: A Space Odyssey*, a spaceship containing two astronauts is on a long-term mission to Jupiter. A model of their ship could be a uniform pencil-like rod (containing the propulsion systems) with a uniform sphere (the crew habitat and flight deck) attached to one end (Figure 11-23). The design is such that the radius of the sphere is much smaller than the length of the rod. At a location a few meters away from the ship, at point P on the perpendicular bisector of the rodlike section, what would be the direction of the gravitational field due to the ship alone (that is, assuming all other gravitational fields are negligible)? Explain your answer. At a large distance from the ship, what would be the dependence of the ship's gravitational field on the distance from the ship?

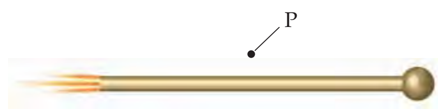

FIGURE 11-23 Problem 16

ESTIMATION AND APPROXIMATION

17 • Estimate the mass of our galaxy (the Milky Way) if the Sun orbits the center of the galaxy with a period of 250 million years at a mean distance of 30,000 $c \cdot y$. Express the mass in terms of multiples of the solar mass M_S. (Neglect the mass farther from the center than the Sun, and assume that the mass closer to the center than the Sun exerts the same force on the Sun, as would a point particle of the same mass located at the center of the galaxy.) SSM

18 •• Besides studying samples of the lunar surface, the Apollo astronauts had several ways of determining that the moon is *not* made of green cheese. Among these ways are measurements of the gravitational acceleration at the lunar surface. Estimate the gravitational acceleration at the lunar surface if the moon were, in fact, a solid block of green cheese and compare your answer to the known value of the gravitational acceleration at the lunar surface.

19 •• **CONTEXT-RICH, ENGINEERING APPLICATION** You are in charge of the first manned exploration of an asteroid. You are concerned that, due to the weak gravitation field and resulting low escape speed, tethers might be required to bind the explorers to the surface of the asteroid. Therefore, if you do not wish to use tethers, you have to be careful about which asteroids to choose to explore. Estimate the largest radius the asteroid can have that would still allow you to escape its surface by jumping. Assume spherical geometry and reasonable rock density.

20 ••• One of the great discoveries in astronomy in the past decade is the detection of planets outside the solar system. Since 1996, more than 100 planets have been detected orbiting stars other than the Sun. While the planets themselves cannot be seen directly, telescopes can detect the small periodic motion of the star as the star and planet orbit around their common center of mass. (This is measured using the *Doppler effect*, which is discussed in Chapter 15.) Both the period of this motion and the variation in the speed of the star over the course of time can be determined observationally. The mass of the star is found from its observed luminance and from the theory of stellar structure. *Iota Draconis* is the eighth brightest star in the constellation Draco. Observations show that a planet, with an orbital period of 1.50 y, is orbiting this star. The mass of Iota Draconis is $1.05M_{\text{Sun}}$. (*a*) Estimate the size (in AU) of the semimajor axis of this planet's orbit. (*b*) The radial speed of the star is observed to vary by 592 m/s. Use conservation of momentum to find the mass of the planet. Assume the orbit is circular, we are observing the orbit edge-on, and no other planets orbit Iota Draconis. Express the mass as a multiple of the mass of Jupiter.

21 ••• One of the biggest unresolved problems in the theory of the formation of the solar system is that, while the mass of the Sun is 99.9 percent of the total mass of the solar system, it carries only about 2 percent of the total angular momentum. The most widely accepted theory of solar system formation has as its central hypothesis the collapse of a cloud of dust and gas under the force of gravity, with most of the mass forming the Sun. However, because the net angular momentum of this cloud is conserved, a simple theory would indicate that the Sun should be rotating much more rapidly than it currently is. In this problem, you are to show why it is important that most of the angular momentum was somehow transferred to the planets. (*a*) The Sun is a cloud of gas held together by the force of gravity. If the Sun were rotating too rapidly, gravity could not hold it together. Using the known mass of the Sun (1.99×10^{30} kg) and its radius (6.96×10^{8} m), estimate the maximum angular speed that the Sun can have if it is to stay intact. What is the period of rotation corresponding to this rotation rate? (*b*) Calculate the orbital angular momentum of Jupiter and of Saturn from their masses (318 and 95.1 Earth masses, respectively), mean distances from the Sun (778 and 1430 million km, respectively), and orbital periods (11.9 and 29.5 y, respectively). Compare them to the experimentally measured value of the Sun's angular momentum of $1.91 \times 10^{41}\ \text{kg} \cdot \text{m}^2/\text{s}$. (*c*) If we were to somehow transfer all of Jupiter's and Saturn's angular momentum to the Sun, what would be the Sun's new rotational period? The Sun is not a uniform sphere of gas, and its moment of inertia is given by the formula $I = 0.059MR^2$. Compare this to the maximum rotational period of Part (*a*).

KEPLER'S LAWS

22 • The new comet Alex-Casey has a very elliptical orbit with a period of 127.4 y. If the closest approach of Alex-Casey to the Sun is 0.1 AU, what is its greatest distance from the Sun?

23 • The radius of Earth's orbit is 1.496×10^{11} m and that of Uranus is 2.87×10^{12} m. What is the orbital period of Uranus?

24 • The asteroid Hektor, discovered in 1907, is in a nearly circular orbit of radius 5.16 AU about the Sun. Determine the period of this asteroid.

25 •• One of the so-called "Kirkwood gaps" in the asteroid belt occurs at an orbital radius at which the period of the orbit is half that of Jupiter's. The reason there is a gap for orbits of this radius is because of the periodic pulling (by Jupiter) that an asteroid experiences at the same location with every *other* orbit around the Sun. Repeated tugs from Jupiter of this kind would eventually change the orbit of such an asteroid. Therefore, all asteroids that would otherwise have orbited at this radius have presumably been cleared away from the area due to this resonance phenomenon. How far from the Sun is this particular 2:1 resonance "Kirkwood" gap? SSM

26 •• The tiny Saturnian moon, Atlas, is locked into what is known as an orbital resonance with another moon, Mimas, whose orbit lies outside that of Atlas. The ratio between periods of these orbits is 3:2, that is, for every 3 orbits of Atlas, Mimas completes 2 orbits. Thus, Atlas, Mimas and Saturn are aligned at intervals equal to two orbital periods of Atlas. If Mimas orbits Saturn at a radius of 186,000 km, what is the radius of Atlas's orbit?

27 •• The asteroid Icarus, discovered in 1949, was so named because its highly eccentric elliptical orbit brings it close to the Sun at perihelion. The eccentricity e of an ellipse is defined by the relation $r_p = a(1 - e)$, where r_p is the perihelion distance and a is the semimajor axis. Icarus has an eccentricity of 0.83 and a period of 1.1 y. (*a*) Determine the semimajor axis of the orbit of Icarus. (*b*) Determine the perihelion and aphelion distances of the orbit of Icarus.

28 •• **CONTEXT-RICH, ENGINEERING APPLICATION, BIOLOGICAL APPLICATION** A manned mission to Mars and its attendant problems due to the extremely long time the astronauts would spend weightless and without supplies space have been extensively discussed. To examine this issue in a simple way, consider one possible trajectory for the spacecraft: the "Hohmann transfer orbit." This orbit consists of an elliptical orbit tangent to the orbit of Earth at its perihelion and tangent to the orbit of Mars at its aphelion. Given that Mars has a mean distance from the Sun of 1.52 times the mean Sun–Earth distance, calculate the time spent by the astronauts during the outbound part of the trip to Mars. Many adverse biological effects (such as muscle atrophy and decreased bone density) have been observed in astronauts returning from near-Earth orbit after only a few months in space. As the flight doctor, are there any health concerns that you should be aware of?

29 •• **ESTIMATION** Kepler determined distances in the solar system from his data. For example, he found the relative distance from the Sun to Venus (as compared to the distance from the Sun to Earth) as follows. Because Venus's orbit is closer to the Sun than is Earth's orbit, Venus is a morning or evening star—its position in the sky is never very far from the Sun (Figure 11-24). If we suppose

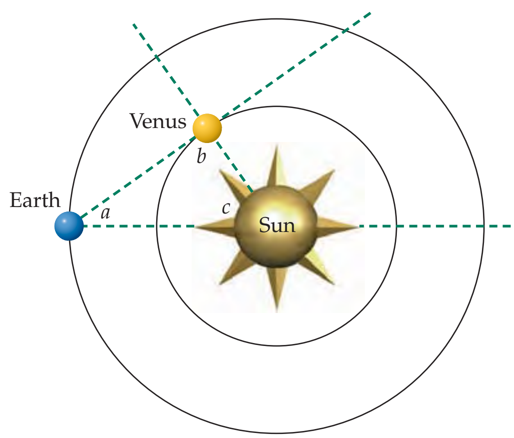

FIGURE 11-24 Problem 29

the orbit of Venus is a perfect circle, then consider the relative orientation of Venus, Earth, and the Sun at maximum extension, that is, when Venus is farthest from the Sun in the sky. (*a*) Under this condition, show that angle b in Figure 11-24 is 90°. (*b*) If the maximum elongation angle a between Venus and the Sun is 47°, what is the distance between Venus and the Sun in AU? (*c*) Use this result to estimate the length of a Venusian "year." SSM

30 •• At apogee, the center of the moon is 406,395 km from the center of Earth and at perigee, the moon is 357,643 km from the center of Earth. What is the orbital speed of the moon at perigee and at apogee? The mass of Earth is 5.98×10^{24} kg.

NEWTON'S LAW OF GRAVITY

31 • Jupiter's satellite Europa orbits Jupiter with a period of 3.55 d at an average orbital radius of 6.71×10^8 m. (*a*) Assuming that the orbit is circular, determine the mass of Jupiter from the data given. (*b*) Another satellite of Jupiter, Callisto, orbits at an average radius of 18.8×10^8 m with an orbital period of 16.7 d. Show that these data are consistent with an inverse-square force law for gravity (*Note:* Do NOT use the value of G anywhere in Part (*b*)). SSM

32 • **Biological Application** Some people think that shuttle astronauts are "weightless" because they are "beyond the pull of Earth's gravity." In fact, this is completely untrue. (*a*) What is the magnitude of the gravitational field in the vicinity of a shuttle orbit? A shuttle orbit is about 400 km above the ground. (*b*) Given the answer in Part (*a*), explain why shuttle astronauts suffer from adverse biological affects such as muscle atrophy even though they are not actually "weightless"?

33 • The mass of Saturn is 5.69×10^{26} kg. (*a*) Find the period of its moon Mimas, whose mean orbital radius is 1.86×10^8 m. (*b*) Find the mean orbital radius of its moon Titan, whose period is 1.38×10^6 s. SSM

34 • Calculate the mass of Earth from the period of the moon, $T = 27.3$ d; its mean orbital radius, $r_m = 3.84 \times 10^8$ m; and the known value of G.

35 • Suppose you leave the solar system and arrive at a planet that has the same mass-to-volume ratio as Earth but has 10 times Earth's radius. What would you weigh on this planet compared with what you weigh on Earth?

36 • Suppose that Earth retained its present mass but was somehow compressed to half its present radius. What would be the value of g at the surface of this new, compact planet?

37 • A planet orbits a massive star. When the planet is at perihelion, it has a speed of 5.0×10^4 m/s and is 1.0×10^{15} m from the star. The orbital radius increases to 2.2×10^{15} m at aphelion. What is the planet's speed at aphelion?

38 • What is the magnitude of the gravitational field at the surface of a neutron star whose mass is 1.60 times the mass of the Sun and whose radius is 10.5 km?

39 •• The speed of an asteroid is 20 km/s at perihelion and 14 km/s at aphelion. (*a*) Determine the ratio of the aphelion to perihelion distances. (*b*) Is this asteroid farther from the Sun or closer to the Sun than Earth, on average? Explain.

40 •• A satellite that has a mass of 300 kg moves in a circular orbit 5.00×10^7 m above Earth's surface. (*a*) What is the gravitational force on the satellite? (*b*) What is the speed of the satellite? (*c*) What is the period of the satellite?

41 •• A superconducting gravity meter can measure changes in gravity on the order $\Delta g/g = 1.00 \times 10^{-11}$. (*a*) You are hiding behind a tree holding the meter, and your 80-kg friend approaches the tree from the other side. How close to you can your friend come before the meter detects a change in g due to his presence? (*b*) You are in a hot air balloon and are using the gravity meter to determine the rate of ascent (assume the balloon has constant acceleration). What is the smallest change in altitude that results in a detectable change in the gravitational field of Earth? SSM

42 •• Suppose that the attractive interaction between a star of mass M and a planet of mass $m \ll M$ is of the form $F = KMm/r$, where K is the gravitational constant. What would be the relation between the radius of the planet's circular orbit and its period?

43 •• Earth's radius is 6370 km and the moon's radius is 1738 km. The acceleration of gravity at the surface of the moon is 1.62 m/s^2. What is the ratio of the average density of the moon to that of Earth? SSM

GRAVITATIONAL AND INERTIAL MASS

44 • The weight of a standard object defined as having a mass of exactly 1.00.... kg is measured to be 9.81 N. In the same laboratory, a second object weighs 56.6 N. (*a*) What is the mass of the second object? (*b*) Is the mass you determined in Part (*a*) gravitational or inertial mass?

45 • **Estimation** The *Principle of Equivalence* states that the free-fall acceleration of any object in a gravitational field is independent of the mass of the object. This can be deduced from the law of universal gravitation, but how well does it hold up experimentally? The Roll–Krotkov–Dicke experiment performed in the 1960s indicates that the free-fall acceleration is independent of mass to at least 1 part in 10^{12}. Suppose two objects are simultaneously released from rest in a uniform gravitational field. Also, suppose one of the objects falls with a constant acceleration of exactly 9.81 m/s^2, while the other falls with a constant acceleration that is greater than 9.81 m/s^2 by one part in 10^{12}. How far will the first object have fallen when the second object has fallen 1.00 mm farther than the first object has? Note that this estimate provides only an upper bound on the difference in the accelerations; most physicists believe that there is no difference in the accelerations.

GRAVITATIONAL POTENTIAL ENERGY

46 • (*a*) If we take the potential energy of a 100-kg object and Earth are zero when the two are separated by an infinite distance, what is the potential energy when the object is at the surface of Earth? (*b*) Find the potential energy of the same object at a height above Earth's surface equal to Earth's radius. (*c*) Find the escape speed for a body projected from this height. SSM

47 • Knowing that the acceleration of gravity on the moon is 0.166 times that on Earth and that the moon's radius is $0.273\,R_E$, find the escape speed for a projectile leaving the surface of the moon. SSM

48 •• What initial speed would a particle need to be given at the surface of Earth if it is to have a final speed that is equal to its escape speed when it is very far from Earth? Neglect any effects due to air resistance.

49 •• **Context-Rich, Engineering Application** While preparing its budget for the next fiscal year, NASA wants to report to the nation a rough estimate of the cost (per kilogram) of launching a modern satellite into near-Earth orbit. You are chosen for this task, because you know both physics and accounting. (*a*) Determine the energy, in kW·h, necessary to place a 1.0-kg object in low-Earth orbit. In low-Earth orbit, the height of the object above the surface of Earth is much smaller than Earth's radius. Take the orbital height to be 300 km. (*b*) If this energy can be obtained at a typical electrical energy rate of \$0.15/kW·h, what is the minimum cost of launching a 400-kg satellite into low-Earth orbit? Neglect any effects due to air resistance.

50 •• The science fiction writer Robert Heinlein once said, "If you can get into orbit, then you're halfway to anywhere." Justify this statement by comparing the minimum energy needed to place a satellite into low Earth orbit (h = 400 km) to that needed to set it completely free from the bonds of Earth's gravity. Neglect any effects due to air resistance.

51 •• An object is dropped from rest from a height of 4.0×10^6 m above the surface of Earth. If there is no air resistance, what is its speed when it strikes Earth? SSM

52 •• An object is projected straight upward from the surface of Earth with an initial speed of 4.0 km/s. What is the maximum height it reaches?

53 •• A particle is projected from the surface of Earth with a speed twice the escape speed. When it is very far from Earth, what is its speed?

54 ••• When we calculate escape speeds, we usually do so with the assumption that the object from which we are calculating escape speed is isolated. This is, of course, generally not true in the solar system. Show that the escape speed at a point near a system that consists of two stationary massive spherical objects is equal to the square root of the sum of the squares of the escape speeds from each of the two objects considered individually.

55 ••• Calculate the minimum necessary speed, relative to Earth, for a projectile launched from the surface of Earth to escape the solar system. The answer will depend on the direction of launch. Explain the choice of direction you would make for the direction of the launch in order to minimize the necessary launch speed relative to Earth. Neglect Earth's rotational motion and effects due to air resistance.

56 ••• An object is projected vertically from the surface of Earth at less than the escape speed. Show that the maximum height reached by the object is $H = R_E H'/(R_E - H')$, where H' is the height that it would reach if the gravitational field were constant. Neglect any effects due to air resistance.

GRAVITATIONAL ORBITS

57 •• A 100-kg spacecraft is in a circular orbit about Earth at a height $h = 2R_E$. (*a*) What is the orbital period of the spacecraft? (*b*) What is the spacecraft's kinetic energy? (*c*) Express the angular momentum L of the spacecraft about the center of Earth in terms of the kinetic energy K and find the numerical value of L.

58 •• **ESTIMATION** The orbital period of the moon is 27.3 d, the average center-to-center distance between the moon and Earth is 3.82×10^8 m, the length of an Earth year 365.25 d, and the average center-to-center distance between Earth and the Sun is 1.50×10^{11} m. Use this data to estimate the ratio of the mass of the Sun to the mass of Earth. Compare this estimation to the measured ratio of 3.33×10^5. List some neglected factors that might account for any discrepancy.

59 •• Many satellites orbit Earth at maximum altitudes above Earth's surface of 1000 km or less. *Geosynchronous* satellites, however, orbit at an altitude of 35 790 km above Earth's surface. How much more energy is required to launch a 500-kg satellite into a geosynchronous orbit than into an orbit 1000 km above the surface of Earth? SSM

60 ••• **CONTEXT-RICH, ENGINEERING APPLICATION** The idea of a spaceport orbiting Earth is an attractive proposition for launching probes and/or manned missions to the outer planets of the solar system. Suppose such a "platform" has been constructed, and orbits Earth at a distance of 450 km above Earth's surface. Your research team is launching a lunar probe into an orbit that has its perigee at the spaceport's orbital radius, and its apogee at the moon's orbital radius. (*a*) To launch the probe successfully, first determine the orbital speed for the platform. (*b*) Next, determine the necessary speed relative to the platform that is necessary to launch the probe so that it attains the desired orbit. Assume that any effects due to the gravitational pull of the moon on the probe are negligible. In addition, assume that the launch takes place in a negligible amount of time. (*c*) You have the probe designed to radio back when it has reached apogee. How long after launch should you expect to receive this signal from the probe (neglect the second or so delay for the transit time of the signal back to the platform)?

THE GRAVITATIONAL FIELD ($\vec{g}$)

61 • A 3.0-kg space probe experiences a gravitational force of 12 N$\hat{i}$ as it passes through point P. What is the gravitational field at point P?

62 • The gravitational field at some point is given by $\vec{g} = 2.5 \times 10^{-6}$ N/kg $\hat{j}$. What is the gravitational force on a 0.0040 kg object located at that point?

63 •• A point particle of mass m is on the x axis at $x = L$ and an identical point particle is on the y axis at $y = L$. (*a*) What is the direction of the gravitational field at the origin? (*b*) What is the magnitude of this field? SSM

64 •• Five objects, each of mass M, are equally spaced on the arc of a semicircle of radius R, as in Figure 11-25. An object of mass m is located at the center of curvature of the arc. (*a*) If M is 3.0 kg, m is 2.0 kg, and R is 10 cm, what is the gravitational force on the particle of mass m due to the five objects? (*b*) If the object whose mass is m is removed, what is the gravitational field at the center of curvature of the arc?

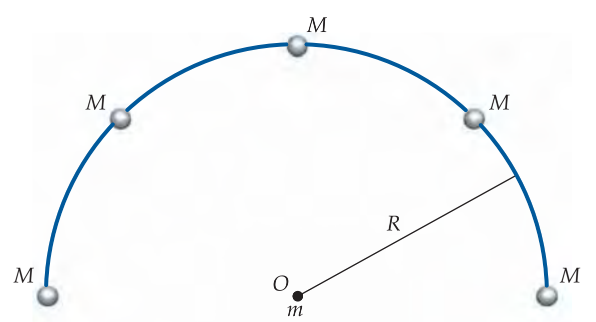

FIGURE 11-25 Problem 64

65 •• A point particle of mass $m_1 = 2.0$ kg is at the origin and a second point particle of mass $m_2 = 4.0$ kg is on the x axis at $x = 6.0$ m. Find the gravitational field $\vec{g}$ at (*a*) $x = 2.0$ m, and (*b*) $x = 12$ m. (*c*) Find the point on the x axis for which $g = 0$.

66 •• Show that on the x axis, the maximum value of g for the field of Example 11-7 occurs at points $x = \pm a/\sqrt{2}$.

67 ••• A nonuniform thin rod of length L lies on the x axis. One end of the rod is at the origin, and the other end is at $x = L$. The rod's mass per unit length λ varies as $\lambda = Cx$, where C is a constant. (Thus, an element of the rod has mass $dm = \lambda\,dx$.) (*a*) Determine the total mass of the rod. (*b*) Determine the gravitational field due to the rod on the x axis at $x = x_0$, where $x_0 > L$. SSM

68 •• A uniform thin rod of mass M and length L lies on the positive x axis with one end at the origin. Consider an element of the rod of length dx, and mass dm, at point x, where $0 < x < L$. (*a*) Show that this element produces a gravitational field at a point x_0 on the x axis in the region $x_0 > L$ is given by $dg_x = -\dfrac{GM}{L(x_0 - x)^2}\,dx$. (*b*) Integrate this result over the length of the rod to find the total gravitational field at the point x_0 due to the rod. (*c*) Find the gravitational force on a point particle of mass m_0 at x_0. (*d*) Show that for $x_0 \gg L$, the field of the rod approximates the field of a point particle of mass M at $x = 0$.

THE GRAVITATIONAL FIELD ($\vec{g}$) DUE TO SPHERICAL OBJECTS

69 • A uniform thin spherical shell has a radius of 2.0 m and a mass of 300 kg. What is the gravitational field at the following distances from the center of the shell: (*a*) 0.50 m, (*b*) 1.9 m, (*c*) 2.5 m?

70 • A uniform thin spherical shell has a radius of 2.00 m and a mass of 300 kg and its center is located at the origin of a coordinate system. Another uniform thin spherical shell with a radius of 1.00 m and a mass of 150 kg is inside the larger shell, with its center at 0.600 m on the x axis. What is the gravitational force of attraction between the two shells?

71 •• Two widely separated solid spheres, S_1 and S_2, each have radius R and mass M. Sphere S_1 is uniform, whereas the density of S_2 is given by $\rho(r) = C/r$, where r is the distance from its center. If the gravitational field strength at the surface of S_1 is g_1, what is the gravitational field strength at the surface of S_2? SSM

72 •• Two widely separated uniform solid spheres, S_1 and S_2, have equal masses, but different radii, R_1 and R_2. If the gravitational field strength on the surface of S_1 is g_1, what is the gravitational field strength on the surface of S_2?

73 •• Two concentric uniform thin spherical shells have masses M_1 and M_2 and radii a and $2a$, as in Figure 11-26. What is the magnitude of the gravitational force on a point particle of mass m (not shown) located (*a*) a distance $3a$ from the center of the shells? (*b*) a distance $1.9a$ from the center of the shells? (*c*) a distance $0.9a$ from the center of the shells?

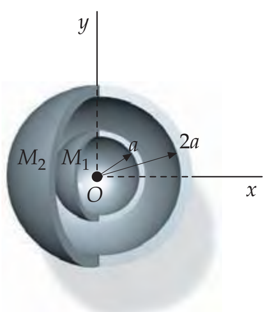

FIGURE 11-26 Problem 73

74 •• The inner spherical shell in Problem 73 is shifted so that its center is now on the x axis at $x = 0.8a$. What is the magnitude of the gravitational force on a particle of point mass m located on the x axis at (*a*) $x = 3a$? (*b*) $x = 1.9a$? (*c*) $x = 0.9a$?

75 •• Suppose you are standing on a spring scale in an elevator that is descending at costant speed in a mine shaft located on the equator. Model Earth as a homogeneous sphere.

(*a*) Show that the force on you due to Earth's gravity alone is proportional to your distance from the center of the planet.

(*b*) Assume that the mine shaft is located on the equator and is vertical. Do not neglect Earth's rotational motion. Show that the reading on the spring scale is proportional to your distance from the center of the planet. SSM

76 •• **CONTEXT-RICH** Suppose Earth were a nonrotating uniform sphere. As a reward for earning the highest lab grade, your physics professor chooses your laboratory team to participate in a gravitational experiment at a deep mine on the equator. This mine has an elevator shaft going 15.0 km into Earth. Before making the measurement, you are asked to predict the decrease in the weight of a team member, who weighs 800 N at the surface of Earth, when she is at the bottom of the shaft. The density of Earth's crust actually increases with depth. Is your answer higher or lower than the actual experimental result?

77 •• A solid sphere of radius R has its center at the origin. It has a uniform mass density ρ_0, except that the sphere has a spherical cavity in it of radius $r = \frac{1}{2}R$ centered at $x = \frac{1}{2}R$, as in Figure 11-27. Find the gravitational field at points on the x axis for $|x| > R$. *Hint: The cavity may be thought of as a sphere of mass $m = (4/3)\pi r^3 \rho_0$ plus a sphere of "negative" mass $-m$.* SSM

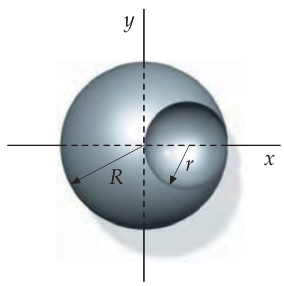

FIGURE 11-27 Problem 77

78 ••• For the sphere with the cavity in Problem 77, show that the gravitational field is uniform throughout the cavity, and find its magnitude and direction there.

79 ••• A straight, smooth tunnel is dug through a uniform spherical planet of mass density ρ_0. The tunnel passes through the center of the planet and is perpendicular to the planet's axis of rotation, which is fixed in space. The planet rotates with a constant angular speed ω, so objects in the tunnel have no apparent weight. Find the required angular speed of the planet ω.

80 ••• The density of a sphere is given by $\rho(r) = C/r$. The sphere has a radius of 5.0 m and a mass of 1.0×10^{11} kg. (*a*) Determine the constant C. (*b*) Obtain expressions for the gravitational field for the regions (1) $r > 5.0$ m, and (2) $r < 5.0$ m.

81 ••• A small-diameter hole is drilled into the sphere of Problem 80 toward the center of the sphere to a depth of 2.0 m below the sphere's surface. A small mass is dropped from the surface into the hole. Determine the speed of the small mass when it strikes the bottom of the hole. SSM

82 ••• **Context-Rich, Engineering Application** As a geologist for a mining company, you are working on a method for determining possible locations of underground ore deposits. Assume that where the company owns land the crust of Earth is 40.0 km thick and has a density of about 3000 kg/m^3. Suppose a spherical deposit of heavy metals with a density of 8000 kg/m^3 and radius of 1000 m is centered 2000 m below the surface. You propose to detect it by determining its effect on the local surface value of g. Find $\Delta g/g$ at the surface directly above this deposit, where Δg is the increase in the gravitational field due to the deposit.

83 ••• Two identical spherical cavities are made in a lead sphere of radius R. The cavities each have a radius $R/2$. They touch the outside surface of the sphere and its center as in Figure 11-28. The mass of a solid uniform lead sphere of radius R is M. Find the force of attraction on a point particle of mass m located a distance d from the center of the lead sphere as shown. SSM

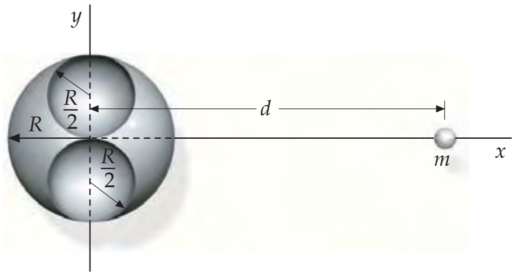

FIGURE 11-28 Problem 83

84 ••• A globular cluster is a roughly spherical collection of up to millions of stars bound together by the force of gravity. Astronomers can measure the velocities of stars in the cluster to study its composition and to get an idea of the mass distribution within the cluster. Assuming that all of the stars have approximately the same mass and are distributed uniformly within the cluster, show that the mean speed of a star in a circular orbit around the center of the cluster should increase linearly with its distance from the center.

GENERAL PROBLEMS

85 • The mean distance of Pluto from the Sun is 39.5 AU. Calculate the period of Pluto's orbital motion.

86 • Calculate the mass of Earth using the known values of G, g, and R_E.

87 •• The force exerted by Earth on a particle of mass m a distance r ($r > R_E$) from the center of Earth has the magnitude mgR_E^2/r^2, where $g = GM_E/R_E^2$. (*a*) Calculate the work you must do to move the particle from distance r_1 to distance r_2. (*b*) Show that when $r_1 = R_E$ and $r_2 = R_E + h$, the result can be written as $W = mgR_E^2[(1/R_E) - 1/(R_E + h)]$. (*c*) Show that when $h \ll R_E$, the work is given approximately by $W = mgh$.

88 •• The average density of the moon is $\rho = 3340$ kg/m^3. Find the minimum possible period T of a spacecraft orbiting the moon.

89 •• A *neutron star* is a highly condensed remnant of a massive star in the last phase of its evolution. It is composed of neutrons (hence the name), because the star's gravitational force causes electrons and protons to "coalesce" into the neutrons. Suppose at the end of its current phase, the Sun collapsed into a neutron star (it cannot actually do this because it does not have enough mass) of radius 12.0 km, without losing any mass in the process. (*a*) Calculate the ratio of the gravitational acceleration at the surface of the Sun following the collapse compared to the value at the surface of the Sun today. (*b*) Calculate the ratio of the escape speed from the surface of the neutron-Sun to the Sun's value today. SSM

90 •• **Context-Rich, Engineering Application** Suppose the Sun could collapse into a neutron star of radius 12.0 km, as in Problem 89. Your research team is in charge of sending a probe from Earth to study the transformed Sun, and the probe needs to end up in a circular orbit 4500 km from the neutron-Sun's center. (*a*) Calculate the orbital speed of the probe. (*b*) Later on, plans call for construction of a permanent spaceport in that same orbit. To transport equipment and supplies, scientists on Earth need you to determine the escape speed for rockets launched from the spaceport (relative to the spaceport) in the direction of the spaceport's orbital velocity at takeoff time. What is that speed, and how does it compare to the escape speed at the surface of Earth?

91 •• A satellite is circling the moon (radius 1700 km) close to the surface at a speed v. A projectile is launched vertically up from the moon's surface at the same initial speed v How high will the projectile rise?

92 •• *Black holes* are objects whose gravitational field is so strong that not even light can escape. One way of thinking about this is to consider a spherical object whose density is so large that the escape speed at its surface is greater than the speed of light, c. If a star's radius is smaller than a value called the *Schwarzschild radius* R_S, then the star will be a black hole, that is, light originating from its surface cannot escape. (*a*) For a nonrotating black hole, the Schwarzschild radius depends only upon the mass of the black hole. Show that it is related to that mass M by $R_S = (2GM)/c^2$. (*b*) Calculate the value of the Schwarzschild radius for a black hole whose mass is ten solar masses.

93 •• In a binary star system, two stars follow circular orbits about their common center of mass. If the stars have masses m_1 and m_2 and are separated by a distance r, show that the period of rotation is related to r by $T^2 = 4\pi^2 r^3/[G(m_1 + m_2)]$.

94 •• Two particles of masses m_1 and m_2 are released from rest at a large separation distance. Find their speeds v_1 and v_2 when their separation distance is r. The initial separation distance is given as large, but large is a relative term. Relative to what distance is it large?

95 •• Uranus, the seventh planet in the solar system, was first observed in 1781 by William Herschel. Its orbit was then analyzed in terms of Kepler's laws. By the 1840s, observations of Uranus clearly indicated that its true orbit was different from the Keplerian calculation by an amount that could not be accounted for by observational uncertainty. The conclusion was that there must be another influence other than the Sun and the known planets lying inside Uranus's orbit. This influence was hypothesized to be due to an eighth planet, whose predicted orbit was described independently in 1845 by two astronomers: John Adams (no relation to the former president of the United States) and Urbain LeVerrier. In September of 1846, John Galle, searching in the sky at the place predicted by Adams and LeVerrier, made the first observation of Neptune. Uranus and Neptune are in orbit about the Sun with periods of 84.0 and 164.8 years, respectively. To see the effect that Neptune had on Uranus, determine the ratio of the gravitational force between Neptune and Uranus to that between Uranus and the Sun, when Neptune and Uranus are at their closest approach to one another (i.e., when aligned with the

Sun). The masses of the Sun, Uranus, and Neptune are 333,000, 14.5, and 17.1 times that of Earth, respectively. SSM

96 •• It is believed that there is a "supermassive" black hole at the center of our galaxy. One datum that leads to this conclusion is the important recent observation of stellar motion in the vicinity of the galactic center. If one such star moves in an elliptical orbit with a period of 15.2 years and has a semimajor axis of 5.5 light-days (the distance light travels in 5.5 days), what is the mass around which the star moves in its Keplerian orbit?

97 •• Four identical planets are arranged in a square, as shown in Figure 11-29. If the mass of each planet is M and the edge length of the square is a, what must their speed be if they are to orbit their common center under the influence of their mutual attraction? SSM

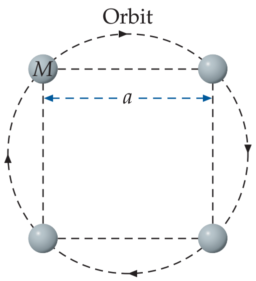

FIGURE 11-29 Problem 97

98 •• A hole is drilled from the surface of Earth to its center, as in Figure 11-30. Ignore Earth's rotation and any effects due to air resistance, and model Earth as a uniform sphere. (*a*) How much work is required to lift a particle of mass m from the center of Earth to Earth's surface? (*b*) If the particle is dropped from rest at the surface of Earth, what is its speed when it reaches the center of Earth? (*c*) What is the escape speed for a particle projected from the center of Earth? Express your answers in terms of m, g, and R_E.

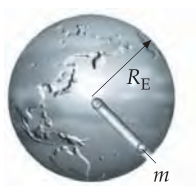

FIGURE 11-30 Problem 98

99 •• A thick spherical shell of mass M and uniform density has an inner radius R_1 and an outer radius R_2. Find the gravitational field g_r as a function of r for $0 < r < \infty$. Sketch a graph of g_r versus r.

100 •• (*a*) A thin uniform ring of mass M and radius R lies in the $x = 0$ plane and is cenered at the origin. Sketch a plot of the gravitational field g_x versus x for all points on the x axis. (*b*) At what point, or points, on the axis is the magnitude of g_x a maximum?

101 ••• Find the magnitude of the gravitational field that is at a distance r from an infinitely long uniform thin rod whose mass per unit length is λ.

102 ••• One question in early planetary science was whether each of the rings of Saturn were solid or were, instead, composed of individual chunks, each in its own orbit. The issue could be resolved by an observation in which astronomers would measure the speed of the inner and outer portions of the ring. If the inner portion of the ring moved more slowly than the outer portion, then the ring was solid; if the opposite was true, then it was actually composed of separate chunks. Let us see how this results from a theoretical viewpoint. Let the radial width of a given ring (there are many) be Δr, the average distance of that ring from the center of Saturn be represented by R, and the average speed of that ring be v_{avg}. (*a*) If the ring is solid, show that the *difference* in speed between its outermost and innermost portions, Δv, is given by the expression $\Delta v = v_{\text{out}} - v_{\text{in}} \approx v_{\text{avg}}(\Delta r/R)$. Here, v_{out} is the speed of the outermost portion of the ring, and v_{in} is the speed of the innermost portion. (*b*) If, however, the ring is composed of many small chunks, show that $\Delta v \approx -\frac{1}{2}(v_{\text{avg}}(\Delta r/R))$. (Assume that $\Delta r \ll R$.)

103 ••• Find the gravitational potential energy of the thin rod in Example 11-8 and a point particle of mass m_0 that is on the x axis at $x = x_0$ where $x_0 \geq \frac{1}{2}L$. (*a*) Show that the potential energy shared by an element of the rod of mass dm (shown in Figure 11-14) and the point particle of mass m_0, is given by

$$dU = -\frac{Gm_0\,dm}{x_0 - x_s} = \frac{GMm_0}{L(x_0 - x_s)}\,dx_s$$

where $U = 0$ at $x_0 = \infty$. (*b*) Integrate your result for Part (*a*) over the length of the rod to find the total potential energy for the system. Generalize your function $U(x_0)$ to any place on the x axis in the region $x > L/2$ by replacing x_0 with a general coordinate x and write it as $U(x)$. (*c*) Compute the force on m_0 at a general point x using $F_x = -dU/dx$ and compare your result with $m_0 g$, where g is the field at x_0 calculated in Example 11-8. SSM

104 ••• A uniform sphere of mass M is located near a thin, uniform rod of mass m and length L, as in Figure 11-31. Find the gravitational force of attraction exerted by the sphere on the rod.

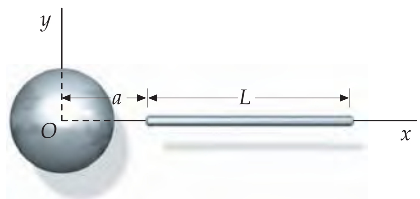

FIGURE 11-31 Problem 104

105 ••• A thin uniform 20-kg rod with a length equal to 5.0 m is bent into a semicircle. What is the gravitational force exerted by the rod on a 0.10-kg point mass located at the center of curvature of the circular arc?

106 ••• Both the Sun and the moon exert gravitational forces on the oceans of Earth, causing tides. (*a*) Show that the ratio of the force exerted on a point particle on the surface of Earth by the Sun to that exerted by the moon is $M_S r_m^2 / M_m r_S^2$. Here M_S and M_m represent the masses of the Sun and moon, and r_S and r_m are the distances of the particle from Earth to the Sun and Earth to the moon, respectively. Evaluate this ratio numerically. (*b*) Even though the Sun exerts a much greater force on the oceans than does the moon, the moon has a greater effect on the tides because it is the *difference* in the force from one side of Earth to the other that is important. Differentiate the expression $F = Gm_1m_2/r^2$ to calculate the change in F due to a small change in r. Show that $dF/F = -2\,dr/r$. (*c*) The oceanic *tidal bulge* (that is, the elongation of the liquid water of the oceans causing two opposite high and two opposite low spots) is caused by the difference in gravitational force on the oceans from one side of Earth to the other. Show that for a small difference in distance compared to the average distance, the ratio of the differential gravitational force exerted by the Sun to the differential gravitational force exerted by the moon on Earth's oceans is given by $\Delta F_S/\Delta F_m \approx (M_S r_m^3)/(M_m r_S^3)$. Calculate this ratio. What is your conclusion? Which object, the moon or the Sun, is the main cause of the tidal stretching of the oceans on Earth?

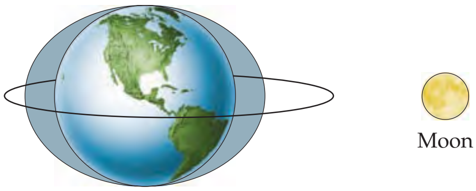

FIGURE 11-32 **Problem 106** The lunar tidal bulges (exaggerated here) are due to the difference in the gravitational pull of the moon on opposite sides of Earth.

107 ••• **CONTEXT-RICH, ENGINEERING APPLICATION** United Federation Starship *Excelsior* drops two small robotic probes toward the surface of a neutron star for exploration. The mass of the star is the same as that of the Sun, but the star's diameter is only 10 km. The robotic probes are linked together by a 1.0-m-long steel cord (which includes communication lines between the two probes), and are dropped vertically (that is, one always above the other). The ship hovers at rest above the star's surface. As the Chief of Materials Engineering on the ship, you are concerned that the communication between the two probes, a crucial aspect of the mission, will not survive. (*a*) Outline your briefing session to the mission commander and explain the existence of a "stretching force" that will try to pull the robots apart as they fall toward the planet. (See Problem 106 for hints.) (*b*) Assume that the cord in use has a breaking tension of 25 kN and that the robots each have a mass of 1.0 kg. How close will the robots be to the surface of the star before the cord breaks?

CHAPTER 12

LARGE FORCES AND TORQUES ARE OFTEN EXERTED ON CONSTRUCTION CRANES SUCH AS THIS ONE. CRANES HAVE TO BE BOTH RIGID AND WELL ANCHORED IF THEY ARE TO WITHSTAND SUCH FORCES AND TORQUES AND NOT COLLAPSE. *(Eric M. Anderson/Tower Cranes of America, Inc.)*

Static Equilibrium and Elasticity

? Tower cranes are a part of the landscape of cities around the world. The model shown has a maximum reach of 81 m. Counterweights are used to counterbalance the load and prevent the crane from tipping over. (See Example 12-5.)

In this chapter, we study the forces and torques needed to keep extended objects static (stationary). For example, the forces exerted by the cables of a suspension bridge must be known so the cables can be designed to be strong enough to support the bridge. Similarly, cranes must be designed so that they do not topple over when lifting a weight.

In this chapter, we study the equilibrium of rigid bodies and then briefly consider the deformations and elastic forces that arise when real solids are under stress.

12-1 CONDITIONS FOR EQUILIBRIUM

A necessary condition for a particle at rest to remain at rest is that the net force acting on it remains zero. Similarly, a necessary condition for the center of mass of a rigid object to remain at rest is that the net force acting on the object remains zero. A rigid object can rotate, even when its center of mass is at rest, but then the object is not in *static equilibrium.* Therefore, a second necessary condition for a rigid object to remain in static equilibrium is that the net torque acting on it about *any* axis must remain zero. This condition gives us the option to choose any point or any axis for calculating torques, an option that greatly simplifies the solution of most static problems.

The two necessary conditions for a rigid body to be in static equilibrium are as follows:

1. The net external force acting on the body must remain zero:

$$\Sigma \vec{F} = 0 \qquad \text{12-1}$$

2. The net external torque about any point must remain zero:

$$\Sigma \vec{\tau} = 0 \qquad \text{12-2}$$

CONDITIONS FOR EQUILIBRIUM

12-2 THE CENTER OF GRAVITY

In Section 4 of Chapter 9, the center of gravity is introduced in terms of torques about an axis. Here we introduce the center of gravity in terms of torques about a point. Figure 12-1*a* shows a rigid object in static equilibrium and a point O. We consider the object to be composed of many small mass elements. The force of gravity on the ith small mass element is $\vec{F}_{gi}$, and the total force of gravity on the object is $\vec{F}_g = \Sigma \vec{F}_{gi}$. If $\vec{r}_i$ is the position vector of the ith particle relative to O, then $\vec{\tau}_i = \vec{r}_i \times \vec{F}_{gi}$, where $\vec{\tau}_i$ is the torque due to $\vec{F}_{gi}$ about O. The net gravitational torque about O is then $\vec{\tau}_{\text{net}} = \Sigma(\vec{r}_i \times \vec{F}_{gi})$. Conveniently, the net torque due to gravity about a point can be calculated as if the entire force of gravity $\vec{F}_g$ were applied at a single point, the **center of gravity** (see Figure 12-1*b*). That is,

$$\vec{\tau}_{\text{net}} = \vec{r}_{\text{cg}} \times \vec{F}_g \qquad \text{12-3}$$

CENTER OF GRAVITY

where $\vec{r}_{\text{cg}}$ is the position vector of the center of gravity relative to O.

If the gravitational field $\vec{g}$ is uniform over the object (as is nearly always the case for objects of less than astronomical size), we can write $\vec{F}_{gi} = m_i\vec{g}$. Summing both sides of this gives $\vec{F}_g = M\vec{g}$, where $M = \Sigma m_i$ is the mass of the object. The net torque is the sum of the individual torques. That is,

$$\vec{\tau}_{\text{net}} = \sum_i (\vec{r}_i \times \vec{F}_{gi}) = \sum_i (\vec{r}_i \times m_i\vec{g}) = \sum_i (m_i\vec{r}_i \times \vec{g})$$

Factoring $\vec{g}$ from the term on the right gives

$$\vec{\tau}_{\text{net}} = \left(\sum_i m_i\vec{r}_i\right) \times \vec{g}$$

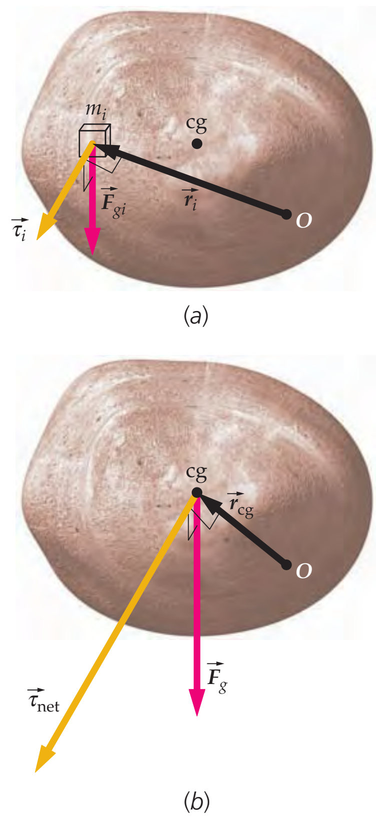

FIGURE 12-1 The direction of the torque is gotten by applying the right-hand rule for cross products. (*a*) $\vec{\tau}_i$ is the torque about O due to the gravitational force $\vec{F}_{gi}$ on the i th element of mass. (*b*) The net gravitational torque $\vec{\tau}$ about O can be calculated by considering the total gravitational force $\vec{F}_g$ to be applied at a point called the center of gravity.

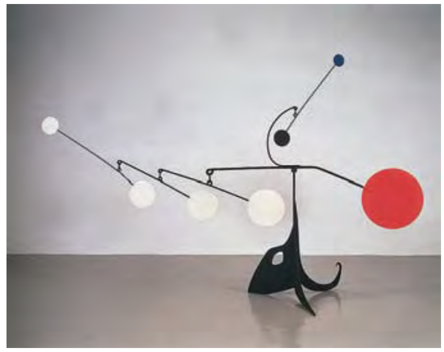
and substituting for $\Sigma m_i \vec{r}_i$ using the definition of center of mass ($M\vec{r}_{\mathrm{cm}} = \Sigma m_i \vec{r}_i$), we obtain

$$\vec{\tau}_{\mathrm{net}} = M\vec{r}_{\mathrm{cm}} \times \vec{g} = \vec{r}_{\mathrm{cm}} \times M\vec{g} = \vec{r}_{\mathrm{cm}} \times \vec{F}_g \qquad \text{12-4}$$

Equations 12-3 and 12-4 are valid for any choice of the point O only if $\vec{r}_{\mathrm{cg}} = \vec{r}_{\mathrm{cm}}$. That is, the center of gravity and the center of mass coincide if the object is in a uniform gravitational field.

If O is directly above the center of gravity, then $\vec{r}_{\mathrm{cg}}$ and $\vec{F}_g$ are both in the same direction (downward), so $\vec{\tau}_{\mathrm{net}} = \vec{r}_{\mathrm{cg}} \times \vec{F}_g = 0$. For example, when a mobile is suspended with its center of gravity directly below its suspension point, the net torque on the mobile about the suspension point is zero, so it is in static equilibrium.



The center of gravity of the Calder mobile is directly below the suspension point. *(Copyright © 2002 Estate of Alexander Calder/ Artists Rights Society (ARS), New York.)*

12-3 SOME EXAMPLES OF STATIC EQUILIBRIUM

For most examples and problems in this chapter, all the forces are perpendicular to the z axis. It is therefore best in such problems to calculate torques about an axis parallel to the z axis (rather than about a point). For figures in this chapter, the z axis is typically perpendicular to the page, and out of the page is frequently chosen as $+z$ direction. Calculating torques about the z axis and choosing out of the page as the $+z$ direction is equivalent to choosing counterclockwise as positive and clockwise as negative. (If into the page is chosen as the $+z$ direction, then clockwise is positive and counterclockwise is negative.)

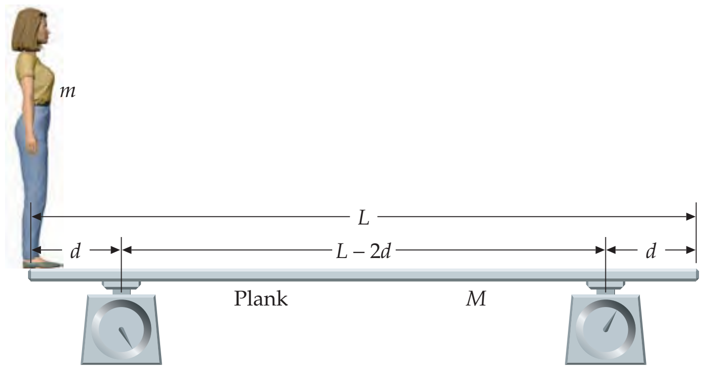


FIGURE 12-2

Example 12-1 Walking the Plank

A uniform plank of length $L = 3.00$ m and mass $M = 35$ kg is supported by scales a distance $d = 0.50$ m from the ends of the board, as shown in Figure 12-2. (*a*) Find the reading on the scales when Mary, whose mass $m = 45$ kg, stands on the left end of the plank. (*b*) Sergio climbs onto the plank and walks toward Mary, who jumps to the floor when the plank starts to tip. Sergio keeps walking all the way to the left end of the plank, and when he gets there the scale supporting the right end of the plank reads zero. Find Sergio's mass.

PICTURE The readings on the scales are the magnitudes of the forces Mary and Sergio exert on the boards. To find these magnitudes, we apply the two conditions for equilibrium to the system consisting of Mary plus the plank.

SOLVE

(*a*) 1. Draw a free-body diagram of the system consisting of Mary and the plank (Figure 12-3). Forces $\vec{F}_{\mathrm{L}}$ and $\vec{F}_{\mathrm{R}}$ are the forces exerted by the left and right scales.

2. Set the net force equal to zero, taking upward as positive: $\Sigma F_y = 0$

$F_{\mathrm{L}} + F_{\mathrm{R}} - Mg - mg = 0$

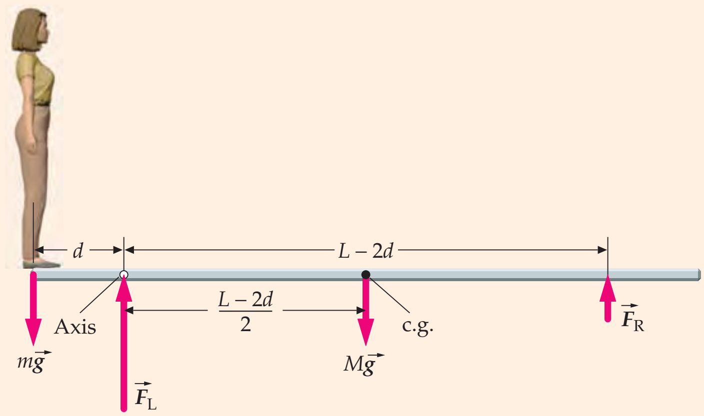

FIGURE 12-3

3. Calculate the net torque about the axis directed out of the page (making counterclockwise positive) and through the point of application of $\vec{F}_L$:

$$\Sigma\tau = F_L(0) + F_R(L - 2d) - Mg\frac{L - 2d}{2} + mgd$$

4. Set the net torque equal to zero and solve for F_R:

$$0 = F_R(L - 2d) - Mg\frac{L - 2d}{2} + mgd$$

$$\text{so} \quad F_R = \left(\frac{1}{2}M - \frac{d}{L - 2d}m\right)g$$

5. Substitute this result for F_R into the step-2 result and solve for F_L:

$$F_L = Mg + mg - \left(\frac{1}{2}M - \frac{d}{L - 2d}m\right)g = \left(\frac{1}{2}M + \frac{L - d}{L - 2d}m\right)g$$

6. Substitute numerical values to obtain numerical values for the forces:

$$F_R = \left(\frac{1}{2}35\text{ kg} - \frac{0.50\text{ m}}{1.5\text{ m}}45\text{ kg}\right)(9.81\text{N/kg})$$

$$= 61.3\text{ N} = \boxed{61\text{ N}}$$

$$F_L = \left(\frac{1}{2}35\text{ kg} + \frac{2.5\text{ m}}{2.0\text{ m}}45\text{kg}\right)(9.81\text{ N/kg})$$

$$= 723\text{ N} = \boxed{7.2 \times 10^2\text{ N}}$$

(*b*) Using the Part-(*a*) step-4 result, set $F_R = 0$ and solve for m:

$$0 = \left(\frac{1}{2}M - \frac{d}{L - 2d}m\right)g$$

$$\text{so} \quad m = \frac{L - 2d}{2d}M = \frac{2.0\text{ m}}{1.0\text{ m}}35\text{ kg} = \boxed{70\text{ kg}}$$

CHECK In part (*a*), the sum $F_L + F_R$ should equal Mary's weight plus the weight of the plank. This total weight is $(M + m)g = (35\text{ kg} + 45\text{ kg})(9.81\text{ N/kg}) = 7.8 \times 10^2\text{ N}$. Also, $F_L + F_R = 723\text{ N} + 61\text{ N} = 7.8 \times 10^2\text{ N}$, as expected. In part (*b*), Sergio is 0.50 m from the axis, and the center of gravity of the plank is 1.00 m from the axis, when the system is balanced with $F_R = 0$ and with Mary no longer on the plank. Thus, we expect Sergio's mass to be twice the mass of the plank.

Example 12-1 can be solved using an axis through the center of the plank, but in this case both F_L and F_R appear in the torque equation, hence the algebra is a bit more complex. In general, a statics problem can be simplified by computing the torques about an axis through the line of action of one of the unknown forces, as when we chose the axis through the point of application of force F_L in Example 12-1.

PROBLEM-SOLVING STRATEGY

Choosing the Axis

PICTURE Keep in mind the conditions for equilibrium ($\Sigma\vec{F} = 0$ and $\Sigma\tau = 0$).

SOLVE

1. To obtain an algebraically simple solution, choose an axis through the line of action of the force you have the least information about.
2. Then, equate the sum of the torques about this axis equal to zero.

CHECK Try finding alternative ways to solve a problem to check the plausibility of your solution.

Example 12-2 Force on an Elbow

You hold a 6.0-kg weight in your hand with your forearm making a 90° angle with your upper arm, as shown in Figure 12-4. Your biceps muscle exerts an upward force $\vec{F}_m$ that acts 3.4 cm from the pivot point O at the elbow joint. Model the forearm and hand as a 30.0-cm-long uniform rod with a mass of 1.0 kg. (*a*) Find the magnitude of $\vec{F}_m$ if the distance from the weight to the pivot point (elbow joint) is 30 cm, and (*b*) find the magnitude and direction of the force exerted on the elbow joint by the upper arm.

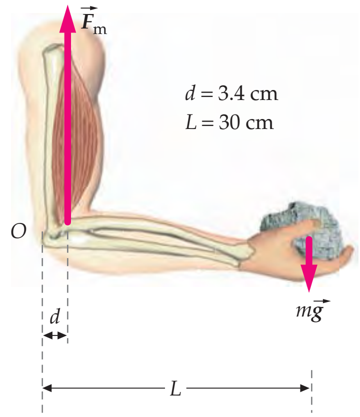

FIGURE 12-4

PICTURE To find the two forces, apply the two conditions for static equilibrium ($\Sigma\vec{F} = 0$ and $\Sigma\tau = 0$) to the forearm.

SOLVE

(*a*) 1. Draw a free-body diagram of the forearm (Figure 12-5). Model the forearm as a horizontal rod.

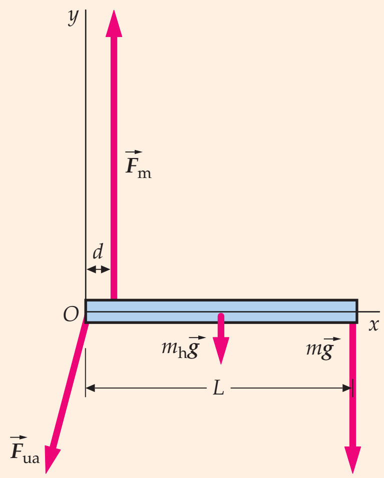

FIGURE 12-5

2. The force we know least about is the force of the upper arm on the elbow joint $\vec{F}_{ua}$ (we know neither its magnitude nor its direction). Apply $\Sigma\tau = 0$ about an axis directed out of the page and through the point of application of $\vec{F}_{ua}$:

$$F_{ua}(0) - m_h g\frac{L}{2} + F_m d - mgL = 0$$

so

$$F_m = \left(\frac{1}{2}m_h + m\right)g\frac{L}{d}$$

$$= \left(\frac{1}{2}(1.0\text{ kg}) + 6.0\text{ kg}\right)(9.81\text{ N/kg})\frac{30\text{ cm}}{3.4\text{ cm}}$$

$$= 563\text{ N} = \boxed{5.6 \times 10^2\text{ N}}$$

(*b*) Apply $\Sigma F_x = 0$ and $\Sigma F_y = 0$ to obtain $\vec{F}_{ua}$:

$$F_{ua\,x} + 0 + 0 + 0 = 0$$

and $F_{ua\,y} + F_m - m_h g - mg = 0$

so $F_{ua\,x} = 0$

and

$$F_{ua\,y} = (m + m_h)g - F_m$$
$$= (7.0\text{ kg})(9.81\text{ N/kg}) - 563\text{ N}$$
$$= -494\text{ N}$$

Therefore,

$$\vec{F}_{ua} = \boxed{4.9 \times 10^2\text{ N, down}}$$

CHECK F_{ua} can be found in one step by choosing the axis to be through the point where the biceps attaches to the forearm. Setting net torque equal to zero gives $F_{ua}(3.4\text{ cm}) + F_m(0) - (6.0\text{ kg})(9.81\text{ N/kg})(30.0\text{ cm} - 3.4\text{ cm}) - (1.0\text{ kg})(9.81\text{ N/kg})(15.0\text{ cm} - 3.4\text{ cm}) = 0$. This equation yields $F_{ua} = 4.9 \times 10^2$ N, the same as our Part-(*b*) result.

TAKING IT FURTHER (1) The force that must be exerted by the muscle is 9.6 times the weight of the object! In addition, as the muscle pulls upward, the upper arm must push downward to keep the forearm in equilibrium. The force exerted by the upper arm is 8.4 times greater than the object's weight. (2) This example and plausibility check show that we can choose the axis to be wherever it is convenient for our calculation.

Example 12-3 Hanging a Sign *Try It Yourself*

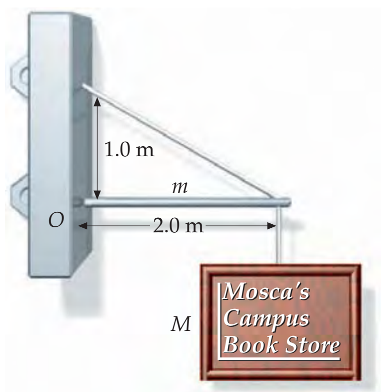

FIGURE 12-6

The manager of the campus bookstore has ordered a new 20-kg sign to hang in front of the store, from the end of a rod that will be attached to the wall by a wire (Figure 12-6). The manager needs to know how strong a wire is needed. She knows you are taking a physics course, so she asks you to calculate the tension in the wire. She is also concerned about how much force the rod puts on the wall, so she asks you to calculate that as well. The rod has a length of 2.0 m and a mass of 4.0 kg, and the wire is attached to a point on the wall 1.0 m above the rod.

PICTURE The conditions for the rod to be in equilibrium are $\Sigma F_x = 0$, $\Sigma F_y = 0$, and $\Sigma\tau = 0$, where the torques are to be calculated about an axis through the line of action of the force we have the least information about. The force exerted by the rod on the wall is equal but opposite to the force exerted by the wall on the rod.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. Draw a free-body diagram for the rod (Figure 12-7).	
2. Set $\Sigma\tau = 0$ about an axis perpendicular to the page and through point O, which is on the line of action of the force of the wall on the rod:	$TL\sin\theta - MgL - mg\frac{L}{2} = 0$ so $T = \frac{(M + \frac{1}{2}m)g}{\sin\theta}$
3. Use trigonometry to solve for θ:	$\theta = \tan^{-1}\frac{1}{2} = 26.6°$
4. Solve the step-2 result for T:	$T = 483\text{ N} = \boxed{4.8 \times 10^2\text{ N}}$
5. Set $\Sigma F_x = 0$ and $\Sigma F_y = 0$ and, using your values for T and θ, solve for F_x and F_y:	$F_x + T_x = 0$ $F_y + T_y - Mg - mg = 0$ so $F_x = 432\text{ N}$, $F_y = 19.2\text{ N}$
6. Solve for the force $\vec{F}'$ exerted by the rod on the wall. The force exerted by the rod on the wall and that by the wall on the rod constitute a N3L pair:	$\vec{F}' = -\vec{F} = \boxed{-4.3 \times 10^2\text{ N}\hat{i} - 19\text{ N}\hat{j}}$

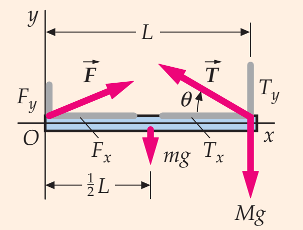

FIGURE 12-7

CHECK The x and y components of the force on the wall by the rod are both negative, as expected.

Example 12-4 Raising a Wheel *Try It Yourself*

A wheel of mass M and radius R (Figure 12-8) rests on a horizontal surface against a step of height $h(h < R)$. The wheel is to be raised over the step by a horizontal force $\vec{F}$ applied to the axle of the wheel, as shown. Find the minimum force F_{min} necessary to raise the wheel over the step.

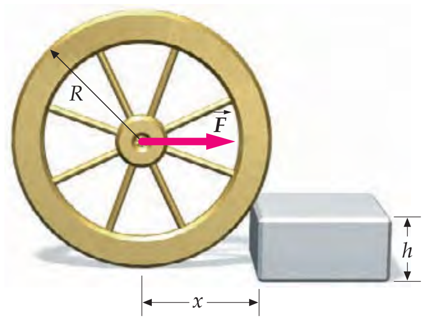

FIGURE 12-8

PICTURE If the magnitude of F is less than F_{min}, the surface at the bottom of the wheel exerts an upward normal force on the wheel. If F is increased, this normal force decreases. Apply the conditions for static equilibrium to find the value of F that will hold the wheel in place when the normal force is zero.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. Draw a free-body diagram of the wheel (Figure 12-9).	
2. Apply $\Sigma\tau = 0$ to the wheel. Both the direction and the magnitude of $\vec{F}'$ are unknown, so follow the guidelines and calculate torques about an axis through its point of application. Obtain expressions for the moment arms from the free-body diagram and solve for F_{min}:	$\Sigma\tau = F_{\text{min}}(R - h) - Mgx = 0$ so $F_{\text{min}} = \frac{Mgx}{R - h}$
3. Use the Pythagorean theorem to express x in terms of h and R:	$x = \sqrt{h(2R - h)}$
4. Substitute $\sqrt{h(2R - h)}$ for x to obtain an expression for F_{min}:	$F_{\text{min}} = \boxed{\frac{\sqrt{h(2R - h)}}{R - h}Mg}$

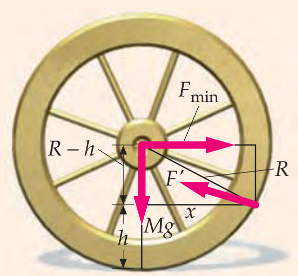

FIGURE 12-9

CHECK We evaluate F_{min} for the limiting cases of $h = 0$ and $h = R$. There is no curb for $h = 0$, so we expect F_{min} to equal zero, and for $h = R$ we expect that no force is big enough to get the wheel to roll up the step. Our step-4 result gives $F_{\text{min}} = 0$ if $h = 0$, as expected, and gives $F_{\text{min}} \to \infty$ as $h \to R$, again as expected.

TAKING IT FURTHER Applying $\Sigma\tau = 0$ about the axis through the center of the wheel shows that $\vec{F}'$ is directed toward the wheel's center. (Otherwise, there would be a nonzero net torque about the axis.)

Example 12-5 Balancing a Crane

Figure 12-10 shows a standard K-10000 tower crane. The horizontal members extending to either side of the tower are called *jibs.* The tower is 12 m across. The forward jib is 80 m long with a mass of $m_{\text{FJ}} = 80$ t (1 t = 1 tonne = 1000 kg). The counterweight (cw) jib is 44 m long with mass of $m_{\text{cwJ}} = 31$ t, the fixed counterweight has a mass of $m_{\text{Fcw}} = 100$ t, the outer mobile cw has a mass of $m_{\text{OMcw}} = 40$ t, the inner mobile cw has a mass of $m_{\text{IMcw}} = 83$ t, and the tower has a mass of $m_{\text{T}} = 100$ t. A load with a mass of $m_{\text{L}} = 100$ t is suspended from the center of the forward jib. Is the crane balanced or unbalanced? If unbalanced, would you move the load toward or away from the tower in order to balance the load?

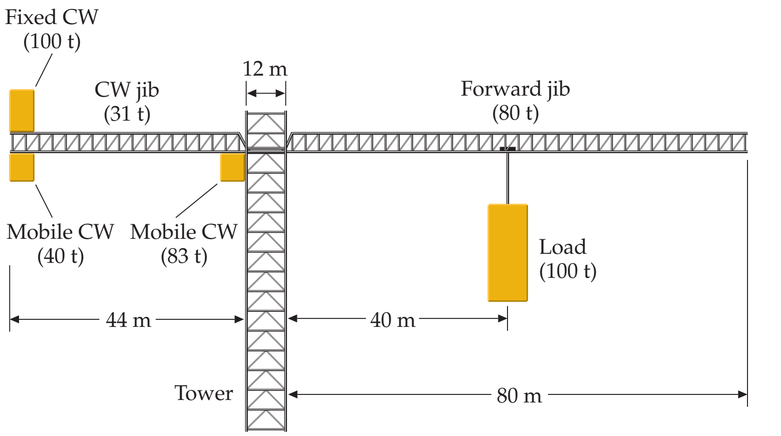

FIGURE 12-10 CW stands for counterweight.

PICTURE The crane is balanced if the center of gravity, and thus the center of mass, is inside the tower. Model each jib as a uniform rod and each counterweight as a point mass. Calculate the x component of the center of mass of the crane and load, where the $+x$ direction it to the right in Figure 12-10. If the center of gravity is within the tower, the crane is balanced.

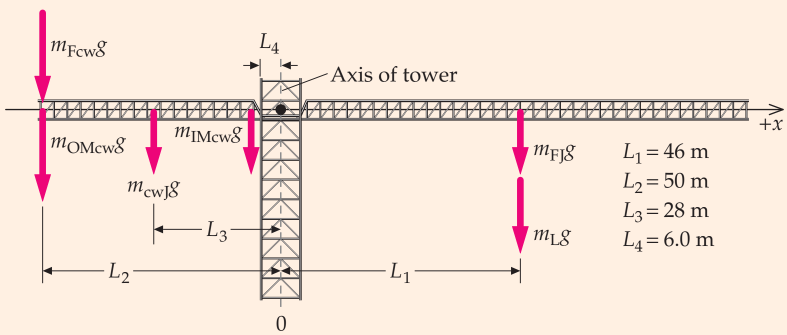

FIGURE 12-11

SOLVE

1. Draw a free-body diagram of the crane and load (Figure 12-11). Draw the x axis with the origin at the center of the tower.

2. Calculate the center of mass of the system:

$$Mx_{\text{cm}} = m(m_{\text{FJ}} + m_{\text{L}})L_1 + m_{\text{T}}(0) - (m_{\text{Fcw}} + m_{\text{OMcw}})L_2 - m_{\text{cwJ}}L_3 - m_{\text{IMcw}}L_4$$

$$\text{so} \quad x_{\text{cm}} = \frac{(180\text{ t})(46\text{ m}) + 0 - (140\text{ t})(50\text{ m}) - (31\text{ t})(28\text{ m}) - (83\text{ t})(6.0\text{ m})}{180\text{ t} + 100\text{ t} + 140\text{ t} + 31\text{ t} + 83\text{ t}} = -0.16\text{ m}$$

3. If the center of mass is outside the tower, the crane is unbalanced:

The center of gravity is 16 cm to the left of the axis of the tower. The center of mass is within the tower so $\boxed{\text{the crane is balanced.}}$

CHECK The left end of the cw jib is at $x = -50$ m, and the right end of the forward jib is at $x = 86$ m. Thus, the step-2 result is plausible because it is within the range $-50\text{ m} \leq x \leq +86\text{ m}$. This is a somewhat crude plausibility check, but if the step-2 result was not within this range, the result would definitely not be plausible.

TAKING IT FURTHER The tower is fastened to a rotating platform that is firmly anchored to a massive concrete base.

Example 12-6 A Leaning Ladder

A uniform 5.0-m ladder weighing 60 N leans against a frictionless vertical wall, as shown in Figure 12-12. The foot of the ladder is 3.0 m from the wall. What is the minimum coefficient of static friction necessary between the ladder and the floor if the ladder is not to slip?

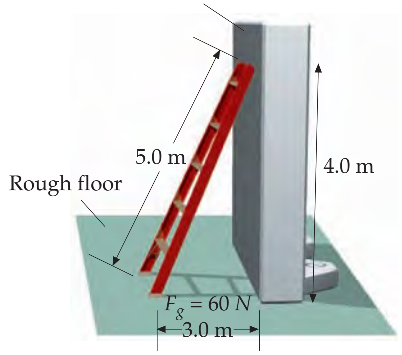

FIGURE 12-12

PICTURE There are three conditions for the ladder to be in equilibrium: $\Sigma F_x = 0$, $\Sigma F_y = 0$, and $\Sigma\tau = 0$. Apply these along with $f_s \le \mu_s F_n$ to solve for the minimum value of μ_s needed to prevent slipping.

SOLVE

1. Draw a free-body diagram of the ladder as shown in Figure 12-13. The forces acting on the ladder are the force due to gravity $\vec{F}_g$, the force $\vec{F}_1$ exerted by the wall (because the wall is frictionless, it exerts only a normal force), and the force exerted by the floor, which consists of a normal component F_n and a frictional component f_s.

2. The minimum coefficient of static friction relates the magnitude of the frictional force f_s and the magnitude of the normal force F_n. To solve for $\mu_{s\,min}$, we first solve for f_s and F_n:
$$\mu_s \ge \frac{f_s}{F_n} \quad \text{so} \quad \mu_{s\,min} = \frac{f_s}{F_n}$$

3. Set $\Sigma F_x = 0$ and $\Sigma F_y = 0$:
$$f_s - F_1 = 0 \quad \text{and} \quad F_n - F_g = 0$$

4. Solve for f_s and F_n:
$$f_s = F_1 \quad \text{and} \quad F_n = F_g = 60\text{ N}$$

5. Set $\Sigma\tau = 0$ about an axis directed out of the page and through the foot of the ladder, the point of application of the force we know the least about:
$$F_1(4.0\text{ m}) - F_g(1.5\text{ m}) = 0$$

6. Solve for the force F_1:
$$F_1 = \frac{F_g(1.5\text{ m})}{4.0\text{ m}} = \frac{(60\text{ N})(1.5\text{ m})}{4.0\text{ m}} = 22.5\text{ N}$$

7. Use this result for F_1, and $f_s = F_1$ from step 4, to find f_s:
$$f_s = F_1 = 22.5\text{ N}$$

8. Use the results for f_s and F_n to obtain $\mu_{s\,min}$ from step 2:
$$\mu_{s\,min} = \frac{f_s}{F_n} = \frac{22.5\text{ N}}{60\text{ N}} = 0.375 = \boxed{0.38}$$

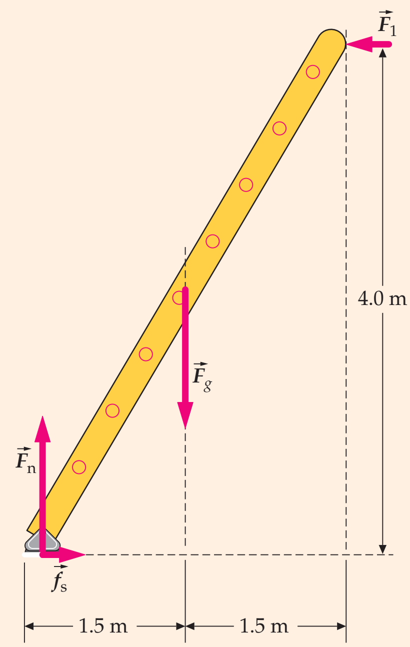

FIGURE 12-13

CHECK In the free-body diagram for the ladder shown in Figure 12-14, the lines of action of $\vec{F}_g$ and $\vec{F}_1$ intersect at point P. This means the torques about P due to $\vec{F}_g$ and $\vec{F}_1$ must both be equal to zero. Because the sum of all the torques about point P must equal zero, we know the torque about P due to $\vec{F}_2$ must also equal zero. This means the line of action of $\vec{F}_2$ must pass through point P as well. Consequently, $\tan\theta' = 4.0\text{ m}/1.5\text{ m} = F_n/f_s$, which means $f_s/F_n = 1.5/4.0 = 0.375$. This value of f_s/F_n is the same as that obtained in step 8.

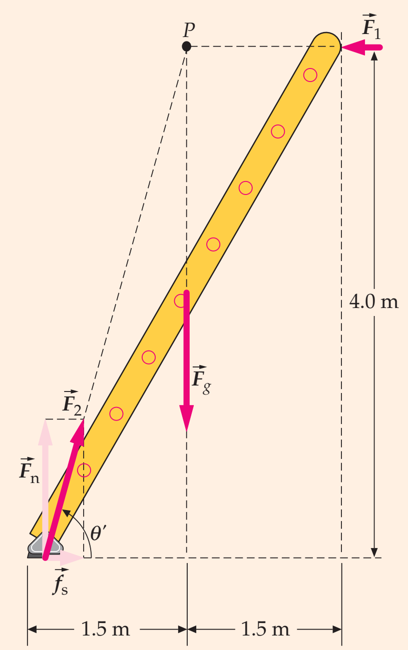

FIGURE 12-14

! If an object is in static equilibrium under the influence of three forces, where the lines of action of any two of the forces intersect at a point, the lines of action of all three forces will intersect at that same point.

PRACTICE PROBLEM 12-1

Show that if an object is in static equilibrium under the influence of three forces, where the lines of action of two of the forces intersect at a point, the lines of action of all three forces will intersect at that same point.

COUPLES

The forces $\vec{F}_n$ and $\vec{F}_g$ in Figure 12-13 of Example 12-6 are equal in magnitude, opposite in direction, and are not collinear. Such a pair of forces, called a **couple,** tends to produce an angular acceleration, but its net force is zero. The forces $\vec{f}_s$ and $\vec{F}_1$ in Figure 12-13 also constitute a couple. Figure 12-15 shows a couple consisting of forces $\vec{F}_1$ and $\vec{F}_2$ a distance D apart. The torque produced by this couple about an arbitrary point O is

$$\vec{\tau} = \vec{r}_1 \times \vec{F}_1 + \vec{r}_2 \times \vec{F}_2 = \vec{r}_1 \times \vec{F}_1 + \vec{r}_2 \times (-\vec{F}_1) = (\vec{r}_1 - \vec{r}_2) \times \vec{F}_1 \qquad 12\text{-}5$$

This result does not depend on the choice of the point O.

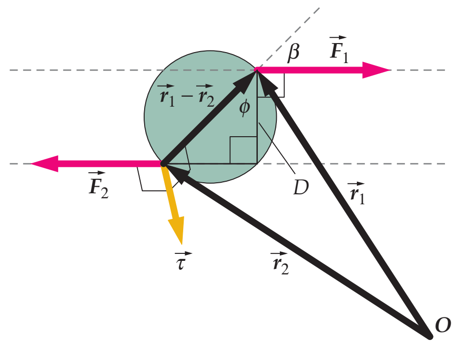

FIGURE 12-15 The torque $\vec{\tau}$ produced by the two forces is directed into the page—perpendicular to the plane containing the two forces. D is the perpendicular distance between the lines of action of the two forces.

> The torque produced by a couple is the same about all points in space.

The magnitude of the torque exerted by a couple is

$$\tau = FD \qquad 12\text{-}6$$

where F is the magnitude of either force and D is the perpendicular distance between the lines of action of the two forces.

PRACTICE PROBLEM 12-2

Show that the magnitude of $(\vec{r}_1 - \vec{r}_2) \times \vec{F}_1$ (see Equation 12-5) is FD (see Equation 12-6), where D (shown in Figure 12-15) is the distance between the lines of action of the two forces and F is the magnitude of either force.

Example 12-7 Tipping the Block

In visiting a marble quarry you notice half of a \$100 bill (Figure 12-16) sticking out from under a block of marble of mass m, height H, and with a square cross section of edge-length L. You try to retrieve the \$100 bill, but it is stuck. To retrieve it, you push the block with a horizontal force a distance h above the floor. How hard do you have to push to cause the block to tip up (slightly), thus freeing the \$100 bill? (Assume friction is sufficient to prevent the block from slipping.)

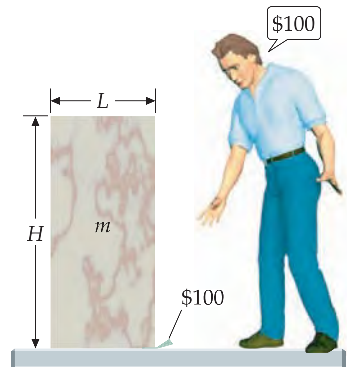

FIGURE 12-16

PICTURE Assume you are pushing so hard that if you pushed just slightly harder, the block would start to tip up. Draw a free-body diagram of the block, and apply the conditions for equilibrium. If there are any couples, use Equation 12-6 to calculate the magnitude of the torque.

SOLVE

1. Assume the block is on the verge of tipping up, and draw a free-body diagram of the block (Figure 12-17). Draw the normal force at the left edge of the block (see the remark at the end of this example).

2. To relate the forces, apply $\Sigma F_x = ma_x$ and $\Sigma F_y = ma_y$ to the block, where $a_x = a_y = 0$:
   $\Sigma F_x = 0 \Rightarrow F_{app} = f_s$
   and $\Sigma F_y = 0 \Rightarrow mg = F_n$

3. Identify any couples:
   $\vec{F}_{app}$ and $\vec{f}_s$ form couple 1
   and $m\vec{g}$ and $\vec{F}_n$ form couple 2

4. Choose counterclockwise as positive and, using Equation 12-6, calculate the torque due to each couple:
   $\tau_1 = +F_{app}h$ and $\tau_2 = -mg\frac{1}{2}L$

5. Using $\Sigma\tau = 0$, solve for F_{app}:
   $F_{app}h - mg\frac{1}{2}L = 0$
   so $F_{app} = \boxed{\dfrac{L}{2h}mg}$

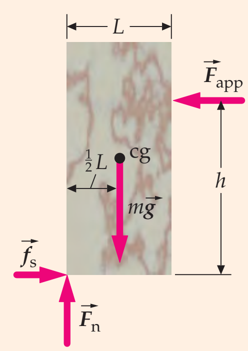

FIGURE 12-17

CHECK We expect that the higher up on the block you push, the more gently you need to push to start the block rotating. The step-6 result meets this expectation. That is, as h increases F_{app} decreases.

TAKING IT FURTHER The normal force is uniformly distributed across the bottom of the block before you start to push on the block. When you do push on the block, the harder you push, the farther the centroid (the effective center) of the distribution of the normal force moves to the left. When you push so hard that the block is on the verge of tipping up, the centroid of the normal force is at the left edge of the bottom of the block.

CONCEPT CHECK 12-1

There is a minimal-effort solution to this example. There is a specific axis choice such that the first step-6 equation is immediately obtained by setting the sum of the torques about the axis equal to zero. What is the axis choice used in the minimal-effort solution?

12-4 STATIC EQUILIBRIUM IN AN ACCELERATED FRAME

By an accelerated frame, we mean a reference frame that is accelerating, but is not rotating, relative to an inertial reference frame. The net force on an object that remains at rest relative to an accelerated reference frame is not equal to zero. An object at rest relative to the accelerated frame has the same acceleration as the frame. The two conditions for an object to be in static equilibrium in an accelerated reference frame follow:

1. $\Sigma\vec{F} = m\vec{a}_{cm}$
   where $\vec{a}_{cm}$ is the acceleration of the center of mass, which is also the acceleration of the reference frame.

2. $\Sigma\vec{\tau}_{cm} = 0$
   The sum of the torques about the center of mass must be zero.

The second condition follows from the fact that Newton's second law for rotation, $\Sigma\vec{\tau}_{cm} = I_{cm}\vec{\alpha}$, holds for torques about the center of mass whether or not the center of mass is accelerating.*

Example 12-8 Moving the Block

A truck (Figure 12-18a) carries a uniform block of marble of mass m, height h, and square cross section of edge-length L. What is the greatest acceleration the truck can have without the block tipping over? Assume that the block tips before it slides.

PICTURE There are three forces on the block, a gravitational force, a static frictional force, and a normal force. The acceleration of the block is due to the frictional force, as shown in Figure 12-18b. This force exerts a counterclockwise torque about the center of mass of the block. The only other force that exerts a torque about the center of mass of the block is the normal force. If the truck and block are not accelerating, the normal force is distributed uniformly across the bottom of the block. If the magnitude of the acceleration is small, this distribution shifts and the effective point of application of the normal force† moves to the left to provide a balancing torque about the center of mass. The greatest balancing torque this force can exert is when the effective normal force is at the edge of the base of the block, as shown.

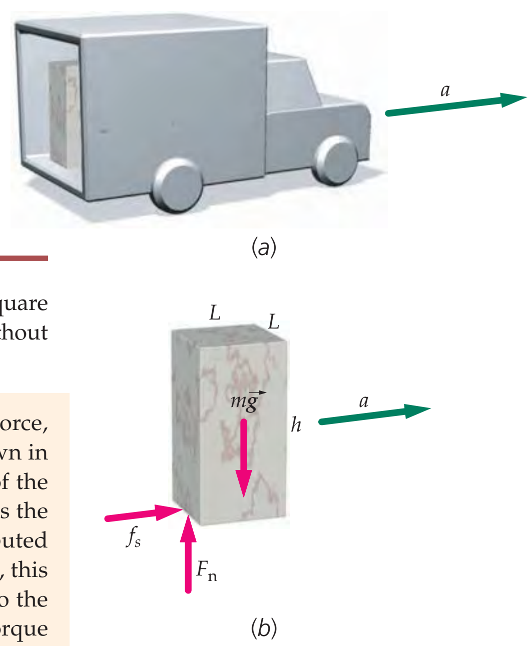

FIGURE 12-18

* See the discussion surrounding Equation 9-30.

† By "effective point of application" of the normal force, we mean the point where the entire normal force can be considered to be applied for the purpose of calculating the torque exerted by the force.

SOLVE

1. Draw a free-body diagram of the block (Figure 12-19).
2. Apply $\Sigma F_y = ma_{cmy}$ to the block, and then solve for the normal force: $F_n - mg = 0$ so $F_n = mg$
3. Apply $\Sigma F_x = ma_{cmx}$ to the block: $f_s = ma$
4. Apply $\Sigma\tau_{cm} = 0$: $f_s\dfrac{h}{2} - F_n d = 0$, where $d \le \frac{1}{2}L$
5. If $d = \frac{1}{2}L$, then the acceleration is maximum. Substitute $\frac{1}{2}L$ for d, ma_{max} for f_s, and mg for F_n, and solve for a_{max}: $ma_{max}\dfrac{h}{2} - mg\dfrac{L}{2} = 0$ so $a_{max} = \boxed{\dfrac{L}{h}g}$

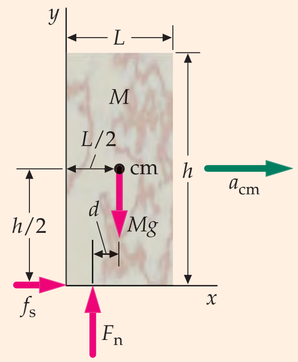

FIGURE 12-19

CHECK One would expect a_{max} to be larger for a short wide block (small h and large L) than for a tall narrow block (large h and small L). Our step-5 result meets this expectation.

12-5 STABILITY OF ROTATIONAL EQUILIBRIUM

There are three categories of rotational equilibrium for an object: stable, unstable, or neutral. **Stable rotational equilibrium** occurs when the torques that arise from a small angular displacement of the object from equilibrium tend to rotate the object back toward its equilibrium orientation. Stable equilibrium is illustrated in Figure 12-20*a*. When the cone is tipped slightly as shown, the resulting gravitational torque about the pivot point tends to restore the cone to its original orientation. Note that this slight tipping lifts the center of gravity, increasing the gravitational potential energy.

Unstable rotational equilibrium, illustrated in Figure 12-20*b*, occurs when the torques that arise from a small angular displacement of the object tends to rotate the object even farther away from its equilibrium orientation. A slight tipping of the cone causes it to fall over because the torque due to the gravitational force tends to rotate it away from its original orientation. Here the rotation lowers the center of gravity and decreases the gravitational potential energy.

The cone resting on a horizontal surface in Figure 12-20*c* illustrates **neutral rotational equilibrium.** If the cone is rolled slightly, there is no torque that tends

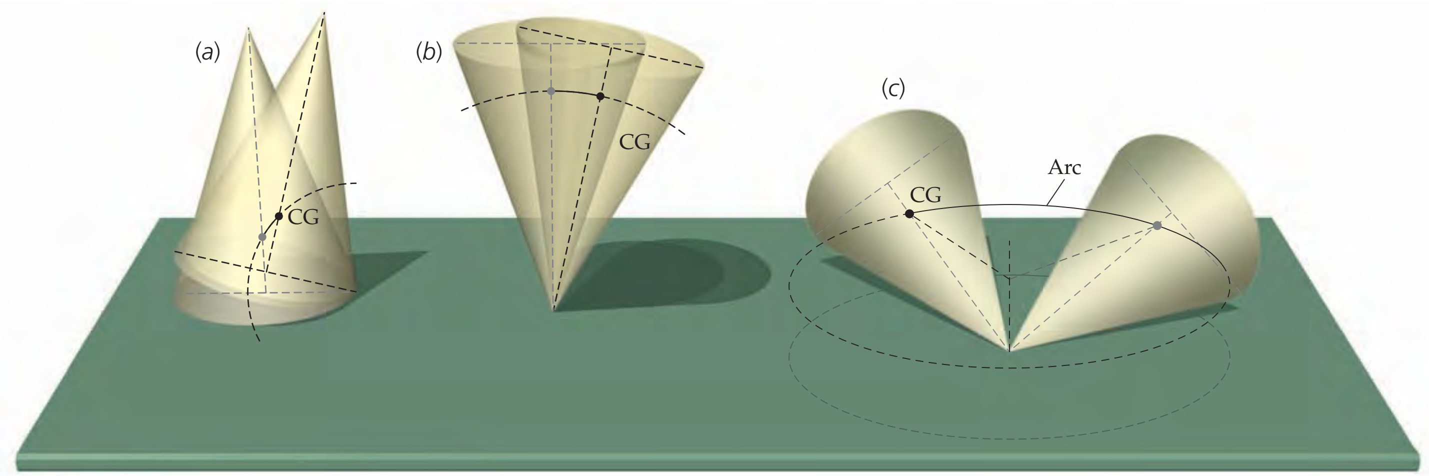

FIGURE 12-20 If slight rotation raises the center of gravity, as in (*a*), the equilibrium is stable. If a slight rotation lowers the center of gravity, as in (*b*), the equilibrium is unstable. If a slight rotation neither raises nor lowers the center of gravity, as in (*c*), the equilibrium is neutral.

to rotate it either back toward, or away from, its original orientation. As the cone rotates, the height of its center of gravity remains unchanged, so the gravitational potential energy does not change.

In summary, if a system is rotated slightly from an equilibrium orientation, the equilibrium position is stable if the system returns to its original orientation, unstable if it rotates farther away, and neutral if there are no torques tending to rotate it in either direction.

Because "rotated slightly" is a relative term, stability is also relative. One example of equilibrium may be more or less stable than another. A rod is balanced on one end, as in Figure 12-21*a*. Here, if the disturbance is very small (Figure 12-21*b*), the rod will move back toward its original position, but if the disturbance is great enough so that the center of gravity no longer lies over the base of support (Figure 12-21*c*), the rod will fall.

We can improve the stability of a system by either lowering the center of gravity or widening the base of support. Figure 12-22 shows a nonuniform rod that is loaded so that its center of gravity is near one end. If it stands on its heavy end so that the center of gravity is low (Figure 12-22*a*), it is much more stable than if it stands on the other end so that the center of gravity is high (Figure 12-22*b*).

In Figure 12-23, the system is stable for any angular displacement because the resulting torque always rotates the system back toward its equilibrium position.

Standing or walking upright is difficult for a human because the center of gravity is high, and must be kept over a relatively small base of support, the feet. Human infants take about a year to learn to walk. A four-footed creature has a much easier time, in part because its base of support is wider and its center of gravity is lower. Newborn kittens can walk almost immediately.

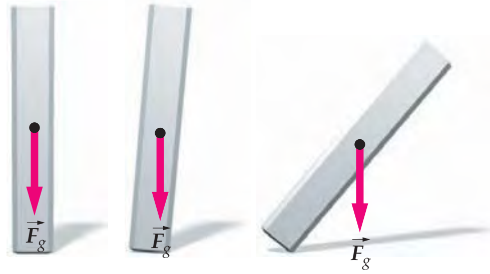

FIGURE 12-21 Stability of equilibrium is relative. If the rod in (*a*) is rotated slightly, as in (*b*), it returns to its original equilibrium position as long as the center of gravity lies over the base of support. (*c*) If the rotation is too great, the center of gravity is no longer over the base of support, and the rod falls over.

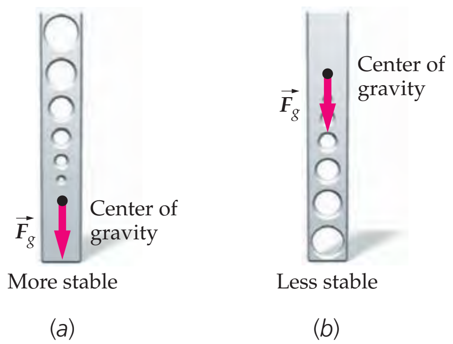

FIGURE 12-22 When a nonuniform rod rests on its heavy end (so its center of gravity is low), as in (*a*), the equilibrium is more stable than when its center of gravity is high, as in (*b*).

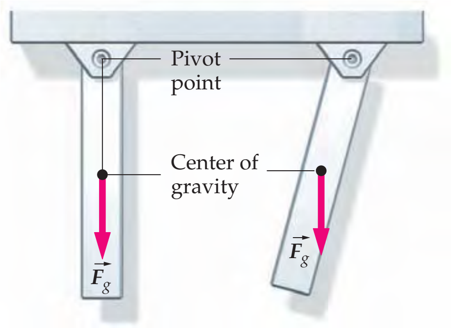

FIGURE 12-23

12-6 INDETERMINATE PROBLEMS

When objects are not rigid, but are deformable, we need more information to determine the forces required for equilibrium. Consider a pickup truck resting on a frictionless horizontal surface. Suppose there is a very heavy object on one side of the trunk bed, and suppose we wish to calculate the normal force exerted by the road on each of the four truck tires. Consider the truck plus the heavy object as the system and assume we know the location of each tire, the system's weight, and the location of the center of gravity. Is this knowledge sufficient to allow us to calculate the magnitudes of the four normal forces? The answer to this question is no. The magnitude of each normal force is unknown, so we need four independent equations to solve for the four unknowns. Because the system is in equilibrium, the conditions for equilibrium can only supply us with three independent equations. Let the road surface be in the *xy* plane. The first condition for equilibrium is that the sum of the external forces is equal to zero. This provides

The toddler is relatively unstable (in comparison to a kitten). *(Photodisk.)*

only one equation ($\Sigma F_z = 0$) because all the forces are vertical. The second condition for equilibrium is that the sum of the external torques about any point is equal to zero. This provides two additional equations, $\Sigma\tau_x = 0$ and $\Sigma\tau_y = 0$. The reason there are no vertical torque components is because torque vectors are cross products ($\vec{\tau} = \vec{r} \times \vec{F}$), and the direction of a cross product is perpendicular to each vector in the product. Because the forces on the truck are all vertical, all the torque vectors are horizontal.

There are two external forces acting on the truck: the force of gravity and the normal forces by the road on the tires. Let the road surface be in the xy plane. If we choose the contact point of one of the tires with the road as our origin, the torque exerted by all the forces about that point has both x and y components. All the forces are vertical, so all the torque vectors must be horizontal. There are no z components because there are no horizontal forces. We thus obtain two equations by setting the net torque equal to zero, and a third equation by setting the net vertical force equal to zero. We need another equation to find the force exerted by the road on each of the four tires. Because we do not have another equation at our disposal, the forces cannot be determined. If we let air out of one of the tires and pump up another tire to a greater pressure, the car remains in equilibrium, but the force exerted on each tire changes. Clearly, the forces on the tires in this problem are not determined by the information given. The tires are not rigid bodies. To some extent, every object is deformable.

12-7 STRESS AND STRAIN

If a solid object is subjected to forces that tend to stretch, shear, or compress the object, its shape changes. If the object returns to its original shape when the forces are removed, it is said to be **elastic.** Most objects are elastic for forces up to a certain maximum, called the **elastic limit.** If the forces exceed the elastic limit, the object does not return to its original shape but is permanently deformed.

Figure 12-24 shows a solid bar subjected to a stretching or **tensile force *F*** acting equally to the right and to the left. The bar is in equilibrium, but the forces acting on it tend to increase its length. The fractional change in the length $\Delta L/L$ of a segment of the bar is called the **strain**:

$$\text{Strain} = \frac{\Delta L}{L} \qquad 12\text{-}7$$

The ratio of the force F to the cross-sectional area A is called the **tensile stress**:

$$\text{Stress} = \frac{F}{A} \qquad 12\text{-}8$$

Figure 12-25 shows a graph of stress versus strain for a typical solid bar. The graph is linear until point A. Up to this point, known as the proportional limit, the strain is proportional to the stress. The result that strain varies linearly with stress is known as Hooke's law. Point B in Figure 12-25 is the elastic limit of the material. If the bar is stretched beyond this point, it is permanently deformed. If an even greater stress is applied, the material eventually breaks, shown happening at point C. The ratio of stress to strain in the linear region of the graph is a constant called **Young's modulus** Y:

$$Y = \frac{\text{Stress}}{\text{Strain}} = \frac{F/A}{\Delta L/L} \qquad 12\text{-}9$$

YOUNG'S MODULUS DEFINED

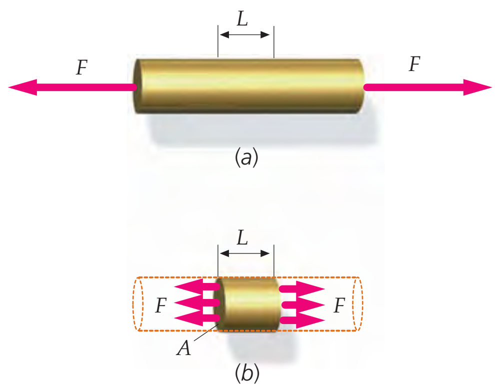

FIGURE 12-24 (*a*) A solid bar subjected to stretching forces of magnitude F acting on each other. (*b*) A small section of the bar of length L. The elements of the bar to the left and right of this section exert forces on the section. These forces are distributed equally over the cross-sectional area. The force per unit area is the stress.

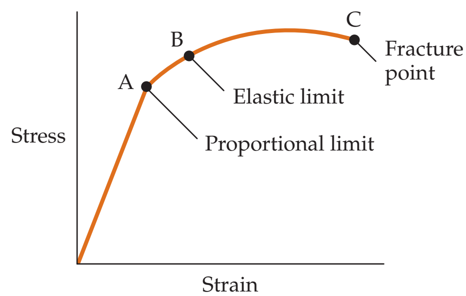

FIGURE 12-25 A graph of stress versus strain. Up to point A, the strain is proportional to the stress. Beyond the elastic limit at point B, the bar will not return to its original length when the stress is removed. At point C, the bar fractures.

Table 12-1 Young's Modulus Y and Strengths of Various Materials[†]

Material	Y, GN/m^2[‡]	Tensile strength, MN/m^2	Compressive strength, MN/m^2
Aluminum	70	90	
Bone			
Tensile	16	200	
Compressive	9		270
Brass	90	370	
Concrete	23	2	17
Copper	110	230	
Iron (wrought)	190	390	
Lead	16	12	
Steel	200	520	520

[†] These values are representative. Actual values for particular samples may differ.
[‡] $1\ GN = 10^3\ MN = 1 \times 10^9\ N$.

See **Math Tutorial** *for more information on*
Direct and Inverse Proportions

The dimensions of Young's modulus are those of force divided by area. Approximate values of Young's modulus for various materials are listed in Table 12-1.

PRACTICE PROBLEM 12-3
Suppose that the biceps muscle of your right arm has a maximum cross-sectional area of $12\ cm^2 = 1.2 \times 10^{-3}\ m^2$. What is the stress in the muscle if it exerts a force of 300 N?

If a bar is subjected to forces that tend to compress it rather than stretch it, the stress is called **compressive stress.** For many materials, Young's modulus for compressive stress is the same as that for tensile stress. Note that for compressive strain, ΔL, in Equation 12-7 is then taken to be the *decrease* in the length of the bar. If the tensile or compressive stress is too great, the bar breaks. The stress at which breakage occurs is called the **tensile strength,** or in the case of compression, the **compressive strength.** Approximate values of the tensile and compressive strengths of various materials are listed in Table 12-1. Note from the table that the compressive strength of bone is greater than the tensile strength. Also note that, for bone, Young's modulus is significantly larger for tensile stress than for compressive stress. These differences have biological significance, because the major job of bone is to resist the compressive load exerted by contracting muscles.

To measure the tensile strength, the rod is stretched until it breaks. *(Vince Streano/CORBIS.)*

Example 12-9 Elevator Safety — *Context-Rich*

While working with an engineering company during the summer, you are assigned to check the safety of an elevator system in a new office building. The elevator has a maximum load of 1000 kg, including its own mass, and is supported by a steel cable 3.0 cm in diameter and 300 m long at full extension. There will be safety concerns if the steel stretches more than 3.0 cm. Your job is to determine whether or not the elevator is safe as planned, given a maximum acceleration of the system of $1.5\ m/s^2$.

PICTURE L is the length of the unstressed cable, F is the magnitude of the force acting on it, and A is its cross-sectional area. The stretch in the cable ΔL is related to Young's modulus by $Y = (F/A)/(\Delta L/L)$. From Table 12-1, we find the numerical value of Young's modulus for steel, $Y = 2.0 \times 10^{11}\ N/m^2$.

SOLVE

1. The amount the cable is stretched, ΔL, is related to Young's modulus:

$$Y = \frac{F/A}{\Delta L/L} \quad \text{so} \quad \Delta L = \frac{FL}{AY}$$

2. To find the force acting on the cable, we apply Newton's second law to the elevator. There are two forces on the elevator, the force F of the cable and the gravitational force:

$$F - mg = ma_y$$

$$\text{so} \quad F_{\max} = m(g + a_{y\max}) = (1000\text{ kg})(9.81\text{ N/kg} + 1.5\text{ N/kg}) = 1.13 \times 10^4\text{ N}$$

3. Substitute into the step-1 result and obtain the maximum amount of stretch:

$$\Delta L = \frac{F_{\max}L}{AY} = \frac{F_{\max}L}{\pi r^2 Y} = \frac{(1.13 \times 10^4\text{ N})(300\text{ m})}{\pi(0.015\text{ m})^2(2.0 \times 10^{11}\text{ N/m}^2)} = 2.40\text{ cm}$$

4. Report your results to your boss:

> According to my calculations, the most the cable will stretch is 2.4 cm, only 20 percent less than the 3.0-cm limit. However, in reading the footnote to the table, I note that the values given for Young's modulus are representative values, and that actual values vary from sample to sample. I recommend that you consult an engineer and get a professional evaluation.

CHECK Is the step-3 expression for ΔL dimensionally correct? Young's modulus has the dimensions of force per unit area, so AY has the dimensions of force. Thus, the dimension of $F_{\max}$ in the numerator cancels the dimension of AY in the denominator. The expression has the dimensions of length and is dimensionally correct.

PRACTICE PROBLEM 12-4 A 1.5-m-long wire has a cross-sectional area of 2.4 mm^2. It is hung vertically and stretches 0.32 mm when a 10-kg block is attached to it. Find (*a*) the stress, (*b*) the strain, and (*c*) Young's modulus for the wire.

In Figure 12-26, a force F_s is applied tangentially to the top of a block of Jello. Such a force is called a **shear force.** The ratio of the shear force F_s to the area A is called the **shear stress**:

$$\text{Shear stress} = \frac{F_s}{A} \qquad 12\text{-}10$$

A shear stress tends to deform an object, as shown in Figure 12-26. The ratio $\Delta X/L$ is called the **shear strain**:

$$\text{Shear strain} = \frac{\Delta X}{L} = \tan\theta \qquad 12\text{-}11$$

where θ is the shear angle shown in the figure. The ratio of the shear stress to the shear strain is called the **shear modulus** M_s:

$$M_s = \frac{\text{Shear stress}}{\text{Shear strain}} = \frac{F_s/A}{\Delta X/L} = \frac{F_s/A}{\tan\theta} \qquad 12\text{-}12$$

DEFINITION—SHEAR MODULUS

The shear modulus is also known as the **torsion modulus.** The torsion modulus is approximately constant for small stresses, which implies that the shear strain varies linearly with the shear stress. This observation is known as Hooke's law for torsional stress. In a torsion balance, such as that used in Cavendish's apparatus for measuring the universal gravitational constant G, the torque (which is related to the stress) is proportional to the angle of twist (which equals the strain for small angles). Approximate values of the shear modulus for various materials are listed in Table 12-2.

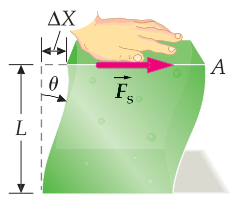

FIGURE 12-26 The application of the horizontal force $\vec{F}_s$ to the Jello causes a shear stress defined as the force per unit area. The ratio $\Delta X/L = \tan\theta$ is the shear strain and A is the horizontal cross-sectional area of the Jello.

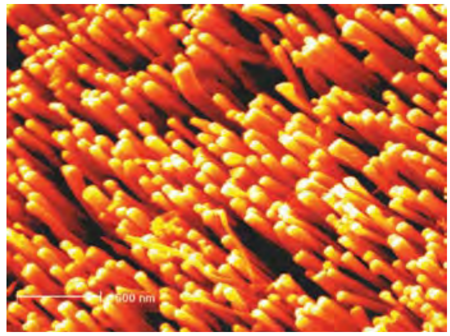
Table 12-2 Approximate Values of the Shear Modulus M_s of Various Materials

Material	M_s, GN/m^2
Aluminum	30
Brass	36
Copper	42
Iron	70
Lead	5.6
Steel	84
Tungsten	150

Physics Spotlight

Carbon Nanotubes: Small and Mighty



Carbon nanotubes are produced in large numbers. *(Courtesy of Prof. Zhong Lin Wang, Georgia Tech.)*

The most common form of pure carbon is graphite—slippery, strong sheets one atom thick. The lattice of carbon atoms in graphite is arranged in a hexagonal pattern, much like the hexagonal pattern of chicken wire. Carbon-atom lattices can also form tubes that are a few nanometers in diameter, and a few micrometers long. Because of their small size, they have been dubbed *nanotubes*. Nanotube walls can contain a single layer of atoms, or they can consist of many nested tubes, in a multiwalled tube.

Nanotubes can have different properties, depending on the orientation of the lattice, and the diameter of the tube. More than 300 different types of carbon nanotubes have been identified. Each production method[*] makes between 10 and 50 different types of nanotubes at once.[†] Isolating a large pure group of nanotubes is a difficult process.[‡,#] Most nanotubes are sold in batches containing between 65 and 95 percent nanotubes. The cost is per gram, and purer types are more expensive. (The remaining impurities are different forms of carbon.) Nanotubes differ dramatically[°] from carbon fibers currently used in composites. Carbon fibers are a specialized type of manufactured graphite, but they are not hollow tubes.

Because nanotubes are so small, new methods of measuring their tensile strength and Young's modulus were created.[§,¶] Young's modulus for single-walled nanotubes was measured[**] at an average of 1.25 TN/m^2, with a range[††] of 0.32 to 1.47 TN/m^2. These values are more than five times stronger than steel by volume, and many more times stronger by weight. Multiwalled carbon nanotubes have a greater variation in Young's modulus,[‡‡] from 270 GN/m^2 to 950 GN/m^2, and their tensile strength ranges from 11 GN/M^2 to 63 GN/m^2. Carbon nanotubes have higher tensile strength and a much higher Young's modulus than Kevlar™ fibers,[##] at an equivalent weight. Nanotubes are the stiffest materials known, and have the highest tensile strength known.

Carbon nanotubes can not only take stress with a low rate of strain, but can also exert strong stresses. Carbon nanotubes have recently been shown to exert pressures of 40.53 GN/m^2 on metal crystals trapped within them, when the tubes are radiated and treated with heat.[°°] (This is about one-tenth the pressure at Earth's core!) As the tubes shrink, they squeeze the metal into very fine hairs.

Although nanotubes themselves are extremely strong, threads,[§§] fibers,[¶¶] and ribbons[***] spun from them are not as strong. But these products still have high tensile strengths and high Young's moduli. Much of the strength of nanotubes comes from the regular lattice of carbon atoms. If defects exist in that lattice, the nanotube is weakened.[†††] (This also explains the wide variation in tested strengths of carbon nanotubes.) Because billions of nanotubes are required for even medium-scale applications, statistically these larger applications cannot have the same strength per unit volume (or per unit mass) as individual nanotubes.[‡‡‡] Still, even a small amount of relatively pure nanotubes can add strength and stiffness to existing materials. By weight, 5 percent nanotubes in a composite can more than double the tensile strength and stiffness of the composite.[###] Wherever strong, lightweight materials are needed, carbon nanotubes have a bright future.

Summary

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Equilibrium of a Rigid Object		
Conditions	1. The net external force acting on the object must be zero:	
	$\Sigma\vec{F} = 0$	12-1
	2. The net external torque about any point must be zero:	
	$\Sigma\vec{\tau} = 0$	12-2
	(The sum of the torques about any axis also equals zero.)	
Stability	The equilibrium of an object can be classified as stable, unstable, or neutral. An object resting on some surface will be in equilibrium if its center of gravity lies over its base of support. Stability can be improved by lowering the center of gravity or by increasing the width of the base.	
2. Center of Gravity	The force of gravity exerted on the various parts of an object can be replaced by a single force, the total gravitational force, acting at the center of gravity:	
	$\vec{\tau}_{\text{net}} = \sum_i (\vec{r}_i \times \vec{F}_{gi}) = \vec{r}_{\text{cg}} \times \vec{F}_g$	12-3
	For an object in a uniform gravitational field, the center of gravity coincides with the center of mass.	
3. Couples	A pair of equal and opposite forces constitutes a couple. The torque produced by a couple is the same about any point in space.	
	$\vec{\tau} = (\vec{r}_1 - \vec{r}_2) \times \vec{F}_1 \quad \text{so} \quad \tau = FD$	12-5, 12-6
	where D is the distance between the lines of action of the forces.	
4. Accelerated Reference Frame	The conditions for static equilibrium in an accelerated reference frame are	
	1. $\Sigma\vec{F} = m\vec{a}_{\text{cm}}$, where $\vec{a}_{\text{cm}}$ is the acceleration of the center of mass, which is also the acceleration of the reference frame.	
	2. $\Sigma\vec{\tau}_{\text{cm}} = 0$ The sum of the external torques about the center of mass must be zero.	
5. Stress and Strain		
Young's modulus	$Y = \dfrac{\text{Stress}}{\text{Strain}} = \dfrac{F/A}{\Delta L/L}$	12-9
Shear modulus	$M_s = \dfrac{\text{Shear stress}}{\text{Shear strain}} = \dfrac{F_s/A}{\Delta X/L} = \dfrac{F_s/A}{\tan\theta}$	12-12

Answer to Concept Check

12-1 A horizontal axis along the lowest edge of the block on the side opposite the side that is being pushed (Figure 12-17). (The torques about this axis due to the normal and frictional forces are both equal to zero.)

Answers to Practice Problems

12-1 Forces $\vec{F}_1$, $\vec{F}_2$, and $\vec{F}_3$ act on the object. The object is in equilibrium, so the torques due to these forces about any point must sum to zero. Let P be the point of intersection of the lines of action of forces $\vec{F}_1$ and $\vec{F}_2$. Then the torques about P due to $\vec{F}_1$ and $\vec{F}_2$ each must equal zero, so the torque about P due to $\vec{F}_3$ must also equal zero. It follows that the line of action of $\vec{F}_3$ must pass through point P.

12-2 The angle between $\vec{r}_1 - \vec{r}_2$ and $\vec{F}_1$ is β (Figure 12-15), so $|\vec{\tau}| = |(\vec{r}_1 - \vec{r}_2) \times \vec{F}_1| = |\vec{r}_1 - \vec{r}_2| F \sin\beta$. Because $D = |\vec{r}_1 - \vec{r}_2| \sin\beta$, $|\vec{\tau}| = FD$.

12-3 Stress $= F/A = 2.5 \times 10^5\ \text{N/m}^2$. The maximum stress that can be exerted is approximately the same for all human muscles. Greater forces can be exerted by muscles with greater cross-sectional areas.

12-4 (*a*) $4.1 \times 10^7\ \text{N/m}^2$, (*b*) 2.1×10^{-4}, (*c*) 190 GN/m^2

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

For all problems, use 9.81 m/s^2 for the free-fall acceleration and neglect friction and air resistance unless instructed to do otherwise.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • True or false: SSM

(*a*) $\sum_i \vec{F}_i = 0$ is sufficient for static equilibrium to exist.

(*b*) $\sum_i \vec{F}_i = 0$ is necessary for static equilibrium to exist.

(*c*) In static equilibrium, the net torque about any point is zero.

(*d*) An object in equilibrium cannot be moving.

2 • True or false:

(*a*) The center of gravity is always at the geometric center of a body.

(*b*) The center of gravity must be located inside an object.

(*c*) The center of gravity of a baton is located between the two ends.

(*d*) The torque produced by the force of gravity about the center of gravity is always zero.

3 • The horizontal bar in Figure 12-27 will remain horizontal if (*a*) $L_1 = L_2$ and $R_1 = R_2$, (*b*) $M_1R_1 = M_2R_2$, (*c*) $M_2R_1 = M_1R_2$ (*d*) $L_1M_1 = L_2M_2$, (*e*) $R_1L_1 = R_2L_2$.

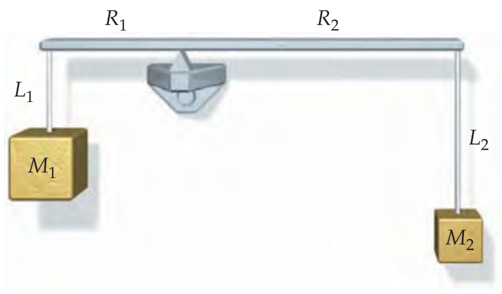

FIGURE 12-27 Problem 3

4 • Sit in a chair with your back straight. Now try to stand up without leaning forward. Explain why you cannot do it.

5 • **ENGINEERING APPLICATION** You have a job digging holes for posts to support signs for a Louisiana restaurant (called Mosca's). Explain why the higher above the ground a sign is mounted, the farther the posts should extend into the ground.

6 • A father (mass M) and his son (mass m) begin walking out toward opposite ends of a balanced see-saw. As they walk, the see-saw stays exactly horizontal. What can be said about the relationship between the father's speed V and the son's speed v?

7 • Travel mugs that people might set on the dashboards of their cars are often made with broad bases and relatively narrow mouths. Why would travel mugs be designed with this shape, rather than have the roughly cylindrical shape that mugs normally have?

8 •• **ENGINEERING APPLICATION** The sailors in the photo are using a technique called "hiking out." What purpose does positioning themselves in this way serve? If the wind were stronger, what would they need to do to keep their craft stable?

Sailors who are hiking out. *(Peter Andrews/Reuters/Corbis.)*

9 •• An aluminum wire and a steel wire of the same length L and diameter D are joined end-to-end to form a wire of length $2L$. One end of wire is then fastened to the ceiling and an object of mass M is attached to the other end. Neglecting the mass of the wires, which of the following statements is true? (*a*) The aluminum portion will stretch by the same amount as the steel portion. (*b*) The tensions in the aluminum portion and the steel portion are equal. (*c*) The tension in the aluminum portion is greater than that in the steel portion. (*d*) None of the above SSM

ESTIMATION AND APPROXIMATION

10 •• A large crate weighing 4500 N rests on four 12-cm-high blocks on a horizontal surface (Figure 12-28). The crate is 2.0 m long, 1.2 m high, and 1.2 m deep. You are asked to lift one end of the crate using a long steel pry bar. The fulcrum on the pry bar is 10 cm from the end that lifts the crate. Estimate the length of the bar you will need to lift the end of the crate.

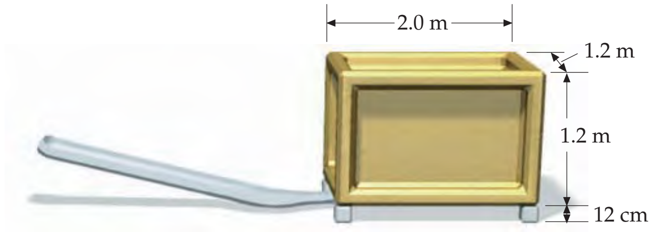

FIGURE 12-28 Problem 10

11 •• **ENGINEERING APPLICATION** Consider an atomic model for Young's modulus. Assume that a large number of atoms are arranged in a cubic array, with each atom at a corner of a cube and each atom a distance a from its six nearest neighbors. Imagine that each atom is attached to its six nearest neighbors by little springs each with spring constant k. (*a*) Show that this material, if stretched, will have a Young's modulus $Y = k/a$. (*b*) Using Table 12-1 and assuming that $a \approx 1.0$ nm, estimate a typical value for the "atomic spring constant" k in a metal. SSM

12 •• By considering the torques about the centers of the ball joints in your shoulders, estimate the force your deltoid muscles (those muscles on top of the shoulder) must exert on your upper arm to keep your arm held out and extended at shoulder level. Then, estimate the force they must exert when you hold a 10-lb weight out to the side at arm's length.

CONDITIONS FOR EQUILIBRIUM

13 • Your crutch is pressed against the sidewalk with a force $\vec{F}_c$ along its own direction, as in Figure 12-29. This force is balanced by the normal force $\vec{F}_n$ and a frictional force $\vec{f}_s$. (*a*) Show that when the force of friction is at its maximum value, the coefficient of friction is related to the angle θ by $\mu_s = \tan\theta$. (*b*) Explain how this result applies to the forces on your foot when you are not using a crutch. (*c*) Explain why it is advantageous to take short steps when walking on slippery surfaces?

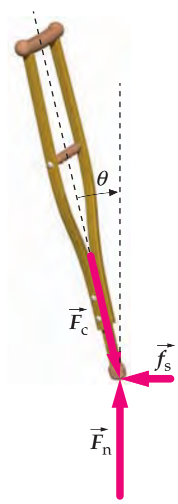

FIGURE 12-29
Problem 13

14 •• A thin uniform rod of mass M is suspended horizontally by two vertical wires. One wire is at the left end of the rod, and the other wire is 2/3 of the length of the rod from the left end. (*a*) Determine the tension in each wire. (*b*) An object is now hung by a string attached to the right end of the rod. When this happens, it is noticed that the rod remains horizontal but the tension in the wire on the left vanishes. Determine the mass of the object.

THE CENTER OF GRAVITY

15 • An automobile has 58 percent of its weight on the front wheels. The front and back wheels on each side are separated by 2.0 m. Where is the center of gravity located?

STATIC EQUILIBRIUM

16 • Figure 12-30 shows a lever of negligible mass with a vertical force F_{app} being applied to lift a load F. The *mechanical advantage* of the lever is defined as $M = F/F_{app\,min}$, where $F_{app\,min}$ is the smallest force necessary to lift the load F. Show that for this simple lever system, $M = x/X$, where x is the moment arm (distance to the pivot) for the applied force, and X is the moment arm for the load.

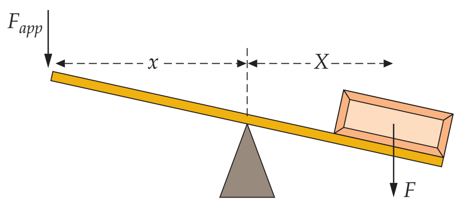

FIGURE 12-30 Problem 16

17 • **ENGINEERING APPLICATION** Figure 12-31 shows a 25-foot sailboat. The mast is a uniform 120-kg pole that is supported on the deck and held fore and aft by wires as shown. The tension in the *forestay* (wire leading to the bow) is 1000 N. Determine the tension in the *backstay* (wire leading aft) and the normal force that the deck exerts on the mast. (Assume that the frictional force the deck exerts on the mast to be negligible.) SSM

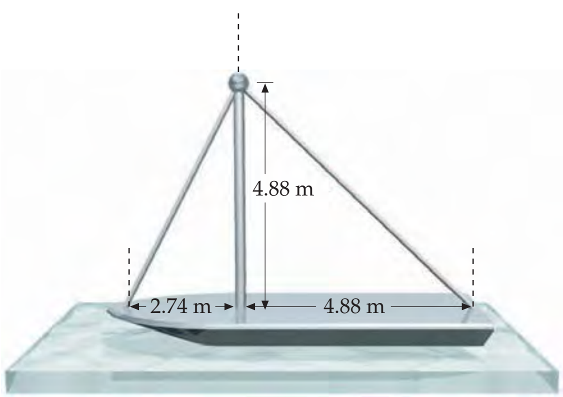

FIGURE 12-31 Problem 17

18 •• A uniform 10.0-m beam of mass 300 kg extends over a ledge as in Figure 12-32. The beam is not attached, but simply rests on the surface. A 60.0-kg student intends to position the beam so that he can walk to the end of it. What is the maximum distance the beam can extend past end of the ledge and still allow him to perform this feat?

FIGURE 12-32 Problem 18

19 •• **BIOLOGICAL APPLICATION** A *gravity board* is a convenient and quick way to determine the location of the center of gravity of a person. It consists of a horizontal board supported by a fulcrum at one end and a scale at the other end. To demonstrate this in class, your physics professor calls on you to lie horizontally on the board with the top of your head directly above the fulcrum point as shown in Figure 12-33. The fulcrum is 2.00 m from the scale. In preparation for this experiment, you had accurately weighed yourself and determined your mass to be 70.0 kg. When you are at rest on the gravity board, the scale advances 250 N beyond its reading when the board is there by itself. Use this data to determine the location of your center of gravity relative to your feet. SSM

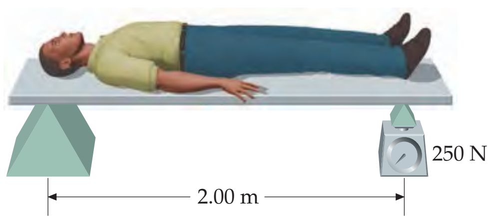

FIGURE 12-33 Problem 19

20 •• A stationary 3.0-m board of mass 5.0 kg is hinged at one end. A force $\vec{F}$ is applied vertically at the other end, and the board makes a 30° angle with the horizontal. A 60-kg block rests on the board 80 cm from the hinge as shown in Figure 12-34. (*a*) Find the magnitude of the force $\vec{F}$. (*b*) Find the force exerted by the hinge. (*c*) Find the magnitude of the force $\vec{F}$ as well as the force exerted by the hinge, if $\vec{F}$ is exerted, instead, at right angles to the board.

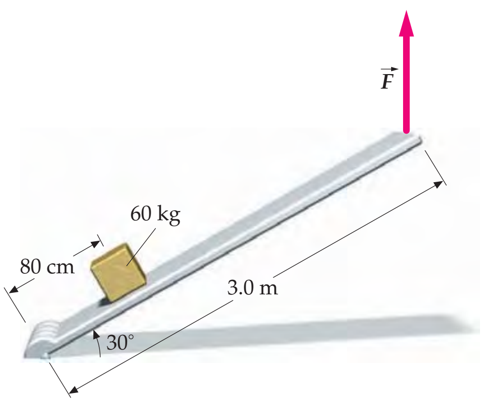

FIGURE 12-34 Problem 20

21 •• A cylinder of mass M is supported by a frictionless trough formed by a plane inclined at 30° to the horizontal on the left and one inclined at 60° on the right, as shown in Figure 12-35. Find the force exerted by each plane on the cylinder.

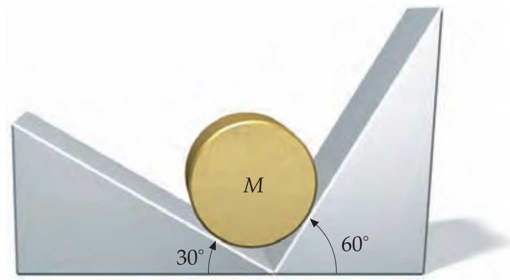

FIGURE 12-35 Problem 21

22 •• A uniform 18-kg door that is 2.0 m high by 0.80 m wide is hung from two hinges that are 20 cm from the top and 20 cm from the bottom. If each hinge supports half the weight of the door, find the magnitude and direction of the horizontal components of the forces exerted by the two hinges on the door.

23 •• Find the force exerted on the strut by the hinge at A for the arrangement in Figure 12-36 if (*a*) the strut is weightless, and (*b*) the strut weighs 20 N.

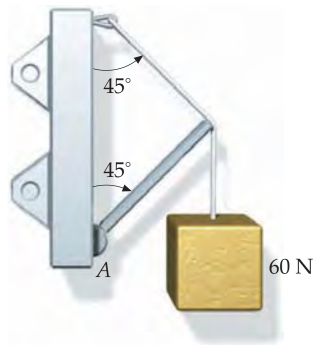

FIGURE 12-36 Problem 23

24 •• Julie has been hired to help paint the trim of a building, but she is not convinced of the safety of the apparatus. A 5.0-m plank is suspended horizontally from the top of the building by ropes attached at each end. Julie knows from previous experience that the ropes being used will break if the tension exceeds 1.0 kN. Her 80-kg boss dismisses Julie's worries and begins painting while standing 1.0 m from the end of the plank. If Julie's mass is 60 kg and the plank has a mass of 20 kg, over what range of positions can Julie stand to join her boss without causing the ropes to break?

25 •• A cylinder of mass M and radius R rolls against a step of height h, as shown in Figure 12-37. When a horizontal force of magnitude F is applied to the top of the cylinder, the cylinder remains at rest. (*a*) Find an expression for the normal force exerted by the floor on the cylinder. (*b*) Find an expression for the horizontal force exerted by the edge of the step on the cylinder. (*c*) Find an expression for the vertical component of the force exerted by the edge of the step on the cylinder. SSM

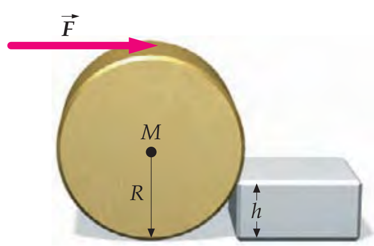

FIGURE 12-37 Problem 25

26 •• For the cylinder in Problem 25, find an expression for the minimum magnitude of the horizontal force $\vec{F}$ that will roll the cylinder over the step if the cylinder does not slide on the edge.

27 •• **CONTEXT-RICH** Figure 12-38 shows a hand holding an epee, a weapon used in the sport of fencing, which you are taking as a physical education elective. The center of mass of your epee is 24 cm from the pommel (the end of the epee at the grip). You have weighed it so you know that the epee's mass is 0.700 kg and its full length is 110 cm. (*a*) At the beginning of a match you hold it straight out in static equilibrium. Find the total force exerted by your hand on the epee. (*b*) Find the torque exerted by your hand on the epee. (*c*) Your hand, being an extended object, actually exerts its force along the length of the epee grip. Model the total force exerted by your hand as two oppositely directed forces whose lines of action are separated by the width of your hand (taken to be 10.0 cm). Find the magnitudes and directions of these two forces.

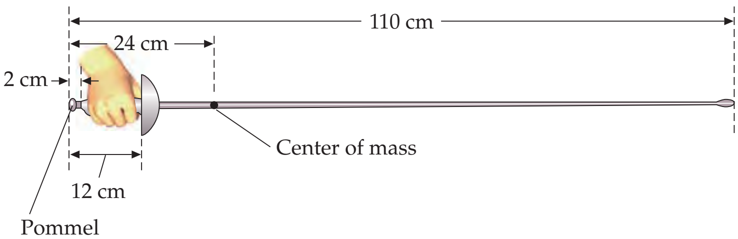

FIGURE 12-38 Problem 27

28 •• A large gate weighing 200 N is supported by hinges at the top and bottom, and is further supported by a wire, as shown in Figure 12-39. (*a*) What must the tension in the wire be for the force on the upper hinge to have no horizontal component? (*b*) What is the horizontal force on the lower hinge? (*c*) What are the vertical forces on the hinges?

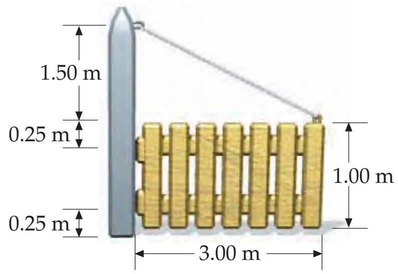

FIGURE 12-39 Problem 28

29 •• **CONTEXT-RICH** On a camping trip, you moor your boat at the end of a dock in a river that is rapidly flowing to the right. The boat is anchored to the dock by a chain 5.0 m long, as shown in Figure 12-40. A 100-N weight is suspended from the center in the chain. This will allow the tension in the chain to change as the force of the current which pulls the boat away from the dock and to the right varies. The drag force by the water on the boat depends on the speed of the water. You decide to apply the principles of statics you learned in physics class. (Ignore the weight of the chain.) The drag force on the boat is 50 N. (*a*) What is the tension in the chain? (*b*) How far is the boat from the dock? (*c*) The maximum tension the chain can sustain is 500 N. What is the minimum drag force on the boat that would snap the chain?

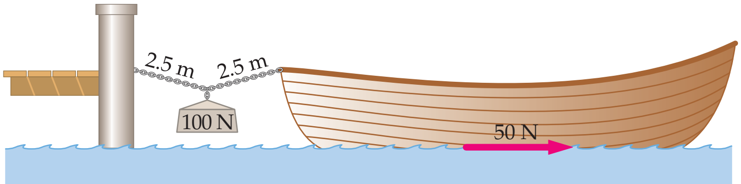

FIGURE 12-40 Problem 29

30 •• Romeo takes a uniform 10-m ladder and leans it against the smooth (frictionless) wall of the Capulet residence. The ladder's mass is 22 kg and the bottom rests on the ground 2.8 m from the wall. When Romeo, whose mass is 70 kg, gets 90 percent of the way to the top, the ladder begins to slip. What is the coefficient of static friction between the ground and the ladder?

31 •• Two 80-N forces are applied to opposite corners of a rectangular plate, as shown in Figure 12-41. (*a*) Find the torque produced by this couple using the Equation 12-6. (*b*) Show that the result is the same as if you determine the torque about the lower left-hand corner. SSM

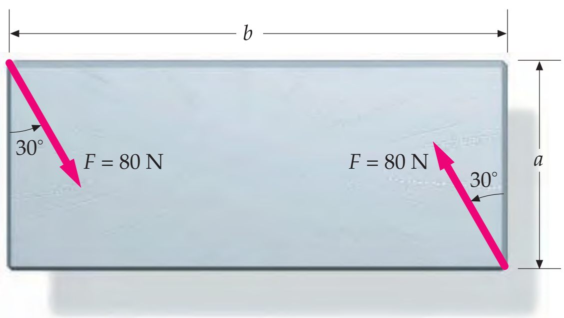

FIGURE 12-41 Problem 31

32 •• A uniform cube of side a and mass M rests on a horizontal surface. A horizontal force $\vec{F}$ is applied to the top of the cube, as in Figure 12-42. This force is not sufficient to move or tip the cube. (*a*) Show that the force of static friction exerted by the surface and the applied force constitute a couple, and find the torque exerted by the couple. (*b*) The torque exerted by the couple is balanced by the torque exerted by the couple consisting of the normal force on the cube and the gravitational force on the cube. Use this fact to find the effective point of application of the normal force when $F = Mg/3$. (*c*) Find the greatest magnitude of $\vec{F}$ for which the cube will not tip. (Assuming the cube does not slip.)

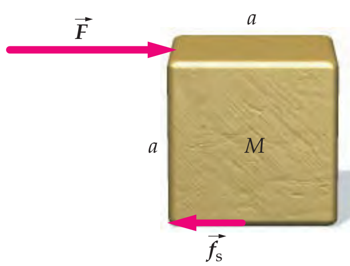

FIGURE 12-42 Problem 32

33 •• A ladder of negligible mass and of length L leans against a slick wall making an angle of θ with the horizontal floor. The coefficient of friction between the ladder and the floor is μ_s. A man climbs the ladder. What height h can he reach before the ladder slips? SSM

34 •• A uniform ladder of length L and mass m leans against a frictionless vertical wall, making an angle of 60° with the horizontal. The coefficient of static friction between the ladder and the ground is 0.45. If your mass is four times that of the ladder, how high can you climb before the ladder begins to slip?

35 •• A ladder of mass m and length L leans against a frictionless vertical wall, so that it makes an angle θ with the horizontal. The center of mass of the ladder is a height h above the floor. A force F directly away from the wall pulls on the ladder at its midpoint. Find the minimum coefficient of static friction μ_s for which the top end of the ladder will separate from the wall before the lower end begins to slip.

36 •• A 900-N man sits on top of a stepladder of negligible mass that rests on a frictionless floor as in Figure 12-43. There is a cross brace halfway up the ladder. The angle at the apex is $\theta = 30°$. (*a*) What is the force exerted by the floor on each leg of the ladder? (*b*) What is the tension in the cross brace? (*c*) If the cross brace is moved down toward the bottom of the ladder (maintaining the same angle θ), will its tension be the same, greater, or less than when it was at its higher position? Explain your answer.

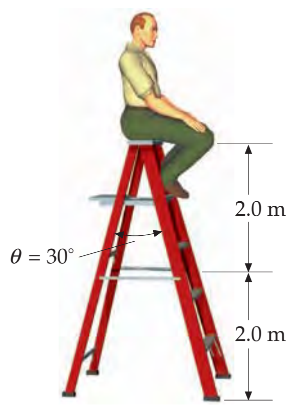

FIGURE 12-43 Problem 36

37 •• A uniform ladder rests against a frictionless vertical wall. The coefficient of static friction between the ladder and the floor is 0.30. What is the smallest angle between the ladder and the horizontal such that the ladder will not slip?

38 ••• A uniform log with a mass of 100 kg, a length of 4.0 m, and a radius of 12 cm is held in an inclined position, as shown in Figure 12-44. The coefficient of static friction between the log and the horizontal surface is 0.60. The log is on the verge of slipping to the right. Find the tension in the support wire and the angle the wire makes with the vertical wall.

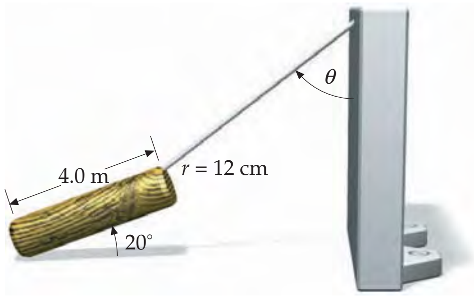

FIGURE 12-44 Problem 38

39 ••• A tall, uniform, rectangular block sits on an inclined plane, as shown in Figure 12-45. A cord attached to the top of the block prevents it from falling down the incline. What is the maximum angle θ for which the block will not slide on the incline? Assume the block has a height-to-width ratio, b/a, of 4.0 and the coefficient of static friction between it and the incline is $\mu_s = 0.80$. SSM

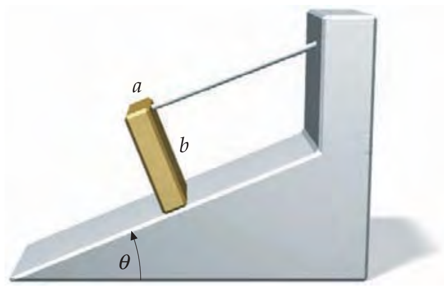

FIGURE 12-45 Problem 39

STRESS AND STRAIN

40 • A 50-kg ball is suspended from a steel wire of length 5.0 m and radius 2.0 mm. By how much does the wire stretch?

41 • Copper has a tensile strength of about $3.0 \times 10^8\ \mathrm{N/m^2}$. (*a*) What is the maximum load that can be hung from a copper wire of diameter 0.42 mm? (*b*) If half this maximum load is hung from the copper wire, by what percentage of its length will it stretch? SSM

42 • A 4.0-kg mass is supported by a steel wire of diameter 0.60 mm and length 1.2 m. How much will the wire stretch under this load?

43 • As a runner's foot pushes off on the ground, the shearing force acting on an 8.0-mm-thick sole is shown in Figure 12-46. If the force of 25 N is distributed over an area of 15 cm², find the angle of shear θ, given that the shear modulus of the sole is $1.9 \times 10^5\ \mathrm{N/m^2}$. SSM

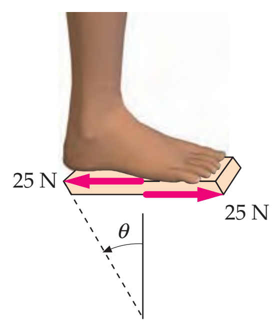

FIGURE 12-46 Problem 43

44 •• A steel wire of length 1.50 m and diameter 1.00 mm is joined to an aluminum wire of identical dimensions to make a composite wire of length 3.00 m. Find the resulting change in length of this composite wire if an object with a mass of 5.00 kg is hung vertically from one of its ends. (Neglect any effects the masses of two wires have on the changes in their lengths.)

45 •• Equal but opposite forces of magnitude F are applied to both ends of a thin wire of length L and cross-sectional area A. Show that if the wire is modeled as a spring, the force constant k is given by $k = AY/L$ and the potential energy stored in the wire is $U = \frac{1}{2}F\Delta L$, where Y is Young's modulus and ΔL is the amount the wire has stretched. SSM

46 •• The steel E string of a violin is under a tension of 53.0 N. The diameter of the string is 0.200 mm and the length under tension is 35.0 cm. Find (*a*) the unstretched length of this string, and (*b*) the work needed to stretch the string.

47 •• **ENGINEERING APPLICATION, SPREADSHEET** During a materials science experiment on the Young's modulus of rubber, the teaching assistant supplies you and your team with a rubber strip that is rectangular in cross section. She tells you to first measure the cross section dimensions, and you find their values are 3.0 mm × 1.5 mm. The lab write-up calls for the rubber strip to be suspended vertically and various (known) masses attached to its lower end. Your team obtains the following data for the length of the strip as a function of the load (mass) suspended from the end of the strip:

Load, kg	0.0	0.10	0.20	0.30	0.40	0.50
Length, cm	5.0	5.6	6.2	6.9	7.8	8.8

(*a*) Use a **spreadsheet** or **graphing calculator** to find Young's modulus for the rubber strip over this range of loads. *Hint: It is probably best to plot F/A versus $\Delta L/L$. Why?*

(*b*) Find the energy stored in the strip when the load is 0.15 kg. (See Problem 45.)

(*c*) Find the energy stored in the strip when the load is 0.30 kg. Is it twice as much as your answer to Part (*b*)? Explain.

48 •• A large mirror is hung from a nail, as shown in Figure 12-47. The supporting steel wire has a diameter of 0.20 mm and an unstretched length of 1.7 m. The distance between the points of support at the top of the mirror's frame is 1.5 m. The mass of the mirror is 2.4 kg. How much will the distance between the nail and the mirror increase due to the stretching of the wire as the mirror is hung?

FIGURE 12-47 Problem 48

49 •• Two masses, M_1 and M_2, are supported by wires that have equal lengths when unstretched. The wire supporting M_1 is an aluminum wire 0.70 mm in diameter, and the one supporting M_2 is a steel wire 0.50 mm in diameter. What is the ratio M_1/M_2 if the two wires stretch by the same amount?

50 •• A 0.50-kg ball is attached to one end of an aluminum wire that has a diameter of 1.6 mm and an unstretched length of 0.70 m. The other end of the wire is fixed to the top of a post. The ball rotates about the post in a horizontal plane at a rotational speed such that the angle between the wire and the horizontal is 5.0°. Find the tension in the wire and the increase in its length due to the tension in the wire.

51 •• An elevator cable is to be made of a new type of composite developed by Acme Laboratories. In the lab, a sample of the cable that is 2.00 m long and has a cross-sectional area of 0.200 mm² fails under a load of 1000 N. The actual cable used to support the elevator will be 20.0 m long and have a cross-sectional area of 1.20 mm². It will need to support a load of 20,000 N safely. Will it? SSM

52 •• If a material's density remains constant when it is stretched in one direction, then (because its total volume remains constant), its length must decrease in one or both of the other directions. Take a rectangular block of length x, width y, and depth z, and pull on it so that its new length $x' = x + \Delta x$. If $\Delta x \ll x$ and $\Delta y/y = \Delta z/z$, show that $\Delta y/y = -\frac{1}{2}\Delta x/x$.

53 •• You are given a wire with a circular cross section of radius r and a length L. If the wire is made from a material whose density remains constant when it is stretched in one direction, then show that $\Delta r/r = -\frac{1}{2}\Delta L/L$, assuming that $\Delta L \ll L$. (See Problem 52.) SSM

54 ••• For most materials listed in Table 12-1, the tensile strength is two to three orders of magnitude lower than Young's modulus. Consequently, most of these materials will break before their strain exceeds 1 percent. Of man-made materials, nylon has about the greatest extensibility—it can take strains of about 0.2 before breaking. But spider silk beats anything man-made. Certain forms of spider silk can take strains on the order of 10 before breaking! (*a*) If such a thread has a circular cross-section of radius r_0 and unstretched length L_0, find its new radius r when stretched to a length $L = 10L_0$. (Assume that the density of the thread remains constant as it stretches.) (*b*) If the Young's modulus of the spider thread is Y, calculate the tension needed to break the thread in terms of Y and r_0.

GENERAL PROBLEMS

55 • **BIOLOGICAL APPLICATION** A standard bowling ball weighs 16 pounds. You wish to hold a bowling ball in front of you, with your elbow bent at a right angle. Assume that your biceps attaches to your forearm at 2.5 cm out from the elbow joint, and that your biceps muscle pulls vertically upward, that is, it acts at right angles to the forearm. Also assume that the ball is held 38 cm out from the elbow joint. Let the mass of your forearm be 5.0 kg and assume its center of gravity is located 19 cm out from the elbow joint. How much force must your biceps muscle apply to the forearm in order to hold out the bowling ball at desired angle? SSM

56 •• **BIOLOGICAL APPLICATION, CONTEXT-RICH** A biology laboratory at your university is studying the location of a person's center of gravity as a function of her or his body weight. They pay well and you decide to volunteer. The location of your center of gravity when standing erect is to be determined by having you lie on a uniform board (mass of 5.00 kg, length 2.00 m) supported by two scales, as shown in Figure 12-48. If your height is 188 cm and the left scale reads 445 N while the right scale reads 400 N, where is your center of gravity relative to your feet? Assume the scales are both exactly the same distance from the two ends of the board, are separated by 178 cm, and are set to each read zero before you get on the platform.

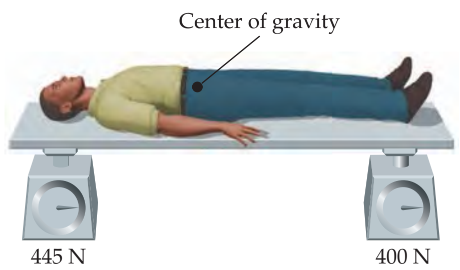

FIGURE 12-48 Problem 56

57 •• Figure 12-49 shows a mobile consisting of four objects hanging on three rods of negligible mass. Find the values of the unknown masses of the objects if the mobile is to balance. *Hint: Find the mass m_1 first.*

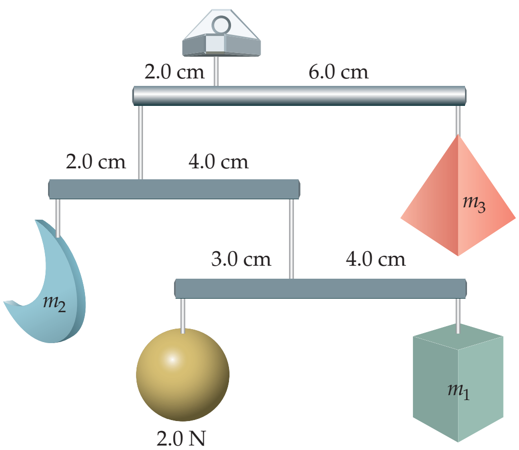

FIGURE 12-49 Problem 57

58 •• ENGINEERING APPLICATION, CONTEXT-RICH Steel construction beams, with an industry designation of "W12 × 22," have a weight of 22 pounds per foot. A new business in town has hired you to place its sign on a 4.0 m long steel beam of this type. The design calls for the beam to extend outward horizontally from the front brick wall (Figure 12-50). It is to be held in place by a 5.0-m-long steel cable. The cable is attached to one end of the beam and to the wall above the point at which the beam is in contact with the wall. During an initial stage of construction, the beam is *not* to be bolted to the wall, but to be held in place solely by friction. (*a*) What is the minimum coefficient of friction between the beam and the wall for the beam to remain in static equilibrium? (*b*) What is the tension in the cable in this case?

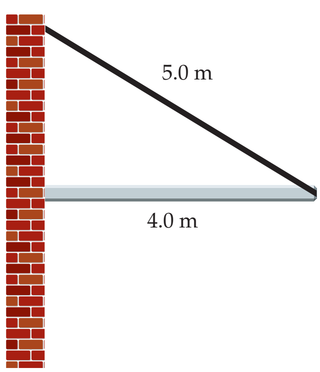

FIGURE 12-50 Problem 58

59 ••• Consider a rigid 2.5-m-long beam (Figure 12-51) that is supported by a fixed 1.25-m-high post through its center and pivots on a frictionless bearing at its center atop the vertical 1.25-m-high post. One end of the beam is connected to the floor by a spring that has a force constant $k = 1250$ N/m. When the beam is horizontal, the spring is vertical and unstressed. If an object is hung from the opposite end of the beam, the beam settles into an equilibrium position where it makes an angle of 17.5° with the horizontal. What is the mass of the object? SSM

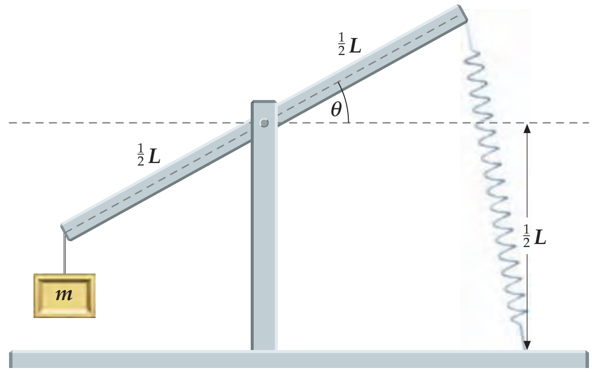

FIGURE 12-51 Problem 59

60 •• A rope and pulley system, called a *block and tackle*, is used to raise an object of mass M (Figure 12-52) at constant speed. When the end of the rope moves downward through a distance L, the height of the lower pulley is increased by h. (*a*) What is the ratio L/h? (*b*) Assume that the mass of the block and tackle is negligible and that the pulley bearings are frictionless. Show that $FL = Mgh$ by applying the work–energy principle to the block–tackle object.

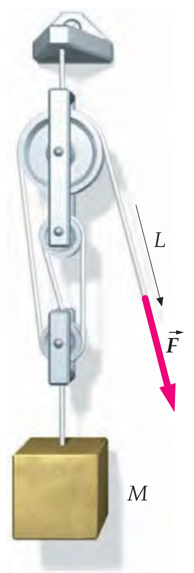

FIGURE 12-52 Problem 60

61 •• A plate of mass M in the shape of an equilateral triangle is suspended from one of its corners, and a mass m is suspended from another of its corners. If the base of the triangle makes an angle of 6.0° with the horizontal, what is the ratio m/M?

62 •• A standard six-sided pencil is placed on a notebook (Figure 12-53). Find the minimum coefficient of static friction μ_s such that, if the upper cover is raised, the pencil rolls down the incline rather than sliding.

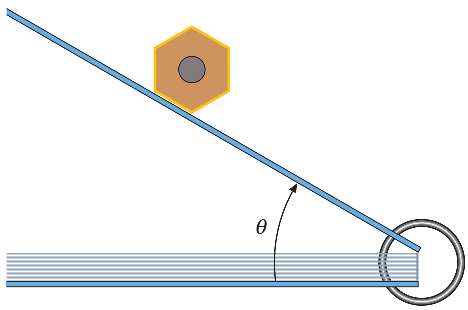

FIGURE 12-53 Problem 62

63 •• An 8.0-kg box that has a uniform density and is twice as tall as it is wide rests on the floor of a truck. What is the maximum coefficient of static friction between the box and floor so that the box will slide toward the rear of the truck rather than tip when the truck accelerates forward on a level road?

64 •• A balance scale has unequal arms. The scale is balanced with a 1.50-kg block on the left pan and a 1.95 kg block on the right pan (Figure 12-54). If the 1.95-kg block is removed from the right pan and the 1.50-kg block is then moved to the right pan, what mass on the left pan will balance the scale?

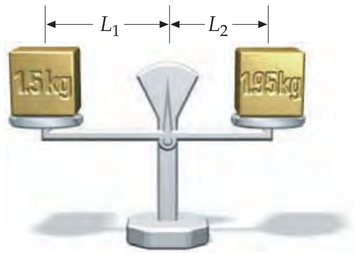

FIGURE 12-54 Problem 64

65 •• A cube leans against a frictionless wall, making an angle of θ with the floor, as shown in Figure 12-55. Find the minimum coefficient of static friction μ_s between the cube and the floor that is needed to prevent the cube from slipping. SSM

FIGURE 12-55 Problem 65

66 •• Figure 12-56 shows a 5.00-kg 1.00-m-long rod hinged to a vertical wall and supported by a thin wire. The wire and rod each make angles of 45° with the vertical. When a 10.0-kg block is suspended from the midpoint of the rod, the tension T in the supporting wire is 52.0 N. If the wire will break when the tension exceeds 75 N, what is the maximum distance from the hinge at which the block can be suspended?

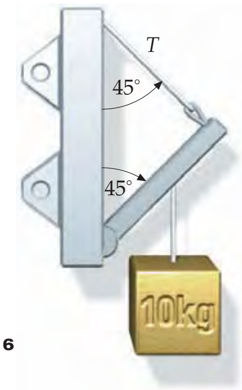

FIGURE 12-56
Problem 66

67 •• Figure 12-57 shows a 20.0-kg ladder leaning against a frictionless wall and resting on a frictionless horizontal surface. To keep the ladder from slipping, the bottom of the ladder is tied to the wall by a thin wire. When no one is on the ladder, the tension in the wire is 29.4 N. (The wire will break if the tension exceeds 200 N.) (*a*) If an 80.0-kg person climbs halfway up the ladder, what force will be exerted by the ladder against the wall? (*b*) How far from the bottom end of the ladder can an 80.0-kg person climb? SSM

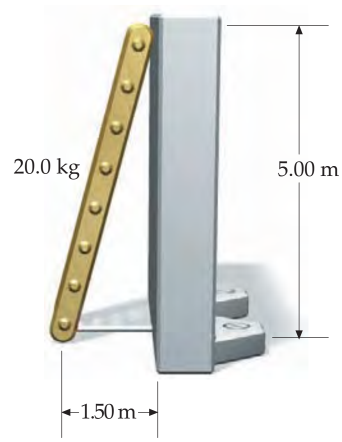

FIGURE 12-57
Problem 67

68 •• A 360-kg object is supported on a wire attached to a 15-m-long steel bar that is pivoted at a vertical wall and supported by a cable as shown in Figure 12-58. The mass of the bar is 85 kg. With the cable attached to the bar 5.0 m from the lower end, as shown, what are the tension in the cable and the force exerted by the wall on the steel bar?

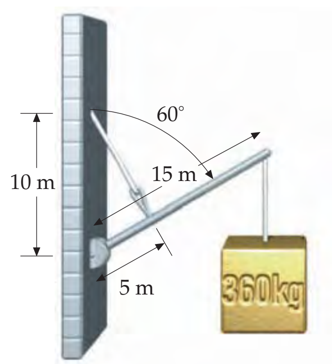

FIGURE 12-58
Problem 68

69 •• Repeat Problem 63 if the truck accelerates up a hill that makes an angle of 9.0° with the horizontal.

70 •• A thin uniform rod 60 cm long is balanced 20 cm from one end when an object whose mass is ($2m + 2.0$ grams) is at the end nearest the pivot and an object of mass m is at the opposite end (Figure 12-59*a*). Balance is again achieved if the object whose mass is ($2m + 2.0$ grams) is replaced by the object of mass m and no object is placed at the other end of the rod (Figure 12-59*b*). Determine the mass of the rod.

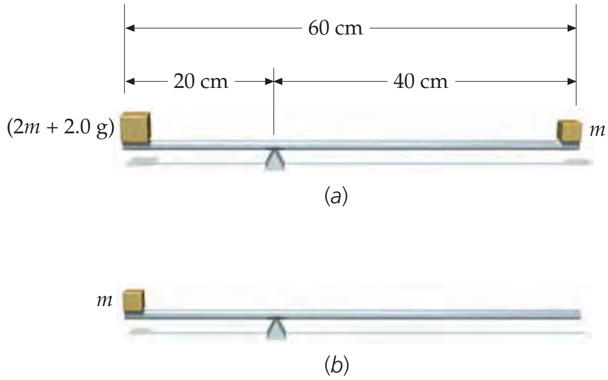

FIGURE 12-59 Problem 70

71 ••• **SPREADSHEET** There are a large number of identical uniform bricks, each of length L. If they are stacked one on top of another lengthwise (see Figure 12-60), the maximum offset that will allow the top brick to rest on the bottom brick is $L/2$. (*a*) Show that if this two-brick stack is placed on top of a third brick, the maximum offset of the second brick on the third brick is $L/4$. (*b*) Show that, in general, if you have a stack of N bricks, the maximum offset of the $(n-1)$th brick (counting down from the top) on the nth brick is L/n. (*c*) Write a **spreadsheet** program to calculate total offset (the sum of the individual offsets) for a stack of N bricks, and calculate this for $L = 20$ cm and $N = 5, 10,$ and 100. (*d*) Does the sum of the individual offsets approach a finite limit as $N \to \infty$? If so, what is that limit? SSM

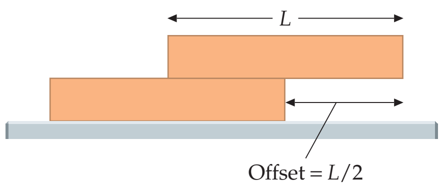

FIGURE 12-60 Problem 71

72 •• A uniform sphere of radius R and mass M is held at rest on an inclined plane of angle θ by a horizontal string, as shown in Figure 12-61. Let $R = 20$ cm, $M = 3.0$ kg, and $\theta = 30°$. (*a*) What is the tension in the string? (*b*) What is the normal force exerted on the sphere by the inclined plane? (*c*) What is the frictional force acting on the sphere?

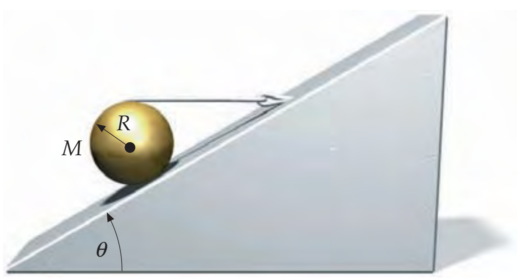

FIGURE 12-61 Problem 72

73 ••• The legs of a tripod make equal angles of 90° with each other at the apex, where they join together. A 100-kg block hangs from the apex. What are the compressional forces in the three legs?

74 ••• Figure 12-62 shows a 20-cm-long uniform beam resting on a cylinder that has a radius of 4.0-cm. The mass of the beam is 5.0 kg, and that of the cylinder is 8.0 kg. The coefficient of static friction between beam and cylinder is zero, whereas the coefficients of static friction between the cylinder and the floor, and between the beam and the floor, are *not* zero. Are there any values for these coefficients of static friction such that the system is in static equilibrium? If so, what are these values? If not, explain why none exist.

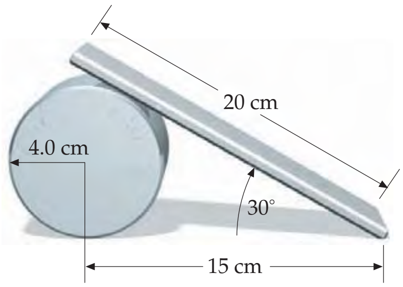

FIGURE 12-62 Problem 74

75 ••• Two solid smooth (frictionless) spheres of radius r are placed inside a cylinder of radius R, as in Figure 12-63. The mass of each sphere is m. Find the force exerted by the bottom of the cylinder on the bottom sphere, the force exerted by the wall of the cylinder on each sphere, and the force exerted by one sphere on the other. Express all forces in terms of m, R, and r. SSM

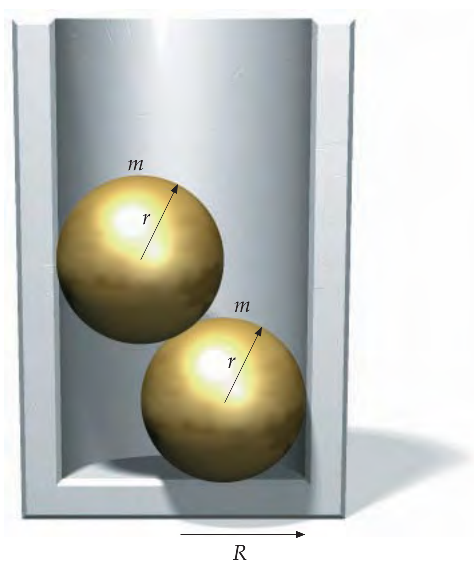

FIGURE 12-63 Problem 75

76 ••• A solid cube of edge-length a balanced atop a cylinder of diameter d is in unstable equilibrium if $d \ll a$ (Figure 12-64), and is in stable equilibrium if $d \gg a$. The cube does not slip on the cylinder. Determine the minimum value of the ratio d/a for which the cube is in stable equilibrium.

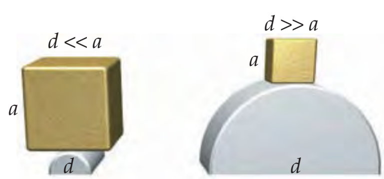

FIGURE 12-64 Problem 76

CHAPTER 13

CANAL BOATS IN SCOTLAND ARE ABLE TO TRAVEL BETWEEN THE FORTH & CLYDE CANAL AND THE UNION CANAL THANKS TO THE FALKIRK WHEEL. EACH OF THE TWO GONDOLAS OF THE WHEEL LIFTS 300 METRIC TONS [ONE METRIC TON (1 TONNE) IS EQUAL TO 1000 kg] OF WATER AND MAY ACCOMMODATE UP TO FOUR 20-m-LONG BOATS AT ANY ONE TIME. A VERY SMALL TORQUE AND A VERY SMALL AMOUNT OF ENERGY ARE REQUIRED TO ROTATE THIS MASSIVE WHEEL. *(Powered by Light/Alan Spencer/Alamy.)*

Fluids

Consider the air that fills our lungs, the blood that flows through our bodies, and even the rain that falls on us as we hurry to and from class. Air, blood, and rainwater are all fluids. It may seem odd to think of air as a fluid, but fluids include both liquids and gases. Liquids flow until they occupy the lowest possible regions of the space in which they are contained, be it a plastic bottle, a lock in a canal, or behind a dam. Unlike liquids, gases expand to fill their containers. To better understand fluid behavior is to better understand much about our own bodies and our interactions with the world around us.

Civil engineers employ their knowledge of fluids to design dams, which are thicker at the bottom than at the top. Automotive and aerospace engineers use wind tunnels to observe the flow of air around cars and aircraft to help them evaluate the aerodynamic aspects of particular vehicles. Blood-pressure gauges are used by medical professionals to measure the pressure of our blood.

We begin this chapter by studying fluids at rest, taking into account the density of and the pressure in fluids, as well as buoyancy and Archimedes' principle. Then, we study steady-state flow while emphasizing laminar flow.

? Why does it not require a large torque and a large amount of energy to rotate such a massive wheel? (See Example 13-8.)

13-1 DENSITY

In a gas, the average distance between two molecules is large compared with the size of a molecule. The molecules have little influence on one another except during their brief collisions. In a liquid or solid, the molecules are close together and exert forces on one another that are comparable to the forces that bind atoms into molecules. Molecules in a liquid form temporary short-range bonds that are continually broken and reformed due to the proximity of the molecules as they bump into each other. These bonds hold the liquid together; if the bonds were not present, the liquid would immediately evaporate and the molecules would escape as a vapor. The strength of the bonds in a liquid depends on the type of molecule that makes up the liquid. For example, the bonds between helium molecules are very weak and, for this reason, helium does not liquefy at atmospheric pressure unless the temperature is 4.2 K or lower. The ratio of the mass of an object to its volume is called its *average density*:

$$\text{Average density} = \frac{\text{Mass}}{\text{Volume}}$$

DEFINITION—AVERAGE DENSITY

If the mass of substance within a small element of volume dV is dm, then the density of the substance at the location of the volume element is

$$\rho = \frac{dm}{dV} \qquad 13\text{-}1$$

DEFINITION—DENSITY

where ρ (the lowercase Greek letter rho) is used to denote density. Because the gram was originally defined as the mass of one cubic centimeter of liquid water, the density of liquid water in cgs (centimeter–gram–second) units is 1 g/cm^3. Converting to SI units, we obtain for the density of water

$$\rho_{\rm w} = \frac{1\ \text{g}}{\text{cm}^3} \times \frac{\text{kg}}{10^3\ \text{g}} \times \left(\frac{100\ \text{cm}}{1\ \text{m}}\right)^3 = 1000\ \text{kg/m}^3 \qquad 13\text{-}2$$

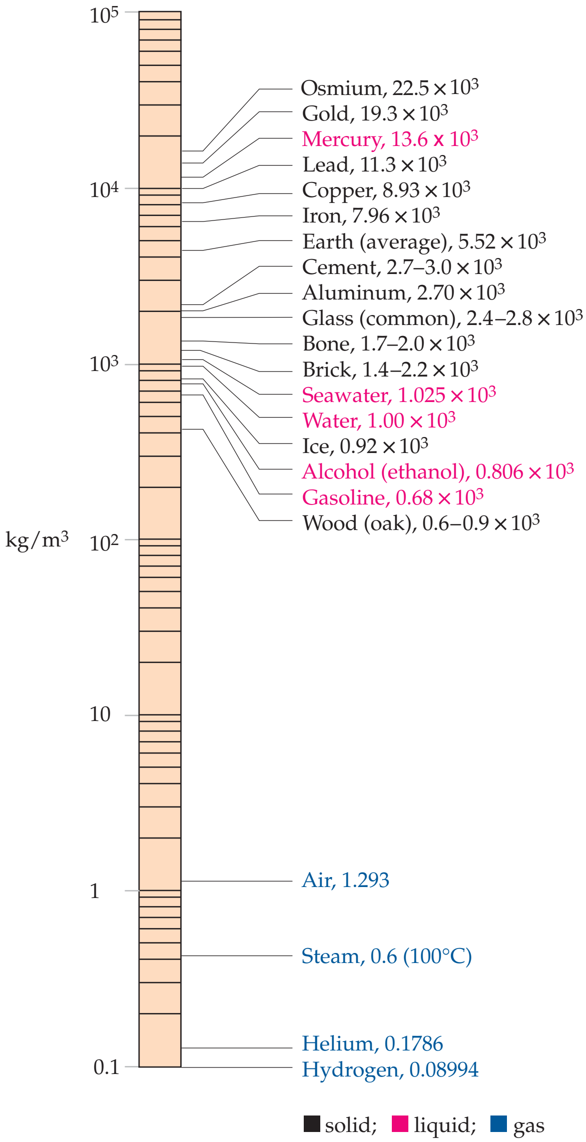
Precise measurements of density must take temperature into account, because the densities of most solids and liquids, including water, vary with temperature. Equation 13-2 gives the maximum value for the density of water, which occurs at 4°C. Table 13-1 lists the densities of some common substances.

A convenient unit of volume for fluids is the **liter** (L):

$$1\ \text{L} = 10^3\ \text{cm}^3 = 10^{-3}\ \text{m}^3$$

In terms of this unit, the density of water at 4°C is 1.00 kg/L = 1.00 g/mL. When the average density of a solid object is greater than that of water, it sinks in water, and when a solid object's average density is less than the density of water, it floats. The ratio of the density of a substance to that of a reference substance, usually water, is its **specific gravity.** For example, the specific gravity of aluminum is 2.7, meaning that a volume of aluminum has 2.7 times the mass of an equal volume of water.

Table 13-1 Densities of Selected Substances



The density values exceed five orders of magnitude.

The specific gravities of objects that sink when submerged in water range from 1 to about 22.5 (for the densest element, osmium).

Most solids and liquids expand only slightly when heated, and contract only slightly when subjected to an increase in external pressure. Because these changes in volume are relatively small, we often treat the densities of solids and liquids as approximately independent of temperature and pressure. The density of a gas, on the other hand, depends strongly on the pressure and temperature, so these variables must be specified when reporting the densities of gases. By convention, the standard conditions for the measurement of physical properties are atmospheric pressure at sea level and a temperature of 0°C. The densities for the substances listed in Table 13-1 are for these conditions. Note that the densities of liquids and solids are considerably greater than those of gases. For example, the density of liquid water is about 800 times that of air under standard conditions.

Example 13-1 Calculating Density

A flask is filled to the brim with 200-mL of water at 4.0°C. When the flask is heated to 80.0°C, 6.0 g of water spill out. What is the density of water at 80°C? (Assume that the expansion of the flask is negligible.)

PICTURE The density of water at 80°C is $\rho' = m'/V$, where $V = 0.200\text{ L} = 200\text{ cm}^3$ is the volume of the flask, and m' is the mass remaining in the flask after 6.0 g spill out. We find m' by first finding the mass of water originally in the flask.

SOLVE

1. Let ρ' be the density of water at 80°C and let m' be the mass of the water remaining in the flask of volume $V = 200$ mL. Relate ρ' to m' using the definition of density: $\rho' = \dfrac{m'}{V}$
2. Calculate the original mass m of water in the flask at 4.0°C using $\rho = 1.00$ kg/L and the definition of density: $m = \rho V = (1.00\text{ kg/L})(0.200\text{ L}) = 0.200\text{ kg}$
3. Calculate the mass of water remaining after 6 g spill out: $m' = m - 6\text{ g} = 0.200\text{ kg} - 0.006\text{ kg} = 0.194\text{ kg}$
4. Use this value of m' to find the density of water at 80°C: $\rho' = \dfrac{m'}{V} = \dfrac{0.194\text{ kg}}{0.200\text{ L}} = \boxed{0.970\text{ kg/L}}$

CHECK The density of water at 4.0°C is 1.00 kg/L. The density of water is greatest at 4.0°C so we expect the density of water at 80°C to be less than 1.00 kg/L. Our step-3 result confirms this expectation.

PRACTICE PROBLEM 13-1 A solid metal cube 8.00 cm on an edge has a mass of 4.08 kg. (*a*) What is the average density of the cube? (*b*) If the cube is made from a single element listed in Table 13-1, what is the element?

PRACTICE PROBLEM 13-2 A gold brick is 5.0 cm × 10 cm × 20 cm. What is its mass?

13-2 PRESSURE IN A FLUID

When a fluid such as water is in contact with a solid surface, the fluid exerts a force normal (perpendicular) to the surface at each point on the surface. The force per unit area is called the **pressure** P of the fluid:

$$P = \frac{F}{A} \tag{13-3}$$

DEFINITION—PRESSURE

The SI unit of pressure is the newton per square meter (N/m^2), which is called the **pascal** (Pa):

$$1 \text{ Pa} = 1 \text{ N/m}^2 \qquad 13\text{-}4$$

In the U.S. customary system, pressure is usually given in pounds per square inch (lb/in^2). Another common unit of pressure is the atmosphere (atm), which approximately equals the air pressure at sea level. One atmosphere is defined as exactly 101.325 kilopascals (kPa), which is about 14.70 lb/in^2:

$$1 \text{ atm} = 101.325 \text{ kPa} \approx 14.70 \text{ lb/in}^2 \qquad 13\text{-}5$$

Other units of pressure in common use are discussed later in this chapter.

If the pressure on an object increases, the ratio of the increase in pressure, ΔP, to the fractional decrease in volume, $(-\Delta V/V)$, is called the **bulk modulus:**

$$B = -\frac{\Delta P}{\Delta V/V} \qquad 13\text{-}6$$

DEFINITION—BULK MODULUS

Like other elastic moduli (Young's modulus and shear modulus were introduced in Section 12-7), bulk modulus is a ratio of stress to strain, with ΔP the stress and $-\Delta V/V$ the strain. (All stable materials decrease in volume when subjected to an increase in external pressure. Thus, the negative sign in Equation 13-6 means that B is always positive.)

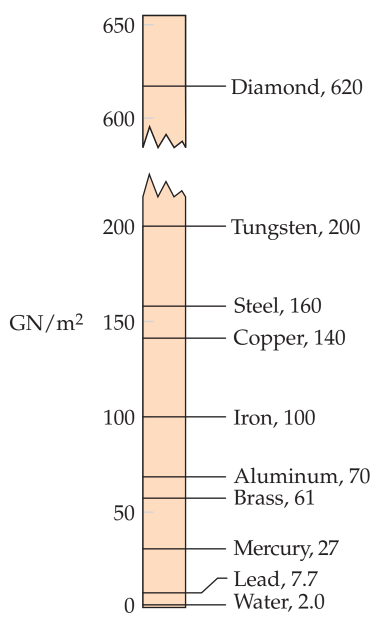
The more difficult it is to compress a material, the smaller is the fractional volume decrease $-\Delta V/V$ for a given pressure increase ΔP, and hence the greater the bulk modulus. The **compressibility** is the reciprocal of the bulk modulus. (The easier it is to compress a material, the larger the compressibility.) Liquids, gases, and solids all have a bulk modulus. Because liquids and solids are relatively incompressible, they have large values of B, and these values are relatively independent of temperature and pressure. Gases, on the other hand, are easily compressed, and their values for B depend strongly on pressure and temperature. Table 13-2 charts values for the bulk modulus of various materials.

As any scuba diver knows, the pressure in a lake or ocean increases with depth. Similarly, the pressure of the atmosphere decreases with altitude. For a liquid, whose density is approximately constant throughout, the pressure increases linearly with depth. We can see this by considering a column of liquid of cross-sectional area A, as shown in Figure 13-1. To support the weight of the liquid in the column of height Δh, the pressure at the bottom of the column must be greater than the pressure at the top. The weight of the liquid in the column is

$$F_g = mg = (\rho V)g = \rho A\,\Delta h g$$

where ρ and V are the density and volume of the liquid. If P_0 is the pressure at the top and P is the pressure at

Table 13-2 Approximate Values for the Bulk Modulus B of Various Materials



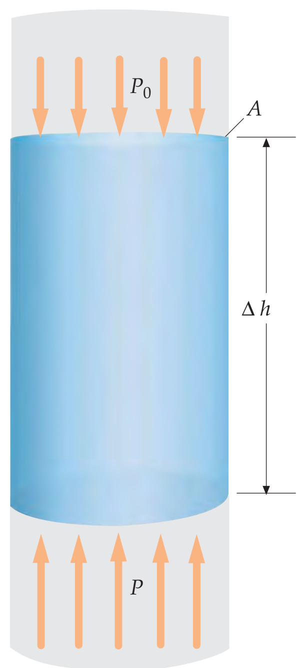


FIGURE 13-1

! Force is a vector quantity, but pressure is a scalar quantity. (Pressure is the magnitude of the force per unit area.)

the bottom, the net upward force exerted by this pressure difference is $PA - P_0A$. Setting this net upward force equal to the weight of the column, we obtain

$$PA - P_0A = (\rho A\,\Delta h g)$$

or

$$P = P_0 + \rho g\,\Delta h \quad (\rho \text{ constant}) \qquad 13\text{-}7$$

PRACTICE PROBLEM 13-3
How far below the surface of a lake is a scuba diver if the pressure is equal to 2.00 atm? (The pressure at the surface is 1.00 atm.)

(Corbis.)

Example 13-2 Force on a Dam

A rectangular dam 30 m wide supports a body of water to a depth of 25 m. Find the total horizontal force on the dam due to both water and air pressure.

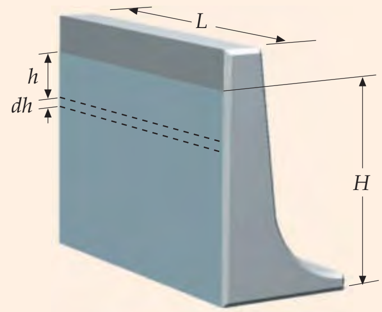

FIGURE 13-2

PICTURE Because the pressure varies with depth, we cannot merely multiply the pressure times the area of the dam to find the force exerted by the water. Instead we can consider the force exerted on a strip of surface of length $L = 30$ m, height dh, and area $dA = L\,dh$ at a depth h (Figure 13-2), and then integrate from $h = 0$ to $h = H = 25$ m. The water pressure at depth h is $P_{at} + \rho gh$, where P_{at} is the atmospheric pressure. Neglect any variation in air pressure over the 25-m height of the dam.

SOLVE

1. Express the force dF of the water on the element of length L and height dh in terms of the pressure $P_{at} + \rho hg$ on the dam by the water:

$$dF = P\,dA = (P_{at} + \rho gh)L\,dh$$

2. Integrate from $h = 0$ to $h = H$ to find the horizontal component of the force of the water on the dam:

$$F = \int_{h=0}^{h=H} dF = \int_0^H (P_{at} + \rho gh)L\,dh$$
$$= P_{at}LH + \frac{1}{2}\rho gLH^2$$

3. The downstream surface of the dam is not vertical. Sketch an edge-on view (Figure 13-3) of a horizontal strip across the downstream side of the surface, a strip of length L and width ds. Let dh be the height of the strip:

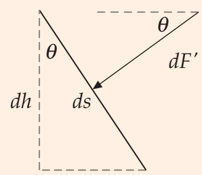

FIGURE 13-3

4. Relate the force dF' exerted on this strip by the air to the pressure of the air and the area of the strip:

$$dF' = P_{at}\,dA = P_{at}L\,ds$$

5. Express the horizontal component of dF'_x in terms of dh:

$$dF'_x = dF\cos\theta = P_{at}L\,ds\cos\theta = P_{at}L\,dh$$

6. Integrate from $h = 0$ to $h = H$ to find the horizontal component of the force of the air on the downstream side of the dam:

$$F' = \int_{h=0}^{h=H} dF' = \int_0^H P_{at}L\,dh = P_{at}LH$$

7. The net horizontal force on the dam is $F - F'_x$:

$$F - F'_x = (P_{at}LH + \tfrac{1}{2}\rho gLH^2) - P_{at}LH = \tfrac{1}{2}\rho gLH^2$$
$$= \tfrac{1}{2}(1000\text{ kg/m}^3)(9.81\text{ N/kg})(30\text{ m})(25\text{ m})^2$$
$$= 9.20 \times 10^7\text{ N} = \boxed{9.2 \times 10^7\text{ N}}$$

CHECK The net horizontal force on the dam is independent of air pressure, as expected. This is as expected because the pressure of the air on the surface of the water increases the pressure throughout the water by one atmosphere, and the air presses on the downstream side of the dam a pressure of one atmosphere.

TAKING IT FURTHER Dams typically are thicker at the bottom than at the top because the pressure on the dam increases with the depth of the water.

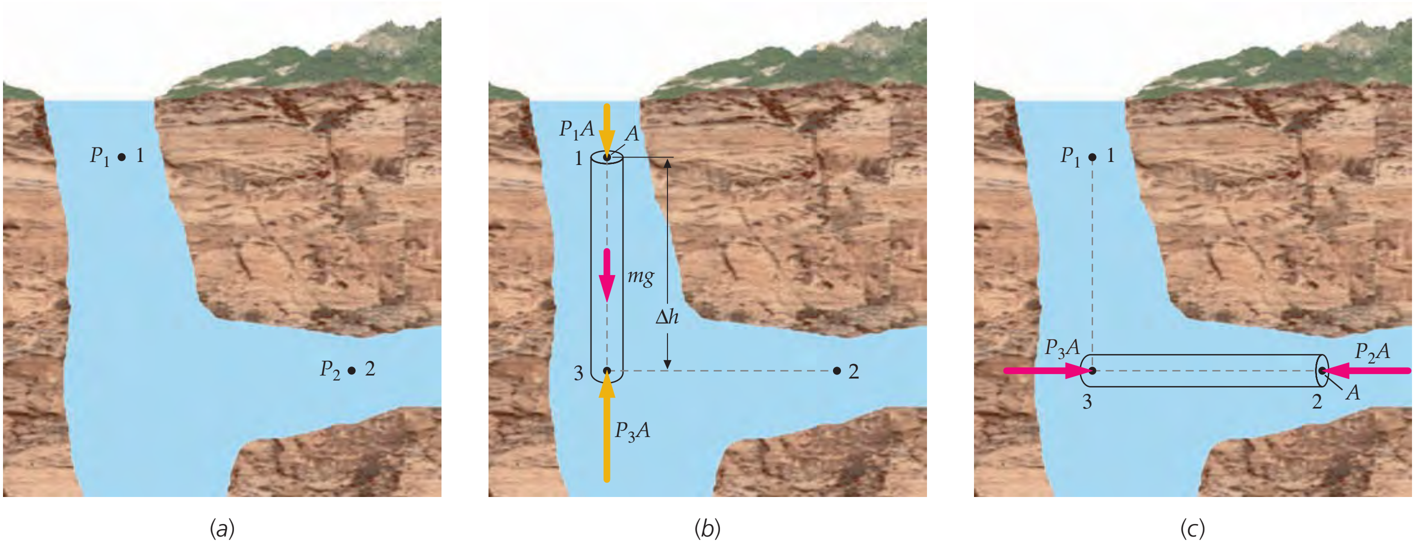

FIGURE 13-4

The result that the pressure increases linearly with depth holds for a liquid in any container, independent of the shape of the container. Furthermore, the pressure is the same at all points at the same depth. We can see this by comparing the pressure at point 1 in Figure 13-4*a* with the pressure at point 2, which is inside an underwater cave. First, we compare the pressure at points 1 and 3, where point 3 is a point directly below 1 at the same depth as point 2 (Figure 13-4*b*). Consider the vertical forces on the vertical column of water of height Δh and cross-sectional area A between points 1 and 3. The upward force on the column, P_3A, balances the two downward forces P_1A and mg, where $m = \rho A\,\Delta h$ is the mass of the water in the column ($A\,\Delta h$ is the volume of the column). That is, $P_3A = P_1A + (\rho A\,\Delta h g)$. Dividing both sides by A gives

$$P_3 = P_1 + \rho g\,\Delta h$$

Next consider the forces on the horizontal cylinder of water, also of cross-sectional area A, connecting points 2 and 3 (Figure 13-4*c*). There are two forces with components along the cylinder's axis, P_3A and P_2A. The fact that these forces balance each other means that $P_3 = P_2$. It follows that

$$P_2 = P_1 + \rho g\,\Delta h$$

If we increase the pressure in a container of water by pressing down on the top surface with a piston, the increase in pressure is the same throughout the liquid. This holds for both liquids and gasses and is known as **Pascal's principle,** named after Blaise Pascal (1623–1662):

> A pressure change applied to a confined fluid is transmitted undiminished to every point in the fluid and to the walls of the container.
>
> PASCAL'S PRINCIPLE

A common application of Pascal's principle is the hydraulic lift shown in Figure 13-5.

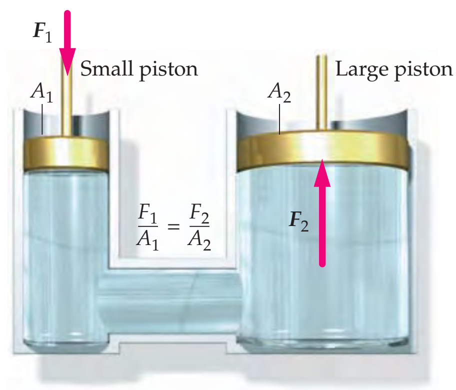

FIGURE 13-5 Hydraulic lift. A small force F_1 on the small piston produces an increase in pressure F_1/A_1 that is transmitted by the liquid to the large piston. Because the pressure changes are the same throughout the fluid, the forces exerted on the pistons are related by $F_2/A_2 = F_1/A_1$. Because the area of the large piston is much greater than that of the small piston, the force on the large piston $F_2 = (A_2/A_1)F_1$ is much greater than F_1.

Example 13-3 A Hydraulic Lift

The large piston in a hydraulic lift has a radius of 20 cm. What force must be applied to the small piston of radius 2.0 cm to raise a car of mass 1500 kg?

PICTURE The pressure P times the area A_2 of the large piston must equal the weight mg of the car. The force F_1 that must be exerted on the small piston is this pressure times the area A_1 (Figure 13-5).

SOLVE

1. The force F_1 is the pressure P times the area A_1: $F_1 = PA_1$

2. The pressure P times the area A_2 equals the weight of the car: $PA_2 = mg$ so $P = \frac{mg}{A_2}$

3. Substitute this result for P into the step-1 result and calculate F_1:

$$F_1 = PA_1 = \frac{mg}{A_2}A_1 = mg\frac{A_1}{A_2} = mg\frac{\pi r_1^2}{\pi r_2^2}$$
$$= (1500\text{ kg})(9.81\text{ N/kg})\left(\frac{2.0\text{ cm}}{20\text{ cm}}\right)^2$$
$$= 147\text{ N} = \boxed{150\text{ N}}$$

CHECK The radii differ by a factor of 10, so the areas differ by a factor of $10^2 = 100$. Thus, the forces also differ by a factor of 100.

Figure 13-6 shows water in a container that has sections of different shapes. At first glance, it might seem that the pressure at the bottom of section 3, the section containing the most water, would be greatest and that water would therefore be forced to a greater height in section 2, which is the section with the least water. But that is not observed, a result known as the **hydrostatic paradox.** The pressure depends only on the depth of the water, not on the shape of the container, so at the same depth the pressure is the same in all parts of the container, a finding that can be shown experimentally. Although the water in section 4 of the container weighs more than that in section 2, the portion of the water in section 4 that is not above the opening at the bottom is supported by the horizontal shelf of the section. In fact, the water above the opening at the bottom of section 5 weighs less than the water above an opening of the same size at the bottom of section 1. However, the horizontal shelf of section 5 exerts a downward force on the water—exactly compensating for the shortfall of weight.

! Pressure depends only on the depth of the water, not on the shape of a container. So the pressure is the same for all parts of the container that are at the same depth.

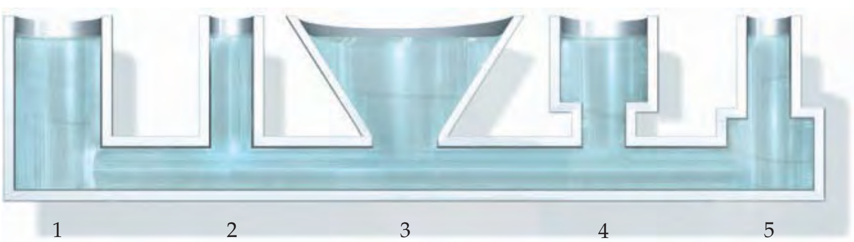

FIGURE 13-6 The hydrostatic paradox. The water level is the same regardless of the shape of the vessel. The weight of those portions of the water not above an opening is supported by the sides of the containers.

We can use the fact that the pressure increases linearly with the depth of a liquid to measure unknown pressures. Figure 13-7 shows a simple pressure gauge, the open-tube manometer. The top of the tube is open to the atmosphere at pressure P_{at}. The other end of the tube is at pressure P, which is to be measured. The difference $P - P_{at}$, called the **gauge pressure** P_{gauge}, is equal to ρgh, where ρ is the density of the liquid in the tube. The pressure you measure in your automobile tire is gauge pressure. When the tire is entirely flat, the gauge pressure is zero, and the absolute pressure of the air remaining in the tire is atmospheric pressure. The absolute pressure P is obtained from the gauge pressure by adding atmospheric pressure to it:

$$P = P_{gauge} + P_{at} \qquad 13\text{-}8$$

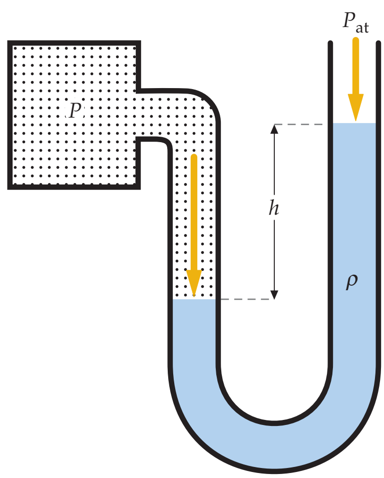

FIGURE 13-7 Open-tube manometer for measuring an unknown pressure P. The difference $P - P_{at}$ equals ρgh.

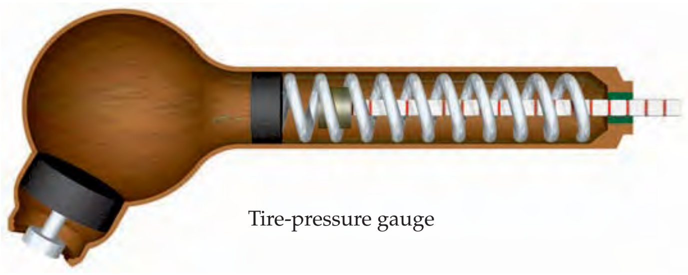

Tire-pressure gauge. The piston pushes the rod to the right until the force of the spring plus the force due to atmospheric pressure balances the force due to the air pressure in the tire.

Checking the tire pressure. *(Vanessa Vick/ Photo Researchers, Inc.)*

Figure 13-8 shows a mercury barometer, which is used to measure atmospheric pressure. The top end of the tube has been closed off and evacuated so that the pressure there is zero. The other end is submerged in a pool of mercury that is open to the atmosphere at pressure P_{at}. The pressure P_{at} is ρgh, where ρ is the density of mercury.

PRACTICE PROBLEM 13-4

At 0°C, the density of mercury is 13.595×10^3 kg/m^3. What is the height of the mercury column in a barometer if the pressure P is exactly 1 atm = 101.325 kPa?

In practice, pressure is often measured in millimeters of mercury, a unit called the **torr,** after the Italian physicist Evangelista Torricelli, or in inches of mercury (written inHg). The various units of pressure are related as follows:

$$\begin{aligned} 1.00 \text{ atm} &= 760 \text{ mmHg} = 760 \text{ torr} \\ &= 29.9 \text{ inHg} = 101 \text{ kPa} = 14.7 \text{ lb/in}^2 \end{aligned} \qquad 13\text{-}9$$

Other units commonly used on weather maps are the **bar** and the **millibar,** which are defined as follows:

$$1 \text{ bar} = 10^3 \text{ millibars} = 100 \text{ kPa} \qquad 13\text{-}10$$

A pressure of 1 atm is about 1.01 percent greater than a pressure of 1 bar.

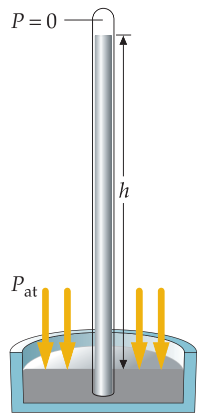

FIGURE 13-8 The space at the top of the mercury column is empty except for mercury vapor. At room temperature the vapor pressure of mercury is less than 10^{-5} atm.

Example 13-4 Blood Pressure in the Aorta

The average gauge pressure in the human aorta is about 100 mmHg. Convert this average blood pressure to kilopascals.

PICTURE Use a conversion factor obtained from Equation 13-9:

SOLVE

We use a conversion factor that can be obtained from Equation 13-9: $P = 100 \text{ mmHg} \times \dfrac{101 \text{ kPa}}{760 \text{ mmHg}} = \boxed{13.3 \text{ kPa}}$

CHECK We expect the pressure to be a small fraction of 1.00 atm. A pressure of 13.3 kPa meets this expectation as 1.00 atm = 101 kPa.

PRACTICE PROBLEM 13-5 Convert a pressure of 45.0 kPa to (*a*) millimeters of mercury, and (*b*) atmospheres.

The relation between pressure and altitude (or depth) is more complicated for a gas than for a liquid. The density of a liquid is essentially constant, whereas the density of a gas is approximately proportional to the pressure. As you go up from the surface of Earth, pressure in a column of air decreases, just as the pressure would decrease as you go up from the bottom in a column of water. But the decrease in air pressure is not linear with distance.

Example 13-5 The Law of Atmospheres

The assumption that the density of air is proportional to the pressure predicts that the pressure decreases exponentially with altitude. Use this assumption to verify this prediction and calculate the altitude at which the pressure is one-half of its value at sea level.

PICTURE Apply Newton's second law to an element of air at altitude y and vertical thickness dy to find an expression for the change in pressure over the change in altitude dy. Integrate this expression, taking into account that the density is proportional to the pressure.

SOLVE

1. Draw a thin horizontal disk-shaped element of air at altitude y, vertical thickness dy, cross-sectional area A, and mass dm. Draw and label all the forces on this element (Figure 13-9):

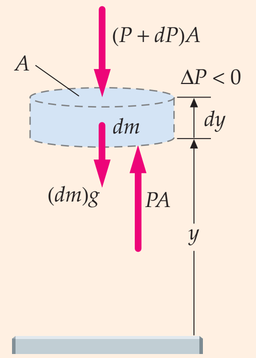

FIGURE 13-9 The pressure below the thin disk-shaped element of air is greater than the pressure above it. This pressure difference produces an upward force on the disk that balances the downward force of gravity on it.

2. Apply Newton's second law to the disk. The acceleration is zero so the sum of the forces equal zero:

$$PA - (P + dP)A - (dm)g = 0$$

3. Simplify the equation and substitute $\rho A\, dy$ for dm:

$$-A\, dP - \rho g A\, dy = 0$$

so $dP = -\rho g\, dy$

4. We are assuming that the density is proportional to pressure, and we know the density ρ_0 and pressure P_0 at sea level ($y = 0$):

$$\frac{\rho}{P} = \frac{\rho_0}{P_0}$$

5. Substitute for ρ in the step-3 result and divide both sides by P to separate variables:

$$dP = -P\frac{\rho_0}{P_0}g\, dy$$

so $$\frac{dP}{P} = -\frac{\rho_0}{P_0}g\, dy$$

6. Integrate from $y = 0$ to $y = y_f$. Let $P = P_f$ be the pressure at altitude y_f:

$$\int_{P_0}^{P_f}\frac{dP}{P} = -\frac{\rho_0}{P_0}g\int_0^{y_f} dy$$

so $$\ln\frac{P_f}{P_0} = -\frac{\rho_0}{P_0}g y_f$$

7. Solve for P_f. Then substitute P for P_f and y for y_f:

$$P_f = P_0 e^{-(\rho_0/P_0)g y_f} \quad \text{or} \quad \boxed{P = P_0 e^{-(\rho_0/P_0)gy}}$$

8. Solve for the height h at which $P = \frac{1}{2}P_0$. Look up the density of air at 1-atm pressure in Table 13-1:

$$\tfrac{1}{2}P_0 = P_0 e^{-(\rho_0/P_0)gh} \Rightarrow h = \frac{P_0}{\rho_0 g}\ln 2$$

so $$h = \frac{(1.01 \times 10^5\ \text{Pa})\ln 2}{(1.29\ \text{kg/m}^3)(9.81\ \text{N/kg})} = \boxed{5.5\ \text{km}}$$

CHECK An altitude of 5.5 km is about 18,000 ft. We know that many people suffer from the effects of oxygen deprivation at this altitude. That people would suffer at half the normal air pressure is not surprising.

TAKING IT FURTHER The step-7 result reveals that air pressure decreases exponentially with altitude. This conclusion means that air pressure decreases by a constant fraction for a given increase in height, as shown in Figure 13-10. At a height of about 5.5 km, the air pressure is half its value at sea level. If we go up another 5.5 km to an altitude of 11 km (a typical altitude for airliners), the pressure is again halved so that it is one-fourth its value at sea level, and so on. At the high altitudes at which commercial jets fly, the cabins must be pressurized. The density of air is approximately proportional to the pressure, so the density of air decreases with altitude. Less oxygen is available on a mountain top than at normal elevations. As a result, exercising in the Rockies is difficult, and climbing in the Himalayas is dangerous.

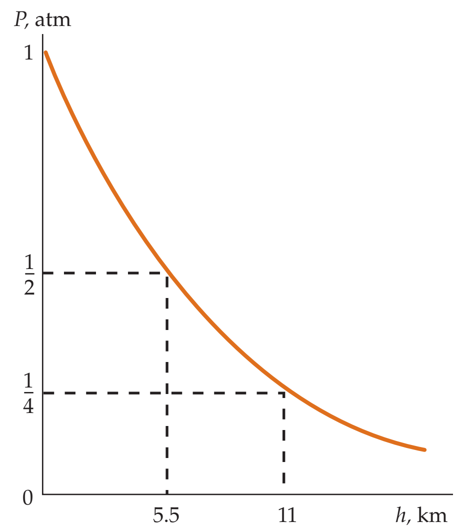

FIGURE 13-10 Variation in pressure with height above Earth's surface. For each 5.5-km increase in height, the pressure decreases by half.

13-3 BUOYANCY AND ARCHIMEDES' PRINCIPLE

If a dense object submerged in water is weighed by suspending it from a spring scale (Figure 13-11*a*), the apparent weight of the object when submerged (the reading on the scale) is less than the weight of the object. This difference exists because the water exerts an upward force that partially balances the force of gravity. This upward force is even more evident when we submerge a piece of cork. When completely submerged, the cork experiences an upward force from the water pressure that is greater than the force of gravity, so when released it accelerates up toward the surface. The force exerted by a fluid on a body wholly or partially submerged in it is called the **buoyant force.** It is equal to the weight of the fluid displaced by the body. (The definition of buoyant force is further refined later in this section.)

> A body wholly or partially submerged in a fluid is buoyed up by a force equal to the weight of the displaced fluid.
>
> ARCHIMEDES' PRINCIPLE

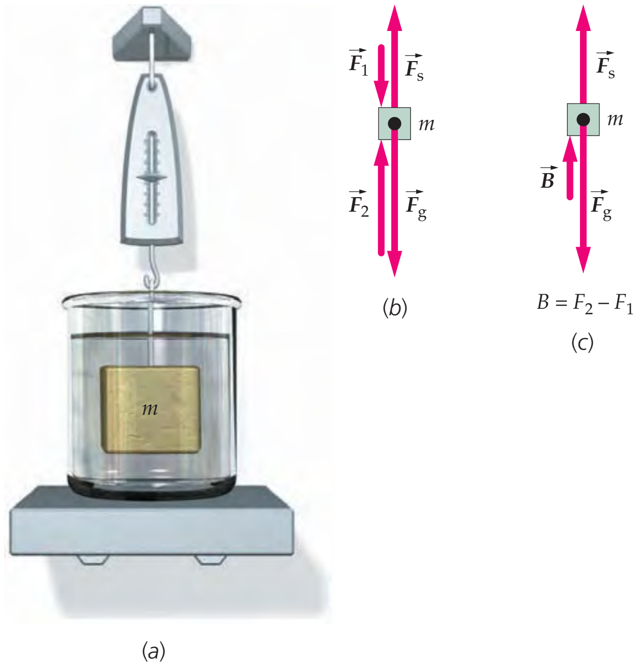

FIGURE 13-11 (*a*) Weighing an object submerged in a fluid. (*b*) Free-body diagram showing the weight $\vec{F}_g$, the force $\vec{F}_s$ of the spring, and the forces $\vec{F}_1$ and $\vec{F}_2$ that are exerted on the object by the surrounding fluid. (*c*) The buoyant force $\vec{B}$, where $\vec{B} = \vec{F}_1 + \vec{F}_2$, is the total force exerted by the fluid on the object.

This result is known as **Archimedes' principle.**

We can derive Archimedes' principle from Newton's laws by considering the forces acting on a portion of a fluid and noting that in static equilibrium the net force must be zero. Figure 13-11*b* shows the vertical forces acting on an object being weighed while submerged. These forces are the force of gravity $\vec{F}_g$ acting down, the force of the spring scale $\vec{F}_s$ acting up, a force $\vec{F}_1$ acting down because of the fluid pressure on the top surface of the object, and a force $\vec{F}_2$ acting up because of the fluid pressing on the bottom surface of the object. Because the spring scale reads a force less than the weight of the object, the magnitude of force $\vec{F}_2$ must be greater than the magnitude of force $\vec{F}_1$. The vector sum of these two forces is equal to the buoyant force $\vec{B} = \vec{F}_1 + \vec{F}_2$ (Figure 13-11*c*). The buoyant force occurs because the pressure of the fluid on the bottom surface of the object is greater than the pressure on the top surface of the object.

In Figure 13-12, the spring scale has been eliminated and the submerged object has been replaced by an equal volume of the fluid (outlined by the dashed lines), which we will refer to as the sample of fluid. The buoyant force $\vec{B} = \vec{F}_1 + \vec{F}_2$ acting on the sample of fluid is identical to the buoyant force that acted on our original object. This is so because the fluid surrounding the sample and the fluid surrounding the object are identically configured; there is no reason to suppose the pressure in the surrounding fluid would not be the same at corresponding points in the two containers. The sample of fluid is in equilibrium, so we know the net force acting on it must be zero. The upward buoyant force thus equals the downward weight of the sample of the fluid:

$$B = F_{gf} \qquad 13\text{-}11$$

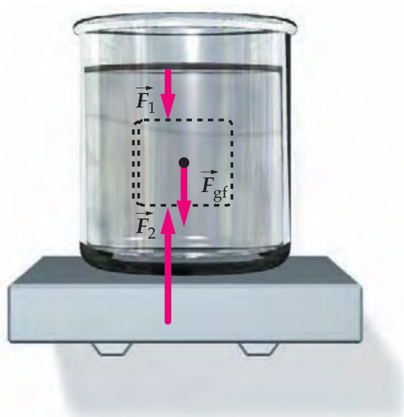

FIGURE 13-12 Figure 13-11 with the submerged body replaced by an equal volume of fluid. The forces $\vec{F}_1$ and $\vec{F}_2$, due to the pressure of the fluid, are the same as in Figure 13-11. The magnitude of the buoyant force is thus equal to the weight F_{gf} of the displaced fluid.

Note that this result does not depend on the shape of the submerged object. If we consider any irregularly shaped portion of a static fluid as our sample, there will be a buoyant force acting on it by the surrounding fluid that exactly supports its weight. Thus, we have derived Archimedes' principle.

Archimedes (287–212 B.C.E.) had been given the task of determining whether a crown (actually a wreath) made for King Hieron II was of pure gold or had been adulterated with some cheaper metal such as silver, and to do this without destroying the crown. For Archimedes, the problem was to determine if the density

(a) Crown and gold nugget have equal weight.

(b) Crown displaces more water than does the gold nugget.

FIGURE 13-13 (*a*) The crown and the gold nugget have equal weight. (*b*) The balance tips because the wreath displaces more water than the gold nugget.

of the irregularly shaped crown was the same as the density of gold. As the story goes, he came upon the solution while sinking himself into a bathtub and immediately rushed home, running naked through the streets of Syracuse shouting "Eureka!" ("I have found it!"). This flash of insight preceded Newton's laws, which we used to derive Archimedes' principle, by some 1900 years. What Archimedes had found was a simple and accurate way to compare the density of the crown with the density of gold by using a balance. He placed the balance over a large basin, suspended the crown from one arm of the balance and an equal mass of pure gold from the other arm. He then added water to the basin (Figure 13-13*a*) submerging the crown and the pure gold. The balance tilted, with the crown rising (Figure 13-13*b*)—indicating that the buoyant force on the crown was greater than that on the pure gold because the volume of water displaced by the crown was greater than that displaced by the pure gold. The crown was less dense than the pure gold.

The apparent weight $F_{\text{g app}}$ of an object submerged in a fluid is the difference between its weight F_{g} and the magnitude of the buoyant force B:

$$F_{\text{g app}} = F_{\text{g}} - B \qquad 13\text{-}12$$

The hot-air balloon and the boat both need buoyancy to float. *(Richard Hamilton Smith/CORBIS.)*

PROBLEM-SOLVING STRATEGY

Solving Problems Using Archimedes' Principle

PICTURE Carefully read the problem statement to determine the situation. Sketching a picture of the situation is often helpful.

SOLVE

1. Apply Archimedes' principle to relate the buoyant force to the weight of the displaced fluid.
2. Apply Newton's second law to the object and solve for the desired quantity.

CHECK Verify that your answer is plausible.

Example 13-6 Is It Really Gold? *Context-Rich*

Your friend is concerned about a gold ring she bought on a recent trip. The ring was expensive, and she would like to know whether it is really made of gold or of something else. You decide to help her, using your knowledge of physics. You weigh the ring and find that it has a weight of 0.158 N. Using a string, you suspend the ring from the scale and, with the ring submerged in water, weigh it again to find a new reading of 0.150 N. Is the ring pure gold?

PICTURE If the ring is pure gold, its density (relative to that of water) is 19.3 (see Table 13-1). Using Archimedes' principle as a guide, determine the density of the ring relative to the density of water.

SOLVE

1. The weight F_g of the ring equals its density ρ_R times its volume V times g. The buoyant force B on the ring (when submerged) equals the density of water ρ_w times Vg:

$$F_g = \rho_R Vg$$
$$B = \rho_w Vg$$

2. Divide the first equation by the second to relate the ratio of the weight to the buoyant force to the ratio of the density to the density of water:

$$\frac{F_g}{B} = \frac{\rho_R Vg}{\rho_w Vg} = \frac{\rho_R}{\rho_w}$$

3. In accord with Newton's second law, B equals the weight minus the apparent weight when submerged:

$$F_{g\,app} = F_g - B \Rightarrow B = F_g - F_{g\,app}$$

4. Substitute for B in step 2:

$$\frac{F_g}{F_g - F_{g\,app}} = \frac{\rho_R}{\rho_w}$$

5. Solve for the ratio ρ_R/ρ_w:

$$\frac{\rho_R}{\rho_w} = \frac{F_g}{F_g - F_{g\,app}} = \frac{0.158\text{ N}}{0.158\text{ N} - 0.150\text{ N}} = \frac{0.158\text{ N}}{0.008\text{ N}}$$

6. The denominator has one significant figure, so the ratio of the densities is determined to one significant figure:

$$\frac{\rho_R}{\rho_w} = \frac{0.158\text{ N}}{0.008\text{ N}} = 19.3 = 20$$

The 2 in the 20 is a significant digit, but the 0 is not.

7. Compare the ratio of the densities with the ratio of the density of gold to the density of water, which is 19.3:

According to the measurement, the ratio of the densities is 2×10^1.

$\boxed{\text{The ring may be pure gold, but the measurement is not accurate enough to be certain.}}$

CHECK The uncertainty in the result is large, which is expected. When two numbers that are almost equal are subtracted there are fewer significant figures in the result than in the original numbers.

TAKING IT FURTHER A scale capable of much greater accuracy is needed to make a more certain determination.

PRACTICE PROBLEM 13-6 A block of an unknown material weighs 3.00 N and has an apparent weight of 1.89 N when submerged in water. What is the material?

PRACTICE PROBLEM 13-7 A piece of lead (specific gravity = 11.3) weighs 80.0 N in air. What does it weigh when submerged in water?

REVISITING THE BUOYANT FORCE

The density of the block shown in Figure 13-14 is greater than the density of the surrounding fluid, and both the block and the scale pan are completely submerged in the fluid. The gravitation force on the block is its weight, $\vec{F}_g$, and the scale is adjusted, so it reads zero when the block is not being supported by the pan (Figure 13-14*b*). If the block is on the pan (Figure 13-14*a*), the scale reading is equal to the magnitude of the apparent weight $F_{g\,app}$ of the block. When the block is on the pan, the fluid is in direct contact with the entire surface of the block—except for those regions of the bottom surface of the block that are in direct contact with the pan. We assume the pan surface is not perfectly flat, but instead has some high and some low regions, and that the pan is in direct contact with the bottom surface of the block only

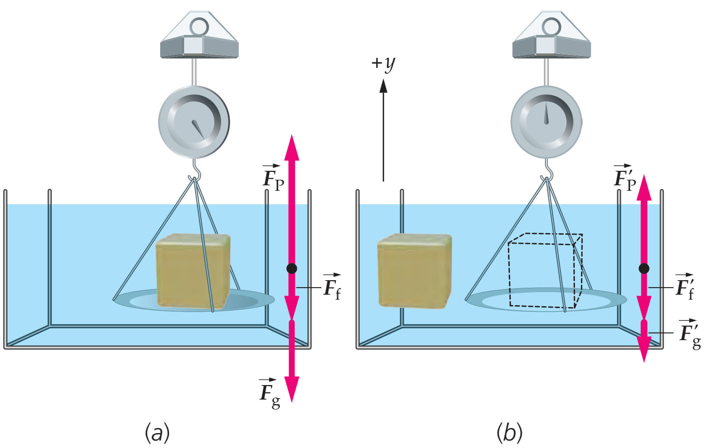

FIGURE 13-14

at the high regions of the pan. (At the low regions of the pan, there is fluid between the pan and the block.) We now analyze this situation to show that the scale reading is equal to the weight of the block less the weight of an equal volume of fluid.

While resting on the pan, the net force exerted by the fluid on the block $\vec{F}_f$ is a combination of the downward force of the fluid on the top surface of the block and the upward force of the fluid on those regions of the bottom surface of the block that are in direct contact with the fluid. (We have drawn $\vec{F}_f$ downward. However, if the fluid were in direct contact with a large enough area of the bottom surface of the block $\vec{F}_f$ would be upward.) The two other vertical forces acting on the block are the gravitational force $\vec{F}_g$ and the upward force $\vec{F}_P$ exerted on the block by the pan at the regions of direct contact between the block and the pan.

In Figure 13-14*b*, the block has been moved off the pan, and in its place is a sample of fluid of identical size and shape (outlined by the dashed lines). The same regions of the surface of the pan are in direct contact with the bottom surface of this sample of fluid as were in direct contact with the block before it was moved. The forces acting on the fluid sample are the forces acting on it by the surrounding fluid $\vec{F}'_f$, the upward force on it by the pan $\vec{F}'_P$, and the gravitational force $\vec{F}'_g$. The forces $\vec{F}_f$ and $\vec{F}'_f$ are equal because, at every point where the sample and the surrounding fluid are in direct contact, the pressure of the surrounding fluid is the same as it was at the same point before the block was moved off the pan.

When the submerged block rests on the pan, the block is in equilibrium, so

$$F_{fy} + F_{Py} + F_{gy} = 0 \qquad \text{or} \qquad F_{fy} + F_P - F_g = 0$$

and when the block is moved off the pan, the fluid sample in its place is in equilibrium, so

$$F'_{fy} + F'_P - F'_g = 0$$

Subtracting these equations, exploiting that $F'_{fy} = F_{fy}$ and rearranging gives

$$F_P - F'_P = F_g - F'_g$$

where $F_P - F'_P$ is the decrease in the scale reading when the block is moved off the pan. Thus, $F_P - F'_P$ is the apparent weight of the submerged block. That is,

$$F_{g\,\text{app}} = F_g - F'_g$$

It is common parlance to refer to $F_g - F_{g\,\text{app}}$ as the buoyant force B. Rearranging gives

$$B = F_g - F_{g\,\text{app}} = F'_g$$

This is the same expression for the buoyant force as is in Equation 13-12, which was established with the fluid in direct contact with 100 percent of the surface of the submerged object.

Example 13-7 Measuring the Fat

To determine the percentage of fat in this man's body, his density is measured by weighing him while he is submerged in the water. *(David Burnett/ Woodfin Camp and Assoc.)*

You decide to enroll in a fitness program. To determine your initial fitness, at the first meeting your percentage of body fat is measured. Your percentage of body fat can be estimated by measuring your body density (the average density of your body). Fat is less dense than muscle or bone. Assume the average density of fat is $0.90 \times 10^3\ \text{kg/m}^3$ and the average density of lean tissue (everything except fat) is $1.1 \times 10^3\ \text{kg/m}^3$. Measuring your body density involves measuring your apparent weight while you are submerged in water with the air completely exhaled from your lungs. (In practice, the amount of air remaining in the lungs is estimated and corrected for.) Suppose that your apparent weight when submerged in water is 5 percent of your weight. What percentage of your body mass is fat?

PICTURE For the person, the total volume equals the volume of the fat plus the volume of the lean, and the total mass equals the mass of the fat plus the mass of the lean. The volume and average density are related to the mass by $m = \rho V$. The fraction of fat equals the mass of the fat divided by the total mass and the fraction of lean equals the mass of the lean divided by the total mass. Also, the fraction of fat plus the fraction of lean equals 1.

SOLVE

1. Using Equations 13-2 and 13-3, find the ratio of your body's density to the density of water:

$$\frac{\rho}{\rho_{\text{water}}} = \frac{F_g}{F_g - F_{g\,\text{app}}} = \frac{F_g}{F_g - 0.05F_g} = 1.05$$

2. Your total body volume equals the volume of fat plus the volume of lean tissue:

$$V_{\text{tot}} = V_{\text{fat}} + V_{\text{lean}}$$

3. Because mass equals density times volume, volume equals mass divided by density. Substitute the corresponding mass-to-density ratio for each volume in the step-2 result:

$$\frac{m_{\text{tot}}}{\rho} = \frac{m_{\text{fat}}}{\rho_{\text{fat}}} + \frac{m_{\text{lean}}}{\rho_{\text{lean}}}$$

4. The mass of fat is $f_{\text{fat}}m_{\text{tot}}$, where f_{fat} is the fraction of fat, and the mass of lean is $f_{\text{lean}}m_{\text{tot}}$, where f_{lean} is the fraction of lean. Substitute for m_{fat} and m_{lean} in the step-3 result:

$$\frac{m_{\text{tot}}}{\rho} = \frac{f_{\text{fat}}m_{\text{tot}}}{\rho_{\text{fat}}} + \frac{f_{\text{lean}}m_{\text{tot}}}{\rho_{\text{lean}}}$$

5. The fraction of fat plus the fraction of lean tissue equals 1:

$$f_{\text{fat}} + f_{\text{lean}} = 1$$

6. Divide both sides of the step-4 result by m_{tot} and substitute $1 - f_{\text{fat}}$ for f_{lean}:

$$\frac{1}{\rho} = \frac{f_{\text{fat}}}{\rho_{\text{fat}}} + \frac{(1 - f_{\text{fat}})}{\rho_{\text{lean}}}$$

7. Solve the step-6 result for f_{fat}:

$$f_{\text{fat}} = \frac{1 - (\rho_{\text{lean}}/\rho)}{1 - (\rho_{\text{lean}}/\rho_{\text{fat}})}$$

8. Using the step-1 result, substitute for ρ in the step-7 result and solve for f_{fat}:

$$f_{\text{fat}} = \frac{1 - (\rho_{\text{lean}}/1.05\rho_{\text{water}})}{1 - (\rho_{\text{lean}}/\rho_{\text{fat}})} = \frac{1 - (1.1/1.05)}{1 - (1.1/0.90)} = 0.21$$

9. Convert to a percentage:

$$100\% \times f_{\text{fat}} = \boxed{21\%}$$

CHECK You are an adult male and are not overweight. The charts inform you that for adult males, a body-fat percentage between 18% and 25% is acceptable. Thus, the step-9 result is a plausible result.

PRACTICE PROBLEM 13-8 If Ed's apparent weight when submerged is zero, what is his body-fat percentage?

Example 13-8 Which Weighs the Most? *Conceptual*

Consider five identical beakers (Figure 13-15). The water level in each beaker is up to the point of overflowing. A toy boat is floating on the surface of Beaker *A*. A second toy boat, one that tipped over and sank to the bottom, is in Beaker *B*. An ice cube is floating on the surface of Beaker *C*. The block of wood submerged in Beaker *D* is tethered to the bottom by a thread and dab of superglue. (There is nothing in Beaker *E* except water.) The two boats, the ice cube, and the block of wood have equal masses. The density of the submerged boat is twice that of water, and the density of the block of wood is half that of water. Each beaker rests on a scale. Rank the readings on the scales from most to least.

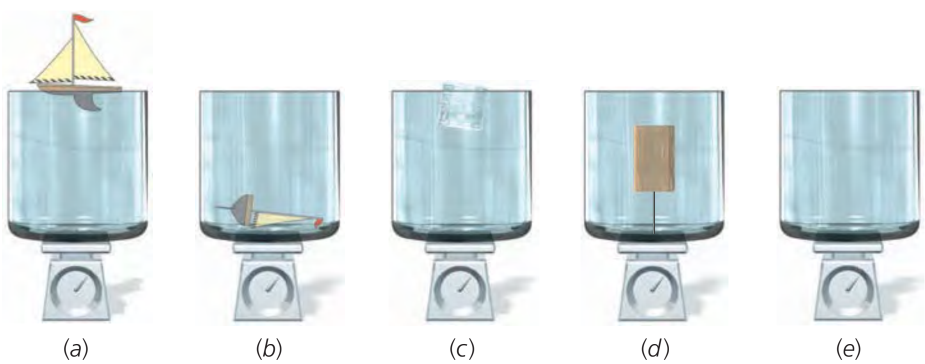

FIGURE 13-15

PICTURE The reading of each scale is equal to the total weight of the system resting on it. In each case, the system consists of the beaker, the water in the beaker, and any object submerged in, or floating on, the water. Beaker *E* contains the most water. The buoyant force on an object is equal to the weight of the fluid it displaces, a submerged object displaces its own volume of water, and a floating object displaces its own weight of water. The amount of water in each of the beakers equals the amount of water in Beaker *E* less the amount of water displaced by a floating or submerged object.

SOLVE

1. Let $F_{g\,A}$ be the reading on the scale under Beaker *A*, let $F_{g\,B}$ be the reading on the scale under Beaker *B*, and so on. In addition, let $F_{g\,obj}$ be the weight of each of the objects (they have identical weights). A floating object displaces its own weight of water. Calculate the weight of the water displaced by each floating object:

   The weight of the water displaced by the floating boat is $F_{g\,obj}$, and the weight displaced by the floating ice cube is also $F_{g\,obj}$.

2. A submerged object displaces its own volume of water. Calculate the weight of the water displaced by each submerged object:

   The weight of the water displaced by the submerged wooden block is $2F_{g\,obj}$ and the weight displaced by the submerged boat is $\frac{1}{2}F_{g\,obj}$.

3. In each case, the system consists of a beaker, the water in the beaker, and any object submerged in, or floating on, the water. In addition, the weight of water in each beaker equals the weight of water in Beaker *E* less the weight of water displaced by an object. Calculate the total weight of the system on each scale:

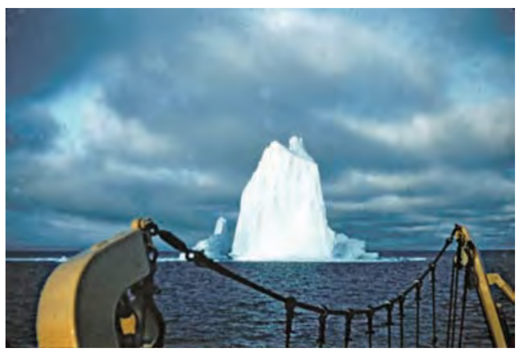
Beaker	Weight
A	$F_{g\,sys} = (F_{g\,E} - F_{g\,obj}) + F_{g\,obj} = F_{g\,E}$
B	$F_{g\,sys} = (F_{g\,E} - \frac{1}{2}F_{g\,obj}) + F_{g\,obj} = F_{g\,E} + \frac{1}{2}F_{g\,obj}$
C	$F_{g\,sys} = (F_{g\,E} - F_{g\,obj}) + F_{g\,obj} = F_{g\,E}$
D	$F_{g\,sys} = (F_{g\,E} - 2F_{g\,obj}) + F_{g\,obj} = F_{g\,E} - F_{g\,obj}$
E	$F_{g\,sys} = (F_{g\,E} - 0) + 0 = F_{g\,E}$

4. The reading on the scale equals the weight of the system $F_{g\,sys}$.

   The reading on the scale with the sunken boat has the highest reading, the reading on the scale with the submerged block has the lowest reading, and the readings on the other three scales are equal.

CHECK The water pressure at the bottom of each beaker is the same because the water has the same depth in all of the beakers. This means that the water pushes down on the bottoms of Beakers *A*, *C*, *D*, and *E* with identical forces. Thus, the readings on the scales under Beakers *A*, *C*, and *E* are identical. For Beaker *D*, in addition to the water pushing down the thread pulls up, so the reading on the scale under Beaker *D* is less than the readings on the scales under Beakers *A*, *C*, and *E*. For Beaker *B*, the submerged boat pushes down on the bottom of the beaker with a force per unit area that exceeds the water pressure there, so the reading on the scale under Beaker *B* is largest of them all.

TAKING IT FURTHER The Falkirk Wheel is perfectly balanced for the same reason that the readings on the scales under Beakers *A*, *C*, and *E* are equal. As long as the depths of the water in the two gondolas remain equal, and the boats in the gondolas (if any) remain floating, the wheel will remain in perfect balance. Because it remains in balance, only a small effort is needed to rotate the wheel.



The tallest iceberg seen in the North Atlantic extended about 168 m above sea level, about the same height as the Washington Monument. This iceberg was sighted in Melville Bay, Greenland, in 1957. *(Courtesy of the U.S. Coast Guard International Ice Patrol.)*

Example 13-9 An Iceberg

Find the fraction of the volume of an iceberg that is below sea level.

PICTURE Let V be the volume of the iceberg and V_{sub} be the volume that is submerged. The weight of the iceberg is $\rho_{IB}Vg$ and the buoyant force due to the seawater is $\rho_{SW}V_{sub}g$. The densities of ice and seawater are found in Table 13-1.

SOLVE

1. Because the iceberg is in equilibrium, the buoyant force equals its weight:

$$F_g = B$$
$$\rho_{IB} V g = \rho_{SW} V_{sub} g$$

2. Solve for V_{sub}/V:

$$f = \frac{V_{sub}}{V} = \frac{\rho_{IB}}{\rho_{SW}} = \frac{0.92 \times 10^3\ \mathrm{kg/m^3}}{1.025 \times 10^3\ \mathrm{kg/m^3}} = 0.898 = \boxed{0.90}$$

CHECK We have all seen an ice cube floating in fresh water. The great majority of the ice cube is submerged. We expect pretty much the same for an iceberg floating in seawater, and our step-2 result agrees with our expectation. Because the density of seawater is 2 to 3% more than the density of fresh water, ice floats a bit higher in seawater than in fresh water.

If we replace ρ_{SW} in the preceding calculation with ρ_f, the density of the fluid, we can determine the submerged fraction of an object floating in any fluid. From Example 13-9, the fraction of a floating object of uniform density ρ that is submerged equals the ratio of its density to the density of the fluid.

$$\frac{V_{sub}}{V} = \frac{\rho}{\rho_f} \qquad \text{13-13}$$

Smoke from a burning cigarette. At first the smoke rises in a regular stream, but the simple streamlined flow quickly becomes turbulent and the smoke begins to swirl irregularly. *(Estate of Harold E. Edgerton.)*

13-4 FLUIDS IN MOTION

The behavior of a fluid in motion can be complex. Consider, for example, the rise of smoke from a burning cigarette. At first the smoke rises in a regular stream of warm gas, but the simple streamlined flow quickly becomes turbulent and the smoke begins to swirl irregularly. Turbulent flow is very difficult to describe, even qualitatively. If no turbulence exists, the fluid flows along streamlines. Sophisticated computer programs that simulate streamlines of the air flowing around objects are of great value to automotive design engineers.

Figure 13-16 shows a tube full of fluid. The tube contains a tapered section with decreasing cross-sectional area. The fluid is flowing without turbulence from left to right, and the shaded portion on the left depicts the fluid that passes through cross-sectional surface 1 during time Δt. If the density and speed of the

Streamlined body designs can greatly reduce the drag forces on moving objects such as automobiles or airplanes. *(Takeski Takahara/Photo Researchers, Inc.)*

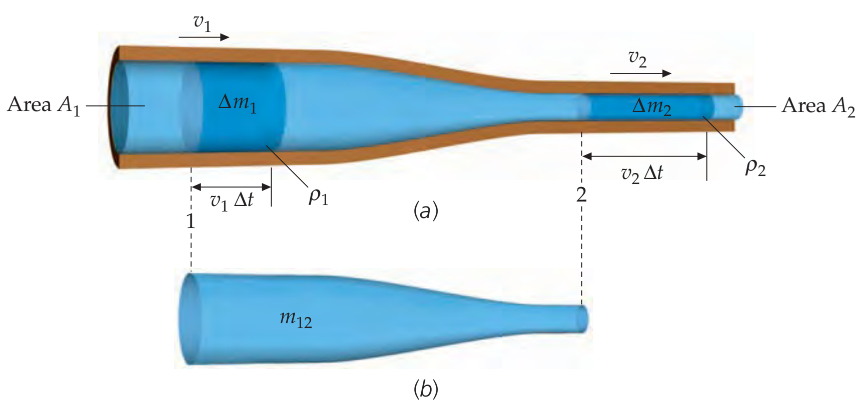


FIGURE 13-16

fluid at this surface are ρ_1 and v_1 and the area of this surface is A_1, then the mass Δm_1 flowing through surface 1 is given by

$$\Delta m_1 = \rho_1 \, \Delta V_1 = \rho_1 A_1 v_1 \, \Delta t$$

where $\Delta V_1 = A_1 v_1 \, \Delta t$ is the volume of the fluid flowing through surface 1 during time Δt. The quantity $I_M = \rho A v$ is called the **mass flow rate.** The dimensions of I_M are mass divided by time. The mass Δm_2 of fluid that passes through surface 2 during the same time Δt and depicted by the shaded portion on the right is given by

$$\Delta m_2 = \rho_2 A_2 v_2 \, \Delta t$$

where ρ_2, v_2, and A_2 are, respectively, the density and speed of the fluid at surface 2, and the cross-sectional area of surface 2.

If the mass flow rate through surface 1 is greater than the mass flow rate through surface 2, then fluid is entering the region between surfaces 1 and 2 faster than it is leaving the region, so the mass of fluid in the region is increasing. The rate at which mass enters the region minus the rate at which mass leaves the region is equal to the rate of change of the accumulated mass in the region. That is,

$$I_{M1} - I_{M2} = dm_{12}/dt \qquad 13\text{-}14$$

CONTINUITY EQUATION

where I_{M1} and I_{M2} are the mass flow rates through surfaces 1 and 2, respectively, and m_{12} is the accumulated mass between surfaces 1 and 2. Equation 13-14 is called the **continuity equation.** Flow in which the motion of the fluid is constant (does not change as time increases) at all points is called **steady-state flow.** If the flow is steady state, then dm_{12}/dt in Equation 13-14 equals zero. In steady-state flow mass flow rate is the same through all cross-sectional surfaces. In addition, the mass flow rate is constant.

The quantity $I_V = Av$ is called the **volume flow rate.** The dimensions of I_V are volume divided by time. In the flow of an incompressible fluid, the instantaneous volume flow rate is the same through any cross-sectional surface perpendicular to the flow. In addition, if the flow is steady-state flow, the volume flow rate is constant:

$$I_V = Av \qquad 13\text{-}15$$

VOLUME FLOW RATE

In an incompressible fluid, the density is equal to a single fixed value throughout the fluid. Liquids are almost always considered incompressible because their densities, to an excellent approximation, do not vary.

The larger arteries branch out into smaller arteries, which in turn branch out into smaller arteries, and so forth. *(P. Motta/ Photo Researchers Inc.)*

PRACTICE PROBLEM 13-9

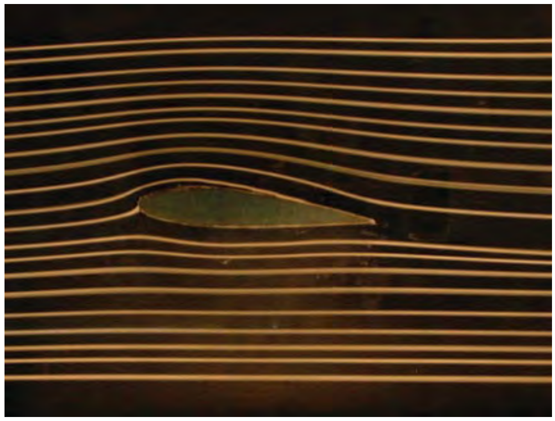
Blood flows in an aorta of radius 1.0 cm at 30 cm/s. What is the volume flow rate?

PRACTICE PROBLEM 13-10

Blood flows from a large artery of radius 0.30 cm, where its speed is 10 cm/s, into a region where the radius has been reduced to 0.20 cm because of thickening of the arterial walls (arteriosclerosis). What is the speed of the blood in the narrower region?

THE BERNOULLI EQUATION

The Bernoulli equation relates the pressure, elevation, and speed of an incompressible **inviscid** fluid in steady **streamlined flow.** Inviscid means without **viscosity,** which is the property of a fluid that causes it to resist flowing. During streamlined flow, the particles of the fluid move along **streamlines,** which are straight or smoothly curved paths that do not intersect. The Bernoulli equation can be derived by applying Newton's second law to a small parcel of the fluid moving along a streamline. As a parcel enters a region of reduced pressure the parcel gains speed because the pressure behind the parcel pushing it forward exceeds the pressure in front of the parcel opposing its motion.



The streamlines are made visible by using smoke trails. In streamlined flow the particles of the fluid follow smoothly curved lines. *(Holger Babinsky. 2003 Phys. Educ. 38 497-503.)*

Applying Newton's second law to a small parcel of air (Figure 13-17) of mass m moving along a horizontal streamline gives

$$F = m\frac{dv}{dt}$$

The fluid has density ρ, and the parcel has area A and width $\Delta\ell$, so the volume and mass of the parcel are $A\,\Delta\ell$ and $m = \rho A\,\Delta\ell$. The force F is due to the pressure P behind the parcel and the slightly different pressure $P + \Delta P$ in front of it. This force is given by

$$F = (P)(A) - (P + \Delta P)A = -A\,\Delta P$$

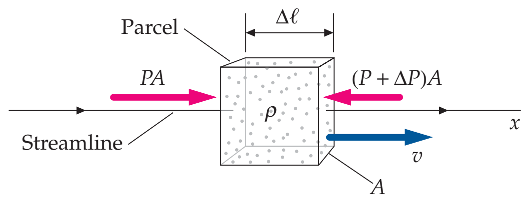


FIGURE 13-17 The small parcel moves along a streamline into a region of reduced pressure.

The parcel is small, so the pressure difference ΔP can be accurately expressed using the differential approximation

$$\frac{\Delta P}{\Delta\ell} = \frac{dP}{dx} \quad \text{so} \quad \Delta P = \frac{dP}{dx}\Delta\ell$$

Substituting for F and m in Newton's second law, gives

$$-A\frac{dP}{dx}\Delta\ell = \rho A\,\Delta\ell\,\frac{dv}{dt}$$

Simplifying this equation, we obtain

$$-dP = \rho\frac{dv}{dt}dx$$

Because $dx/dt = v$, this becomes

$$dP = -\rho v\,dv$$

Integrating both sides gives

$$\int_{P_1}^{P_2} dP = -\rho\int_{v_1}^{v_2} v\,dv$$

where the density ρ was factored from the integral on the right. Factoring ρ from the integral restricts the validity of the results to situations where the density remains constant. Evaluating the integrals gives

$$P_2 - P_1 = \tfrac{1}{2}\rho v_1^2 - \tfrac{1}{2}\rho v_2^2$$

Rearranging gives the Bernoulli equation for flow along a horizontal streamline,

$$P_2 + \tfrac{1}{2}\rho v_2^2 = P_1 + \tfrac{1}{2}\rho v_1^2 \qquad 13\text{-}16$$

The Bernoulli equation for flow along a streamline that is not horizontal is derived in Problem 13-63. The result is

$$P_2 + \rho g h_2 + \tfrac{1}{2}\rho v_2^2 = P_1 + \rho g h_1 + \tfrac{1}{2}\rho v_1^2 \qquad \text{13-17}a$$

THE BERNOULLI EQUATION

where h_1 and h_2 are the initial and final heights, respectively.

The Bernoulli equation can be restated

$$P + \rho g h + \tfrac{1}{2}\rho v^2 = \text{constant} \qquad \text{13-17}b$$

THE BERNOULLI EQUATION

! The Bernoulli equation relates pressure and speed between two points that are on a single streamline of an inviscid fluid.

A special application of the Bernoulli equation is for a fluid at rest. Then $v_1 = v_2 = 0$, and we obtain

$$P_1 - P_2 = \rho g h_2 - \rho g h_1 = \rho g\,\Delta h$$

This is the same as Equation 13-7.

Example 13-10 Torricelli's Law

A large tank of water, open at the top, has a small hole through its side a distance h below the surface of the water. Find the speed of the water as it flows out the hole.

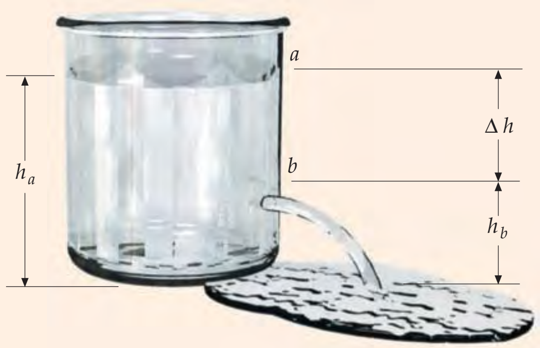

FIGURE 13-18

PICTURE The streamlines begin at the top of the water and continue through the small hole. We apply the Bernoulli equation to points a and b in Figure 13-18. Because the diameter of the hole is much smaller than the diameter of the tank, we can neglect the speed of the water at the top (point a).

SOLVE

1. The Bernoulli equation with $v_a = 0$ gives: $\quad P_a + \rho g h_a + 0 = P_b + \rho g h_b + \tfrac{1}{2}\rho v_b^2$

2. The pressure at point a and at point b is the same, P_{at}, because both points are open to the atmosphere: $\quad P_a = P_{at}$ and $P_b = P_{at}$

   so $\quad P_{at} + \rho g h_a + 0 = P_{at} + \rho g h_b + \tfrac{1}{2}\rho v_b^2$

3. Solve the step-2 result for the speed v_b of the water flowing from the hole: $\quad v_b^2 = 2g(h_a - h_b) = 2g\,\Delta h$

   so $\quad v_b = \boxed{\sqrt{2g\,\Delta h}}$

CHECK We can solve this directly using conservation of mechanical energy with the water and Earth as the system. The mass m of water that flows out of the hole in the short time Δt equals the mass of water that has "disappeared" from the top of the tank. Thus, the decrease in potential energy is $mg\,\Delta h$, while the increase in kinetic energy is $\tfrac{1}{2}mv^2$. Equating these and solving for v gives the step-3 result.

PRACTICE PROBLEM 13-11 If the water flowing out of the hole is directed vertically upward, how high does it rise?

CONCEPT CHECK 13-1

In an Olympic swimming pool the water is continuously cycled through a filter by a pump. The water reenters the pool through underwater nozzles. The stream of water exiting the nozzles extends almost the entire length of the pool before dissipating. As the water in the stream loses speed, does its pressure increase as the Bernoulli equation (Equation 13-16) seems to indicate?

In Example 13-10, the water emerges from the hole with a speed equal to the speed it would have if it dropped in free-fall a distance h. This finding is known as *Torricelli's law*.

In Figure 13-19, water is shown flowing through a horizontal pipe that has a constricted section. Because both sections of the pipe are at the same elevation, $h_2 = h_1$, in Equation 13-17*a*. Then the Bernoulli equation becomes

$$P + \tfrac{1}{2}\rho v^2 = \text{constant} \qquad \text{13-18}$$

When the fluid moves into the constriction, the area A gets smaller, so the speed v must get larger because Av remains constant. But because $P + \frac{1}{2}\rho v^2$ is constant, when the speed becomes larger, the pressure must become less. Thus, the pressure in the constriction is reduced.

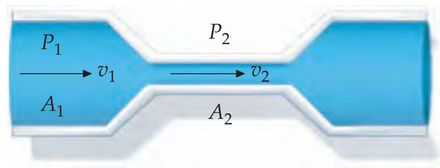

FIGURE 13-19 Constriction in a pipe carrying a moving fluid. The pressure is lower in the narrow section of the pipe where the fluid is moving faster.

> As air, or another fluid, passes through a constriction, its speed increases and its pressure drops.
>
> VENTURI EFFECT

This result is often referred to as the **venturi effect** and the constriction is referred to as a **venturi.** Equation 13-18 is an important result that applies to many situations in which we can ignore changes in height. Racing cars exploit the venturi effect to increase the downforce on the car. This reduction results in an increase in the normal force on the car by the pavement, and thus allows for the higher static frictional forces needed to control the speed and direction of the car.

The streamlines in Figure 13-20 are drawn to pictorially represent the flow of the fluid. The direction of the lines indicates the direction of flow and the distance between lines indicates the speed of the flow. The smaller the distances between the lines, the greater the speed of the fluid. For horizontal flow, where the speed increases, the pressure decreases, so a decrease in the distance between streamlines is accompanied by a decrease in pressure.

The wing on this Formula 1 racing car deflects the air upward, increasing downforce on the car for better control at high speeds. In addition, an underbody venturi reduces the pressure under the car body. The downforce associated with this pressure reduction is called the ground effect. *(Schlegelmilch/Corbis.)*

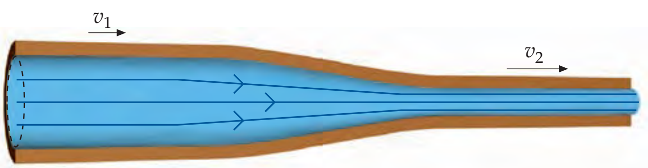

FIGURE 13-20

FIGURE 13-21 When the bulb of an atomizer is squeezed, the air is forced through the constriction in the horizontal tube, which reduces the pressure there below atmospheric pressure. Because of the resulting pressure difference, the liquid in the jar, which is open to the atmosphere is pumped up through the vertical tube, enters the air stream, and emerges from the nozzle. A similar effect occurs in the carburetor of a gasoline lawnmower engine.

CONCEPT CHECK 13-2

In the atomizer shown in Figure 13-21, the horizontal tube is constricted at the point where the vertical tube joins it. Is the constriction functional, or is it there because the vertical tube is narrower than the horizontal tube? Explain.

Example 13-11 A Venturi Meter

A *venturi meter*, used to measure the flow rate of an incompressible inviscid fluid, is shown in Figure 13-22. The fluid of density ρ_F passes through a pipe of cross-sectional area A_1 that has a constriction of cross-sectional area A_2. Because the fluid gains speed as it enters the constricted section, the pressure in the constricted section is less than in the other portions of the pipe. The two parts of the pipe are connected with a U-tube manometer partially filled with a liquid of density ρ_L. The pressure difference is measured by the difference in the levels of the liquid in the U-tube, Δh. Express the velocity v_1 in terms of the measured height Δh and the known quantities ρ_F, ρ_L, and $r = A_1/A_2$.

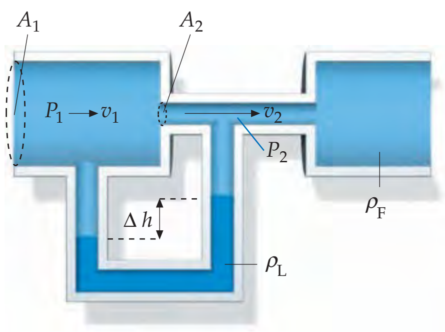

FIGURE 13-22 A venturi meter.

PICTURE The pressures P_1 and P_2 in the two regions are related to the speeds v_1 and v_2 by the Bernoulli equation. The pressure difference is related to the height Δh. You can express v_2 in terms of v_1 and the areas A_1 and A_2 by the continuity equation.

SOLVE

1. Write the Bernoulli equation for constant elevation for the two regions.

$$P_1 + \tfrac{1}{2}\rho_F v_1^2 = P_2 + \tfrac{1}{2}\rho_F v_2^2$$

2. Write the continuity equation for the two regions, and solve for v_2 in terms of v_1 and r, where $r = A_1/A_2$.

$$v_2 A_2 = v_1 A_1$$

$$\text{so} \quad v_2 = \frac{A_1}{A_2} v_1 = r v_1$$

3. Substitute your result for v_2 into the equation in step 1 and obtain an equation for $P_1 - P_2$.

$$P_1 - P_2 = \tfrac{1}{2}\rho_F(v_2^2 - v_1^2) = \tfrac{1}{2}\rho_F(r^2 - 1)v_1^2$$

4. Write $P_1 - P_2$ in terms of the difference in height Δh of the liquid in the arms of the U-tube. This pressure difference equals the pressure drop in the column of height Δh of the liquid, less the pressure drop and that in the column of the same height of the fluid.

$$P_1 - P_2 = \rho_L g\,\Delta h - \rho_F g\,\Delta h = (\rho_L - \rho_F)g\,\Delta h$$

5. Equate the two expressions for $P_1 - P_2$ and solve for v_1 in terms of Δh.

$$\tfrac{1}{2}\rho_F(r^2 - 1)v_1^2 = (\rho_L - \rho_F)g\,\Delta h$$

$$\text{so} \quad v_1 = \boxed{\sqrt{\frac{2(\rho_L - \rho_F)g\,\Delta h}{\rho_F(r^2 - 1)}}}$$

CHECK Let us check the dimensions of the expression for v_1 in step 5. A ratio of two densities is dimensionless, as is the ratio of two areas, r. Therefore, the dimension of the expression for v_1 is the same as the dimension of $\sqrt{2g\,\Delta h}$. The dimension of g is length divided by time squared, so the dimension of gh is length squared divided by time squared. Thus, the dimension of the square root of gh is length divided by time—the dimension of speed. The step-5 result is dimensionally correct.

PRACTICE PROBLEM 13-12 Find v_1 if $\Delta h = 3$ cm, $r = 4$, the fluid is air ($\rho_F = 1.29$ kg/m^3), and the liquid in the U-tube portion of the venturi meter is water ($\rho_w = 10^3$ kg/m^3).

Air is a compressible fluid, so the calculation in Practice Problem 13-12 is not as accurate as the calculation in the Example 13-10. Strictly speaking, the Bernoulli equation and the continuity equation hold only for incompressible fluids.

An airplane wing is an airfoil (Figure 13-23) that in normal circumstances causes streamlines to curve—following the curve of the airfoil surfaces. (The streamlines fail to follow the surfaces during an undersirable event occurance a stall.) During our analysis of how the curved streamlines produce lift (the upward force on the wing), we will neglect any variations in pressure due to the effects of gravity on the air. In addition, the analysis will be done in a frame of reference moving with the wing.

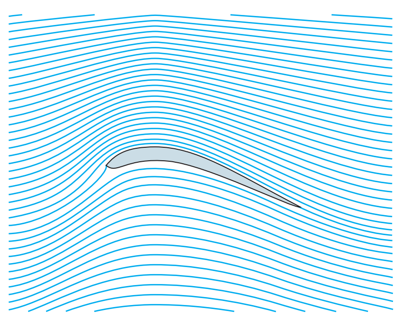

FIGURE 13-23 The purpose of an airfoil is to cause the streamlines to curve. Under normal conditions the streamlines will follow the curve of the airfoil. The airfoil shown is very thin, like the wing of a raptor. It is very efficient in creating lift.

A parcel of air in moving along a curved streamline is accelerating in the centripetal direction—toward the center of curvature of the streamline. For the streamlines above the wing, the direction of this acceleration is more or less downward. Thus, the net force on the parcel is downward. This means the air pressure just above the parcel is greater than the air pressure just below the parcel. As a result, the air pressure is greater at points far above the wing than at points next to the upper surface of the wing. The pressure far above the wing is the ambient air pressure, so we can conclude that the pressure at the upper surface of the wing is less than the ambient air pressure. The parcels in the streamlines that pass below the wing also accelerate downward. Thus, the pressure far below the wing is less than the pressure at the lower surface of the wing. The pressure far below the wing is equal to the ambient air pressure, so we can conclude that the pressure at the lower surface of the wing is greater than the ambient air pressure. The lift on the wing is due to the pressure immediately below the wing being greater than the pressure immediately above the wing.

Applying Newton's second law ($F = ma$) to a parcel of air (Figure 13-24) with area A and thickness Δr, moving at speed v, we get

$$(P + \Delta P)(A) - PA = (\rho A\, \Delta r)\frac{v^2}{r}$$

where r is the distance of the parcel from the center of curvature of the streamline, ρ is the density of air, P is the pressure of the parcel surface closest to the center of curvature, and $P + \Delta P$ is the pressure at the opposite surface of the parcel. Simplifying and rearranging this equation gives

$$\frac{\Delta P}{\Delta r} = \rho\frac{v^2}{r}$$

As Δr approaches zero this becomes

$$\frac{\partial P}{\partial r} = \rho\frac{v^2}{r} \qquad 13\text{-}19$$

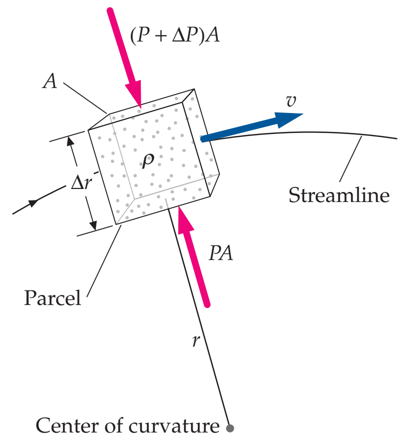

FIGURE 13-24 The centripetal force on a parcel moving along a curved streamline is due to a pressure difference across the parcel.

The derivative in this equation is a partial derivative because it represents the rate of change of pressure perpendicular to the streamlines. The pressure also varies along the direction tangent to the streamlines.

We now show how the pressure varies with position along a streamline. Consider a small parcel of air moving along a streamline that passes over the wing. When the parcel is far in front of the wing, it is at ambient pressure. As the parcel moves into the region above the wing, it moves into a region of lower pressure. The parcel gains speed as it enters this region because the pressure behind the parcel pushing it forward is greater than the pressure in front of it pushing it backward. Suppose point 1 is far in front of the wing and point 2 is directly above the wing and on the same streamline. The pressures at these two points are then related by the Bernoulli equation:

$$P_1 + \tfrac{1}{2}\rho v_1^2 = P_2 + \tfrac{1}{2}\rho v_2^2 \qquad 13\text{-}20$$

(The Bernoulli equation is only approximately valid in this context, because air is both compressible and viscous.) Point 1 is far in front of the wing, so P_1 is equal to the ambient air pressure and v_1 is the speed of the air at point 1. In the previous paragraph we showed the pressure P_2 above the wing to be less than the ambient air pressure. Equation 13-20 reveals that if $P_2 < P_1$, then $v_2 < v_1$. That is, the Bernoulli equation predicts that the parcels of air gain speed as they enter the low-pressure region above the wing. In addition, the parcels of air that enter the high-pressure region below the wing lose speed, as predicted by the Bernoulli equation.

Now we consider a spinning baseball moving through still air. Figure 13-25 shows this situation from a reference frame moving with the ball. As the ball spins, it tends to drag air around with it. As a result, the streamlines are curved as shown. Is the air pressure greater immediately above the ball or immediately below it? (As before, we are neglecting any changes in air pressure due to the effects of gravity.) The air pressure is greater immediately below the ball, as we shall explain. The surrounding air exerts pressure forces on the packets of air moving along the streamlines. If the streamlines are curved, there are resultant pressure forces on the packets in the centripetal direction. Thus, as with the wing, the pressure immediately above the ball is

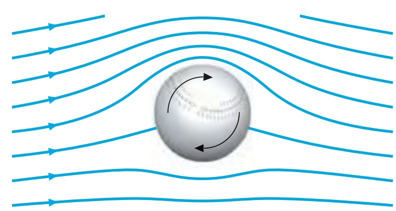

FIGURE 13-25 The ball is moving from right to left, so in the reference frame of the ball, the air moves from left to right, as shown.

significantly less than the pressure far above the ball—which is equal to the ambient air pressure. The streamlines just below the ball are almost straight, so the pressure just below the ball is almost the same as the pressure far below the ball, which is equal to the ambient air pressure. Thus, pressure immediately below the ball is greater than the pressure immediately above the ball. As a result the air exerts an upward force on the ball. The ball will not fall as fast as it would if gravity alone were acting on it.

Although the Bernoulli equation is very useful for qualitative descriptions of many features of fluid flow, such descriptions are often grossly inaccurate when compared with the quantitative results of experiments. Prominent reasons for the discrepancies are that gases like air are hardly incompressible, and liquids like water are hardly inviscid, which invalidates the assumptions made in deriving the Bernoulli equation. In addition, it is often difficult to maintain steady, streamlined flow without turbulence, and the introduction of turbulence can greatly affect the results.

* VISCOUS FLOW

According to Bernoulli's equation, when a fluid flows steadily through a long, narrow, horizontal pipe of constant cross section, the pressure along the pipe will be constant. In practice, however, we observe a pressure drop as we move along the direction of the flow. Put another way, a pressure difference is required to push a fluid through a horizontal pipe. This pressure difference is needed because the fluid flows in very thin layers, and the thin layer of fluid in contact with the pipe is held stationary by forces exerted on it by the pipe. As we move away from the surface of the pipe, the speed of each successive layer is slightly greater than the speed of the layer next to it on one side, and each layer is held back by forces exerted on it by the slightly slower-moving layer next to it on one side (just as each lamina is pulled forward by forces exerted on it by the slightly faster-moving lamina next to it on the other side). These forces between adjacent layers are called **viscous forces.** As a result of viscous forces, the velocity of the fluid is not constant across the diameter of the pipe. Instead, it is greatest near the center of the pipe and approaches zero where the fluid is in contact with the walls of the pipe (Figure 13-26). Let P_1 be the pressure at point 1 and P_2 be that at point 2, a distance L downstream from point 1. The pressure drop $\Delta P = P_1 - P_2$ is proportional to the volume flow rate:

$$\Delta P = P_1 - P_2 = I_V R \qquad 13\text{-}21$$

DEFINITION: RESISTANCE

where $I_V = vA$ is the volume flow rate and the proportionality constant R is the *resistance* to flow, which depends on the length of the pipe L, the radius r, and the viscosity of the fluid.

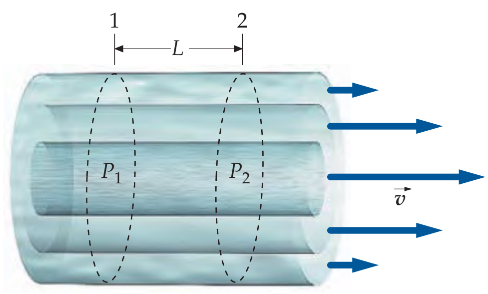

FIGURE 13-26 When a viscous fluid flows through a pipe, the speed is greatest at the center of the pipe. At the walls of the pipe, the speed of the fluid approaches zero.

Example 13-12 Resistance to Blood Flow

Blood flows from the aorta through the major arteries, the small arteries, the capillaries, and the veins until it reaches the right atrium. During the course of that flow, the (gauge) pressure drops from about 100 torr to zero. If the volume flow rate is 800 mL/s, find the total resistance of the circulatory system.

PICTURE The resistance is related to the pressure drop and volume flow rate by Equation 13-21. We can use Equation 13-9 to convert from torr to kPa.

SOLVE

Write the resistance in terms of the pressure drop and volume flow rate, and convert all terms to SI units:

$$R = \frac{\Delta P}{I_V} = \frac{100\text{ torr}}{0.800\text{ L/s}} \times \frac{101\text{ kPa}}{760\text{ torr}} \times \frac{1\text{ L}}{10^3\text{ cm}^3} \times \frac{1\text{ cm}^3}{10^{-6}\text{ m}^3}$$

$$= 16.61\text{ kPa}\cdot\text{s/m}^3 = \boxed{16.6\text{ kPa}\cdot\text{s/m}^3}$$

CHECK We could have used 1 Pa = 1 N/m^2 to write the result as 16.6 kN·s/m^5. The dimensions of resistance are the dimensions of pressure divided by the dimensions of volume flow rate. The dimensions of pressure are the dimensions of force divided by the dimension of length squared, and the dimensions of volume flow rate are the dimension of length cubed divided by the dimension of time. Thus, the dimensions of resistance are the dimensions of pressure times the dimension of time divided by the dimension of length raised to the fifth power. The units of the result have the correct dimensions, so the result is plausible.

To define the coefficient of viscosity of a fluid, we consider a fluid that is confined between two rectangular parallel plates, each of area A, separated by a distance z, as shown in Figure 13-27. The upper plate is pulled at a constant speed v by a force $\vec{F}$, while the bottom plate is held at rest. A force is needed to pull the upper plate because the fluid next to the plate exerts a viscous drag force opposing its motion. The fluid flows in thin layers, or **lamina,** and the motion is called **laminar flow.** The speed of the lamina in contact with the upper plate is v, the speed of the lamina in contact with the lower plate approaches zero, and the speeds of the laminas increase linearly with distance from the lower plate. The force $\vec{F}$ on the upper plate is found to be directly proportional to v and A and inversely proportional to the plate separation z. The proportionality constant is the **coefficient of viscosity** η:

$$F = \eta\frac{vA}{z} \qquad \text{13-22}$$

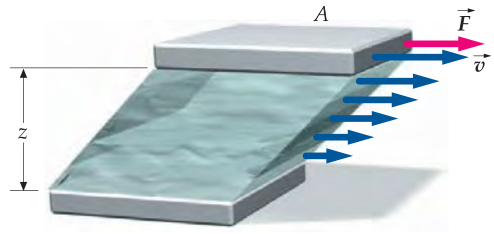

FIGURE 13-27 Two plates of equal area with a viscous fluid between them. When the upper plate is moved relative to the lower one, each layer of fluid exerts a drag force on the adjacent layers. The force needed to pull the upper plate is directly proportional to v and the area A, and inversely proportional to z, the separation between the plates.

The SI unit of viscosity is the N·s/m^2 = Pa·s. An older cgs unit still in common use is the **poise,** named after the French physicist Jean Poiseuille. These units are related by

$$1\ \text{Pa}\cdot\text{s} = 10\ \text{poise} \qquad \text{13-23}$$

Table 13-3 lists the coefficients of viscosity for several fluids at various temperatures. Typically, the viscosity of a liquid increases as the temperature decreases. Thus, in cold climates, a less viscous grade of oil is used to lubricate automobile engines in the winter than in summer.

Table 13-3 Coefficients of Viscosity for Various Fluids

Fluid	t, °C	η, mPa·s
Water	0	1.8
	20	1.00
	60	0.65
Blood (whole)	37	4.0
Engine oil (SAE 10W)	30	200
Glycerin	0	10,000
	20	1,410
	60	81
Air	20	0.018

Poiseuille's law The resistance to flow R in Equation 13-21 for steady flow through a circular tube of radius r can be shown to be

$$R = \frac{8\eta L}{\pi r^4} \qquad \text{13-24}$$

Equations 13-21 and 13-24 can be combined to give the pressure drop over a length L of a circular tube of radius r:

$$\Delta P = \frac{8\eta L}{\pi r^4} I_\text{V} \qquad \text{13-25}$$

POISEUILLE'S LAW

Equation 13-25 is known as **Poiseuille's law.** Note the inverse r^4 dependence of the pressure drop. If the radius of the tube is halved, the pressure drop for a given volume flow rate is increased by a factor of 16; or a pressure 16 times as great is needed to pump the fluid through the tube at the original volume flow rate. Thus, for example, if the diameter of a person's blood vessels or arteries is reduced for some reason, either the volume flow rate of the blood is greatly reduced, or the blood pressure must escalate to maintain the volume flow rate. For water flowing through a long garden hose open at one end and connected to a constant pressure source at the other end, the pressure drop is fixed. It equals the difference in pressure between that at the water source and atmospheric pressure at the open end. The volume flow rate is then proportional to the fourth power of the radius. Thus, the volume flow rate increases by a factor of more than 5 when you switch to a three-quarter-inch-diameter hose from a half-inch-diameter hose. That is so because $(0.75/0.50)^4 = 5.1$.

Poiseuille's law applies only to the laminar flow of a fluid of constant viscosity. In some fluids, viscosity changes with velocity, violating Poiseuille's law. Blood, for example, is a complex fluid consisting of solid particles of various shapes suspended in a liquid. Red blood cells are disk-shaped objects that are randomly oriented at low speeds, but at high speeds tend to become oriented to facilitate the flow. Thus, the viscosity of blood decreases as the flow speed increases, so Poiseuille's law cannot be strictly applied. Nevertheless, Poiseuille's law is a good approximation that is very useful for obtaining a qualitative understanding of blood flow.

In Chapter 25 the flow of electrical current I through metal wires is studied. One of the basic relations in that chapter is Ohm's law, $\Delta V = IR$, where ΔV is the potential difference and R is the electrical resistance of the wire. As we shall see, Ohm's law is analogous to Poiseuille's law, $\Delta P = I_V R$.

TURBULENCE: REYNOLDS NUMBER

When the flow speed of a fluid becomes sufficiently great, laminar flow breaks down and turbulence sets in. The critical speed above which the flow through a tube is turbulent depends on the density and viscosity of the fluid and on the radius of the tube. The flow of a fluid can be characterized by a dimensionless number called the **Reynolds number,** N_R, which is defined by

$$N_R = \frac{2r\rho v}{\eta} \qquad 13\text{-}26$$

where v is the average speed of the fluid. Experiments have shown that the flow will be laminar if the Reynolds number is less than about 2000 and turbulent if it is greater than 3000. Between these values, the flow is unstable and may change from one type to the other.

False-color view of turbulence of blood flowing into and out of the heart as seen by magnetic resonance imaging (MRI). Systolic ejection from the left ventricle into the aorta is seen in red, and diastolic filling of the ventricles in blue. *(Pickler International.)*

Example 13-13 Blood Flow in the Aorta

Calculate the Reynolds number for blood flowing at 30 cm/s through an aorta of radius 1.0 cm. Assume that blood has a viscosity of 4.0 mPa·s and a density of 1060 kg/m³.

PICTURE Because N_R is dimensionless, we can use any system of units as long as we are consistent.

SOLVE

Write Equation 13-26 for the Reynolds number, expressing each quantity in SI units:

$$N_R = \frac{2r\rho}{\eta} = \frac{2(0.010\text{ m})(1060\text{ kg/m}^3)(0.30\text{ m/s})}{4.0 \times 10^{-3}\text{ Pa}\cdot\text{s}}$$

$$= 1590 = \boxed{1.6 \times 10^3}$$

CHECK Because the Reynolds number is less than 2000, this flow will be laminar rather than turbulent. We expect the flow of blood to be nonturbulent, so our result is plausible.

Physics Spotlight

Automotive Aerodynamics: Ride with the Wind

The shape and finish of a car's body can reduce drag and increase fuel economy. As a result, many recent passenger cars have a half-teardrop shape in profile. However, the curve of the air flow over the top of this type of car creates a region of low pressure at the top of the car. This low pressure provides lift, which reduces the normal force upon the road. This makes it harder for the driver to safely maneuver curves. Lift is proportional to the square of the speed. At speeds achieved during car races, the lift can be significant. The lift results in a loss of traction, which on curves can determine the outcome of a race.

Automotive engineers call an increase in normal force "downforce," which is negative lift. In order to increase speeds on curves, different racing teams use different methods to increase the downforce on their cars. Formula 1 and Indy cars use large airfoils shaped like upside down airplane wings to create low pressure underneath the cars that will give increases in downforce. Airfoils were first introduced to Indy cars in 1972. The one-lap record speed increased by 20 mph that year.[*] Indy cars also contour the bottoms of their cars, to reduce the pressure underneath their cars. At racing speeds, the downforce-to-weight ratio can exceed one at racing speeds.[†,‡] Some race cars have even used fans to pull air quickly under the car's body,[#] although most racing rules do not allow them today.

The most visible modifications to NASCAR cars are aerodynamic. They have stiff skirts on the sides, and a very low spoiler in front. A spoiler extends the width of the car in back, and on some tracks, a roof spoiler is required. The spoilers increase the drag of the car, so the car does not go faster than safety concerns demand. In rare cases, aero flaps open on the roof of the car when cars drift rapidly sideways or backwards. In fact, an entire class of accidents has been prevented because these flaps were introduced in 1994.[°]

In 1994, Formula 1 banned the use of bottom contouring in cars, and required that the car bottoms be flattened. The intent was to reduce the speed of the races, as two drivers had died in crashes.[§] Teams had two weeks to implement these rules, and figure out how to maintain as much "downforce" as possible.[¶] All these teams use computation fluid dynamics (CFD) modeling programs, as well as scale wind tunnels for testing ideas before implementing them.

Race teams are not the only groups to use wind tunnels and CFD programs to test their designs. A group at the Georgia Tech Research Institute modeled the turbulence behind semitrucks, and tested their models in a small-scale wind tunnel. They found that by adding a system of slits and air compressors, they could decrease a truck's drag by up to 35 percent at highway speeds.[**] In road tests,[††] the system was shown to improve overall fuel economy by 8 to 9 percent.[‡‡] Some of the same technology that has been used to make cars go very quickly may soon be used to save over a billion gallons of gasoline a year.

At highway speeds aerodynamic drag is reduced because of the jets of air along the back edge of the truck body of this prototype. *(Courtesy of Georgia Institute of Technology.)*

Summary

1. Density, specific gravity, and pressure are defined quantities that are important in fluid statics and dynamics.
2. Pascal's principle, Archimedes' principle and the Bernoulli equation are derived from Newton's laws.

*3. The venturi effect is a special case of Bernoulli's equation.

4. A transverse pressure gradient always accompanies curved streamlines.

*5. Poiseuille's law accounts for pressure drops due to viscosity; Reynolds number is used to predict whether flow is laminar or turbulent.

TOPIC	RELEVANT EQUATIONS AND REMARKS	
1. Density	The density of a substance is the ratio of its mass to its volume: $$\rho = \frac{dm}{dV}$$ The densities of most solids and liquids are approximately independent of temperature and pressure, whereas those of gases depend strongly on these quantities.	13-1
2. Specific Gravity	The specific gravity of a substance is the ratio of its density to that of another substance, usually water.	
3. Pressure	$$P = \frac{F}{A}$$	13-3
Units	$1\ \text{Pa} = 1\ \text{N/m}^2$	13-4
	$1\ \text{atm} = 760\ \text{mmHg} = 760\ \text{torr} = 29.9\ \text{inHg} = 101.325\ \text{kPa} = 14.7\ \text{lb/in.}^2$	13-9
	$1\ \text{bar} = 10^3\ \text{millibars} = 100\ \text{kPa}$	13-10
Gauge pressure	Gauge pressure is the difference between the absolute pressure and atmospheric pressure: $$P = P_{\text{gauge}} + P_{\text{at}}$$	
In a static liquid	$P = P_0 + \rho g\ \Delta h$ (ρ constant)	13-7
In a gas	In a gas such as air, pressure decreases exponentially with altitude.	
Bulk modulus	$$B = -\frac{\Delta P}{\Delta V/V}$$	13-6
4. Pascal's Principle	Pressure changes applied to a confined fluid are transmitted undiminished to every point in the fluid and to the walls of the container.	
5. Archimedes' Principle	A body wholly or partially submerged in a fluid is buoyed up by a force equal to the weight of the displaced fluid.	
***6. Fluid Flow**		
Mass flow rate and continuity equation	$I_M = \rho A v$ — Mass flow rate	
	$I_{M1} - I_{M2} = dm_{12}/dt$ — Continuity equation	13-14
Volume flow rate and continuity equation for an incompressible fluid	$I_V = Av$ — Volume flow rate	
	$A_1v_1 = A_2v_3$ — Incompressible fluid	
Bernoulli equation	Along a streamline of a nonviscous, incompressible fluid undergoing steady flow: $$P + gh + \tfrac{1}{2}\rho v^2 = \text{constant}$$	13-17*b*
Venturi effect	As air, or another fluid, passes through a constriction its speed increases and its pressure drops	

TOPIC	RELEVANT EQUATIONS AND REMARKS	
Resistance to fluid flow	$\Delta P_2 = I_V R$	13-21
Coefficient of viscosity	$\eta = \dfrac{F/A}{v/z}$	13-22
Poiseuille's law for viscous flow	$\Delta P = RI_V = \dfrac{8\eta L}{\pi r^4} I_V$	13-25
Laminar flow, turbulent flow, and the Reynolds number	The flow will be laminar if the Reynolds number N_R is less than about 2000 and turbulent if it is greater than 3000, where N_R is given by N_R $N_R = \dfrac{2r\rho v}{\eta}$	13-26

Answers to Concept Checks

13-1 No. The water packets are not slowing because they are entering a region of higher pressure. Instead they are slowing because of viscous drag forces on them. The Bernoulli equation is valid only if viscous forces are negligible.

13-2 The constriction is functional. The narrow region is a venturi. When the bulb is vigorously squeezed, the pressure in the constricted region drops below atmospheric pressure due to the venturi effect. This reduces the pressure in the vertical tube so the air pressure on the top of the liquid in the reservoir is able to push the liquid up the vertical tube and into the horizontal air stream.

Answers to Practice Problems

13-1 (*a*) 7.97 kg/L, (*b*) iron

13-2 19 kg

13-3 With $P_0 = 1.00$ atm $= 101$ kPa, $P = 2.00$ atm, $\rho = 1000\ \text{kg/m}^3$, and $g = 9.81$ N/kg, we have $\Delta h = \Delta P/\rho g = 10.3$ m. The pressure at a depth of 10.3 m is twice that at the surface.

13-4 $h = P/\rho g = 0.760\ \text{m} = 760\ \text{mm}$

13-5 (*a*) 338 mmHg, (*b*) 0.444 atm

13-6 The specific gravity of the material is 2.7, which is the specific gravity of aluminum. The material is aluminum.

13-7 72.9 N

13-8 45 percent

13-9 $I_V = vA = 9.4 \times 10^{-5}\ \text{m}^3/\text{s}$. It is customary to give the pumping rate of the heart in liters per minute. Using $1\ \text{m}^3 = 1000$ L and 1 min $= 60$ s, we have $I_V = 5.7$ L/min.

13-10 If v_1 and v_2 are the initial and final speeds and A_1 and A_2 are the initial and final areas, Equation 13-15 gives

$$v_2 = \frac{A_1}{A_2} v_1 = \frac{\pi(0.30\ \text{cm})^2}{\pi(0.20\ \text{cm})^2}(10\ \text{cm/s}) = 23\ \text{cm/s}$$

13-11 The water shoots upward a distance h; that is, to the same level as the surface of the water in the tank.

13-12 5.51 m/s

Problems

In a few problems, you are given more data than you actually need; in a few other problems, you are required to supply data from your general knowledge, outside sources, or informed estimate.

Interpret as significant all digits in numerical values that have trailing zeros and no decimal points.

- • Single-concept, single-step, relatively easy
- •• Intermediate-level, may require synthesis of concepts
- ••• Challenging
- SSM Solution is in the *Student Solutions Manual*
- Consecutive problems that are shaded are paired problems.

CONCEPTUAL PROBLEMS

1 • If the gauge pressure is doubled, the absolute pressure will be (*a*) halved, (*b*) doubled, (*c*) unchanged, (*d*) increased by a factor greater than 2, (*e*) increased by a factor less than 2.

2 • Two spherical objects differ in size and mass. Object A has a mass that is eight times the mass of object B. The radius of object A is twice the radius of object B. How do their densities compare? (*a*) $\rho_A > \rho_B$, (*b*) $\rho_A < \rho_B$, (*c*) $\rho_A = \rho_B$, (*d*) Not enough information is given to compare their densities.

3 • Two objects differ in density and mass. Object A has a mass that is eight times the mass of object B. The density of object A is four times the density of object B. How do their volumes compare? (*a*) $V_A = \frac{1}{2}V_B$, (*b*) $V_A = V_B$, (*c*) $V_A = 2V_B$, (*d*) Not enough information is given to compare their volumes. SSM

4 • A sphere is constructed by gluing together two hemispheres. The density of each hemisphere is uniform, but the density of one is greater than the density of the other. True or false: The average density of the sphere is the numerical average of the two different densities. Clearly explain your reasoning.

5 • **Biological Application, Context-Rich** In several jungle adventure movies, the hero and heroine escape the bad guys by hiding underwater for extended periods of time. To do this, they breathe through long vertical hollow reeds. Imagine that in one movie, the water is so clear that to be safely hidden, the two are at a depth of 15 m. As a science consultant to the movie producers, you tell them that this depth is not realistic and the knowledgeable viewer will laugh during this scene. Explain why this is so.

6 •• Two objects are balanced as in Figure 13-28. The objects have identical volumes but different masses. Assume all the objects in the figure are denser than water and thus none will float. Will the equilibrium be disturbed if the entire system is completely immersed in water? Explain your reasoning.

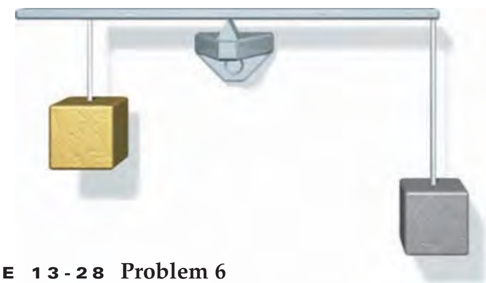

FIGURE 13-28 Problem 6

7 •• A solid 200-g block of lead and a solid 200-g block of copper are completely submerged in a aquarium filled with water. Each block is suspended just above the bottom of the aquarium by a thread. Which of the following is true? SSM

(*a*) The buoyant force on the lead block is greater than the buoyant force on the copper block.
(*b*) The buoyant force on the copper block is greater than the buoyant force on the lead block.
(*c*) The buoyant force is the same on both blocks.
(*d*) More information is needed to choose the correct answer.

8 •• A 20-cm^3 block of lead and a 20-cm^3 block of copper are completely submerged in an aquarium filled with water. Each is suspended just above the bottom of the aquarium by a thread. Which of the following is true?

(*a*) The buoyant force on the lead block is greater than the buoyant force on the copper block.
(*b*) The buoyant force on the copper block is greater than the buoyant force on the lead block.
(*c*) The buoyant force is the same on both blocks.
(*d*) More information is needed to choose the correct answer.

9 •• Two bricks are completely submerged in water. Brick 1 is made of lead and has rectangular dimensions of 2″ × 4″ × 8″. Brick 2 is made of wood and has rectangular dimensions of 1″ × 8″ × 8″. *True or false:* The buoyant force on brick 2 is larger than the buoyant force on brick 1.

10 •• Figure 13-29 shows an object called a "Cartesian diver." The diver consists of a small tube, open at the bottom, with an air bubble at the top, inside a closed plastic soda bottle that is partly filled with water. The diver normally floats, but sinks when the bottle is squeezed hard. (*a*) Explain why this happens. (*b*) Explain the physics behind how a submarine can "silently" sink vertically simply by allowing water to flow into empty tanks near its keel. (*c*) Explain why a person floating in water will oscillate up and down on the water's surface as he or she breathes in and out.

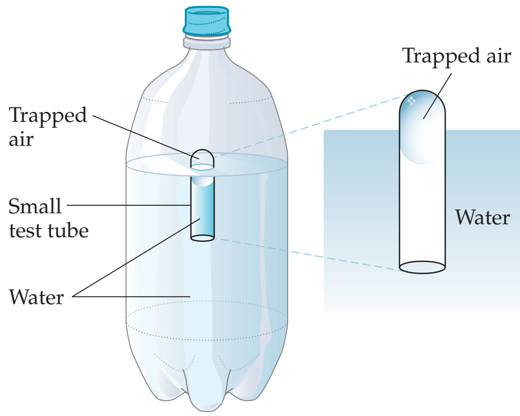

FIGURE 13-29 Problem 10

11 •• A certain object has a density just slightly less than that of water so that it floats almost completely submerged. However, the object is more compressible than water. What happens if the floating object is given a slight downward push? Explain.

12 •• In Example 13-11, the fluid is accelerated to a greater speed as it enters the narrow part of the pipe. Identify the forces that act on the fluid at the entrance to the narrow region to produce this acceleration.

13 •• An upright glass of water is accelerating to the right along a flat, horizontal surface. What is the origin of the force that produces the acceleration on a small element of water in the middle of the glass? Explain by using a diagram. *Hint: The water surface will not remain level as long as the glass of water is accelerating. Draw a free-body diagram of the small element of water.* SSM

14 •• You are sitting in a boat floating on a very small pond. You take the anchor out of the boat and drop it into the water. Does the water level in the pond rise, fall, or remain the same? Explain your answer.

15 •• A horizontal pipe narrows from a diameter of 10 cm at location A to 5.0 cm at location B. For a nonviscous incompressible fluid flowing without turbulence from location A to location B, how do the flow speeds v (in m/s) compare at the two locations? (*a*) $v_A = v_B$, (*b*) $v_A = \frac{1}{2}v_B$, (*c*) $v_A = \frac{1}{4}v_B$, (*d*) $v_A = 2v_B$, (*e*) $v_A = 4v_B$

16 •• A horizontal pipe narrows from a diameter of 10 cm at location A to 5.0 cm at location B. For a nonviscous incompressible fluid flowing without turbulence from location A to location B, how do the pressures P compare at the two locations? (*a*) $P_A = P_B$, (*b*) $P_A = \frac{1}{2}P_B$, (*c*) $P_A = \frac{1}{4}P_B$, (*d*) $P_A = 2P_B$, (*e*) $P_A = 4P_B$, (f) There is not enough information to compare the pressures quantitatively.

17 •• **BIOLOGICAL APPLICATION** Figure 13-30 is a diagram of a prairie dog tunnel. The geometry of the two entrances are such that entrance 1 is surrounded by a mound and entrance 2 is surrounded by flat ground. Explain how the tunnel remains ventilated, and indicate in which direction air will flow through the tunnel. SSM

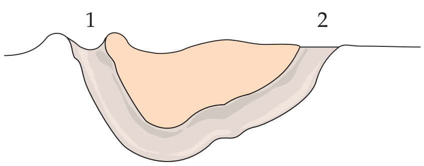

FIGURE 13-30 Problem 17

ESTIMATION AND APPROXIMATION

18 •• Your undergraduate research project involves atmospheric sampling. The sampling device has a mass of 25.0 kg. Estimate the diameter of a helium-filled balloon required to lift the device off the ground. Neglect the mass of the balloon "skin" and the small buoyancy force on the device itself.

19 ••• **CONTEXT-RICH** Your friend wants to start a business giving hot-air balloon rides. The empty balloon, the basket and the occupants have a total maximum mass of 1000 kg. If the balloon has a diameter of 22.0 m when fully inflated with hot air, estimate the required density of the hot air. Neglect the buoyancy force on the basket and people.

DENSITY

20 • Find the mass of a solid lead sphere with a radius equal to 2.00 cm.

21 • Consider a room measuring 4.0 m × 5.0 m × 4.0 m. Under normal atmospheric conditions at Earth's surface, what would be the mass of the air in the room? SSM

22 • An average neutron star has approximately the same mass as the Sun, but is compressed into a sphere of radius roughly 10 km. What would be the approximate mass of a teaspoonful of matter that dense?

23 •• A 50.0-g ball consists of a plastic spherical shell and a water-filled core. The shell has an outside diameter equal to 50.0 mm and an inside diameter equal to 20.0 mm. What is the density of the plastic?

24 •• A 60.0-mL flask is filled with mercury at 0°C (Figure 13-31). When the temperature increases to 80°C, 1.47 g of mercury spills out of the flask. Assuming that the volume of the flask stays constant, find the change in the density of mercury at 80°C if its density at 0°C is 13 645 kg/m^3.

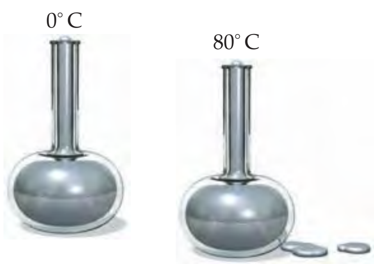

FIGURE 13-31 Problem 24

25 •• One sphere is made of gold and has a radius r_{Au} and another sphere is made of copper and has a radius r_{Cu}. If the spheres have equal mass, what is the ratio of the radii, r_{Au}/r_{Cu}?

26 ••• Since 1983, the U.S. Mint has coined pennies that are made out of zinc with a copper cladding. The mass of this type of penny is 2.50 g. Model the penny as a uniform cylinder of height 1.23 mm and radius 9.50 mm. Assume the copper cladding is uniformly thick on all surfaces. If the density of zinc is 7140 kg/m^3 and that of copper is 8930 kg/m^3, what is the thickness of the copper cladding?

PRESSURE

27 • Barometer readings are commonly given in inches of mercury (inHg). Find the pressure in inches of mercury equal to 101 kPa.

28 • The pressure on the surface of a lake is P_{at} = 101 kPa. (*a*) At what depth is the pressure $2P_{at}$? (*b*) If the pressure at the top of a deep pool of mercury is P_{at}, at what depth is the pressure $2P_{at}$?

29 • **BIOLOGICAL APPLICATION** When at cruising altitude, a typical airplane cabin will have an air pressure equivalent to an altitude of about 2400 m. During the flight, ears often equilibrate, so that the air pressure inside the inner ear equalizes with the air pressure outside the plane. The Eustachian tubes allow for this equalization, but can become clogged. If an Eustachian tube is clogged, pressure equalization may not occur on descent and the air pressure inside an inner ear may remain equal to the pressure at 2400 m. In that case, by the time the plane lands and the cabin is repressurized to sea-level air pressure, what is the net force on one ear drum due to this pressure difference, assuming the ear drum has an area of 0.50 cm^2?

30 • The axis of a cylindrical container is vertical. The container is filled with equal masses of water and oil. The oil floats on top of the water, and the open surface of the oil is at a height h above the bottom of the container. What is the height, h, if the pressure at the bottom of the water is 10 kPa greater than the pressure at the top of the oil? Assume the oil density is 875 kg/m^3.

31 • **ENGINEERING APPLICATION** A hydraulic lift is used to raise a 1500-kg automobile. The radius of the shaft of the lift is 8.00 cm and the radius of the compressor's piston is 1.00 cm. How much force must be applied to the piston to raise the automobile? *Hint: The shaft of the lift is the other piston.* SSM

32 • **ENGINEERING APPLICATION** A 1500-kg car rests on four tires, each of which is inflated to a gauge pressure of 200 kPa. If the four tires support the car's weight equally, what is the area of contact of each tire with the road?

33 •• What pressure increase is required to compress the volume of 1.00 kg of water from 1.00 L to 0.99 L? Could this compression occur in the ocean, where the maximum depth is about 11 km? Explain.

34 •• When a woman in high-heeled shoes takes a step, she momentarily places her entire weight on one heel of her shoe. If her mass is 56.0 kg and if the area of the heel is 1.00 cm^2, what is the pressure exerted on the floor by the heel? Compare your answer to the pressure exerted by one foot of an elephant on a flat floor. Assume the elephant's mass is 5000 kg, that he has all four feet equally distributed on the floor, and that each foot has an area of 400 cm^2.

35 •• In the seventeenth century, Blaise Pascal performed the experiment shown in Figure 13-32. A wine barrel filled with water was coupled to a long tube. Water was added to the tube until the barrel burst. The radius of the barrel's lid was 20 cm and the height of the water in the tube was 12 m. (*a*) Calculate the force exerted on the lid due to the pressure increase. (*b*) If the tube had an inner radius of 3.0 mm, what mass of water in the tube caused the pressure that burst the barrel?

FIGURE 13-32
Problem 35

36 •• **Biological Application** Blood plasma flows from a bag through a tube into a patient's vein, where the blood pressure is 12 mmHg. The specific gravity of blood plasma at 37°C is 1.03. What is the minimum elevation of the bag so that the plasma flows into the vein?

37 •• **Biological Application** Many people have imagined that if they were to float the top of a flexible snorkel tube out of the water, they would be able to breathe through it while walking underwater (Figure 13-33). However, they generally do not take into account just how much water pressure opposes the expansion of the chest and the inflation of the lungs. Suppose you can just breathe while lying on the floor with a 400-N (90-lb) weight on your chest. How far below the surface of the water could your chest be for you still to be able to breathe, assuming your chest has a frontal area of 0.090 m^2?

FIGURE 13-33
Problem 37

38 •• **Engineering Application** In Example 13-3, a 150-N force is applied to a small piston to lift a car that weighs 15 000 N. Demonstrate that this does not violate the law of conservation of energy by showing that, when the car is lifted some distance *h*, the work done by the 150-N force acting on the small piston equals the work done on the car by the large piston.

39 •• A 5.00-kg lead sinker is accidentally dropped overboard by fishermen in a boat directly above the deepest portion of the Marianas trench, near the Philippines. By what percentage does the volume of the sinker change, by the time it settles on the trench bottom, which is 10.9 km below the surface?

40 ••• The volume of a cone of height h and base radius r is $V = \pi r^2 h/3$. A jar in the shape of a cone of height 25 cm has a base with a radius equal to 15 cm. The jar is filled with water. Then its lid (the base of the cone) is screwed on and the jar is turned over so its lid is horizontal. (*a*) Find the volume and weight of the water in the jar. (*b*) Assuming the pressure inside the jar at the top of the cone is equal to 1 atm, find the excess force exerted by the water on the base of the jar, where by excess force we mean the force minus the force exerted by air pressure on the outside of the base of the jar. Explain how this force can be greater than the weight of the water in the jar.

BUOYANCY

41 • A 500-g piece of copper, with specific gravity of 8.96, is suspended from a spring scale and is submerged in water (Figure 13-34). What force does the spring scale read?

FIGURE 13-34
Problem 41

42 • When a certain rock is suspended from a spring scale, the scale-display reads 60 N. However, when the suspended stone is submerged in water, the display reads 40 N. What is the density of the rock?

43 • A block of an unknown material weighs 5.00 N in air and 4.55 N when submerged in water. (*a*) What is the density of the material? (*b*) From what material is the block likely to have been made? SSM

44 • A solid piece of metal weighs 90.0 N in air and 56.6 N when submerged in water. What is the density of this metal?

45 •• A homogeneous solid object floats on water, with 80.0 percent of its volume below the surface. When placed in a second liquid, the same object floats on that liquid with 72.0 percent of its volume below the surface. Determine the density of the object and the specific gravity of the liquid.

46 •• A 5.00-kg iron block is suspended from a spring scale and is submerged in a fluid of unknown density. The spring scale reads 6.16 N. What is the density of the fluid?

47 •• A large piece of cork weighs 0.285 N in air. When held submerged underwater by a spring scale, as shown in Figure 13-35, the spring scale reads 0.855 N. Find the density of the cork.

FIGURE 13-35
Problem 47

48 •• A helium balloon lifts a basket and cargo with a total weight of 2000 N under standard conditions, at which the density of air is 1.29 kg/m^3 and the density of helium is 0.178 kg/m^3. What is the minimum volume of the balloon?

49 •• An object has "neutral buoyancy" when its density equals that of the liquid in which it is submerged, which means that it neither floats nor sinks. If the average density of an 85-kg diver is 0.96 kg/L, what mass of lead should the dive master suggest be added to give the diver neutral buoyancy? SSM

50 •• A 1.00-kg beaker containing 2.00 kg of water rests on a scale. A 2.00-kg block of aluminum (density 2.70×10^3 kg/m^3) suspended from a spring scale is submerged in the water, as in Figure 13-36. Find the readings of both scales.

FIGURE 13-36 Problem 50

51 •• ENGINEERING APPLICATION When cracks form at the base of a dam, the water seeping into the cracks exerts a buoyant force that tends to lift the dam. As a result, the dam can topple. Estimate the buoyant force exerted on a 2.0-m-thick by 5.0-m-long dam wall by water seeping into cracks at its base. The water level in the lake is 5.0 m above the cracks.

52 •• ENGINEERING APPLICATION, CONTEXT-RICH Your team is in charge of launching a large helium weather balloon that is spherical in shape, and whose radius is 2.5 m and total mass is 15 kg (balloon plus helium plus equipment). (*a*) What is the initial upward acceleration of the balloon when it is released from sea level? (*b*) If the drag force on the balloon is given by $F_D = \frac{1}{2}\pi r^2 \rho v^2$, where r is the balloon radius, ρ is the density of air, and v the balloon's ascension speed, calculate the terminal velocity of the ascending balloon.

53 ••• ENGINEERING APPLICATION A ship sails from seawater (specific gravity 1.025) into freshwater, and therefore sinks slightly. When its 600,000-kg load is removed, it returns to its original level. Assuming that the sides of the ship are vertical at the water line, find the mass of the ship before it was unloaded. SSM

CONTINUITY AND BERNOULLI'S EQUATION

Note: **For the problems in this section, assume laminar nonviscous steady-state flow in all cases unless otherwise indicated.**

54 • Water flows at 0.65 m/s through a 3.0-cm-diameter hose that terminates in a 0.30-cm-diameter nozzle. Assume laminar nonviscous steady-state flow. (*a*) At what speed does the water pass through the nozzle? (*b*) If the pump at one end of the hose and the nozzle at the other end are at the same height, and if the pressure at the nozzle is 1.0 atm, what is the pressure at the pump outlet?

55 • Water is flowing at 3.00 m/s in a horizontal pipe under a pressure of 200 kPa. The pipe narrows to half its original diameter. (*a*) What is the speed of flow in the narrow section? (*b*) What is the pressure in the narrow section? (*c*) How do the volume flow rates in the two sections compare? SSM

56 •• The pressure in a section of horizontal pipe with a diameter of 2.00 cm is 142 kPa. Water flows through the pipe at 2.80 L/s. If the pressure at a certain point is to be reduced to 101 kPa by constricting a section of the pipe, what should the diameter of the constricted section be?

57 •• BIOLOGICAL APPLICATION Blood flows at 30 cm/s in an aorta of radius 9.0 mm. (*a*) Calculate the volume flow rate in liters per minute. (*b*) Although the cross-sectional area of a capillary is much smaller than that of the aorta, there are many capillaries, so their total cross-sectional area is much larger. If all the blood from the aorta flows into the capillaries and the speed of flow through the capillaries is 1.0 mm/s, calculate the total cross-sectional area of the capillaries. Assume laminar nonviscous steady-state flow. SSM

58 •• Water flows through a 1.0-m-long conical section of pipe that joins a cylindrical pipe of radius 0.45 m, on the left, to a cylindrical pipe of radius 0.25 m, on the right. If the water flows into the 0.45-m pipe with a speed of 1.50 m/s, and if we assume laminar nonviscous steady-state flow, (*a*) what is the speed of flow in the 0.25-m pipe? (*b*) What is the speed of flow at a position x in the conical section, if x is the distance measured from the left-hand end of the conical section of pipe?

59 •• ENGINEERING APPLICATION The \$8-billion, 800-mile-long Alaskan Pipeline has a maximum volume flow rate of 240,000 m^3 of oil per day. Most of the pipeline has a radius of 60.0 cm. Find the pressure P' at a point where the pipe has a 30.0-cm radius. Take the pressure in the 60.0-cm-radius sections to be $P = 180$ kPa and the density of oil to be 800 kg/m^3. Assume laminar nonviscous steady-state flow.

60 •• Water flows through a Venturi meter like that in Example 13-11 with a pipe diameter of 9.50 cm and a constriction diameter of 5.60 cm. The U-tube manometer is partially filled with mercury. Find the volume flow rate of the water if the difference in the mercury level in the U-tube is 2.40 cm.

61 •• ENGINEERING APPLICATION, CONTEXT-RICH Horizontal flexible tubing for carrying cooling water extends through a large electromagnet used in your physics experiment at Fermi National Accelerator Laboratory. A minimum volume flow rate of 0.0500 L/s through the tubing is necessary to keep your magnet cool. Within the magnet volume, the tubing has a circular cross section of radius 0.500 cm. In regions outside the magnet, the tubing widens to a radius of 1.25 cm. You have attached pressure sensors to measure differences in pressure between the 0.500- and 1.25-cm sections. The lab technicians tell you that if the flow rate in the system drops below 0.050 L/s, the magnet is in danger of overheating and that you should install an alarm to sound a warning when the flow rate drops below that level. What is the critical pressure difference at which you should program the sensors to send the alarm signal (and is this a minimum, or maximum, pressure difference)? Assume laminar nonviscous steady-state flow. SSM

62 •• Figure 13-37 shows a Pitot-static tube, a device used for measuring the speed of a gas. The inner pipe faces the incoming fluid, while the ring of holes in the outer tube is parallel to the gas flow. Show that the speed of the gas is given by $v_2 = 2gh(\rho_L - \rho_g)/\rho_g$, where ρ_L is the density of the liquid used in the manometer and ρ_g is the density of the gas.

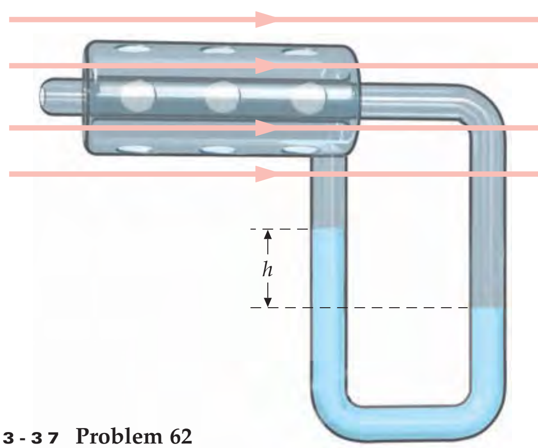

FIGURE 13-37 Problem 62

63 ••• Derive the Bernoulli equation in more generality than is done in the text, that is, allow for the fluid to change elevation during its movement. Using the work-energy theorem, show that when changes in elevation are allowed, Equation 13-16 becomes $P_1 + \rho g h_1 + \frac{1}{2}\rho v_1^2 = P_2 + \rho g h_2 + \frac{1}{2}\rho v_2^2$ (Equation 13-17). SSM

64 ••• A large keg of height H and cross-sectional area A_1 is filled with root beer. The top is open to the atmosphere. There is a spigot opening of area A_2, which is much smaller than A_1, at the bottom of the keg. (*a*) Show that when the height of the root beer is h, the speed of the root beer leaving the spigot is approximately $\sqrt{2gh}$. (*b*) Show that if $A_2 \ll A_1$, the rate of change of the height h of the root beer is given by $dh/dt = -(A_2/A_1)(2gh)^{1/2}$. (*c*) Find h as a function of time if $h = H$ at $t = 0$. (*d*) Find the total time needed to drain the keg if $H = 2.00$ m, $A_1 = 0.800\ \text{m}^2$, and $A_2 = 1.00 \times 10^{-4}A_1$. Assume laminar nonviscous flow.

65 •• A siphon is a device for transferring a liquid from one container to another. The tube shown in Figure 13-38 must be filled to start the siphon, but once this has been done, fluid will flow through the tube until the liquid surfaces in the containers are at the same level. (*a*) Using Bernoulli's equation, show that the speed of water in the tube is $v = \sqrt{2gd}$. (*b*) What is the pressure at the highest part of the tube?

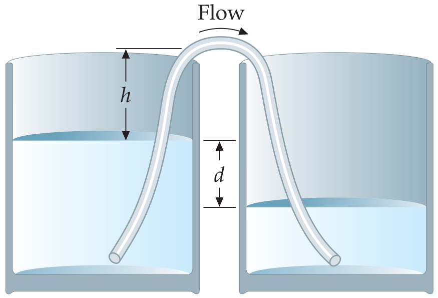

FIGURE 13-38 Problem 65

66 •• A fountain designed to spray a column of water 12 m into the air has a 1.0-cm-diameter nozzle at ground level. The water pump is 3.0 m below the ground. The pipe to the nozzle has a diameter of 2.0 cm. Find the pump pressure necessary if the fountain is to operate as designed. (Assume laminar nonviscous steady-state flow.)

67 •• Water at 20°C exits a circular tap moving straight down with a flow rate of 10.5 cm^3/s. (*a*) If the diameter of the tap is 1.20 cm, what is the speed of the water? (*b*) As the fluid falls from the tap, the stream of water narrows. What is the new diameter of the stream at a point 7.50 cm below the tap? Assume that the stream still has a circular cross section and neglect any effects of drag forces acting on the water. (*c*) If turbulent flows are characterized by Reynolds numbers above 2300 or so, how far does the water have to fall before it becomes turbulent? Does this match your everyday observations?

68 •• **Engineering Application, Context-Rich** To better fight fires in your seaside community, the local fire brigade has asked you to construct a pump system to draw seawater from the ocean to the top of the steep cliff adjacent to the water where most of the homes are. If the cliff is 12.0 m high, and the pump is capable of producing a gauge pressure of 150 kPa, how much water (in L/s) can be pumped using a hose with a radius of 4.00 cm?

69 ••• **Multistep** In Figure 13-39, H is the depth of the liquid and h is the distance from the surface of the liquid to the pipe inserted in the tank's side. (*a*) Find the distance x at which the water strikes the ground after exiting the pipe as a function of h and H. (*b*) Show that, for a given value of H, there are two values of h (whose average value is $\frac{1}{2}H$), both of which give the same distance x. (*c*) Show that for a given value of H, x is a maximum when $h = \frac{1}{2}H$. Find the maximum value for x as a function of H.

FIGURE 13-39 Problem 69

*VISCOUS FLOW

70 • Water flows through a horizontal 25.0-cm-long tube with an inside diameter of 1.20 mm at 0.300 mL/s. Find the pressure difference required to drive this flow if the viscosity of water is 1.00 mPa·s. Assume laminar flow.

71 • Find the diameter of a tube that would give double the flow rate for the pressure difference in Problem 70.

72 • **Biological Application** Blood takes about 1.00 s to pass through a 1.00-mm-long capillary in the human circulatory system. If the diameter of the capillary is 7.00 μm and the pressure drop is 2.60 kPa, find the viscosity of blood. Assume laminar flow.

73 • An abrupt transition occurs at Reynolds numbers of about 3×10^5, where the drag on a sphere moving through a fluid abruptly decreases. Estimate the speed at which this transition occurs for a baseball, and comment on whether it should play a role in the physics of the game. SSM

74 •• A horizontal pipe of radius 1.5 cm and length 25 m is connected to the output that can sustain an output gauge pressure of 10 kPa. What is the speed of 20°C water flowing through the pipe? If the temperature of the water is 60°C, what is the speed of the water in the pipe?

75 •• A very large tank is filled to a depth of 250 cm with oil that has a density of 860 kg/m^3 and a viscosity of 180 mPa·s. If the container walls are 5.00 cm thick, and a cylindrical hole of radius 0.750 cm is bored through the base of the container, what is the initial volume flow rate (in L/s) of the oil through the hole?

76 ••• The drag force on a moving sphere at a very low Reynolds number is given by $F_D = 6\pi\eta a v$, where η is the viscosity of the surrounding fluid and a is the radius of the sphere. (This relation is called Stokes' law.) Using this information, find the terminal speed of ascent for a spherical 1.0-mm-diameter carbon dioxide bubble rising in a carbonated beverage ($\rho = 1.1$ kg/L and $\eta = 1.8$ mPa·s). How long should it take for this bubble to rise 20 cm (the height of the drinking glass)? Is this length of time consistent with your observations?

GENERAL PROBLEMS

77 • Several teenagers swim toward a rectangular, wooden raft that is 3.00 m wide and 2.00 m long. If the raft is 9.00 cm thick, how many 75.0-kg teenage boys can stand on top of the raft without the raft becoming submerged? Assume the wood density is 650 kg/m^3. SSM

78 • A thread attaches a 2.7-g Ping-Pong ball to the bottom of a beaker. When the beaker is filled with water so that the ball is totally submerged, the tension in the thread is 7.0 mN. Determine the diameter of the ball.

79 • Seawater has a bulk modulus of $2.30 \times 10^9\ \mathrm{N/m^2}$. Find the difference in density of seawater at a depth where the pressure is 800 atm as compared to the density at the surface which is $1025\ \mathrm{kg/m^3}$. Neglect any effects due to changes in either temperature or salinity.

80 • A solid cube with 0.60-m edge length is suspended from a spring balance. When the cube is submerged in water, the spring balance reads 80 percent of the reading for when the cube is in air. Determine the density of the cube.

81 •• A 1.5-kg block of wood floats on water with 68 percent of its volume submerged. A lead block is placed on the wood, fully submerging the wood to a depth where the lead remains entirely out of the water. Find the mass of the lead block. SSM

82 •• A Styrofoam cube, 25 cm on an edge, is placed on one pan of a balance. The balance is in equilibrium when a 20-g mass of brass is placed on the other pan. Find the mass of the Styrofoam cube. Neglect the buoyant force of the brass mass, but do not neglect the buoyant force of the air on the Styrofoam cube.

83 •• A spherical shell of copper with an outer diameter of 12.0 cm floats on water with half its volume above the water's surface. Determine the inner diameter of the shell. The cavity inside the spherical shell is empty.

84 •• A 200-mL beaker that is half-filled with water is on the left pan of a balance, and a sufficient amount of sand is placed on the right pan to bring the balance to equilibrium. A cube 4.0 cm on an edge that is attached to a string is then lowered into the water until the cube is completely submerged, but not touching the bottom of the beaker. A piece of brass of mass m is then added to the right pan to restore equilibrium. What is m?

85 •• **ENGINEERING APPLICATION, CONTEXT-RICH** Crude oil has a viscosity of about $0.800\ \mathrm{Pa \cdot s}$ at normal temperature. You are the chief design engineer in charge of constructing a 50.0-km horizontal pipeline that connects an oil field to a tanker terminal. The pipeline is to deliver oil at the terminal at a rate of 500 L/s, and the flow through the pipeline is to be laminar. Assuming that the density of crude oil is $700\ \mathrm{kg/m^3}$, estimate the diameter of the pipeline that should be used. SSM

86 •• Water flows through the pipe in Figure 13-40 and exits to the atmosphere at the right end of section C. The diameter of the pipe is 2.00 cm at A, 1.00 cm at B, and 0.800 cm at C. The gauge pressure in the pipe at the center of section A is 1.22 atm and the flow rate is 0.800 L/s. The vertical pipes are open to the air. Find the level (above the flow midline as shown) of the liquid-air interfaces in the two vertical pipes. Assume laminar nonviscous flow.

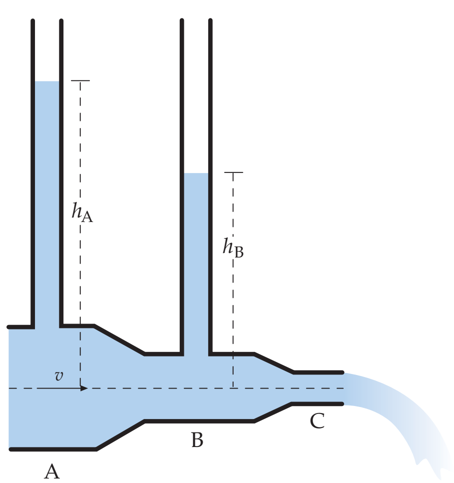

FIGURE 13-40 Problem 98

87 •• **ENGINEERING APPLICATION, CONTEXT-RICH** You are employed as a tanker truck driver for the summer. Heating oil is delivered to customers for winter usage by your large tanker truck. The delivery hose has a 1.00-cm radius. The specific gravity of the oil is 0.875, and its coefficient of viscosity is $200\ \mathrm{mPa \cdot s}$. What is the minimum time it will take you to fill a customer's 55-gal oil drum, if laminar flow through the hose must be maintained? SSM

88 •• A U-tube is filled with water until the liquid level reaches 28 cm above the bottom of the tube (Figure 13-41a). Oil, which has a specific gravity of 0.78, is now poured into one arm of the U-tube until the level of the water in the other arm of the tube reaches 34 cm above the bottom of the tube (Figure 13-41b). Find the levels of the oil–water and oil–air interfaces in the other arm of the tube.

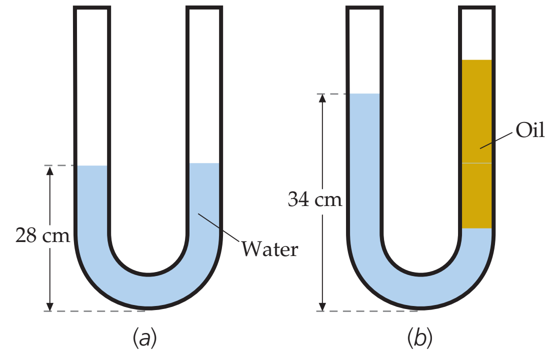

FIGURE 13-41 Problem 88

89 •• A helium balloon can just lift a load that weighs 750 N and has a negligible volume. The skin of the balloon has a mass of 1.5 kg. (*a*) What is the volume of the balloon? (*b*) If the volume of the balloon were twice that found in Part (*a*), what would be the initial acceleration of the balloon when released at sea level carrying a load weighing 900 N? SSM

90 •• A hollow sphere has an inner radius R and an outer radius $2R$. It is made of material of density ρ_0 and is floating in a liquid of density $2\rho_0$. The interior is now completely filled with material of density ρ' such that the sphere just floats completely submerged. Find ρ'.

91 •• According to *the law of atmospheres*, the fractional decrease in atmospheric pressure is proportional to the change in altitude. This law can be expressed as the differential equation $dP/P = -C\,dh$, where C is a positive constant. (*a*) Show that $P(h) = P_0 e^{-Ch}$, where P_0 is the pressure at $h = 0$, is a solution of the differential equation. (*b*) Given that the pressure 5.5 km above sea level is half that at sea level, find the constant C.

92 •• **ENGINEERING APPLICATION** A submarine has a total mass of 2.40×10^6 kg, including crew and equipment. The vessel consists of two parts, the pressure hull, which has a volume of $2.00 \times 10^3\ \mathrm{m^3}$, and the ballast tanks, which have a volume of $4.00 \times 10^2\ \mathrm{m^3}$. When the boat cruises on the surface, the ballast tanks are filled with air at atmospheric pressure; to cruise below the surface, seawater must be admitted into the tanks. (*a*) What fraction of the submarine's volume is above the water surface when the tanks are filled with air? (*b*) How much water must be admitted into the tanks to give the submarine neutral buoyancy? Neglect the mass of any air in the tanks and use 1.025 as the specific gravity of seawater.

93 ••• **BIOLOGICAL APPLICATION** Most species of fish have expandable sacs, commonly known as "swim bladders," that enable fish to rise in the water by filling the bladders with oxygen collected by their gills and to sink by emptying the bladders into the surrounding water. A freshwater fish has an average density equal to 1.05 kg/L when its swim bladder is empty. How large must the volume of oxygen in the fish's swim bladder be if the fish is to have neutral buoyancy? The fish has a mass of 0.825 kg. Assume the density of oxygen in the bladder is equal to air density at standard temperature and pressure.

PART II OSCILLATIONS AND WAVES

CHAPTER 14

Oscillations

MONSTER TRUCKS CAN POWER OVER JUST ABOUT ANYTHING, BUT WHAT KEEPS THESE GIANT TRUCKS FROM THROWING THEIR DRIVERS RIGHT OUT OF THEIR SEATS? MONSTER TRUCKS HAVE MONSTER-SIZE SHOCK ABSORBERS. THESE GIANT SHOCK ABSORBERS HELP DAMPEN THE OSCILLATION OF THE VEHICLE, PROVIDING A SMOOTHER RIDE AS THE OPERATOR DRIVES OVER TOUGH TERRAIN OR EVEN OTHER TRUCKS. *(Jeff Greenberg/Photoedit.)*

? How does a mechanic installing monster truck shock absorbers determine which size shock absorber to use? (See Example 14-13.)

We discuss oscillatory motion in this chapter. The kinematics of motion with constant acceleration is presented in Chapters 2 and 3. In this chapter, the kinematics and dynamics of motion with acceleration that is proportional to displacement from equilibrium is presented. The word "oscillate" means to swing back and forth. Oscillation occurs when a system is disturbed from a position of stable equilibrium. Many familiar examples exist: surfers bob up and down waiting for the right wave, clock pendulums swing back and forth, and the strings and reeds of musical instruments vibrate.

Other, less familiar examples are the oscillations of air molecules in a sound wave and the oscillations of electric currents in radios, television sets, and metal detectors. In addition, many other devices rely on oscillatory motion to function.

In this chapter, we deal mostly with the most fundamental type of oscillatory motion—simple harmonic motion. We also consider both damped and driven oscillations.

14-1 SIMPLE HARMONIC MOTION

A common, very important, and very basic kind of oscillatory motion is **simple harmonic motion** such as the motion of a solid object attached to a spring (Figure 14-1). In equilibrium, the spring exerts no force on the object. When the object is displaced an amount x from its equilibrium position, the spring exerts a force $-kx$, as given by Hooke's law:*

$$F_x = -kx \qquad \text{14-1}$$

LINEAR RESTORING FORCE

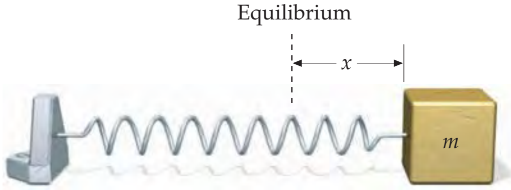

FIGURE 14-1 An object and spring on a frictionless surface. The displacement x, measured from the equilibrium position, is positive if the spring is stretched and negative if the spring is compressed.

where k is the force constant of the spring, a measure of the spring's stiffness. The minus sign indicates that the force is a restoring force; that is, it is opposite to the direction of the displacement from the equilibrium position. Combining Equation 14-1 with Newton's second law ($F_x = ma_x$), we have

$$-kx = ma_x$$

or

$$a_x = -\frac{k}{m}x \quad \left(\text{or} \quad \frac{d^2x}{dt^2} = -\frac{k}{m}x\right) \qquad \text{14-2}$$

The acceleration is proportional to the displacement and the minus sign indicates that the acceleration and the displacement are oppositely directed. This relation is the defining characteristic of simple harmonic motion and can be used to identify systems that will exhibit it:

> In simple harmonic motion, the acceleration, and thus the net force, are both proportional to, and oppositely directed from, the displacement from the equilibrium position.
>
> CONDITIONS FOR SIMPLE HARMONIC MOTION

The time it takes for a displaced object to execute a complete cycle of oscillatory motion—from one extreme to the other extreme and back—is called the **period** T. The reciprocal of the period is the **frequency** f, which is the number of cycles per unit of time:

$$f = \frac{1}{T} \qquad \text{14-3}$$

The unit of frequency is the cycle per second (cy/s), which is called a **hertz** (Hz). For example, if the time for one complete cycle of oscillation is 0.25 s, the frequency is 4.0 Hz.

Figure 14-2 shows how we can obtain x versus t for a mass on a spring. The general equation for such a curve is

$$x = A\cos(\omega t + \delta) \qquad \text{14-4}$$

POSITION IN SIMPLE HARMONIC MOTION

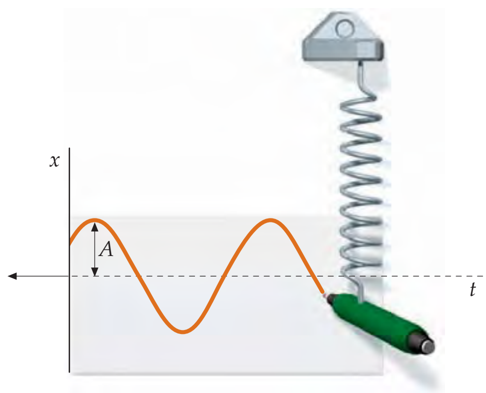

FIGURE 14-2 A marking pen is attached to a mass on a spring, and the paper is pulled to the left. As the paper moves with constant speed, the pen traces out the displacement x as a function of time t. (Here, we have chosen x to be positive when the spring is compressed.)

where A, ω, and δ are constants. The maximum displacement x_{max} from equilibrium is called the **amplitude** A. The argument of the cosine function, $\omega t + \delta$, is

* Hooke's law is introduced in Chapter 4, Section 5.

called the **phase** of the motion, and the constant δ is called the **phase constant,** which equals the phase at $t = 0$. [Note that $\cos(\omega t + \delta) = \sin(\omega t + \delta + [\pi/2])$; thus, whether the equation is expressed as a cosine function or a sine function simply depends on the phase of the oscillation at $t = 0$.] If we have just one oscillating system, we can always choose $t = 0$ so that $\delta = 0$. If we have two systems oscillating with the same frequency but with different phases, we can choose $\delta = 0$ for one of them. The equations for the two systems are then

$$x_1 = A_1 \cos(\omega t)$$

and

$$x_2 = A_2 \cos(\omega t + \delta)$$

If the phase difference δ is 0 or an integer times 2π, then the systems are said to be *in phase.* If the phase difference δ is π or an odd integer times π, then the systems are said to be 180° *out of phase.*

We can show that Equation 14-4 is a solution of Equation 14-2 by differentiating x twice with respect to time. The first derivative of x gives the velocity v_x:

$$v_x = \frac{dx}{dt} = -\omega A \sin(\omega t + \delta) \qquad \text{14-5}$$

VELOCITY IN SIMPLE HARMONIC MOTION

Differentiating velocity with respect to time gives the acceleration:

$$a_x = \frac{dv_x}{dt} = \frac{d^2x}{dt^2} = -\omega^2 A \cos(\omega t + \delta) \qquad \text{14-6}$$

Substituting x for $A \cos(\omega t + \delta)$ (see Equation 14-4) gives

$$a_x = -\omega^2 x \qquad \text{14-7}$$

ACCELERATION IN SIMPLE HARMONIC MOTION

Comparing $a_x = -\omega^2 x$ (Equation 14-7) with $a_x = -(k/m)x$ (Equation 14-2), we see that $x = A\cos(\omega t + \delta)$ is a solution of $d^2x/dt^2 = -(k/m)x$ (Equation 14-2) if

$$\omega = \sqrt{\frac{k}{m}} \qquad \text{14-8}$$

The amplitude A and the phase constant δ can be determined from the initial position x_0 and the initial velocity v_{0x} of the system. Setting $t = 0$ in $x = A\cos(\omega t + \delta)$ gives

$$x_0 = A \cos \delta \qquad \text{14-9}$$

Similarly, setting $t = 0$ in $v_x = dx/dt = -A\omega \sin(\omega t + \delta)$ gives

$$v_{0x} = -A\omega \sin \delta \qquad \text{14-10}$$

By using these equations, we can determine A and δ in terms of x_0, v_{0x}, and ω.

The period T is the shortest time interval satisfying the relation

$$x(t) = x(t + T)$$

for all t. Substituting into this relation using $x(t) = A\cos(\omega t + \delta)$ (Equation 14-4) gives

$$\begin{aligned} A\cos(\omega t + \delta) &= A\cos[\omega(t + T) + \delta] \\ &= A\cos(\omega t + \delta + \omega T) \end{aligned}$$

The swaying of the Citicorp Building in New York City during high winds is reduced by this tuned-mass damper mounted on an upper floor. It consists of a 400-ton sliding block connected to the building by a spring. The force constant is chosen so that the natural frequency of the spring-block system is the same as the natural sway frequency of the building. Set into motion by winds, the building and damper oscillate 180° out of phase with each other, thereby significantly reducing the swaying. *(Citibank.)*

See **Math Tutorial** *for more information on*
Trigonometry

The cosine (and sine) function repeats in value when the phase increases by 2π, so

$$\omega T = 2\pi \quad \text{or} \quad \omega = 2\pi\left(\frac{1}{T}\right)$$

The constant ω is called the **angular frequency.** It has units of radians per second and dimensions of inverse time, the same as angular speed, which is also designated by ω. Substituting $2\pi/T$ for ω in Equation 14-4 gives

$$x = A\cos\left(2\pi\frac{t}{T} + \delta\right)$$

We can see by inspection that each time t increases by T, the ratio t/T increases by 1, the phase increases by 2π, and one cycle of the motion is completed.

The frequency is related to the angular frequency by

$$\omega = 2\pi\frac{1}{T} = 2\pi f \qquad \text{14-11}$$

Because $\omega = \sqrt{k/m}$, the frequency and period of an object on a spring are related to the force constant k and the mass m by

$$f = \frac{1}{T} = \frac{1}{2\pi}\sqrt{\frac{k}{m}} \qquad \text{14-12}$$

The frequency increases with increasing k (spring stiffness) and decreases with increasing mass. Equation 14-12 provides a way to measure the inertial mass of an astronaut in a "weightless" environment.

PRACTICE PROBLEM 14-1

A 0.80-kg object is attached to a spring that has a force constant $k = 400$ N/m. (*a*) Find the frequency and period of motion of the object when it is displaced from equilibrium and then released. (*b*) Repeat Part (*a*) except with a 1.6-kg object attached to the spring in place of the 0.80-kg object. *Hint: Review Example 14-4 first.*

PROBLEM-SOLVING STRATEGY

Solving Simple Harmonic Motion Problems

PICTURE Choose the origin of the x axis at the equilibrium position. For a spring, choose the $+x$ direction so that x is positive if the spring is extended.

SOLVE Do not use the kinematic equations for constant acceleration. Instead, use the equations developed for simple-harmonic motion.

CHECK Make sure your calculator is in the appropriate mode (degrees or radians) when evaluating trigonometric functions and their arguments.

! At just 1 rad/s off resonance, the amplitude drops by a factor of 20. This is not surprising, because the width $\Delta\omega$ of the resonance is only 0.0957 rad/s.

Astronaut Alan L. Bean measures his body mass during the second Skylab mission by sitting in a seat attached to a spring and oscillating back and forth. The total mass of the astronaut plus the seat is related to his frequency of vibration by Equation 14-12. *(NASA.)*

Example 14-1 Riding the Waves

You are sitting on a surfboard that is riding up and down on some swells. The board's vertical displacement y is given by

$$y = (1.2\text{ m})\cos\left(\frac{1}{2.0\text{ s}}t + \frac{\pi}{6}\right)$$

(*a*) Find the amplitude, angular frequency, phase constant, frequency, and period of the motion. (*b*) Where is the surfboard at $t = 1.0$ s? (*c*) Find the velocity and acceleration as functions of time t. (*d*) Find the initial values of the position, velocity, and acceleration of the surfboard.

Surfers waiting. *(David Pu'u/CORBIS.)*

PICTURE We find the quantities asked for in (*a*) by comparing the equation of motion

$$y = (1.2\text{ m})\cos\left(\frac{1}{2.0\text{ s}}t + \frac{\pi}{6}\right)$$

with the standard equation for simple harmonic motion, Equation 14-4. The velocity and acceleration are found by differentiating $y(t)$.

SOLVE

(*a*) 1. Compare this equation with $y = A\cos(\omega t + \delta)$ (Equation 14-4) to get A, ω, and δ:

$$y = (1.2\text{ m})\cos\left(\frac{1}{2.0\text{ s}}t + \frac{\pi}{6}\right)$$

$$A = \boxed{1.2\text{ m}} \quad \omega = \boxed{0.50\text{ rad/s}} \quad \delta = \boxed{\pi/6\text{ rad}}$$

2. The frequency and period are found from ω:

$$f = \frac{\omega}{2\pi} = \frac{0.50\text{ rad/s}}{2\pi} = 0.0796\text{ Hz} = \boxed{0.080\text{ Hz}}$$

$$T = \frac{1}{f} = \frac{1}{0.0796\text{ Hz}} = 12.6\text{ s} = \boxed{13\text{ s}}$$

(*b*) Set $t = 1.0$ s to find the surfboard's position above mean sea level:

$$y = (1.2\text{ m})\cos\left[(0.50\text{ rad/s})(1.0\text{ s}) + \frac{\pi}{6}\right] = \boxed{0.62\text{ m}}$$

(*c*) The velocity and acceleration are obtained from the position by differentiation with respect to time:

$$v_y = \frac{dy}{dt} = \frac{d}{dt}[A\cos(\omega t + \delta)] = -\omega A\sin(\omega t + \delta)$$

$$= -(0.50\text{ rad/s})(1.2\text{ m})\sin\left[(0.50\text{ rad/s})t + \frac{\pi}{6}\right]$$

$$= \boxed{-(0.60\text{ m/s})\sin\left[(0.50\text{ rad/s})t + \frac{\pi}{6}\right]}$$

$$a_y = \frac{dv_y}{dt} = \frac{d}{dt}[-\omega A\sin(\omega t + \delta)] = -\omega^2 A\cos(\omega t + \delta)$$

$$= -(0.50\text{ rad/s})^2(1.2\text{ m})\cos\left[(0.50\text{ rad/s})t + \frac{\pi}{6}\right]$$

$$= \boxed{-(0.30\text{ m/s}^2)\cos\left[(0.50\text{ rad/s})t + \frac{\pi}{6}\right]}$$

(*d*) Set $t = 0$ to find y_0, v_{0y}, and a_{0y}:

$$y_0 = (1.2\text{ m})\cos\frac{\pi}{6} = 1.04 = \boxed{1.0\text{ m}}$$

$$v_{0y} = -(0.60\text{ m/s})\sin\frac{\pi}{6} = \boxed{-0.30\text{ m/s}}$$

$$a_{0y} = -(0.30\text{ m/s}^2)\cos\frac{\pi}{6} = \boxed{-0.26\text{ m/s}^2}$$

CHECK We can check the plausibility of the Part (*d*) results using $a_y = -\omega^2 y$ (Equation 14-7) at $t = 0$, with $y = 1.04$ m and $\omega = 0.50$ rad/s. Substituting into Equation 14-7 gives $a_{0y} = -\omega^2 y_0 = -(0.50\text{ rad/s})^2(1.04\text{ m}) = -0.26\text{ m/s}^2$, the same as the third Part (*d*) result.

Figure 14-3 shows two identical masses attached to identical springs and resting on a horizontal frictionless surface. The spring attached to object 2 is stretched 10 cm and the spring attached to object 1 is stretched 5 cm. If they are released at the same time, which object reaches the equilibrium position first?

According to Equation 14-12, the period depends only on k and m and not on the amplitude. Because k and m are the same for both systems, the periods are the same. Thus, the objects reach the equilibrium position at the same time. The second object has twice as far to go to reach equilibrium, but it will also have twice the speed at any given instant. Figure 14-4 shows a sketch of the position functions for the two objects. This sketch illustrates an important general property of simple harmonic motion:

> The frequency (and thus the period) of simple harmonic motion is independent of the amplitude.

The fact that the frequency in simple harmonic motion is independent of the amplitude has important consequences in many fields. In music, for example, it means that when a note is struck on the piano, the pitch (which corresponds to the frequency) does not depend on how loudly the note is played (which corresponds to the amplitude).† If changes in amplitude had a large effect on the frequency, then musical instruments would be unplayable.

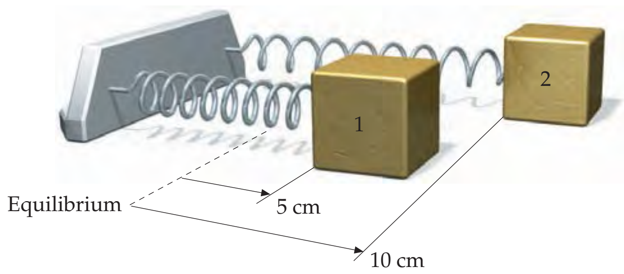

FIGURE 14-3 Two identical mass-spring systems.

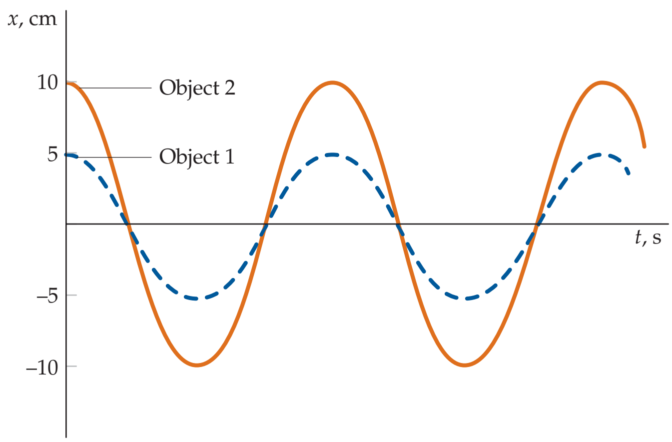

FIGURE 14-4 Plots of x versus t for the systems in Figure 14-3. Both reach their equilibrium positions at the same time.

Example 14-2 An Oscillating Object

An object oscillates with angular frequency $\omega = 8.0$ rad/s. At $t = 0$, the object is at $x = 4.0$ cm with an initial velocity $v_x = -25$ cm/s. (*a*) Find the amplitude and phase constant for the motion. (*b*) Write x as a function of time.

PICTURE The initial position and velocity give us two equations from which to determine the amplitude A and the phase constant δ.

SOLVE

(*a*) 1. The initial position and velocity are related to the amplitude and phase constant. The position is given by Equation 14-4. The velocity is found by taking the derivative with respect to time:

$$x = A\cos(\omega t + \delta) \quad \text{and}$$

$$v_x = \frac{dx}{dt} = -\omega A \sin(\omega t + \delta)$$

2. At $t = 0$ the position and velocity are:

$$x_0 = A\cos\delta \quad \text{and} \quad v_{0x} = -\omega A\sin\delta$$

3. Divide these equations to eliminate A:

$$\frac{v_{0x}}{x_0} = \frac{-\omega A\sin\delta}{A\cos\delta} = -\omega\tan\delta$$

4. Substituting numerical values yields δ:

$$\tan\delta = -\frac{v_{0x}}{\omega x_0} \quad \text{so}$$

$$\delta = \tan^{-1}\left(-\frac{v_{0x}}{\omega x_0}\right) = \tan^{-1}\left[-\frac{-25\text{ cm/s}}{(8.0\text{ rad/s})(4.0\text{ cm})}\right]$$

$$= 0.663\text{ rad} = \boxed{0.66\text{ rad}}$$

† For many musical instruments, there is a slight dependence of frequency on amplitude. The vibration of an oboe reed, for example, is not exactly simple harmonic; thus its pitch depends slightly on how hard it is blown. This effect can be corrected for by a skilled musician.

5. The amplitude can be found using either the x_0 or v_{0x} equation. Here we use x_0:

$$A = \frac{x_0}{\cos\delta} = \frac{4.0\text{ cm}}{\cos 0.663} = \boxed{5.1\text{ cm}}$$

(*b*) Comparing with Equation 14-4 yields x:

$$x = \boxed{(5.1\text{ cm})\cos[(8.0\text{ s}^{-1})t + 0.66]}$$

CHECK To see if the Part-(*b*) result ($x = (5.1\text{ cm})\cos[(8.0\text{ s}^{-1})t + 0.66]$) is plausible, we set t equal to zero and see if $x = 4.0$ cm. That is, $x = (5.1\text{ cm})\cos[(0) + 0.66] = 4.0$ cm. Thus, the Part-(*b*) result is plausible.

If the phase constant δ is 0, Equations 14-4, 14-5, and 14-6 then become

$$x = A\cos\omega t \qquad \text{14-13}a$$

$$v_x = -\omega A\sin\omega t \qquad \text{14-13}b$$

and

$$a_x = -\omega^2 A\cos\omega t \qquad \text{14-13}c$$

These functions are plotted in Figure 14-5.

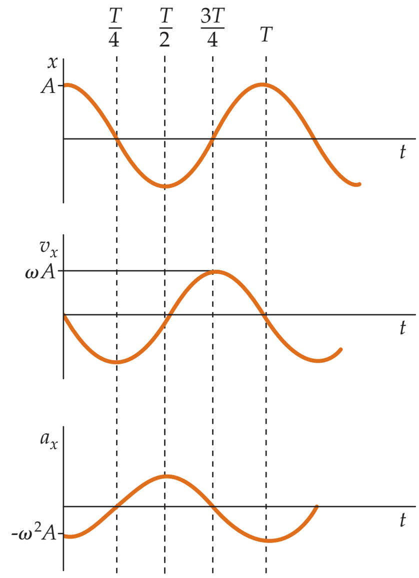

FIGURE 14-5 Plots of x, v_x and a_x as functions of time t for $\delta = 0$. At $t = 0$, the displacement is maximum, the velocity is zero, and the acceleration is negative and equal to $-\omega^2 A$. The velocity becomes negative as the object moves back toward its equilibrium position. After one quarter-period ($t = T/4$), the object is at equilibrium, $x = 0$, $a_x = 0$, and the velocity has its minimum value of $-\omega A$. At $t = T/2$, the displacement is $-A$, the velocity is again zero, and the acceleration is $+\omega^2 A$. At $t = 3T/4$, $x = 0$, $a_x = 0$, and $v_x = +\omega A$.

Example 14-3 A Block on a Spring — *Try It Yourself*

A 2.00-kg block is attached to a spring as in Figure 14-1. The force constant of the spring is $k = 196$ N/m. The block is held a distance 5.00 cm from the equilibrium position and is released at $t = 0$. (*a*) Find the angular frequency ω, the frequency f and the period T. (*b*) Write x as a function of time.

PICTURE For Part (*a*) use Equations 14-8 and 14-12 For Part (*b*) use Equation 14-4.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	**Answers**
(*a*) 1. Calculate ω from $\omega = \sqrt{k/m}$.	$\omega = \boxed{9.90\text{ rad/s}}$
2. Use your result to find f and T.	$f = \boxed{1.58\text{ Hz}}$ $T = \boxed{0.635\text{ s}}$
3. Find A and δ from the initial conditions.	$A = 5.00$ cm $\delta = 0.00$
(*b*) Write $x(t)$ using your results for A, ω, and δ.	$x = \boxed{(5.00\text{ cm})\cos[(9.90\text{ s}^{-1})t]}$

CHECK The block was released from rest, so we expect the velocity at $t = 0$ to be zero. To verify that our Part-(*b*) result is correct, we take the derivative of the expression $x = (5.00\text{ cm})\cos[(9.90\text{ s}^{-1})t]$ and evaluate it at $t = 0$. That is, $v_x(t) = dx/dt = -(4.95\text{ cm/s})\sin[(9.90\text{ s}^{-1})t]$. Evaluating this at $t = 0$ gives $v_x(0) = -(4.95\text{ cm/s})\sin(0) = 0$, as expected.

Example 14-4 Speed and Acceleration of an Object on a Spring

Consider an object on a spring whose position is given by $x = (5.00\text{ cm})\cos(9.90\text{ s}^{-1}t)$. (*a*) What is the maximum speed of the object? (*b*) When does this maximum speed first occur after $t = 0$? (*c*) What is the maximum of the acceleration of the object? (*d*) When does the maximum of the magnitude of the acceleration first occur after $t = 0$?

PICTURE Because the object is released from rest, $\delta = 0$, and the position, velocity, and acceleration are given by Equations 14-13*a*, *b*, and *c*.

SOLVE

(*a*) 1. Equation 14-13*a*, with $\delta = 0$, gives the position. We get the velocity by taking the derivative with respect to time:

$$x = A\cos\omega t$$

$$\text{so}\quad v_x = \frac{dx}{dt} = -\omega A\sin\omega t$$

2. Maximum speed v occurs when $|\sin\omega t| = 1$:

$$v = \omega A|\sin\omega t|$$

$$\text{so}\quad v_{\text{max}} = \omega A = (9.90\text{ rad/s})(5.00\text{ cm}) = \boxed{49.5\text{ cm/s}}$$

(*b*) 1. $|\sin\omega t| = 1$ first occurs when $\omega t = \pi/2$:

$$|\sin\omega t| = 1 \Rightarrow \omega t = \frac{\pi}{2}, \frac{3\pi}{2}, \frac{5\pi}{2}, \ldots$$

2. Solve for t when $\omega t = \pi/2$:

$$t = \frac{\pi}{2\omega} = \frac{\pi}{2(9.90\text{ s}^{-1})} = \boxed{0.159\text{ s}}$$

(*c*) 1. We find the acceleration by taking the derivative of the velocity, obtained in step 1 of Part (*a*):

$$a_x = \frac{dv_x}{dt} = -\omega^2 A\cos\omega t$$

2. Maximum acceleration corresponds to $\cos\omega t = -1$.

$$a_{\text{max}} = \omega^2 A = (9.90\text{ rad/s})^2(5.00\text{ cm}) = \boxed{490\text{ cm/s}^2 \approx \tfrac{1}{2}g}$$

(*d*) The magnitude of the acceleration is maximum when $|\cos\omega t| = 1$, which is when $\omega t = 0, \pi, 2\pi, \ldots$:

$$t = \frac{\pi}{\omega} = \frac{\pi}{9.90\text{ s}^{-1}} = \boxed{0.317\text{ s}}$$

CHECK We expect $|a_x|$ to first be maximum after $t = 0$ when x reaches its first minimum, and we expect x to reach its first minimum one-half cycle after release. That is, we expect $|a_x|$ to be maximum when $t = \frac{1}{2}T$, where T is the period. The period and the angular frequency are related by $\omega = 2\pi f = 2\pi/T$ (Equation 14-11). Substituting $2\pi/T$ for ω in our Part (*d*) result gives $t = \pi/(2\pi/T) = \frac{1}{2}T$, as expected.

SIMPLE HARMONIC MOTION AND CIRCULAR MOTION

A relation exists between simple harmonic motion and circular motion with constant speed. Imagine a particle moving with constant speed v in a circle of radius A (Figure 14-6*a*). Its angular displacement relative to the $+x$ direction is given by

$$\theta = \omega t + \delta \qquad 14\text{-}14$$

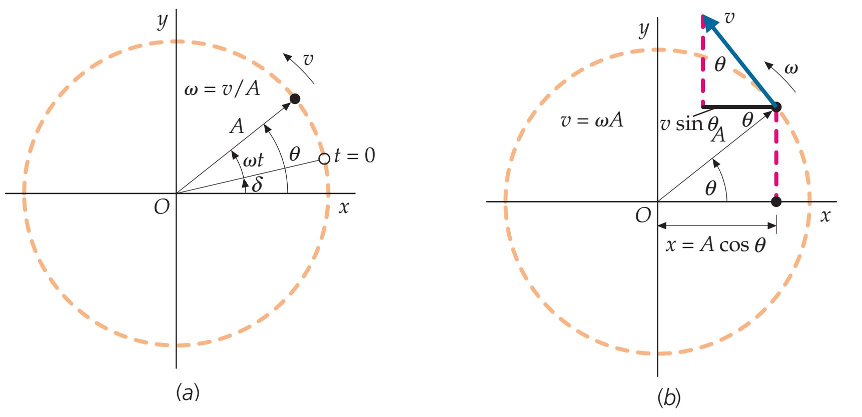

FIGURE 14-6 A particle moves in a circular path with constant speed. (*a*) Its x component of position describes simple harmonic motion, and (*b*) its x component of velocity describes the velocity of the simple harmonic motion.

where δ is the angular displacement at time $t = 0$ and $\omega = v/A$ is the angular speed of the particle. The x component of the particle's position (Figure 14-6b) is

$$x = A\cos\theta = A\cos(\omega t + \delta)$$

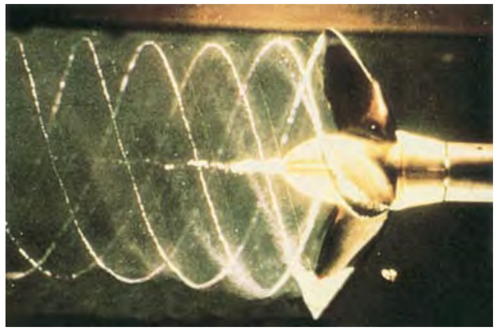
which is the same as Equation 14-4 for simple harmonic motion.

When a particle moves with constant speed in a circle, its projection onto a diameter of the circle moves with simple harmonic motion (see Figure 14-6).

The speed of a particle moving in a circle is $r\omega$, where r is the radius. For the particle in Figure 14-6b, $r = A$, so its speed is $A\omega$. The projection of the velocity vector onto the x axis gives $v_x = -v\sin\theta$. Substituting for v and θ gives

$$v_x = -v\sin\theta = -\omega A\sin(\omega t + \delta)$$

which is the same as Equation 14-5 for simple harmonic motion. The relation between circular motion and simple harmonic motion is nicely demonstrated by the image of the bubble trail produced by a rotating boat propeller.



Bubbles foaming off the edge of a rotating propeller that is moving through water produce a sinusoidal pattern. *(Institute for Marine Dynamics.)*

14-2 ENERGY IN SIMPLE HARMONIC MOTION

When an object on a spring undergoes simple harmonic motion, the system's potential energy and kinetic energy vary with time. Their sum, the total mechanical energy $E = K + U$, is constant. Consider an object a distance x from equilibrium, acted on by a restoring force $-kx$. The system's potential energy is

$$U = \tfrac{1}{2}kx^2$$

This is Equation 7-4. For simple harmonic motion, $x = A\cos(\omega t + \delta)$. Substituting gives

$$U = \tfrac{1}{2}kA^2\cos^2(\omega t + \delta) \qquad \text{14-15}$$

POTENTIAL ENERGY IN SIMPLE HARMONIC MOTION

The kinetic energy of the system is

$$K = \tfrac{1}{2}mv^2$$

where m is the object's mass and v is its speed. For simple harmonic motion, $v_x = -\omega A\sin(\omega t + \delta)$. Substituting gives

$$K = \tfrac{1}{2}m\omega^2A^2\sin^2(\omega t + \delta)$$

Then using $\omega^2 = k/m$,

$$K = \tfrac{1}{2}kA^2\sin^2(\omega t + \delta) \qquad \text{14-16}$$

KINETIC ENERGY IN SIMPLE HARMONIC MOTION

The total mechanical energy E is the sum of the potential and kinetic energies:

$$E = U + K = \tfrac{1}{2}kA^2\cos^2(\omega t + \delta) + \tfrac{1}{2}k\,A\sin^2(\omega t + \delta)$$
$$= \tfrac{1}{2}kA^2[\cos^2(\omega t + \delta) + \sin^2(\omega t + \delta)]$$

Because $\sin^2(\omega t + \delta) + \cos^2(\omega t + \delta) = 1$,

$$E = U + K = \tfrac{1}{2}kA^2 \qquad \text{14-17}$$

TOTAL MECHANICAL ENERGY IN SIMPLE HARMONIC MOTION

This equation reveals an important general property of simple harmonic motion:

> The total mechanical energy in simple harmonic motion is proportional to the square of the amplitude.

For an object at its maximum displacement, the total energy is all potential energy. As the object moves toward its equilibrium position, the kinetic energy of the system increases and its potential energy decreases. As the object moves through its equilibrium position, the kinetic energy of the object is maximum, the potential energy of the system is zero, and the total energy is kinetic.

As the object moves past the equilibrium point, its kinetic energy begins to decrease, and the potential energy of the system increases until the object again stops momentarily at its maximum displacement (now in the other direction). At all times, the sum of the potential and kinetic energies is constant. Figure 14-7*b* and *c* show plots of U and K versus time. These curves have the same shape except that one is zero when the other is maximum. Their average values over one or more cycles are equal, and because $U + K = E$, their average values are given by

$$U_{av} = K_{av} = \tfrac{1}{2}E \qquad \text{14-18}$$

In Figure 14-8, the potential energy U is graphed as a function of x. The total energy E is constant and is therefore plotted as a horizontal line. This line intersects the potential-energy curve at $x = A$ and $x = -A$. At these two points, called the **turning points,** oscillating objects reverse direction and head back toward the equilibrium position. Because $U \le E$, the motion is restricted to $-A \le x \le +A$.

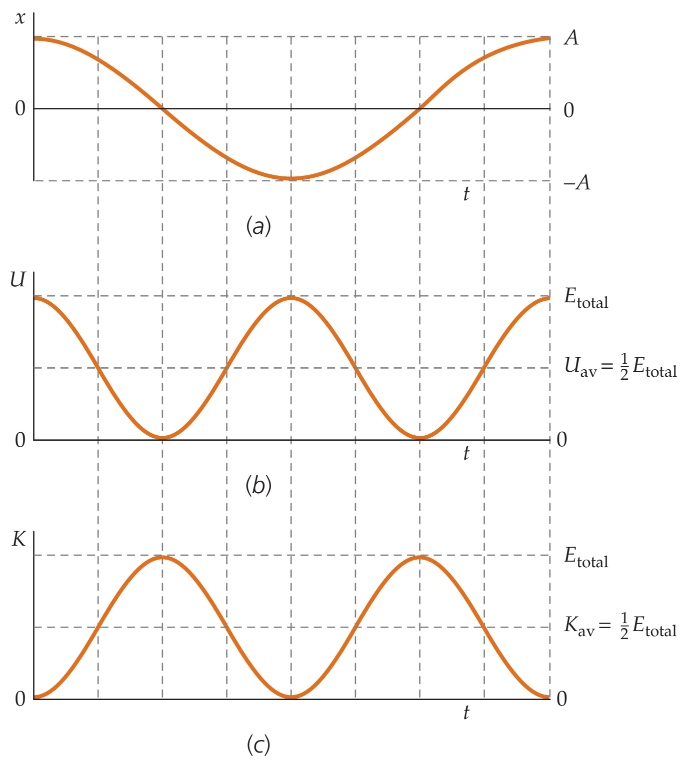


FIGURE 14-7 Plots of x, U, and K versus t.

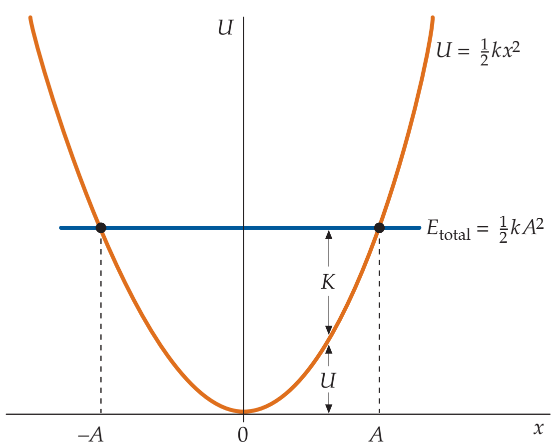

FIGURE 14-8 The potential-energy function $U = \frac{1}{2}kx^2$ for an object of mechanical mass m on a (massless) spring of force constant k. The horizontal blue line represents the total mechanical energy E_{total} for an amplitude of A. The kinetic energy K is represented by the vertical distance $K = E_{total} - U$. $E_{total} \ge U$, so the motion is restricted to $-A \le x \le +A$.

Example 14-5 Energy and Speed of an Oscillating Object

A 3.0-kg object attached to a spring oscillates with an amplitude of 4.0 cm and a period of 2.0 s. (*a*) What is the total energy? (*b*) What is the maximum speed of the object? (*c*) At what position x_1 is the speed equal to half its maximum value?

PICTURE (*a*) The total energy can be found from the amplitude and the force constant, and the force constant can be found from the mass and period. (*b*) The maximum speed occurs when the kinetic energy equals the total energy. (*c*) We can relate the position to the speed by using conservation of energy.

SOLVE

(*a*) 1. Write the total energy E in terms of the force constant k and amplitude A:

$$E = \tfrac{1}{2}kA^2$$

2. The force constant is related to the period and mass:

$$k = m\omega^2 = m\left(\frac{2\pi}{T}\right)^2$$

3. Substitute the given values to find E:

$$E = \frac{1}{2}kA^2 = \frac{1}{2}m\left(\frac{2\pi}{T}\right)^2 A^2 = \frac{1}{2}(3.0\text{ kg})\left(\frac{2\pi}{2.0\text{ s}}\right)^2(0.040\text{ m})^2$$

$$= 2.37 \times 10^{-2}\text{ J} = \boxed{2.4 \times 10^{-2}\text{ J}}$$

(*b*) To find v_{max}, set the kinetic energy equal to the total energy and solve for v:

$$\tfrac{1}{2}mv_{max}^2 = E$$

so $$v_{max} = \sqrt{\frac{2E}{m}} = \sqrt{\frac{2(2.37 \times 10^{-2}\text{ J})}{3.0\text{ kg}}} = 0.126\text{ m/s} = \boxed{0.13\text{ m/s}}$$

(*c*) 1. Conservation of energy relates the position x to the speed v:

$$E = \tfrac{1}{2}mv^2 + \tfrac{1}{2}kx^2$$

2. Substitute $v = \frac{1}{2}v_{max}$ and solve for x_1. It is convenient to find x in terms of E and then write $E = \frac{1}{2}kA^2$ to obtain an expression for x in terms of A:

$$E = \tfrac{1}{2}m(\tfrac{1}{2}v_{max})^2 + \tfrac{1}{2}kx_1^2 = \tfrac{1}{4}(\tfrac{1}{2}mv_{max}^2) + \tfrac{1}{2}kx_1^2 = \tfrac{1}{4}E + \tfrac{1}{2}kx_1^2$$

so $$\tfrac{1}{2}kx_1^2 = E - \tfrac{1}{4}E = \tfrac{3}{4}E$$

and $$x_1 = \pm\sqrt{\frac{3E}{2k}} = \pm\sqrt{\frac{3}{2k}\left(\frac{1}{2}kA^2\right)} = \pm\frac{\sqrt{3}}{2}A$$

$$= \pm\frac{\sqrt{3}}{2}(4.0\text{ cm}) = \boxed{\pm 3.5\text{ cm}}$$

CHECK As expected, the result for Part (*c*), step 2 has two values, one with the spring extended, the other with the spring compressed. In addition, we expected these values to be equal, except for the sign. Further, the positive result is less than 4.0 cm (the amplitude is 4.0 cm), as expected.

PRACTICE PROBLEM 14-2 Calculate ω for this example and find v_{max} from $v_{max} = \omega A$.

PRACTICE PROBLEM 14-3 An object of mass 2.00 kg is attached to a spring that has a force constant 40.0 N/m. The object is moving at 25.0 cm/s when it is at its equilibrium position. (*a*) What is the total energy of the object? (*b*) What is the amplitude of the motion?

* GENERAL MOTION NEAR EQUILIBRIUM

Simple harmonic motion typically occurs when a particle is displaced slightly from a position of stable equilibrium. Figure 14-9 is a graph of the potential energy U versus x for a force that has a position of stable equilibrium and a position of unstable equilibrium. As discussed in Chapter 7, the potential-energy maximum at x_2 on Figure 14-9 corresponds to unstable equilibrium, whereas the minimum at x_1 corresponds to stable equilibrium. Many smooth curves with a minimum as in Figure 14-9 can be closely approximated near the minimum by a parabola. The dashed curve in this figure is a parabolic curve that approximately fits U near the

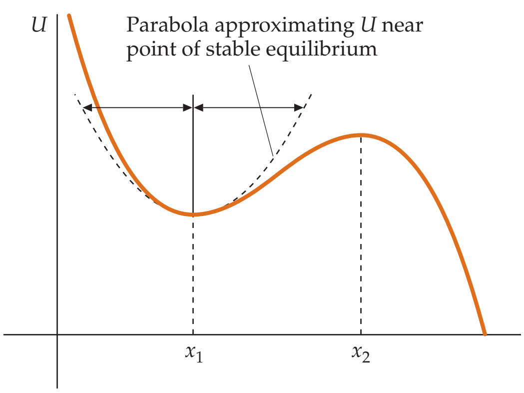

FIGURE 14-9 Plot of U versus x for a force that has a position of stable equilibrium (x_1) and a position of unstable equilibrium (x_2).

stable equilibrium point. The general equation for a parabola that has a minimum at point x_1 can be written

$$U = A + B(x - x_1)^2 \tag{14-19}$$

where A and B are constants. The constant A is the value of U at the equilibrium position $x = x_1$. The force is related to the potential energy curve by $F_x = -dU/dx$. Then

$$F_x = -\frac{dU}{dx} = -2B(x - x_1)$$

If we set $2B = k$, this equation reduces to

$$F_x = -\frac{dU}{dx} = -k(x - x_1) \tag{14-20}$$

According to Equation 14-20, the force is proportional to the displacement from equilibrium and oppositely directed, so the motion will be simple harmonic. Figure 14-9 shows a graph of this system's potential energy function $U(x)$, which has a position of stable equilibrium at $x = x_1$. Figure 14-10 shows a potential-energy function that has a position of stable equilibrium at $x = 0$. The system for this function is a small particle of mass m oscillating back and forth at the bottom of a frictionless spherical bowl.

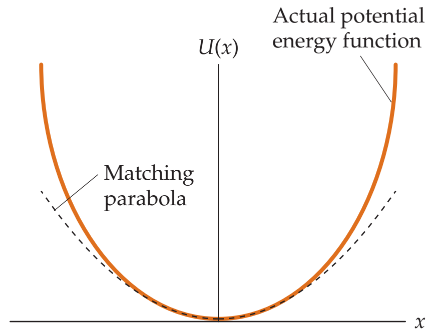

FIGURE 14-10 Plot of U versus x for a small particle oscillating back and forth at the bottom of a spherical bowl.

14-3 SOME OSCILLATING SYSTEMS

OBJECT ON A VERTICAL SPRING

When an object hangs from a vertical spring, there is a downward force mg in addition to the force of the spring (Figure 14-11). If we choose downward as the positive y direction, then the spring's force on the object is $-ky$, where y is the extension of the spring. The net force on the object is then

$$\Sigma F_y = -ky + mg \tag{14-21}$$

We can simplify this equation by changing to a new variable $y' = y - y_0$, where $y_0 = mg/k$ is the amount the spring is stretched when the object is in equilibrium. Substituting $y' + y_0$ for y gives

$$\Sigma F_y = -k(y' + y_0) + mg$$

But $ky_0 = mg$, so

$$\Sigma F_y = -ky' \tag{14-22}$$

Newton's second law ($\Sigma F_y = ma_y$) gives

$$-ky' = m\frac{d^2y}{dt^2}$$

However, $y = y' + y_0$, where $y_0 = mg/k$ is a constant. Thus $d^2y/dt^2 = d^2y'/dt^2$, so

$$-ky' = m\frac{d^2y'}{dt^2}$$

Rearranging gives

$$\frac{d^2y'}{dt^2} = -\frac{k}{m}y'$$

which is the same as Equation 14-2 with y' replacing x. It has the now familiar solution

$$y' = A\cos(\omega t + \delta)$$

where $\omega = \sqrt{k/m}$.

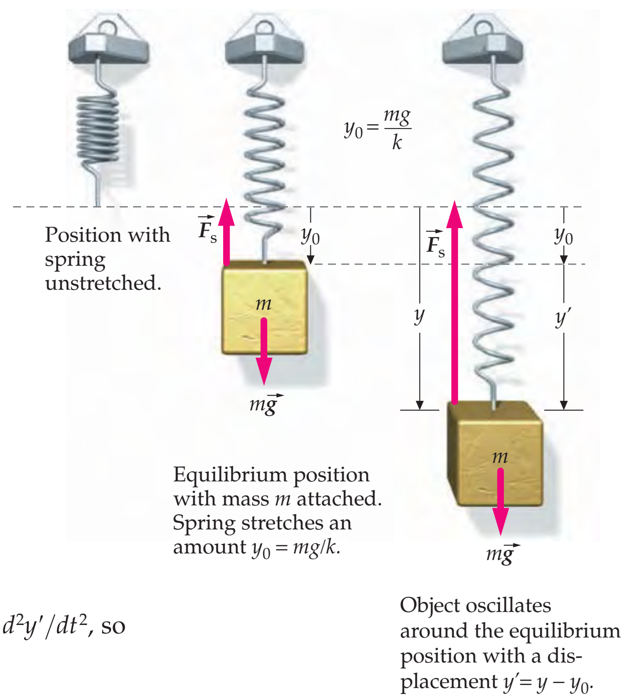

FIGURE 14-11 The Newton's second law equation for the motion of a mass on a vertical spring is greatly simplified if the displacement (y') is measured from the equilibrium position of the spring with the mass attached.

Thus, the effect of the gravitational force mg is merely to shift the equilibrium position from $y = 0$ to $y' = 0$. When the object is displaced from this equilibrium position by the amount y', the net force is $-ky'$. The object oscillates about this equilibrium position with an angular frequency $\omega = \sqrt{k/m}$, the same angular frequency as that for an object on a horizontal spring.

A force is conservative if the work done by it is independent of the path. Both the force of the spring and the force of gravity are conservative, and the sum of these forces (Equations 14-21 and 14-22) also is conservative. The potential energy function U associated with the sum of these forces is the negative of the work done plus an arbitrary integration constant. That is,

$$U = -\int -ky'dy' = \tfrac{1}{2}ky'^2 + U_0$$

where the integration constant U_0 is the value of U at the equilibrium position ($y' = 0$). Thus,

$$U = \tfrac{1}{2}ky'^2 + U_0 \qquad 14\text{-}23$$

Example 14-6 Paper Springs *Context-Rich*

You are showing your nieces how to make paper party decorations using paper springs. One niece makes a paper spring. The spring is stretched 8 cm and has a single sheet of colored paper suspended from it. You want the decorations to bounce at approximately 1.0 cy/s. How many sheets of colored paper should be used for the decoration on that spring if it is to bounce at 1.0 cy/s?

A paper spring (under construction). *(Rhoda Peacher.)*

PICTURE The frequency depends on the ratio of the force constant to the suspended mass (Equation 14-12), and you do not know either the force constant or the mass. However, Hooke's law (Equation 14-1) can be used to find the required ratio from the information given.

SOLVE

1. Write the frequency in terms of the force constant k and the mass M (Equation 14-12), where M is the mass of N sheets. We need to find N:
$$f = \frac{\omega}{2\pi} = \frac{1}{2\pi}\sqrt{\frac{k}{M}}$$

2. The spring stretches a distance of $y_0 = 8.0$ cm when a single sheet of mass m is suspended:
$$ky_0 = mg \quad \text{so} \quad \frac{k}{m} = \frac{g}{y_0}$$

3. The mass of N sheets equals N times the mass of a single sheet:
$$M = Nm$$

4. Using the step-2 and step-3 results, solve for k/M:
$$\frac{k}{M} = \frac{k}{Nm} = \frac{1}{N}\frac{g}{y_0}$$

5. Substitute the step-4 result into the step-1 result and solve for N:
$$f = \frac{1}{2\pi}\sqrt{\frac{k}{M}} = \frac{1}{2\pi}\sqrt{\frac{1}{N}\frac{g}{y_0}}$$
$$\text{so} \quad N = \frac{g}{(2\pi f)^2 y_0} = \frac{9.81\ \text{m/s}^2}{4\pi^2(1.0\ \text{Hz})^2(0.080\ \text{m})} = 3.1$$
$$\boxed{\text{Three sheets are needed.}}$$

CHECK Three or more sheets of construction paper seems plausible. Fifty or one-hundred sheets would likely wreck a paper spring.

TAKING IT FURTHER Note that we did not need to use the value of m or k in this example because the frequency depends on the ratio k/m, which equals g/y_0. In addition, we have neglected the mass of the spring itself. Its mass is probably not negligible compared to the mass of a few sheets of construction paper, so our step-5 result is an approximate result.

PRACTICE PROBLEM 14-4 How much is the paper spring stretched when a decoration made from three sheets of paper is suspended from it and the paper is in equilibrium?

Example 14-7 A Bead on a Block

A block securely attached to a spring oscillates vertically with a frequency of 4.00 Hz and an amplitude of 7.00 cm. A tiny bead is placed on top of the oscillating block just as it reaches its lowest point. Assume that the bead's mass is so small that its effect on the motion of the block is negligible. At what displacement from the equilibrium position does the bead lose contact with the block?

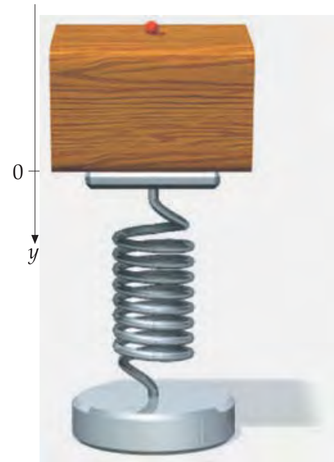

FIGURE 14-12

PICTURE The forces on the bead are its weight mg downward and the upward normal force exerted by the block. The magnitude of this normal force changes as the acceleration changes. As the block moves upward *from equilibrium*, its acceleration and the acceleration of the bead are *downward* and increasing in magnitude. When the acceleration reaches g downward, the normal force will be zero. If the block's downward acceleration becomes even slightly larger, the bead will leave the block.

SOLVE

1. Draw a sketch of the system (Figure 14-12). Include a y coordinate axis with its origin at the equilibrium position and with down as the positive direction:
2. We are looking for the value of y when the acceleration is g downward. Use Equation 14-7:
$$a_y = -\omega^2 y$$
$$g = -\omega^2 y$$
3. Substitute $2\pi f$ for ω and solve for y:
$$g = -(2\pi f)^2 y$$
so $$y = -\frac{g}{(2\pi f)^2} = -\frac{9.81\text{ m/s}^2}{[2\pi(4.00\text{ Hz})]^2} = -0.0155\text{ m} = \boxed{-1.55\text{ cm}}$$

CHECK The bead leaves the block when y is negative, which is when the bead is above the equilibrium position because down was chosen as the positive y direction. This is as expected.

THE SIMPLE PENDULUM

A simple pendulum consists of a string of length L and a bob of mass m. When the bob is released from an initial angle ϕ_0 with the vertical, it swings back and forth with some period T. The units of length, mass, and g, are m, kg, and m/s^2, respectively. If we divide L by g, the meters cancel and we are left with seconds squared, suggesting the form $\sqrt{L/g}$. If the formula for the period contains the mass, then the unit kg must be canceled by some other quantity. But there is no combination of L and g that can cancel mass units. So the period cannot depend on the mass of the bob. Because the initial angle ϕ_0 is dimensionless, we cannot tell whether or not it is a factor in the period. We will see below that for small ϕ_0, the period is given by $T = 2\pi\sqrt{L/g}$.

CONCEPT CHECK 14-1

We might expect the period of a simple pendulum to depend on the mass m of a pendulum bob, the length L of the pendulum, the acceleration due to gravity g, and the initial angle ϕ_0. Find a simple combination of some or all of these quantities that gives the correct dimensions for the period.

A Foucault pendulum at the University of Louisville. In 1851, Leon Foucault suspended a 67-m-long pendulum from the ceiling of the Pantheon in Paris. Because of the rotation of Earth about its axis, the Pantheon rotates about the pendulum. (If the Pantheon were at the North Pole, it would rotate once every 24 hours.) The observation of the building rotating about the plane of the pendulum captured the imagination of the world. *(Courtesy of John Kielkopf/University of Louisville.)*

The forces on the bob are its weight $m\vec{g}$ and the string tension $\vec{T}$ (Figure 14-13). At an angle ϕ with the vertical, the weight has components $mg\cos\phi$ along the string and $mg\sin\phi$ tangential to the circular arc in the direction of decreasing ϕ. Using tangential components, Newton's second law ($\Sigma F_t = ma_t$) gives

$$-mg\sin\phi = m\frac{d^2s}{dt^2} \qquad \text{14-24}$$

where the arc length s is related to the angle ϕ by $s = L\phi$. Repeatedly differentiating both sides of $s = L\phi$ gives

$$\frac{d^2s}{dt^2} = L\frac{d^2\phi}{dt^2}$$

Substituting $Ld^2\phi/dt^2$ into Equation 14-24 for d^2s/dt^2 and rearranging gives

$$\frac{d^2\phi}{dt^2} = -\frac{g}{L}\sin\phi \qquad \text{14-25}$$

Note that the mass m does not appear in Equation 14-25—the motion of a pendulum does not depend on its mass. For small ϕ, $\sin\phi \approx \phi$, and

$$\frac{d^2\phi}{dt^2} \approx -\frac{g}{L}\phi \qquad \phi \ll 1 \qquad \text{14-26}$$

Equation 14-26 is of the same form as Equation 14-2 for an object on a spring. Thus, the motion of a pendulum approximates simple harmonic motion for small angular displacements.

Equation 14-26 can be written

$$\frac{d^2\phi}{dt^2} = -\omega^2\phi, \qquad \text{where } \omega^2 = \frac{g}{L} \qquad \text{14-27}$$

The period of the motion is thus

$$T = \frac{2\pi}{\omega} = 2\pi\sqrt{\frac{L}{g}} \qquad \text{(for small oscillations)} \qquad \text{14-28}$$

PERIOD OF A SIMPLE PENDULUM

The solution of Equation 14-27 is

$$\phi = \phi_0\cos(\omega t + \delta)$$

where ϕ_0 is the maximum angular displacement.

According to Equation 14-28, the greater the length of a pendulum, the greater the period, which is consistent with experimental observation. The period and therefore the frequency are independent of the amplitude of oscillation (as long as the amplitude is small). This statement is a general feature of simple harmonic motion.

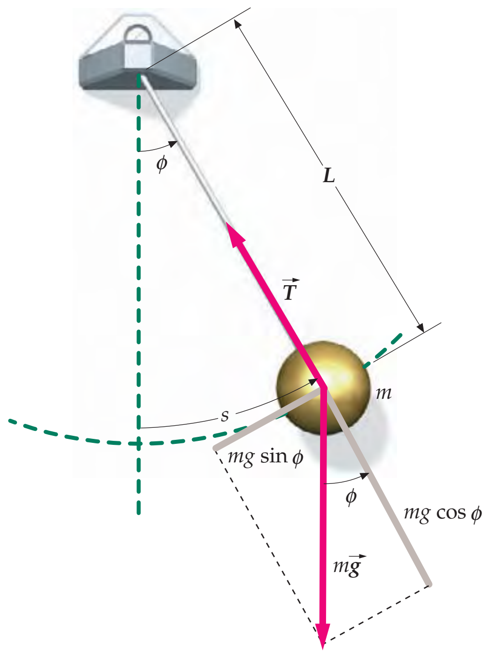

FIGURE 14-13 Forces on a pendulum bob.

! ω is the angular frequency—not the angular speed—of the motion of the pendulum.

PRACTICE PROBLEM 14-5

Find the period of a simple pendulum of length 1.00 m undergoing small oscillations.

The acceleration due to gravity can be measured using a simple pendulum undergoing small oscillations. We need only measure the length L and period T of the pendulum, and using Equation 14-28, solve for g. (To measure T, we usually measure the time for n oscillations and then divide by n, which minimizes measurement error.)

Example 14-8 Timing the Run — *Conceptual*

In a physics lab on one-dimensional kinematics, Liz and Bob are tasked with measuring the time it takes for a glider released from rest on an inclined 2.00-m-long air track to travel various distances. (An air track is a virtually frictionless track.) They tilt the track by putting a 2.0-cm-thick notebook under the legs at one end of the track. They release the glider from the middle of the track and find the time for it to accelerate half the length of the track to be 4.8 s. They then release the glider from the high end of the track and find that the time it takes for the glider to accelerate the entire length of the track is 4.8 s—the same time it took to accelerate half the length of the track. Thinking that the times for the two distances cannot be equal, they repeat both measurements, only to obtain the same results. Confused, they ask the instructor for an explanation. Can you think of a plausible explanation?

PICTURE If the track were perfectly straight, the acceleration would be the same everywhere along the track and the time for the glider to accelerate the entire length of the track, starting from rest, would be greater than the time for it to accelerate only half the length of the track. If the track sagged slightly, however, then the acceleration would be greatest at the high end of the track where the slope is steepest. What would the assumption that the track is sagging predict?

SOLVE

1. Suppose the track sags slightly, in such a way that the track forms a circular arc whose center of curvature is directly above the low end of the track:

   If the track sags as supposed, then the glider would move like the bob of a simple pendulum of length $L = R$, where R is the radius of curvature of the track.

2. The period T of a pendulum is independent of amplitude for small amplitudes:

   The times measured by Liz and Bob would equal $\frac{1}{4}$ the period T of the pendulum, given by Equation 14-28. Because the period of a pendulum is independent of amplitude (for small amplitudes), the times measured by Liz and Bob would be expected to be equal.

CHECK Is the amplitude of the pendulum sufficiently small when the glider is released from the high end of the track? It is if the R is much greater than 2.00 m. Equation 14-28 tells us that the length of the pendulum is given by $L = gT^2/(4\pi^2)$. Substituting $4 \times (4.8\text{ s})$ for T gives $R = L = 92$ m, justifying the supposition that the amplitudes were small.

This clock keeps time by using a torsional oscillator. *(Courtesy of Bill Master/Alibaba. http://yuning.en.alibaba.com.)*

Pendulum in an accelerated reference frame Figure 14-14*a* shows a simple pendulum suspended from the ceiling of a boxcar that has acceleration $\vec{a}_0$, relative to the ground, to the right, and $\vec{a}$ is the acceleration of the bob relative to the ground. Applying Newton's second law to the bob gives

$$\Sigma\vec{F} = \vec{T} + m\vec{g} = m\vec{a} \tag{14-29}$$

If the bob remains at rest relative to the boxcar, then $\vec{a} = \vec{a}_0$ and

$$\Sigma F_x = T\sin\theta_0 = ma_0$$
$$\Sigma F_y = T\cos\theta_0 - mg = 0$$

where θ_0 is the equilibrium angle. Thus, θ_0 is given by $\tan\theta_0 = a_0/g$. If the bob is

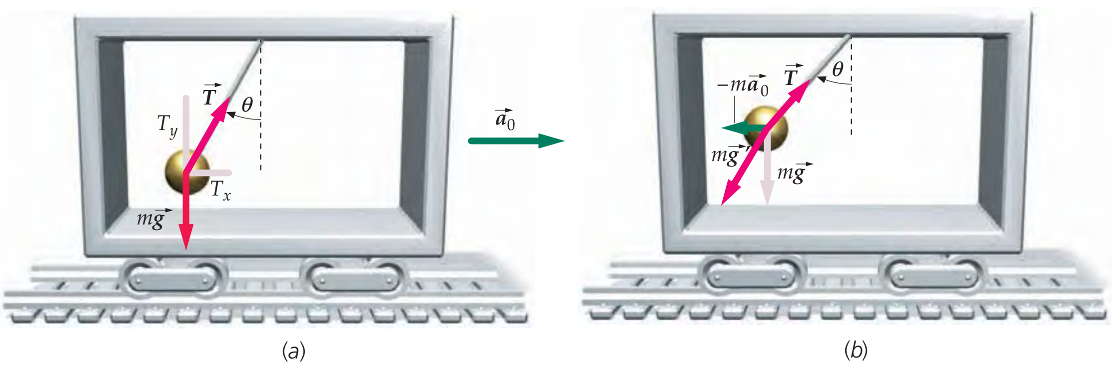

FIGURE 14-14 (*a*) Simple pendulum in apparent equilibrium in an accelerating boxcar. Forces are those as seen from a separate stationary frame. (*b*) Forces on the bob as seen in the accelerated frame. Adding the pseudoforce $-m\vec{a}_0$ is equivalent to replacing $\vec{g}$ by $\vec{g}'$.

moving relative to the boxcar, then $\vec{a}' = \vec{a} - \vec{a}_0$, where $\vec{a}'$ is the acceleration of the bob relative to the boxcar. Substituting for $\vec{a}$ in Equation 14-29 gives

$$\Sigma\vec{F} = \vec{T} + m\vec{g} = m(\vec{a}' + \vec{a}_0)$$

Subtracting $m\vec{a}_0$ from both sides of this equation and rearranging terms gives

$$\vec{T} + m\vec{g}' = m\vec{a}'$$

where $\vec{g}' = \vec{g} - \vec{a}_0$. Thus, by replacing $\vec{g}$ by $\vec{g}'$ and $\vec{a}$ by $\vec{a}'$ in Equation 14-29 we can solve for the motion of the bob relative to the boxcar. The vectors $\vec{T}$ and $m\vec{g}'$ are shown in Figure 14-14*b*. If the string breaks so that $\vec{T} = 0$, then our equation gives $\vec{a}' = \vec{g}'$, which means that $\vec{g}'$ is the free-fall acceleration in the reference frame of the boxcar. If the bob is displaced slightly from equilibrium, it will oscillate with a period T given by Equation 14-28 with g replaced by g'.

PRACTICE PROBLEM 14-6

A simple pendulum of length 1.00 m is in a boxcar that is accelerating horizontally with acceleration $a_0 = 3.00\ \text{m/s}^2$. Find g' and the period T.

Large-Amplitude oscillations When the amplitude of a pendulum's oscillation becomes large, its motion continues to be periodic, but it is no longer a simple harmonic. For an angular amplitude ϕ_0, the period can be shown to be given by

$$T = T_0\left[1 + \frac{1}{2^2}\sin^2\frac{1}{2}\phi_0 + \frac{1}{2^2}\left(\frac{3}{4}\right)^2\sin^4\frac{1}{2}\phi_0 + \cdots\right] \qquad 14\text{-}30$$

PERIOD FOR LARGE-AMPLITUDE OSCILLATIONS

where $T_0 = 2\pi\sqrt{L/g}$ is the period for very small amplitudes. Figure 14-15 shows T/T_0 as a function of amplitude ϕ_0.

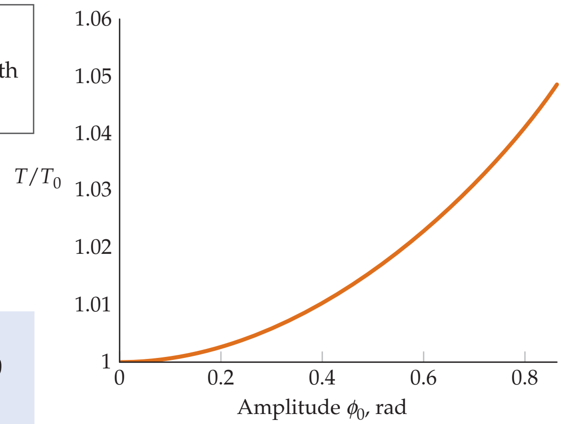

FIGURE 14-15 Note that the values on the vertical axis range from 1 to 1.06. Over a range of ϕ from 0 to 0.8 rad (46°), the period varies by about 5 percent.

Example 14-9 A Pendulum Clock *Try It Yourself*

A simple pendulum clock is calibrated to keep accurate time at an amplitude of $\phi_0 = 10.0°$. When the amplitude has decreased to the point where it is very small, does the clock gain or lose time? About how much time will the clock gain or lose in one day if the amplitude remains very small.

PICTURE To calculate the period when the angular amplitude is 10°, retain only the first correction term to Equation 14-30. That is, use

$$T \approx T_0\left[1 + \frac{1}{2^2}\sin^2\frac{1}{2}\phi_0\right]$$

This equation provides sufficient accuracy because 10° is a fairly small amplitude. The amplitude of the pendulum slowly decreases due to the effects of air drag.

SOLVE

Cover the column to the right and try these on your own before looking at the answers.

Steps	Answers
1. Use Equation 14-30 to determine if T_0 is greater or less than T.	T decreases as ϕ_0 decreases, so $\boxed{\text{the clock gains time.}}$
2. Use Equation 14-30 to find the percentage change $[(T - T_0)/T] \times 100\%$ for $\phi = 10°$. Use only the first correction term.	0.190%
3. Find the number of minutes in a day.	There are 1440 minutes in a day.
4. Combine steps 2 and 3 to find the change in the number of minutes in a day.	The gain is $\boxed{2.73\ \text{min/d}}$

CHECK The first correction term in Equation 14-30 is $\frac{1}{4}\sin^2(10.0°/2) = 1.90 \times 10^{-3}$, so $T = 1.00190T_0$ and $(T - T_0)/T = (1.00190T_0 - T_0)/1.00190T_0 = 0.00190$. This value agrees with our step-2 result.

TAKING IT FURTHER To avoid this gain, pendulum-clock mechanisms are designed to keep the amplitude fairly constant.

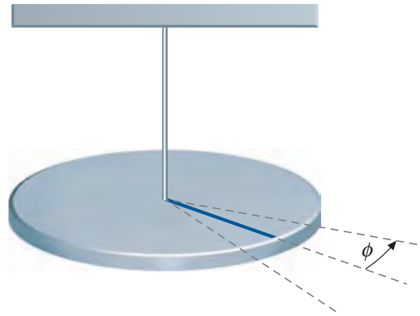

FIGURE 14-16 This torsional pendulum consists of a solid disk suspended by a steel wire.

* THE TORSIONAL OSCILLATOR

A system that undergoes rotational oscillations in a variation of simple-harmonic motion is called a **torsional oscillator.** Figure 14-16 shows a torsional oscillator consisting of a solid disk suspended from a steel wire. If the angular displacement of the disk from the equilibrium position is ϕ then the wire exerts a linear restoring torque τ on the disk given by

$$\tau = -\kappa\phi \tag{14-31}$$

where κ is the **torsional constant** of the wire. Substituting $-\kappa\phi$ for τ in the equation $\tau = I\alpha$ (Newton's second law for rotational motion) gives

$$-\kappa\phi = I\alpha$$

where the angular acceleration $\alpha = d^2\phi/dt^2$. Substituting $d^2\phi/dt^2$ for α and rearranging gives

$$\frac{d^2\phi}{dt^2} = -\frac{\kappa}{I}\phi \tag{14-32}$$

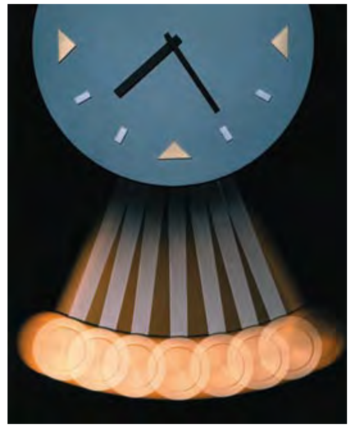
which is identical to Equation 14-2, except with I in place of m, κ in place of k, and ϕ in place of x. Thus, the solution to Equation 14-32 can be written by directly substituting into Equation 14-4. Doing so gives

$$\phi = \phi_0 \cos(\omega t + \delta) \tag{14-33}$$

where $\omega = \sqrt{\kappa/I}$ is the angular frequency—and not the angular speed—of the motion. The period is therefore

$$T = \frac{2\pi}{\omega} = 2\pi\sqrt{\frac{I}{\kappa}} \tag{14-34}$$

PERIOD OF A TORSIONAL OSCILLATOR



All mechanical clocks keep time because the period of the oscillating part of the mechanism remains constant. The period of any pendulum changes with changes in amplitude. However, the driving mechanism of a pendulum clock maintains the amplitude at a constant value. *(Richard Menga/ Fundamental Photographers.)*

* THE PHYSICAL PENDULUM

A rigid object free to rotate about a horizontal axis that is not through its center of mass will oscillate when displaced from equilibrium. Such a system is called a **physical pendulum.** Consider a plane figure with a rotation axis a distance D from the figure's center of mass and displaced from equilibrium by the angle ϕ (Figure 14-17). The torque about the axis has a magnitude $MgD \sin\phi$. For sufficiently small values of ϕ, we can simplify our expression for the torque using the small-angle approximation ($\sin\phi = \phi$). Thus, for small angles the torque is a linear restoring torque given by

$$\tau = -MgD\phi. \tag{14-35}$$

Comparing this with $\tau = -\kappa\phi$ (Equation 14-31), we can see that for small angular displacements the physical pendulum is a torsional oscillator with a torsional constant given by

$$\kappa = MgD$$

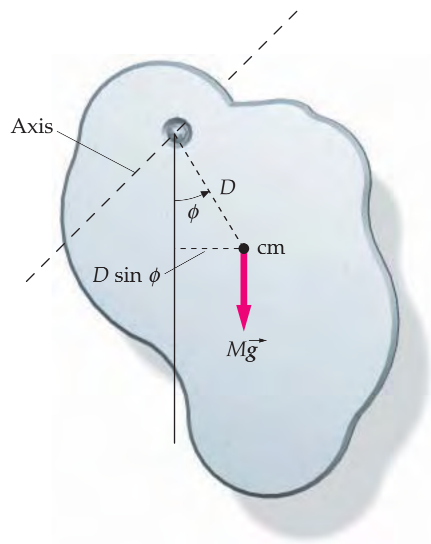


FIGURE 14-17 A physical pendulum.

Thus, the motion of the pendulum is described by Equation 14-33 with $\kappa = MgD$. The period is therefore

$$T = \frac{2\pi}{\omega} = 2\pi\sqrt{\frac{I}{MgD}} \qquad 14\text{-}36$$

PERIOD OF A PHYSICAL PENDULUM

For large amplitudes, the period is given by Equation 14-30, with T_0 given by Equation 14-36. For a simple pendulum of length L, the moment of inertia is $I = ML^2$ and $D = L$. Then, Equation 14-36 gives $T = 2\pi\sqrt{ML^2/(MgL)} = 2\pi\sqrt{L/g}$, the same as Equation 14-28.

! The period of a physical pendulum depends on the distribution of the mass, but not on the total mass M. The moment of inertia I is proportional to M, so the ratio I/M is independent of M.

Example 14-10 A Comfortable Pace *Context-Rich*

You claim that the pace of a comfortable walk can be predicted if we model each leg as a physical pendulum. Your teacher is skeptical about this claim and asks you to back it up. Is your claim correct?

PICTURE A simple model of each leg is that of a uniform rod pivoted at one end. Each leg swings back and forth once every two steps, so the time required to walk 10 steps is $5T$, where T is the period of the "pendulum." How long will it take you to complete 10 steps at a leisurely pace if your prediction is correct? Model your leg as a 0.90-m-long uniform rod pivoted about an axis through one end.

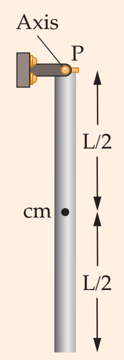

FIGURE 14-18 The distance between the rotation axis and the center of mass is $L/2$.

SOLVE

1. Draw and label a uniform thin rod pivoted about one end (Figure 14-18):

2. The period of a physical pendulum is given by $T = 2\pi\sqrt{I/MgD}$ (Equation 14-36): $\quad T = 2\pi\sqrt{\dfrac{I}{MgD}}$

3. I about the end is found in Table 9-1 and D is half the length of the rod: $\quad I = \frac{1}{3}ML^2 \quad \text{and} \quad D = \frac{1}{2}L$

4. Substitute the expressions for I and D to find T: $\quad T = 2\pi\sqrt{\dfrac{\frac{1}{3}ML^2}{Mg(\frac{1}{2}L)}} = 2\pi\sqrt{\dfrac{2L}{3g}}$

5. The length $L = 0.90$ m and the time for 10 steps is $5T$: $\quad 5T = 5\cdot 2\pi\sqrt{\dfrac{2L}{3g}} = 10\pi\sqrt{\dfrac{2(0.90\text{ m})}{3(9.81\text{ m/s}^2)}} = 7.8\text{ s}$

6. My hypothesis has merit. My hip joint is about 90 cm above the floor and it took me almost 6.7 s to complete 10 leisurely steps. The upper half of my leg is more massive than the lower half, so modeling my leg as a uniform rod is not completely appropriate. In addition, what is a leisurely pace is subject to interpretation.

CHECK Long-legged animals, like elephants and giraffes, seem to walk at a slow, lumbering pace, and short-legged animals, like mice and sandpipers, walk at a fast pace. This conclusion is predicted by this model, because the period of a long pendulum is greater than that of a short pendulum.

Example 14-11 A Swinging Rod

A uniform rod of mass M and length L is free to swing about a horizontal axis perpendicular to the rod and a distance x from the rod's center. Find the period of oscillation for small angular displacements of the rod.

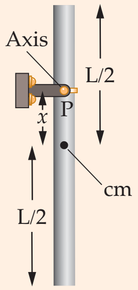

FIGURE 14-19 The distance between the rotation axis and the center of mass is x.

PICTURE The period is given by Equation 14-36. The center of mass is at the center of the rod, so the distance from the center of mass to the rotation axis is x (Figure 14-19). The moment of inertia of a uniform rod can be found from the parallel-axis theorem $I = I_{cm} + MD^2$ (Equation 9-13), where I_{cm} can be found in Table 9-1.

SOLVE

1. The period is given by Equation 14-36: $$T = 2\pi\sqrt{\frac{I}{MgD}}$$

2. $D = x$, and the moment of inertia is given by the parallel-axis theorem. The moment of inertia about a parallel axis through the center of mass is found in Table 9-1: $$D = x$$ $$I = I_{cm} + MD^2 = \tfrac{1}{12}ML^2 + Mx^2$$

3. Substitute these values to find T: $$T = 2\pi\sqrt{\frac{I}{MgD}} = 2\pi\sqrt{\frac{(\frac{1}{12}ML^2 + Mx^2)}{Mgx}}$$ $$= \boxed{2\pi\sqrt{\frac{(\frac{1}{12}L^2 + x^2)}{gx}}}$$

CHECK As $x \rightarrow 0$, $T \rightarrow \infty$ as expected. (If the rotation axis of the rod passes through its center of mass, we do not expect gravity to exert a restoring torque.) Also, if $x = L/2$ we get $T = 2\pi\sqrt{2L/3g}$, the same result as found in step 4 of Example 14-10. In addition, if $x \gg L$ the expression for the period approaches $T = 2\pi\sqrt{x/g}$, which is the expression for the period of a simple pendulum of length x (Equation 14-28).

TAKING IT FURTHER The period T versus distance x from the center of mass for a rod of length 1.00 m is shown in Figure 14-20.
